Preface

This volume includes the articles presented at the "Xth International Conference of Production Research-Americas" (ICPR-Americas 2020), held virtually from Bahía Blanca, Argentina from December 9 to 11, 2020. This conference was organized by the local organizing committee of the city of Bahía Blanca and was sponsored by the *International Foundation of Production Research* (IFPR). This conference aims at exchanging experiences and encouraging collaborative work among researchers and practitioners from the Americas and the Caribbean region.

The first ICPR Americas conference, took place in November 2002 in Saint Louis, Missouri, USA under the general theme of "Production Research and Computational Intelligence for Designing and Operating Complex Global Production Systems". This conference generated very positive responses from the attendees. From then on, the ICPR regional meeting was held at alternate years. The second version of the ICPR-Americas was held in August 2004 in Santiago, Chile with the conference theme "Information and Communication Technologies for Collaborative Operations Management". The third edition of the ICPR-Americas held in Curitiba, Brazil, had the general theme of "Rethinking Operation Systems: New Roles of Technology, Strategy and Organization in the America's Integration Era". This instance sought to promote a deep discussion about the role of Production Engineering in the America's integration process. In 2008, the venue of ICPR-Americas was Sao Paulo, Brazil at the Universidade de Sao Paulo Campus. The conference had the theme "The Role of Emerging Economies in the Future of Global Production: Creating New Multinationals". Bogota, Colombia hosted in 2010 the fifth conference with the subject "Technologies in Logistics and Manufacturing for Small and Medium Enterprises". The sixth edition (2012) was organized around the topic "Production Research in Americas Region: Agenda for the Next Decade" by the University of Santiago de Chile in Santiago. In Lima, Peru, the 2014 edition of ICPR-Americas addressed the general theme of "Towards Sustainable Eco-Industrialization through Applied Knowledge.". The eight edition was held at Valparaíso, Chile in 2016, and more recently, in 2018, the ninth conference was held at Bogotá, Colombia under the topic „Improving Supply Chain Management through Sustainability"

ICPR-Americas 2020 was the first edition carried out in virtual mode, due to the COVID-19 pandemic. Thanks to the participation and commitment of the attendees, the conference was carried out successfully, allowing many young researchers to participate in an international conference, in a year in which these opportunities were scarce. The ICPR-Americas meeting space gave them the opportunity to share their work, as well as exchange ideas and points of view, all in the cordial atmosphere that characterizes the ICPR-Americas conferences.

ICPR-Americas 2020 was organized by a local committee of the National University of the South, supported by the university and IFPR.

The conference received more than 280 papers, of which 245 were accepted and presented during the conference. The nationality of the authors was representative of the vast

majority of the countries of America, not only South America, but also Central and North America. Something that enriched the international experience that each of the participants took from the conference.

A couple of events associated with ICPR-Americas 2020 were also held: the “SIMPOSIO INDUSTRIAL” and the “SEMINARIO de ENSAYOS ESTUDIANTILES”. Both events allowed to broaden the scope and attendance of the conference. The accepted and presented works of both events are compiled within this volume.

Finally, it only remains for us to thank the National University of the South, especially the Departments of Engineering and Mathematics, as well as the General Secretariat of Science and Technology, for the support provided to carry out the event.

ÍNDICE

PLENARY DISSERTATIONS

Manufacturing Scheduling: Old solutions for new problems? Jose M Framinan. **P. 28**

Perspectives and trends of Industry 4.0 in Latin America. Gonzalo Mejía Delgadillo. **P. 30**

Digitalization of manual production and assembly processes for smart factories of the future. Francesco Pilati. **P. 31**

Managing Macro Level Supply Chain Disruptions: Lessons from COVID-19. Srinivas Talluri. **P. 33**

GENERAL SESSION

Advanced Energy Management: a review on Energy Management and I4.0. Caio Cesar Ferreira, Sergio E. Gouvea da Costa, Edson Pinheiro de Lima and Fernando Deschamps. **P. 36**

A simulation-optimization approach for the household energy planning problem considering uncertainty in users preferences. Diego Gabriel Rossit, Sergio Nesmachnow, Jamal Toutouh and Francisco Luna. **P. 40**

Seleção de um Sistema de Gerenciamento de Transportes numa Empresa do Setor Educacional. Goreth de Carvalho Gonçalves, Claudemir Leif Tramarico and Fernando Augusto Silva Marins. **P. 55**

Desarrollo de un modelo matemático para el problema de enrutamiento e inventario con múltiples depósitos (MDIRP). Javier Arias-Osorio and Erick Saenz Hoyos. **P. 70**

Estimating the Dynamic Impact of COVID-19 State-level Mobility Interventions in Brazil. Thyago C. C. Nepomuceno, Marcele Elisa Fontana and Thalles Vitelli Garcez. **P. 80**

Desenvolvimento de produto Lean e Green: um estudo comparativo entre PMEs Brasileiras e Japonesas. Gisele Piovesan, Gilson Oliveira, Shoji Takechi, Kim Tan and Dalmarino Setti. **P. 93**

Multi-objective optimization of a rotary dryer in a semi-dynamic state using evolutionary algorithms. Benjamín Barán, César Oviedo and Michel Galeano. **P. 108**

Modelado mecanístico de procesos de molienda de maíz: Calibración de parámetros para el modelado por elementos discretos (DEM). Manuela Quezada Henry, Alejandro Chiaravalle, Juliana Piña and Ivana Cotabarren. **P. 121**

The time-lagged effect problem on (un)truthful data, a case study on COVID-19 outbreak. Luis Rojo-González. **P. 136**

Nuclear Safety Management after Fukushima accident. A systematic and critical review of the state of the art. Gregorio Acuña, Marcelo Gimenez and Marisa Sanchez. **P. 150**

Planejamento de Vendas e Operações e Planejamento Integrado de Negócios em um Banco Privado do Brasil. Jefferson Barbosa Araujo, Claudemir Leif Tramarico and Fernando Augusto Silva Marins. **P. 165**

Application of the AHP method to assist the strategy of bike share station positioning in the city of São Paulo. Emannuell Cenzi, José João Manrique Franco, Marcelo Rudek and Eduardo de Freitas Rocha Loures. **P. 179**

Hacia el desarrollo de una movilidad inteligente para la ciudad de Bahía Blanca: Primer enfoque sobre la caracterización de la flota vehicular del microcentro. Yamila Soledad Grassi, Nélida Beatriz Brignole and Mónica Fátima Díaz. **P. 189**

Inventario de Emisiones de la Aviación Civil, Navegación Marítima y Ferrocarriles de la ciudad de Bahía Blanca para el año 2018. Yamila Soledad Grassi, Nélida Beatriz Brignole and Mónica Díaz. **P.204**

Minimizing the Bullwhip Effect by Forecasting Supply Chain Demand: Case Study of the Argentine Automotive Sector. Claudio Aballay, Luis Quezada, Miguel Alfaro, Guillermo Fuertes, Marc Dahmen and Manuel Vargas. **P. 219**

Power Scheduling with Interruptions for Residential Demand in Smart Grid. Sebastián Taboh, Isabel Méndez-Díaz and Paula Zabala. **P. 229**

Residents' perception from a Brazilian municipality about the COVID-19 social distancing period. Marcele Elisa Fontana, João Paulo Santos Aragão and José Leão. **P. 244**

Computational system for quantitative intra-criterion evaluation in subjective criterion. Marcele Elisa Fontana and Vilmar Santos Nepomuceno. **P. 256**

Mineração de processos e aprendizado de máquina aplicado ao processo de empréstimos pessoais. Pedro Boareto and Silvana Detro. **P. 267**

Modelos de optimización para la planeación táctica de la operación de recolección de residuos sólidos: Caso de estudio en Colombia. Angie Paola Vargas, Santiago Jaramillo, Francisco Rangel, Daniel Villa and Juan G. Villegas R. **P. 281**

Prediction of Viscoelastic Behavior of LDPE Produced in High-Pressure Tubular Reactors. Maira Dietrich, Adriana Brandolin, Claudia Sarmoria and Mariano Asteasuain. **P. 296**

Efficiency analysis and cavitation prediction: Choice of the most suitable propeller for a Brazilian Navy ship. Igor Pa Costa, Sérgio Mn Maêda, Luiz Fhsb Teixeira, Arthur Pa Costa, Carlos Fs Gomes and Marcos Santos. **P. 300**

Comparative analysis between waterjet and conventional propulsion: A new possibility for use in Brazilian Navy Ships. Igor Costa, Sérgio Mn Maêda, Luiz Fhsb Teixeira, Arthur Pa Costa, Carlof Fs Gomes and Marcos Santos. **P. 312**

System dynamics for flood impact assessment. Case study of two municipalities in South America. Nicolas Giedelmann Lasprilla, Carla Andrea Ocampo Terceros, Elyn L Solano Charris and William J Guerrero Rueda. **P. 326**

Análisis multicriterio aplicado a la selección de un Plan Agregado de Producción. Luciana Tabone, Verónica Mortara, Antonio Morcela, Ignacio Boloquy and Jacqueline Bounoure. **P. 330**

A Computer Vision based Gaze Following Application: Contribution in COVID-19 Scenario. George Martins Silva, Emannuell Dartora Cenzi, Matheus Henrique Sanches Maziero, Marcelo Rudek and Anderson Luis Szejka. **P. 343**

A production planning MILP optimization model for a manufacturing company. Juan Antonio Cedillo-Campos, Neale R. Smith, Rosa G. González-Ramírez, Julio Alonso Stocker, Joaquin Alonso Stocker and Ronald G. Askin. **P. 354**

Alistamiento de pedidos en un almacén de comercio electrónico: Una revisión. Fabian Alexander Torres Cardenas, Carlos Eduardo Diaz Bohorquez, Katia Lineth Merlano Canoles and Karina Lizzeth Castellanos Pico. **P. 366**

O impacto da pandemia COVID-19 nas operações econômicas da "Indústria de Alimentos" no Brasil: Uma Pesquisa documental sobre passado, presente e o futuro. Gleison Hidalgo Martins, Evelin Bortolon and Sonia Ferreira Martins. **P. 381**

An operational planning model to support first mile logistics for small fresh-produce growers. Alvaro M. Majluf-Manzur, Rosa Guadalupe Gonzalez Ramirez, J. René Villalobos and Raimundo Velasco Paredes. **P. 396**

Digital Twin e PHM para Otimização de Níveis de Inventário. Joceir Chaves, Eduardo Loures, Eduardo Santos, Julio Silva and Ricardo Kondo. **P. 411**

Hybrid method PROMETHEE-SAPEVO-M1: multicriteria evaluation of River Combat Vessels to support Amazon defense. Miguel Moreira, Marcos Santos and Carlos Gomes. **P. 420**

Analysis of Packaging Losses in Cocoa Butter Production. Amanda Morais Almeida, Aline Patricia Mano and Sérgio Renato Teixeira Nascimento. **P. 435**

Diretrizes para projetos de IIoT em contexto CPS. Júlio Silva, Eduardo Loures, Eduardo Santos, Ricardo Kondo and Joceir Chaves. **P. 445**

Review: Cadenas de Suministro, desde la colaboración de eslabones a la gestión de cadenas sustentables. Natacha Pino. **P. 458**

Applying a Decision Model to Evaluate the Influence of Digital Transformation Technologies on TOGAF Architecture Principles. Izabelle C. Hannemann de Freitas, Sarah G. Rodrigues, Eduardo de Freitas R. Loures and José Marcelo A. P. Cestari. **P. 473**

El gasto energético de los hogares en Argentina: ¿por qué estudiarlo para mejorar la eficiencia energética? María Florencia Zabaloy and María María Ibáñez Martín. **P. 486**

A branch and bound method to minimize the total flow time in a permutation flow shop with blocking and setup times. João V. S. Robazzi, Marcelo S. Nagano and Mauricio I. Takano. **P. 490**

Suporte a tomada de decisão em healthcare usando BPMN e DMN. Pedro Boareto, Silvana Detro and Eduardo Santos. **P. 500**

Mathematical Modeling of ARGET Copolymerization of Styrene and Acrylonitrile. I: Experimental Validation. Cecilia Fotunatti, Claudia Sarmoria, Adriana Brandolin and Mariano Asteasuain. **P. 515**

Mathematical Modeling of ARGET Copolymerization of Styrene and Acrylonitrile. II: Efficient Calculation of Bivariate Distributions using Parallel Computing. Esteban Pintos, Cecilia Fortunatti, Adriana Brandolin, Claudia Sarmoria and Mariano Asteasuain. **P. 525**

ERP Integration with Performance Analytics: a Systematic Literature Review. Thais C. Pfutzenreuter and Edson Pinheiro De Lima. **P. 536**

Avaliação de Interoperabilidade Empresarial: Uma revisão sistemática da literatura. Angélica Duarte Lima and Eduardo de Freitas Rocha Loures. **P. 550**

Evaluación de la incorporación de residuos de caucho en hormigones para elementos de protección vial. Ana Giselle Cressa and Carlos Baronetto. **P. 563**

Increasing productivity of a beef production line using Lean 6 Sigma. Martha Ramírez-Valdivia and Viviana Vásquez. **P. 575**

COVID-19 Pandemic Effects on the Idiosyncratic Risk of the Brazilian and Emerging Markets. Andre Assis de Salles. **P. 590**

Gas turbines inlet air cooling: mathematical analysis of Brazilian Navy's ships propulsion efficiency. Pedro M Diniz, Alex Gimenez, Sérgio M N Maêda, Igor P A Costa, Carlos F S Gomes and Marcos Santos. **P. 601**

Reducing heat emission in discharge ducts and increasing the global energy efficiency through energy cogeneration. Alex Gimenez, Pedro M Diniz, Igor P A Costa, Sérgio M N Maêda, Carlos F S Gomes and Marcos Santos. **P. 613**

Process Mining and Value Stream Mapping: an incremental approach. Mario Nawcki, Gabriel Zanon, Lícia Santos, Eduardo Santos, Anderson Szejka and Edson Lima. **P. 625**

Agile DMAIC Cycle: An Approach Based on Process Mining. Renan Prado, Wilson Portela, Márcio Catapan and Eduardo Portela. **P. 639**

Environmental impact assessment of industries through a multicriteria decision-making analysis. Juan Martín Mainardi-Remis, Dolores Gutiérrez-Cacciabue and Verónica Beatriz Rajal. **P. 654**

Exact resolution of the Vehicle Routing Problem with Flexible Time Windows. Lucía Barrero, Rodrigo Viera, Franco Robledo, Claudio Risso, Sergio Nesmachnow and Andrei Tchernykh. **P. 658**

Determinants of Smart city commitment among citizens from Bahía Blanca, Argentina. María Verónica Alderete. **P. 673**

Adecuada asignación de los recursos en sistemas de servucción bajo enfoque Lean Services: caso de estudio industria de la hospitalidad. Hernando Garzón Saenz and Andres Redchuk. **P. 690**

Aportes del enfoque Multimetodológico a la gestión de problemáticas derivadas del COVID-19. Avances para una intervención sistémica en grupos poblacionales. Hernán Van Straaten, Melany Segarra Marinetti and Maria Alejandra Castellini. **P. 705**

Modelo multicritério de apoio a tomada de decisão, baseado em Sistema de Informação Geográfico, para a gestão de acidentes de trânsito. Antônio Bezerra, Murilo Damasceno, Cristiany de Souza, Joana Peixoto, Thomas Gonçalo and Eric Ferreira. **P. 720**

Análise das dimensões da inovação pela ótica das camadas de gestão e operacionais. Osvaldo Garcia, George Silva, Diego Nascimento and Eduardo Rocha Loures. **P. 735**

Transición Energética: Interacciones estratégicas ante la redistribución (o no) de impuestos. David-Alejandro Rivera-Correa and Damián-Emilio Gibaja-Romero. **P. 747**

Transparência governamental em tempos de pandemia do COVID-19. Alcenir Vergilio Negri. **P.769**

Current problems to achieve interoperability, influenced by the process domains, difficulties and challenges for the logistics area in its horizontal and vertical integration. Tainá da Rocha, Arthur Beltrame Canciglieri, Anderson Szejka and Osiris Canciglieri Junior. **P. 777**

Un modelo de medición de la calidad del servicio: Caso de una empresa de mantenimiento de motores. Pedro Palominos, Juan Hernandez, Luis Quezada, Astrid Oddershede and Claudio Macuada. **P. 786**

Simulação do agendamento de horários em um restaurante universitário e seu impacto no tempo de espera em filas. Thayse Duarte de Oliveira, Gustavo Valentim Loch, Tiago Lino Bello, Daniela Miray Igarashi, Lucas Lamy, Ivan Moyses Guimarães and Gilmar Schewtschik Filho. **P. 792**

Generación de valor en el área de Finanzas de una organización de servicios de salud. Luciana Tabone, Verónica Mortara and Alicia Zanfrillo. **P. 807**

A study on a new hybrid metaheuristic based on the black hole algorithm for clustering problems. Felipe Kauai, José Pécora Junior and Leonardo de Lima. **P. 822**

Forecasting Demand in Supply Chain for Automotive Spare Parts: Preliminary Literature Review. Lourdes Loza-Hernández, Ma. de Lourdes Nájera López, Javier García-Gutiérrez, Rubén Vázquez Carbajal and Victor Sánchez Guzmán. **P. 835**

Atributos em modelos de maturidade para cadeias de suprimento inteligentes. Gabriella Moreira, Lucas Coelho, Vinícius Comin, Silvana Detro and Eduardo Portela. **P. 851**

Estudio de capacidad de producción en sistemas de producción de calzado basado en simulación. Florencia Dornes, Daniel A. Rossit and Nancy B. López. **P. 865**

Medição de desempenho baseado em dados para máquinas: Revisão sistemática de literatura. Gleison Hidalgo Martins, Pablo Deivid Valle, Silvana Pereira Detro and Fernando Deschamps. **P. 875**

Simulación de eventos discretos para la estimación del nivel de servicio en un laboratorio de análisis de materiales. Josué Rojas-Rodríguez, Gaston Vertiz-Camaron, Jenaro Nosedal-Sánchez and Javier García-Gutiérrez. **P. 890**

Despacho óptimo de buses eléctricos bajo incertidumbre en los tiempos de viaje. Karam Kharrat, Victor Albornoz and Linco Ñanco. **P. 905**

Filosofia Lean em ambientes acadêmicos: Um estudo de caso em uma organização de nível técnico. Jordana Paula Berkenbrock, Edson de Carvalho Ramos, Marcelo Trentin and Flavio Trojan. **P. 917**

Minimizing total implementation cost of a 2-D indoor localization system with a constant accuracy for underground mine tunnels. Andrea Teresa Espinoza Pérez, Daniel Rossit and Oscar C. Vásquez. **P. 931**

Utilização do método PDCA para melhoria de proces-sos: estudo de caso em um centro de distribuição ali-mentícia. Maressa Fontana Mezoni and Sergio Luiz Ribas Pess. **P. 937**

Utilization of Rice Husk (OryzaSativa) for the Elaboration of an Agglomeraet Material for the Construction of Housing in Cucuta, Norte de Sanrander, Colombia. Lizeth Alfonsina Portilla Villarreal, José Alfredo Gutiérrez Durán, Yerson Fabián Quitian Osorio and Maribel Gómez Peñaranda. **P. 950**

Gestion de inventarios para una pyme. Paloma Lillo, Cecilia Montt, Astrid Oddershede, Luis Quezada and Alejandra Valencia. **P. 958**

Current Issues in Flexible Manufacturing using Multicriteria Decision Analysis and Ontology Based Interoperability in an Advanced Manufacturing Environment. Matheus Beltrame Canciglieri, Athon Francisco Curi Staben de Moura Leite, Eduardo de Freitas Rocha Loures, Osiris Canciglieri Junior, Y.M. Goh and Radmehr Monfared. **P. 964**

Estudio de Caso sobre el Cumplimiento de los Principios de Gestión de la Calidad Según la Norma ISO 9001 Versiones 2008 y 2015, de los Empleados de Dos Empresas Cafeteras de Nariño Colombia.. Lizeth Alfonsina Portilla Villarreal, Martha Ramírez-Valdivia and Lorena Alexandra Portilla Villarreal. **P. 977**

Sistema innovador de producción de agua segura: análisis económico y comparación con otras alternativas. Jorge Emilio Almazan, Miguel Cervantes-Schamun, Dolores Gutierrez Cacciabue and Verónica Beatriz Rajal. **P. 995**

Assessing funding options for digital transformation: a study with specialists. Rafaela Plantes Pavloski, Fernando Deschamps, Edson Pinheiro de Lima, Rosemary Francisco and Eduardo Rocha Loures. **P. 999**

Implementação de um modelo de simulação na indústria moveleira. Angelo Rocha, Fernando Deschamps and Silvana Detro. **P. 1005**

A Multiple-Criteria Directional Measure for Resource Management in Hospitalizations. Thyago C. C. Nepomuceno, Wilka M. N. Silva and Késsia T. C. Nepomuceno. **P. 1016**

Long-term evaluation of energy efficiency measures in transport, case study Paraguay. Manuel Olmedo, Eduardo Ortigoza, Diana Valdez, Richard Ríos and Victorio Oxilia. **P. 1022**

Método multicriterio grupal para decisiones rutinarias. José Francisco Zanazzi, José Luis Zanazzi and Daniel Pontelli. **P. 1034**

SPECIAL SESSION: INDUSTRY 4.0

Increasing Confidence in Industry 4.0 through new Software Verification and Validation Techniques. Martin Larrea and Dana Urribarri. **P. 1039**

Modelling the Dynamics of a Smart Factory. Marisa Sánchez, Daniel Rossit and Fernando Tohmé. **P. 1054**

Integración de ROS y Tecnomatix para el desarrollo de gemelos digitales en sistemas de manufactura flexible. Carolina Saavedra Sueldo, Sebastian A. Villar, Mariano De Paula, Silvia B. Urrutia and Gerardo G. Acosta. **P. 1069**

Data Analytics support for the Integrated Planning of Cutting Orders in Banana Crops harvesting: a case study in Colombia. Carlos Paternina-Arboleda, Yanelis Payares-Osorio, Luis E. Ramirez-Polo and Benjamin Thomas Hazen. **P. 1084**

A proposal Roadmap to implement Industry 4.0 in SMEs. Jose Mauricio Mottin de Andrade, Eduardo de Freitas Rocha Loures, Anderson Luiz Szejka and Osiris Canciglieri Junior. **P. 1097**

Digital transformation framework for adequacy of maintenance systems to Industry 4.0. André Venâncio, Eduardo Loures, Ricardo Diogo, Alysson Lumikoski, Neri dos Santos and Fernando Deschamps. **P. 1109**

The emergence of new business and operating models under the Industrial Digital Paradigm Industrial Internet of Things (IIoT), Platforms, and Artificial Intelligence/Machine Learning (AI/ML). Federico Walas Mateo and Andres Redchuk. **P. 1123**

Análise de Maturidade da Indústria 4.0: foco em Países Emergentes. Gustavo de Melo Silva, Gilson Adamczuk Oliveira, Marcelo Gonçalves Trentin and Dalmarino Setti. **P. 1133**

Developing a Resource-based Manufacturing Process Capability Ontology. Dusan Sormaz, Arkopaul Sarkar, David Koonce and Sharmake Farah. **P. 1147**

Process Plan Reasoning based on SPARQL Extension. Arkopaul Sarkar and Dusan Sormaz. **P. 1162**

A Novel Framework for the Shop-floor Scheduling Nervousness. Juan M. Novas. **P. 1178**

Modelo de Maturidade PLM (Product Lifecycle Management) com Conceitos da Indústria 4.0 – Avaliação com base no método AHP. André Luiz Micosky, Kássio Cabral Pereira Dos Santos, Eduardo de Freitas Rocha Loures and Osíris Canciglieri. **P. 1182**

Desarrollo de herramientas para la gestión óptima de envases vacíos de fitosanitarios y sus contenidos residuales. Antonela Elisa Sorichetti, Mariana Gonzalez Prieto, Andrea Alejandra Savoretti, Silvia Elena Barbosa and José Alberto Bandoni. **P. 1197**

Operation Skipping Flow Shop Scheduling and Industry 4.0. Daniel Alejandro Rossit, Adrián Toncovich, Diego Gabriel Rossit and Sergio Nesmachnow. **P. 1212**

Future research agenda to understanding the Sustainable Business Model in Industry 4.0. Grazielle Fatima Gomes Teixeira, Osiris Canciglieri Junior and Anderson Luis Szejka. **P. 1222**

Universities Best Practices in Open Innovation and R&D. Michele Marcos de Oliveira, Osiris Canciglieri Junior and Bernardo Reisdorfer Leite. **P. 1237**

Revisiting the Product-Process Matrix: incorporating distributed manufacturing concepts. Guilherme Brezinski, Alexandre Helmann, André Venâncio, Sérgio Gouvêa, Eduardo Loures and Fernando Deschamps. **P. 1250**

Integrated production and maintenance planning: a systematic literature review. Nicollas Luiz Schweitzer de Souza, Lucio Galvão Mendes, Eugênio Strassburger Rovaris, Enzo Morosini Frazzon and Lynceo Falavigna Braghirolli. **P. 1264**

Development of a Methodology to Analyze Implementation Patterns of Industry 4.0 Technologies in the Santa Fe Region. Oscar Quiroga, Samuel Osina and Mariana Díaz. **P. 1279**

Evidências da Indústria 4.0 no setor eletroeletrônico basileiro: um estudo multicasos a partir da literatura. Fernando Schenatto, Fabiano Carniel and Luís Alberti. **P. 1293**

A Fast and Elitist Multi-objective Genetic Algorithm for Seru Production Assignment Problem Considering Worker Skills and Proficiency. Sofía Magdalena Escobar Forero and Ciro Alberto Amaya Guio. **P. 1310**

Proceso de toma de decisión multicriterio aplicado a máquinas de una línea de producción. Félix Fernández, Eduardo Ortigoza, Victorio Oxilia, Lucas Cáceres, Rodrigo González and Roberto Fariña. **P. 1325**

Estrategias de flexibilización de los sistemas de producción en la industria 4.0: un marco para la caracterización. Diana C. Tascón and Gonzalo Mejía. **P. 1341**

Factores que influyen en la adaptación de la Industria 4.0 a la gestión del mantenimiento en las empresas colombianas. Leidy Marcela Duenas Ramirez, Gustavo Adolfo Villegas Lopez, Sebastian Castiblanco Tique, Carlos Andres Castaño Restrepo, Martin Andres Rosendahl Garcia, Alejandro Lopez Giraldo and Luisa Fernanda Ortiz Vasquez. **P. 1356**

SPECIAL SESSION: **PROCESS INDUSTRY**

Desarrollo de herramientas de soporte a la toma de decisiones en una planta de producción de jugos concentrados. Anibal Blanco, Susana Moreno, Carolina Taraborelli, Flavio D'Angelo, Facundo Iturmendi and Alberto Bandoni. **P. 1369**

Optimización de la Trazabilidad en la Cadena de Suministro de la Carne. Bárbara Verónica Schmidt and Marta Susana Moreno **P. 1384**

Ajuste de parámetros cinéticos de la reacción inversa del gas de agua (RWGS) en la producción de metanol. Constanza Genovese, Ignacio Costilla, Carlos Eugenio Gigola and Nelida Beatriz Brignole. **P. 1399**

Modelo integrado de planificación de decisiones del desarrollo de operaciones upstream. Luciano Benvenutti, Daniel Oscar Borio and Jose Alberto Bandoni. **P. 1412**

Propuesta de una biorrefinería en una industria azucarera cubana aprovechando la biomasa. Ana Celia de Armas Martínez, Yailet Albernas Carvajal, Erenio González Suárez and Gabriela Corsano. **P. 1416**

Modelado matemático de una planta piloto de producción de sidra para la toma de decisiones. Facundo Iturmendi, Carolina Taraborelli, Juan Ignacio Laiglecia, Natalia Bongiovani and Flavio D'Angelo. **P. 1420**

A Nonlinear Parameter Estimation for Biodiesel Production with Nannochloropsis oceanica CCALA 978. Juan Ignacio Laiglecia, Natalia Bongiovani, Facundo Iturmendi, Cecilia Popovich and Patricia Leonardi. **P. 1432**

Programación de Operaciones Eficiente de un Caso de Estudio Real de la Industria Farmacéutica mediante una Metodología de Descomposición Matemática-Algorítmica. Josías Stürtz and Pablo Marchetti. **P. 1436**

Análisis de incertidumbre en modelos de celdas de combustible de hidrógeno de tipo PEM. Ignacio Pérez Correa, Pablo Giunta and Javier Francesconi. **P. 1440**

Robust data reconciliation applied to uncertainty steady state model. Claudia Llanos and Mabel Sánchez. **P. 1451**

Biogas una alternativa Neuquén. Ivone Elisabet Carroza, Gisela Magali Sanchez, Yesenia Martina Perez, Marcela Noemi Gatti, Alberto Camacho and Jose Luis Boiardi. **P. 1466**

SPECIAL SESSION: **FORESTRY**

Tendencias climáticas de la Región Pampeana (Argentina) durante 1960-2019. Federico Ferrelli, Andrea Soledad Brendel, María Cintia Piccolo and Gerardo Miguel Eduardo Perillo. **P. 1476**

Variabilidad climática de la Región Pampeana (Argentina) en el contexto de cambio climático. Andrea Soledad Brendel, Federico Ferrelli and Maria Cintia Piccolo. **P. 1480**

Disminución de la Disponibilidad de Agua Potable por Expansión de la Forestación, en el Sector Costero Oriental de la Provincia de Buenos Aires, Argentina. Leonardo Sánchez Caro, Silvina Claudia Carretero, Fernanda Julia Gaspari and Alfonso Martín Rodríguez Vagaría. **P. 1484**

Energy optimization for the operation of a sawmill. Nicolas Vanzetti, Nestor Steitzer, Gabriela Corsano and Jorge Marcelo Montagna. **P. 1499**

A column generation based algorithm for solving the log transportation problem. Maximiliano R. Bordón, Jorge Marcelo Montagna and Gabriela Corsano. **P. 1514**

Problema de Recogida y Entrega en la Industria Forestal: nuevos modelos y estudio de su performance. Luciana Melchiori, Graciela Nasini, Marcelo Montagna and Gabriela Corsano. **P. 1529**

Desarrollo de un sistema de programacion de ordenes de trabajo con restricciones de sincronizacion para una empresa de la agroindustria de flores. Freddy López, Alfonso Sarmiento and William Guerrero. **P. 1544**

Produccion de biogás y modelado del potencial metanogénico de residuos porcinos y co-sustratos. Marcos Astorga, Margarita Cesano, Marcela Noemí Gatti and Alberto Camacho. **P. 1548**

Evaluación del rendimiento económico y volumétrico de una planificación estratégica en un patrimonio forestal del Norte de la Provincia de Misiones. Mathías Isaac López, Enzo Martín Sanzovo, Julio Eduardo Arce, Hugo Daniel Reis and Diego Ricardo Broz. **P. 1557**

An integrated approach for solving the bucking and routing problems in the forest industry. Maximiliano R. Bordón, Jorge Marcelo Montagna and Gabriela Corsano. **P. 1563**

Uniformidad en la distribución de aplicación de diferentes diseños de pastillas de pulverización. Victor H. Merani, Matilde Mur, Facundo Guilino, Larrieu Luciano, Juan Manuel Vazquez, Mariana Bethouart and Roberto Balbuena. **P. 1578**

Evaluación del Endocarpio de Coco (cocos nucifera) como Sustrato en el Cultivo de Pleurotus Ostreatus en el Municipio de Villa del Rosario, Norte de Santander Colombia. Lizeth Alfonsina Portilla Villarreal, Carlos Jahir Rodríguez Estupiñan, Juan Carlos Mora Santos and Lorena Alexandra Portilla Villarreal. **P. 1592**

Pulverizaciones agrícolas: Comparación de metodologías para su evaluación. Victor H. Merani, Matilde Mur, Facundo Guilino, Larrieu Luciano, Florencia Pi Puig, Juan Manuel Vazquez and Roberto Balbuena. **P. 1606**

Systematic Literature Review of Water-Energy Nexus: An Overview of the field and analysis of the top 50 influential papers. Gabriel Pereira, Arturo Gonzalez and Richard Germán González. **P. 1610**

Efecto del coadyuvante sobre la prestación de diferentes boquillas en espigas de Trigo. Matilde Mur, Victor Merani, Facundo Guilino, Larrieu Luciano, Juan Manuel Vazquez and Roberto Balbuena. **P. 1626**

SPECIAL SESSION: **HEALTH**

Eficiencia espacial en la atención primaria de la salud en Bahía Blanca. Maria Florencia Arnaudo, Fernando Pablo Lago, Alberto Bandoni and Guillermo Durand. **P. 1642**

Comparación de Métodos Multicriterio Grupales: Procesos DRV vs AHP grupal. El caso de la gestión sobre residuos patógenos. Nadia Ayelen Luczywo, José Luis Zanazzi and Catalina Lucía Alberto. **P. 1654**

National Health Systems and doubling time of number of deaths by COVID-19 Coronavirus. Diego Muñoz-Godoy, Samuel Ponce, Naudy Leal, Macarena Albornoz, Manuel Vargas and Guillermo Fuertes. **P. 1668**

Modelación del proceso de programación de pacientes en listas de espera en un hospital público de Chile. Jaime Bustos, José Luis Toro and Sonia Salvo. **P. 1677**

Determinación de los porcentajes de aportación en el sistema de jubilación de una institución de educación superior mediante un modelo de optimización. Marco Antonio Montufar Benitez, Eva Selene Hernandez Gress, José Luis Mota Reyes, Hector Rivera Gomez and Octavio Castilo Acosta. **P. 1681**

SPECIAL SESSION: **FOOD**

Biofilm Formation on Ultrafiltration Membranes by Yeast Strains Isolated from Apple Juice Processing Industries. María del Rosario Agustín, María Clara Tarifa and Lorena I. Brugnoni. **P. 1692**

Modelado Cinético de la Degradación Térmica de Biocompuestos y de Color en Tomate Triturado. Emiliano E. Badin, Pablo D. Ribotta and Alejandro R. Lespinard. **P. 1696**

Evaluación reológica y térmica de oleogeles formulados con ceras de girasol y aceite de girasol alto oleico. Cintia Redondas, Amalia Carelli and Erica Baümler. **P. 1709**

Efecto de la Sustitución Parcial de NaCl con KCl Sobre las Propiedades Sensoriales de Queso Port Salut. Tomás Ramón Gill, Hernán Ramón Allasia, Guillermo Ernesto Hough, Mario Nicolas Lanteri and Alejandro Rafael Lespinard. **P. 1724**

Bioactividad de extractos de bagazo de cerveza. Diana Potes Vecini, Juliana Piña, Mónica Nazareno and Consuelo Pacheco. **P. 1728**

Efecto de la temperatura de secado en la microencapsulación de antioxidantes naturales. Macarena Ortiz, Juliana Piña, Mónica Nazareno and Consuelo Pacheco. **P. 1733**

Estudio cinético de parámetros de calidad nutricional y sensorial en leche tratada térmicamente. María del Milagro Mercatante, Emiliano Emanuel Badin, Javier Ramiro Arballo and Alejandro Rafael Lespinard. **P. 1742**

Nanostructured lipid carrier developed with propolis wax residues. Gabriela Krepper, Centurión María Eugenia and Erica Baümler. **P. 1753**

Relationship between microstructure, rheological behavior and kinetic stability of oleogel emulsions produced with recovered and commercial sunflower waxes. Julie Merchan Sandoval, Amalia Carelli, Erica Baümler and Camila Palla. **P. 1759**

Simulación matemática de un Desolventizador-Tostador industrial. Mauricio M. Coletto, J. Alberto Bandoni and Anibal M. Blanco. **P. 1769**

Comparison between Clarke & Wright and Nearest Neighbor methods on thermal performance of Cold Chain products during generation of distribution route. Luíza Bezerra, Vanina Silva and Diogo Silva. **P. 1784**

Evaluación tecnológica en bodega de una levadura vínica patagónica previamente propagada

en un sustrato no convencional. Sebastian Bravo, Diana Constenla and Adriana Caballero. **P. 1799**

Extracción de compuestos bioactivos de frutillas cv. Albion tratadas con ozono en fase acuosa y almacenadas en refrigeración, y evaluación de sus propiedades antioxidantes. Eunice V. Contigiani, Gabriela M. Jaramillo Sánchez, Ángela R. Romero Bernal, Paula L. Gómez and Stella M. Alzamora. **P. 1805**

Desarrollo de yogur descremado deslactosado reducido en sacarosa mediante hidrólisis enzimática. Marianina Perez Cenci, Rocío Celeste Dominguez, Agustina Rocío Fernandez and Guadalupe Fuertes. **P. 1818**

Ultrastructural Damage and Mycotoxin Accumulation of Aspergillus flavus, A. parasiticus and Fusarium verticillioides as Affected by Flavonoids: a Comparative Study. Paula Sol Pok, Silvia Liliana Resnik and Stella Maris Alzamora. **P. 1832**

Efecto del salado sobre las propiedades reológicas y la estructura de filetes de merluza (Merluccius hubbsi) utilizando diferentes métodos. Marion Daniela Marchetti, Analía Belen Garcia Loredo and María Isabel Yeannes. **P. 1846**

Evaluación de la Viabilidad de Cepas Probióticas de Lactobacillus Encapsuladas en Micropartículas de Pectina para uso en Matrices Vegetales. María Clara Tarifa, Cristian Piqueras, Diego Genovese and Lorena Brugnoni. **P. 1860**

Modelling Planetary Ball Milling of Rice Starch. Luciana González, Maria Loubes and Marcela Tolaba. **P. 1865**

Influence of olive mill waste polyphenols levels on carotenoid production by Rhodotorula mucilaginosa. Carolina Ghilardi, Amalia Antonia Carelli and Maria Virginia Borroni. **P. 1876**

Gelificación del caseinomacropéptido en presencia de sales de calcio (cloruro de calcio y acetato de calcio). Karina Loria, Ana M.R. Pilosof and María Edith Farías. **P. 1882**

Evaluación composicional de bagazo de diferentes estilos de cerveza artesanal para su valorización. Luciana M. Rodriguez, Diana T. Constenla and Ethel E. Pérez. **P. 1897**

Inactivación de Fusarium graminearum en cebada cervecera (Hordeum vulgare L.) mediante ozono en fase acuosa: potencial aplicación en la etapa de malteado. Bibiana Zuluaga Calderón, Stella Maris Alzamora, Héctor Horacio Lucas González and María Bernarda Coronel. **P. 1911**

Valorización de residuos provenientes del salado-madurado de anchoíta (Engraulis anchoita). Marion Daniela Marchetti, Rolando Jimenez Lugo and Marina Czerner. **P. 1922**

Arsénico en agua y alimentos: determinación del perfil de riesgo en Argentina. Silvina Perez, Marion D Marchetti and Alejandra Tomac. **P. 1926**

Microbioma de Engraulis anchoita salada-madurada. Silvina Perez, Maria I Yeannes and Silvia E Murialdo. **P.1931**

Efecto del ozono en fase acuosa sobre las ceras epicuticulares y el color de arándanos (Vaccinium corymbosum L.,cultivar O'Neal). Gabriela M. Jaramillo Sánchez, Eunice V. Contigiani, Stella M. Alzamora and Patricio R. Santagapita. **P. 1935**

Influencia de cultivos autóctonos iniciadores de la fermentación alcohólica sobre atributos sensoriales de vinos Patagónicos. Sebastian Bravo, Silvana del Mónaco, Adriana Caballero, Yolanda Curilen and Manuel Morales. **P. 1950**

Evaluación de emulsiones filmogénicas a base de aislado de soja y cera de abeja. Florencia Salaberría, Agustin Benestante, Ethel Pérez and Erica Baümler. **P. 1965**

Caracterización de propóleos como fuente lipídica con compuestos activos. Florencia Salaberría, María Soledad García Paoloni, Marcelo Pistonesi, Erica Baümler and Ethel Pérez. **P. 1976**

Afinidad del caseinomacropéptido con el CaCl2 a pH neutro. Karina Loria, Ana M.R. Pilosof and María Edith Farías. **P. 1980**

SPECIAL SESSION: **MANAGEMENT**

Project Management Process Resilience: Assessing and Improving the Project Review Process Using FRAM. Vinicius Bigogno Costa, Moacyr M. Cardoso Jr. and Ligia Maria Soto Urbina. **P. 1992**

Medios de pago electrónicos y evasión tributaria: el caso argentino. Florencia Verónica Pedroni, Gabriela Pesce and Anahí Briozzo. **P. 2007**

Building High Performance Teams. Thais C. Pfutzenreuter, Edson Pinheiro de Lima and José R. Frega. **P. 2022**

Human Resources 4.0: Use of Sociometric Badges to Measure Communication Patterns. Regina Moirano, Marisa A. Sanchez, Libor Štěpánek and Gastón Vilches. **P. 2037**

An Optimization Model for University Course Timetabling. A Colombian Case Study. Jaén Suárez-Rodríguez, Juan C. Piña, Laura Malagón-Alvarado, Valentina Blanco, Melissa Correa, Laura De La Rosa, Mariana Lopera, Juan Valderrama and Carlos Vega-Mejía. **P. 2052**

Identificação de fatores para avaliação da qualidade de energia elétrica: os impactos na geração, distribuição e setores de consumo. Virginia Thomasi, Heloísa Pereira Burin, Julio Cezar Mairesse Siluk and Carmen Brum Rosa. **P. 2067**

Diseño de una red de domicilios en tiendas de barrio para abastecimiento de alimentos en tiempos de COVID-19: Un enfoque de optimización lineal. Daniela Granados, Gonzalo Mejía, Laura Tinjaca and Natalia Cárdenas. **P. 2080**

Study of the location of a second fleet for the Brazilian Navy: Structuring and mathematical modeling using SAPEVO-M and VIKOR methods. Isaque Dp Almeida, José Vp Corriça, Arthur Pa Costa, Igor Pa Costa, Sérgio Mn Maêda, Carlos Fs Gomes and Marcos Santos. **P. 2095**

Localización de proveedores de salud en zonas rurales en países en desarrollo: Un enfoque de programación lineal entera mixta. Daniela Granados, Gonzalo Mejía, Gabriela Rico, Daniela Cuéllar, Nicolás Montes and Tania González. **P. 2108**

Multicriteria analysis by the PROMETHEE-SAPEVO-M1 method: a decision analysis for the closure of a bank agency. Miguel Moreira, Marcos Santos and Carlos Gomes. **P. 2123**

Development of a methodological proposal for the creation of strategic maps incorporating feasible futures. Miguel González, Quezada Luis, Pedro Palominos, Astrid Oddershede and John Rios. **P. 2137**

Toma de decisiones multicriterio para identificar los procesos de mayor impacto en la continuidad operacional en una empresa sanitaria en contexto de pandemia. Claudio Macuada, Astrid Oddershede, Luis Quezada, Pedro Palominos and Cecilia Montt. **P. 2141**

Inventory management of aftermarket: case study. Victor Sánchez Guzmán and Lourdes Loza-Hernández. **P. 2146**

Modelo de simulación de la gestión de un Job Shop. Una herramienta de soporte a la toma de decisiones. Jaime Giraldo, Omar Castrillon and Jaime Arango. **P. 2159**

A strategic reference model for the competitiveness of the port supply chain. Luis M. Ascencio, Rosa G. Gonzalez Ramirez and Stefan Voss. **P. 2174**

Adaptation of the Balanced Scorecard to Latin American Higher Education Institutions in the Context of Strategic Management: A Systematic Review with Meta-analysis. Mauricio Hinojosa. **P. 2176**

Visão Baseada em Recursos: O uso da tecnologia Blockchain na Gestão do Conhecimento. Talita Frozza and Andressa Maria Corrêa. **P. 2191**

Key Factors for the Implementation of New Technologies in Manufacturing Systems – Insights from Case Studies. Paulo Henrique Brunheroto, Cassiano Souza Beller, Fernando Deschamps and Edson Pinheiro de Lima. **P. 2206**

How do Industry 4.0 technologies impact performance objectives? Results of an empirical survey in large enterprises and SMEs of the Curitiba Metropolitan Region. Paulo Henrique Brunheroto and Fernando Deschamps. **P. 2221**

Transformação digital na prestação de serviços: mapeamento de tecnologias. Talita Frozza, Fernando José Avancini Schenatto and Edson Pinheiro de Lima. **P. 2236**

Explorando lacunas em modelos de maturidade existentes para avaliação da cadeia de suprimentos inteligente – uma revisão literária. Adalberto dos Santos, Eduardo Alves Portela Santos and Silvana Pereira Detro. **P. 2249**

Service network design problem in freight transportation. A literature review. Jessica Jazmin Vazquez-Azotea, Javier Garcia-Gutierrez, Lourdes Loza-Hernandez and Ma. De Lourdes Najera-Lopez. **P. 2264**

SPECIAL SESSION: **MACHINE LEARNING AND BIG DATA IN INDUSTRIAL PROCESSES**

Exploring Machine Learning Integration with Operations Strategy. Thais C. Pfutzenreuter, Nathália R. G. Chamie, Edson Pinheiro de Lima and Sergio E. Gouvea da Costa. **P. 2273**

A Database Curation for Prediction of the Refractive Index in the Virtual Testing of Polymeric Materials by using Machine Learning. Santiago Ariel Schustik, Fiorella Cravero, Ignacio Ponzoni and Mónica Fátima Diaz. **P. 2285**

Big data analytics process architecture for manufacturing industries: a literature review. Letícia Alves dos Santos Rosolem, Fernando Deschamps, Edson Pinheiro de Lima and José Marcelo Almeida Prado Cestari. **P. 2300**

SPECIAL SESSION: **PRODUCTIVITY**

Melhores práticas em eficiência energética em edifícios comerciais: uma discussão sobre modelos existentes. Barbara Bonfim Catapan, Sergio E. Gouvea da Costa and Edson Pinheiro de Lima. **P. 2315**

Análisis de eficiencia de los bancos nacionales de los países del Mercosur en entornos difusos. Claudia Peretto and Cecilia Solange Cáceres. **P. 2320**

Evaluación de la Eficiencia Técnica de los Centros de Atención Primaria Salud en la Ciudad de Bahía Blanca. Facundo Durán, María Eugenia Elorza, Fernanda Villarreal, María Florencia Arnaudo and Pablo Luis Acrogliano. **P. 2324**

SPECIAL SESSION: **MECHATRONICS**

A Proposal for an Interoperable Data Collection System for Production Control on CNC Machining Lines of a Healthcare Product. Victória R. S. Camargo, Thomas V. B. Amaral, Sofia T. Helena, Matheus Beltrame Canciglieri, Athon Francisco Curi Staben de Moura Leite and Anderson Luis Szejka. **P. 2339**

SPECIAL SESSION: **MECHANICAL**

Máquina Paletizadora: Processo de Desenvolvimento do projeto. Grabriel Krause, Diogo Belle and Fernando José Avancini Schenatto. **P. 2353**

SPECIAL SESSION: **EDUCATION**

Teaching Artificial Intelligence using Project Based Learning. Marc Dahmen, Luis Quezada,

Miguel Alfaro, Guillermo Fuertes, Claudio Aballay and Manuel Vargas. **P. 2369**

Modelización matemática para la toma de decisiones en proyectos interdisciplinarios. Pablo Carranza. **P. 2387**

Restructuración del dictado de materias de Matemática en las carreras de Ingeniería en Alimentos e Ingeniería en Biotecnología. Griselda R. Itovich and Juan I. Laiglecia. **P. 2391**

Autoevaluación y Coevaluación para la mejora continua del trabajo en grupo: Aplicación y experiencia en clases virtuales. Antonella Cavallin and Elda Monetti. **P. 2398**

Modelo matemático para evaluación adaptativa. Sebastián Dávila, Óscar Vásquez and Luis Osorio. **P. 2417**

SPECIAL SESSION: **METAHEURISTICS**

Optimización por Colonia de Hormigas para el Ruteo del Picking en Almacenes de Múltiples Bloques. Jose Alejandro Cano, Emiro Antonio Campo, Alexander Alberto Correa-Espinal and Rodrigo Andrés Gómez-Montoya . **P. 2423**

A decision support tool for the location routing problem during the COVID-19 outbreak in Colombia. Andres Felipe Martinez Reyes, Carlos Quintero Araujo and Elyn Lizeth Solano Charris. **P. 2428**

Simulated Annealing metaheuristic approach for generating alternative corridor locations. Pedro Moreno and Sergio Nesmachnow. **P. 2443**

Algoritmo evolutivo híbrido basado en la división del espacio de los objetivos para el problema de la mochila bi-objetivo. Daniel Alejandro Rossit, Máximo Méndez, Mariano Frutos and Begoña González. **P. 2458**

Redes neuronales LSTM aplicadas a la predicción de oleaje en tiempo real para generación de energía undimotriz en las Islas Canarias. Carlos Hernández, Máximo Méndez, Ricardo Aguasca-Colomo and Begoña González. **P. 2472**

Algoritmos genéticos para la toma de decisiones en la cadena de valor apícola. Luciana Belén Villar, Martín Carlos De Meio Reggiani, Hernán Pedro Vigier and Nélida Beatriz Brignole. **P. 2486**

Dynamic Order Acceptance and Scheduling Approach for On-demand Production with Additive Manufacturing by Considering Idle Costs. Qiang Li, David Zhang and Ibrahim Kucukkoc. **P. 2501**

A Decomposition Approach for the Combined Inventory Routing and Scheduling Problem. Carlos Franco and Eduyn López-Santana. **P. 2515**

Resolución de los problemas Order Batching / Picking a través de un Algoritmo Evolutivo. Fabio Maximiliano Miguel, Mariano Frutos, Máximo Méndez and Fernando Tohmé. **P. 2519**

Una Metaheurística de Recocido Simulado para Resolver un Problema de Ruteo de Vehículos en la Recolección de Residuos. Matías Fermani, Diego Gabriel Rossit and Adrián Toncovich. **P. 2531**

A simulation-based optimization framework for a comparative analysis of different heuristics applied to discrete-event simulation. Juan Pablo Morandé, Rosa González-Ramirez and Sergio Quijada. **P. 2545**

Simulated Annealing Algorithm for In-Plant Milk-Run System. Islam Altin and Aydin Sipahioglu. **P. 2561**

Aplicación de optimización y metaheurísticas al problema de ruteo de vehículos periódico integrando programación y frecuencia de servicio. Sergio Esteban Vega Figueroa, Paula Andrea López Becerra and Eduyn López Santana. **P. 2577**

Un algoritmo de Búsqueda Tabú para el problema de Ruteo de Vehículo Milk Run con ventanas de tiempo (VRPMRTW). Carlos Eduardo

Díaz Bohórquez, Lina Mayerly Lozano Suarez and Laura Ximena Sanchez Rincón. **P. 2581**

Periodic vehicle routing with consistency and synchronization constraints for nanostore fulfilment in emerging markets. Andres Gomez, Juan Carlos Rivera and Juan Guillermo Villegas. **P. 2597**

SPECIAL SESSION: **SCHEDULING**

Nueva representación para la resolución simultánea del batching y scheduling en una planta batch multiproducto. Sergio Ackermann, Yanina Fumero and Jorge Marcelo Montagna. **P. 2602**

Flow-shop con consideraciones energéticas y aplicación de lot-streaming. Florencia D'Amico, Daniel Alejandro Rossit and Mariano Frutos. **P. 2616**

Formulação indexada no tempo e algoritmo heurístico para um problema integrado de localização e sequenciamento. Raphael Kramer and Arthur Kramer. **P. 2630**

Impacto de la productividad y la polifuncionalidad laboral en la gestión de personal: caso aplicado a la industria retail. Silvana Vergara, Jairo Del Villar, James Masson, Natalia Pérez, Cesar Augusto Henao and Virginia González. **P. 2644**

Two-stage stochastic optimization model for personnel days-off scheduling using closed-chained multiskilling structures. Orianna Fontalvo Echavez, Laura Fuentes Quintero, César Augusto Henao and Virginia I. González. **P. 2659**

Beneficios de la polifuncionalidad laboral en la industria retail: Enfoque "k-chaining" con incertidumbre en la demanda. Yessica Mercado Morales and César Augusto Henao. **P. 2672**

Aplicações da Simulação de Monte Carlo em problemas de Programação Linear: uma revisão sistemática da literatura. Jaqueline Marchiore Petri, José Donizetti de Lima and Fernando José Avancini Schenatto. **P. 2687**

2D Nesting and Scheduling in Metal Additive Manufacturing. Ibrahim Kucukkoc, Zixiang Li and Qiang Li. **P. 2702**

A Genetic Algorithm for Flexible Job Shop Scheduling Problem with Scarce Cross Trained Setup Operators. Dolapo Obimuyiwa and Fantahun Defersha. **P. 2717**

Using the k-chaining approach to solve a stochastic days-off-scheduling problem in a retail store. María Abello, Nicole Ospina, Julia De la Ossa, César Henao and Virginia González. **P. 2732**

Heuristic methods for the m-machine blocking flow shop with setup times to minimize hierarchical objective-function. Hugo H. Miyata and Marcelo S. Nagan. **P. 2747**

Heuristics for earliness and tardiness scheduling of identical parallel machines subject to common restrictive due windows. Gustavo A. Rolim and Marcelo S. Nagano. **P. 2762**

The Online Lot Streaming Problem: A Characterization and Solution Approach for Flexible Job Shop Environments. Juan M. Novas. **P. 2777**

Uso de la Programación por Metas y del Proceso Analítico de Jerarquías para la obtención de la mezcla de productos. Claudia Zárate, María Betina Berardi and Alejandra María Esteban. **P. 2781**

Customer order scheduling problem to minimize total tardiness with sequence-dependent setup times. Massimo Pinto Antonioli, Carlos Diego Rodrigues and Bruno de Athayde Prata. **P. 2796**

A Research Direction in Manufacturing Systems Scheduling: A proposal. Fantahun Defersh. **P. 2809**

Modeling and Solving the Total Flow Time Fixed Group Shop Scheduling Problem. Francisco Yuraszeck, Gonzalo Mejía and Jordi Pereira. **P. 2819**

SPECIAL SESSION: **SUSTAINABLE**

Production Planning with Remanufacturing and Environmental Costs. Luciana Vidal, Pedro Piñeyro, Omar Viera, Paula Martínez and Diego Molina. **P. 2824**

Simultaneous lot-sizing and scheduling with recovery options: problem formulation and analysis of the single-product case. Pedro Piñeyro and Daniel Rossit. **P. 2837**

Planificación de minutas alimentarias para el casino central de una Universidad Pública de Chile: Un enfoque para la reducción de la huella de carbono. Javiera García-Leal, Andrea Teresa Espinoza Pérez and Oscar C. Vásquez. **P. 2849**

Technologies investments in the era of digital transformation and sustainable development. Diego Audrey de Lima Lamezon, Edson Pinheiro de Lima and Sergio Eduardo Gouvea da Costa. **P. 2854**

PLENARY SPEAKERS

Manufacturing Scheduling: Old solutions for new problems?

Jose M Framinan[1][0000-0003-0619-8508]

[1] Industrial Management / Laboratory of Engineering for Environmental Sustainability, University of Seville, Ave. Descubrimientos s/n, Sevilla E41092, Spain
framinan@us.es

Abstract. The talk addresses how the production research community can cope with the incoming changes in technology, customers, and environment that are taking place and that we expect that will shape the future manufacturing scenarios. More specifically, the focus is on the scheduling business function and on how it can be performed in these new manufacturing scenarios. Three cases will be used to illustrate these aspects.

Keywords: Manufacturing Scheduling, Industry 4.0.

1 Introduction

A number of technological changes and environmental drivers –some of them summarized in Fig. 1– are dramatically changing the manufacturing landscape, so it seems pertinent to ask how these changes can affect the scheduling function. The potential impact of these changes is exemplified using three cases.

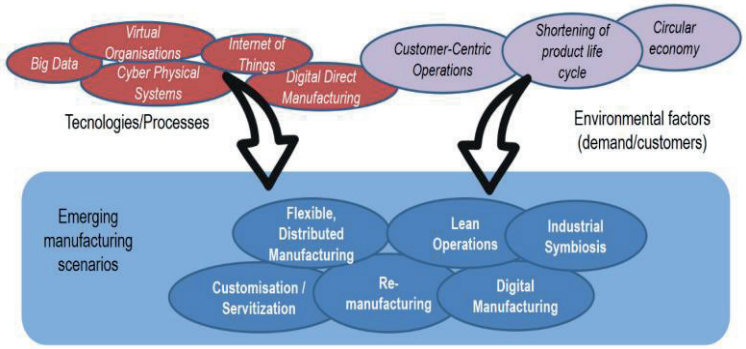

Fig. 1. New manufacturing scenarios

2 Some cases

The first case refers to scheduling Additive Manufacturing (AM) processes, which is an example of 'new' manufacturing scheduling problem that can be addressed using

the standard modelling methodology. So far, most of the research work has been done on the nesting problem (i.e. grouping the parts to be printed), with lesser work on scheduling, and even less in the combined nesting & scheduling problem. Furthermore, the preferred layout is the single/parallel machine, and the hybrid and assembly layouts (required in many cases to address the required polishing and finishing operations) have been insufficiently studied. This situation is rapidly changing, with a fast-increasing number of papers in this area (see e.g.[1] for a review).

The second case refers to the use of real-time information for rescheduling. The technological developments in Industry 4.0 envision a scenario where real-time data from different sources is potentially available. The big question is how this data can be used to improve scheduling performance, as it is clear that these real-time data could be used to reschedule the jobs in order to adapt to the shop floor status. The (limited) studies existing so far (e.g.[2,3]) seem to point out that these advantages should not be taken for granted, and are achieved only under a rather limited set of conditions, including performing complete rescheduling (as opposed to frozen sequences), or using efficient stochastic optimization methods and sophisticated rescheduling policies. This problem constitutes a rich vein of future research topics, ranging from computational complexity issues to reduce the computational effort of the stochastic optimization methods to devising intelligent triggers for rescheduling.

The third case refers to the potential of decentralized scheduling. Decentralized approaches for scheduling (such as the one presented in [4]) are known to be able to handle the extreme complexity of these manufacturing scenarios, however their performance is considered to be inferior to centralized (i.e. optimization) approaches. However, we show in an experiment that this performance gap quickly disappears with the uncertainty of the manufacturing scenario (in our experiment, this uncertainty is modelled using stochastic processing times). One key challenge is to combine both approaches so the advantages of both methodologies are obtained. To do so, new decision frameworks/architectures have to be developed.

Perspectives and trends of Industry 4.0 in Latin America

Gonzalo Mejía Delgadillo [0000-0002-3769-2683]

Universidad de la Sabana, Colombia

gonzalo.mejia@unisabana.edu.co

Abstract

In recent years, the advent of Industry 4.0 technologies has changed the world. Industry 4.0 is clearly not a buzzword or trend; Industry 4.0 and its successors (Industry 4.1? 5.0?, 4.01?) are here to stay. Despite its popularity, there is no agreement on what it exactly is and how it can be implemented; as of today, nobody can simply go shopping for Industry 4.0. Moreover, the adoption pace of such technologies has been dissimilar. Although no society in the world has disregarded the impact of this digital transformation, emerging economies sometimes struggle to "jump on the bandwagon". This comes at no surprise due to shortage of connectivity, infrastructure and… maturity. However, something needs to be done. This talk first introduces the current topics and technologies then addresses new trends and perspectives of Industry 4.0 in Latin America with special focus on production systems, urban transportation, and supply chain. The talk also examines potential areas of application and new research topics specific for the Americas region.

Digitalization of manual production and assembly processes for smart factories of the future

Francesco Pilati[1]

[1] Department of Industrial Engineering - University of Trento, via Sommarive 9, 38123 Trento, Italy

francesco.pilati@unitn.it

Abstract.
Nowadays factories operating within the Industry 4.0 revolution require more and more reliable, fast and automatic tools for production analysis and improvement. Manufacturing companies, in which the human labor still has a crucial role, need digital tools and techniques able to manage complex production systems in terms of resource utilization, product mix, component allocation and material handling optimization.
Within this context, this plenary talk presents an original hardware/software architectures aimed at the human body digitalization and analysis during the execution of manufacturing/assembly tasks within common industrial workstations. The proposed solutions are based on the integration of the multiple sensors technologies with ad hoc software developed for productive and ergonomic analysis of the operator during his work. The suggested hardware integrates network of depth cameras, inertial sensors and other technologies, while original software infrastructure is conceived to automatically and quantitatively provide productive and ergonomic information. The former deals with human task analysis in terms of time execution and used space within the workplace, movements of hands and locations visited by the operator. The latter is focused on full body analysis implementing all the internationally adopted indexes as OWAS, REBA, NIOSH and EAWS. This double perspective makes the proposed digital solution for smart factories of the future a unique and valuable tool for industrial managers oriented to the workplace analysis and design in terms of productivity without neglecting the operator health. Real industrial applications of the proposed technology are presented and key results discussed analyzing multiple settings of production processes in which human operator plays a crucial role.

Managing Macro Level Supply Chain Disruptions: Lessons from COVID-19

Srinivas Talluri

Michigan State University, USA
talluri@broad.msu.edu

Abstract

This talk discusses the current supply chain strategies that may have contributed to the disruptive impact of COVID-19. We suggest both short-term and long-term strategies that companies can utilize to minimize the impact of such a disruption in future. Specific emphasis is on flexibility and redundancy approaches, identifying vulnerabilities in networks, understanding topology of robust and resilient networks, and improving supply chain visibility

Abstract. There are several reasons for an organization to begin managing its energy use more efficiently. Regulations, resource scarcity, environmental impacts, increased consumer pressure and increased competitiveness are all reasons that have highlighted energy management in recent years, both in the political and business landscape. In addition, associated with the expectation of increasing the efficiency of energy management systems, the application of technologies from Industry 4.0 is discussed. While promising, there are still few studies in the literature that address the relationship between these areas. Thus, through an integrative systematic literature review, this paper presents and discusses the concepts and characteristics of Advanced Energy Management Systems, which are based on the integration of Energy Management Systems and I4.0 technologies. The paper guides future works and companies that wish to apply Industry 4.0 technologies to their energy management systems by presenting potential benefits of this integration.

Keywords: Energy Management System, Industry 4.0, Energy Efficiency.

1 Introduction

Energy management (EM) has been widely discussed within organizations in recent years, given the scarcity of energy resources, intensification of legislation, greater awareness by clients, among other reasons. EM is understood as the activities and procedures that systemically seek to reduce both energy consumption and its related costs.

The use of renewable energy sources is an alternative for the long term, however a more efficient use of energy resources is characterized as an immediate countermeasure to the problems faced by organizations [1]. Then, in order to enhance energy management, authors such as [2] and [3] advocate the integration of energy management systems (EMS) with advanced information and communication technologies (AICT), characterized by the elements of Industry 4.0. Among the benefits pointed out in the literature, it can be highlighted the improvement of monitoring and measurement systems, the improvement of data collection and treatment, as well as contributing to and facilitating decision making.

Thus, based on the literature, the main objective of this article is to identify the elements and characteristics of this integration, in order to understand how EMS are correlated with information and communication technologies (ICT). In this paper, this new configuration is called Advanced Energy Management Systems (AEMS).

2 Research design

In order to identify the elements and characteristics of the integration between EM and AICT, the applied methodology was a systematic literature review (SLR).

After a preliminary search in the database, it was noticed that the number of studies that deal with the two themes together or relating them is still scarce. Therefore, as a research strategy, it was decided to carry out two SLR and correlate the themes. The first review deals with Energy Management and the second with Industry 4.0 (I4.0). This strategy was called Integrative Systematic Literature Review (see Figure 1).

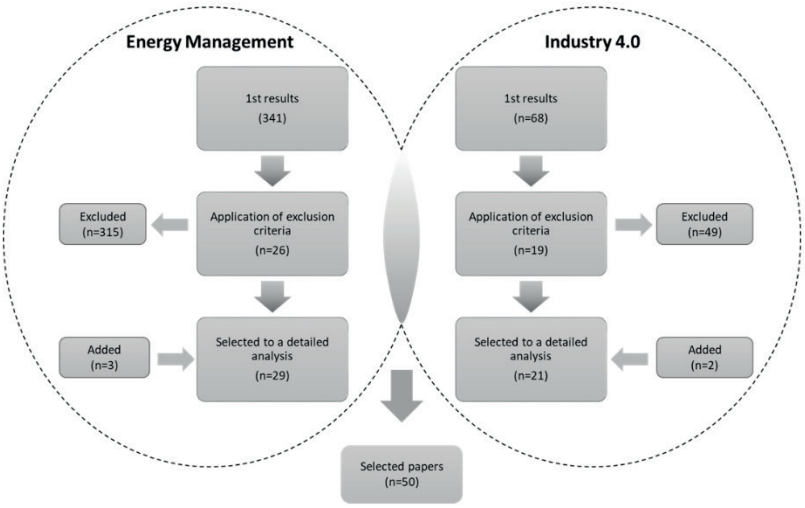

Fig. 1. Integrative Systematic Literature Review

Based on the procedure proposed by [4], the literature reviews assessed the papers registered in the Scopus database. After applying the keywords, a total of 409 papers were found. Following this first result, the papers were filtered through the application of exclusion criteria, leaving 45. After reading these papers, it was found 5 other relevant works (cited by previous authors), which were added at the end. Thus, the final base has a total of 50 works.

The literature reviews were followed by a content analysis that allowed authors to identify concepts and practices of EM and I4.0. Then it was possible to present how these two areas are connected.

3 Advanced energy management systems

EM can be understood as the effective and reasonable use of energy resources, to maximize profits and guarantee competitive positions to the company, through organizational and energy efficiency measures [5]. Although it can be described in a simplified way, this management is composed of activities and systematic procedures that require both the involvement of the areas directly linked to the production processes as well as the support areas [6].

The objectives of EM are to reduce the energy demand for products and services and eliminate waste, maintaining productive capacity [7]. To that end, EMS are used. In the literature, we can find several models, such as those proposed by [8], [6], [9] and [10], which guide the structuring of EMS.

The availability of relevant information is an essential element of EMS, so that not only can the system be properly structured, but also so that projects, activities and decisions are appropriate to the organization's reality and needs. For [8], I4.0 technologies are key elements in this context, as they facilitate the visualization and interpretation of information. Thus, it can be said that they add value to the available data.

I4.0, based on the combination of CPS and IoT, uses the available information and the communication network to expand the exchange of information between business and production processes, in a way that feeds the systems and adds value [11, 12]. Therefore, according to [13], I4.0 makes systems structure more flexible, improves event traceability, improves adherence to individual needs and facilitates decisions, among other benefits.

Thus, given this new scenario, where there is availability and transparency of information, intensification of connectivity between processes and flexibility of systems, EM benefits in several ways. The most evident is the wide availability of data, which allows organizations to carry out control at three different levels, starting with measuring the performance of a production plant, where there is a high level of data aggregation. The intermediate level is aimed at specific production lines or areas, while the last level, in greater detail, is the machine level [8, 14].

Moreover, using this greater availability of data and intelligent numerical controllers, equipment and systems can self-manage, so they have autonomy to adjust their settings and reduce their energy consumption.

Another important contribution of I4.0 to EMS is the ability to connect with other systems, so that integrations of EMS with ERP-type systems or CAx tools are possible [15]. This integration not only makes corrective actions faster, but also allows energy consumption indicators to be related and treated together with traditional performance indicators.

4 Conclusion

By means of an integrative literature review, this paper introduced the concept of Advanced Energy Management Systems, which are based on the integration between Energy Management and I4.0. Among the improvements enabled by this combination, it

can be highlighted the enhancement of control functions, integration of machines and systems, self-control and greater understanding of potential energy savings.

Thus, the use of I4.0 technologies is changing the way energy consumption is managed, moving from diagnostic to prognostic systems, helping to reduce energy costs in manufacturing.

Abstract. Power supply is one of the basic needs in modern *smart homes*. Computer-aid tools help optimizing energy utilization, contributing to sustainable goals of modern societies. For this purpose, this article presents a mathematical formulation to the household energy planning problem and a specific resolution method to build schedules for using deferrable electric that can reduce the cost of the electricity bill while keeping user satisfaction at a satisfactory level. User satisfaction have a great variability, since it is based on human preferences, thus a stochastic simulation-optimization approach is applied for handling uncertainty in the optimization process. Results over instances based on real-world data show the competitiveness of the proposed approach, which is able to compute different compromise solution accounting for the trade-off between these two conflicting optimization criteria.

Keywords: smart cities; energy planning; mixed-integer programming; simulation; multiobjective optimization.

1 Introduction

The paradigm of smart cities aims at increasing resource efficiency in several daily activities that citizens perform in urban environments. In the case of energy management, this aim is not only related to the amount of energy consumed, but also to the infrastructure required to distribute the energy [3]. The capacity of this infrastructure is often conditioned by peak consumption, as it should be able to distribute the energy during the periods of high demand without producing power outages. However, if consumption of a certain area is remarkably

unbalanced (having important variations along the day), this would required a large investment in infrastructure that will be idle the most of the time [10].

The introduction of time-of-use pricing in electricity bills for households is a major contributor to the overall efficiency of the electrical system, since it incentives citizens to have a smoother consumption patron, displacing the usage of electric devices from expensive peak hours to relatively cheaper off-peak hours. This behavior reduces the maximal instant power consumption of an urban area and, therefore, cuts back the required infrastructure investment to handle the peak and the risk of power outages [10]. However, usually off-peak hours, in which electricity is cheaper, are not preferred by users for using their appliances. This effect, which is known as inconvenience due to timing [1], can affect the well-being of the users. Therefore, there is a trade-off between both criteria, i.e., electricity cost and users satisfaction. Intelligent computer-aid tools may help users in the decision-making process of scheduling their deferrable devices [19].

This article proposes a novel mixed integer programming model for scheduling the deferrable electric appliances usage in households, which simultaneously considers minimizing the electricity cost and maximizing the users satisfaction. Users satisfaction measures to what extend the starting time and duration for appliances usage scheduled by the model match the users preferences–which is estimated through the analysis of historical data [4, 5, 22]. However, since this parameter can show certain variability between different days, a simulation-optimization resolution approach that considers this stochastic behaviour is devised. Therefore, the main contributions of the research reported in this work include: i) a compact mathematical formulation for the energy household problem, ii) the application of a stochastic resolution approach to consider uncertain users preferences, and iii) experimental evaluation over instances based on real-world data and analysis of the results.

The article is structured as follows. Section 2 presents the analysis of the main related works. The proposed mathematical formulation is outlined in Section 3. Section 4 describes the proposed simulation-optimization resolution approach. Section 5 describes the computational experimentation conducted to evaluate its effectiveness, and reports the numerical results for realistic problem instances. Finally, Section 6 formulates the conclusions and describes the main lines of future research.

2 Related work

Household energy planning has been considered as a complex problem in the related literature. The deterministic version (scheduling non-interruptible electric appliances) is associated with bin packing [16], a well-known NP-hard problem. Moreover, including uncertainty increases the complexity of the problem [17]. Several articles have considered uncertainty in this kind of problem. For a recent review, we refer to Lu et al. [18] for a comprehensive analysis of the topic and Liang and Zhuang [17], who focused on stochastic applications.

Uncertainty in energy household planning problems has been considered in several aspects. Chen et al. [6] considered uncertainties in the power consumed by the appliances and the renewable solar energy gathered by a photovoltaic array. A three-stages resolution process was proposed. First, a deterministic linear programming optimization model considering mean values for the appliances consumption and maximum solar power generation was solved. A stochastic procedure based on Monte Carlo simulation was applied to the resulting solution. The simulation considers different energy consumption rates of appliances and selects the consumption rate that minimizes the probability of shortcuts, which occurs when the overall consumption of electricity surpass a certain threshold value. Finally, an online adjustment of the previous (offline) solution was applied, which monitors the instant solar power generation and the consumption of appliances in real-time, compensating the household electric balance of the offline solution with a larger power storage in the battery or purchase from the grid. Hemmati and Saboori [12] proposed a particle swarm optimization algorithm to deal with uncertainty of photovoltaic panels in a similar problem. Assuming that the energy generated in the panels has a Gaussian probabilistic distribution, a Monte Carlo simulation was used each time the stochastic the stochastic function has to be evaluated to obtain a sample of the generation values.

Other researchers have used robust optimization, which aims at minimizing the impact of the worst-case scenario, considering that aleatory parameters have a bounded probabilistic distribution [1]. Jacomino and Le [13] presented a robust optimization approach to simultaneously minimize energy cost and maximize the comfort of users. They considered uncertainty in two aspects: the outdoor temperature and the solar radiation (related to weather forecast), that affect the energy to be consumed to satisfy the required indoor temperature, and users decisions related to not programmable services, i.e., despite the scheduled starting time and duration of the appliances the user can modified these conditions when actually using them. For handling uncertainty on users behaviour, a decomposition approach based on estimating the probability of occurrence of each scenario was used. Wang et al. [28] proposed a robust optimization approach for dealing with photovoltaic energy generation in household planning by using a mixed integer quadratic programming model, and Wang et al. [29] for dealing with uncertainty in hot water utilization and outdoor temperature that influences the usage of heating and air conditioning systems.

Other authors, although they have not consider uncertainty in their models, they have explored the trade-off that usually exists between electricity cost and users satisfaction through linear mathematical programming approaches -as it is performed in this work-. Among them, Yahia et al. [30] modeled a bi-objective problem considering these two objectives, which were combined by means of a linear weighted sum to form a unique objective function. They solved two single-household instances, i.e., a real South African case study and an artificial large instance, using LINGO. Additionally, they performed an extensive analysis of the sensitivity of the results to the modifications of certain parameters. The same authors expanded their work in [31] by considering as a third ob-

jective the reduction of the peak load. Moreover, in this last work they solved an instance considering several households simultaneously. They applied and compared three different multiobjective approaches: lexicographic optimization, normalized weighted sum and compromise programming.

This work contributes to the literature in several aspects. Firstly, a novel linear mathematical formulation of the household planning energy problem that explicitly considers users satisfaction as an objective function is presented. Approaches as such are not common in the related work [30]. Moreover, this is an improved mathematical formulation compared to the one presented in our previous work [20] for a similar conceptual model, having a smaller number of variables and restrictions. Secondly, this work considers stochastic users preferences which differentiates it to other linear programming applications in the related work [30, 31]. This leads to the final aspect that differentiates this work that is the application of the simulation-optimization Sample Average Approximation method to handle the uncertainty which has not been applied to this specific problem before.

3 Mathematical formulation

The household energy planning problem addressed in this article aims at reducing expenses of electricity in households while enhancing users satisfaction. This last objective was estimated by considering in which part of the day users prefer to use the appliances (inferred from historical data). Then, the mathematical formulation considers the following elements:

Sets:

- a set of users $U = \left(u_1 \dots u_{|U|}\right)$, each user represents a household;
- a set of time slots $T = \left(t_1 \dots t_{|T|}\right)$ in the planning period;
- sets of domestic appliances $L^u = \left(l_1^u \dots l_{|L|}^u\right)$ for each user u;

Parameters:

- a penalty term ρ^u applied to those users that surpass the maximum electric power contracted;
- a parameter D_l^u that indicates the average time of utilization for user u of appliance $l \in L^u$;
- a parameter C_t that indicates the utilization cost (per kW) of the energy in time slot t;
- a parameter P_l^u that indicates the power (in kW) consumed by appliance l;
- a binary parameter UP_{lt}^u that is 1 if user u prefers to use the appliance $l \in L^u$ at time slot t, 0 in other case;
- a parameter E^u that indicates the maximum electric power contracted by user u;
- a parameter E^{joint} that indicates the maximum electric power that the (whole) set of users U are allowed to consume;

Variables:

- a binary variable x_{lt}^u that indicates if user u has appliance $l \in L^u$ turn on at time slot t;
- a binary variable δ_{lt}^u that indicates if the appliance $l \in L^u$ of user u is turn on from time slot t up to a period of time that its at least equal to D_l^u;
- a binary variable ψ_t^u that indicates if the user is using more power than the maximum power contracted E^u.
- a binary variable Ψ_t^u that indicates if the user is using more power than 130% of the maximum power contracted E^u .

The problem aims at finding a planning function $X = \{x_{lt}^u\}$ for the use of each household appliance that simultaneously maximizes the user satisfaction (given the users preference functions) and minimize the total cost of the energy consumed. The mathematical formulation is outlined in Eqs. (1)-(11).

$$\max F = \sum_{u \in U} \sum_{l \in L^u} \sum_{\substack{t_1 \in T \\ t \leq |T| - D_l^u}} \left(\delta_{lt_1}^u \left(\sum_{\substack{t_2 \in T \\ t_1 \leq t_2 < t_1 + D_l^u}} U P_{lt_2}^u \right) \right) \tag{1}$$

$$\min G = \sum_{t \in T} \sum_{u \in U} \left(\sum_{l \in L^u} x_{lt}^u P_l^u C_t + \rho^u \left(0.3 \psi_t^u + 0.7 \Psi_t^u\right) \right) \tag{2}$$

Subject to

$$\delta_{lt}^u \leq 1 - \frac{D_l^u - \left(\sum_{\substack{t_2 \in T \\ t \leq t_1 < t + D_l^u}} x_{lt_1}^u \right)}{D_l^u}, \ \forall \ u \in U, l \in L^u, t \in T \tag{3}$$

$$\sum_{t \in T} \delta_{lt}^u = n_l^u, \ \forall \ u \in U, l \in L^u \tag{4}$$

$$\psi_t^u \geq \frac{\sum_{l \in L^u} P_l^u x_{lt}^u - E^u}{\sum_{l \in L^u} P_l^u}, \ \forall \ t \in T \tag{5}$$

$$\Psi_t^u \geq \frac{\sum_{l \in L^u} P_l^u x_{lt}^u - 1.3 E^u}{\sum_{l \in L^u} P_l^u}, \ \forall \ t \in T \tag{6}$$

$$\sum_{\substack{u \in U \\ l \in L^u}} P_l^u x_{lt}^u \leq E_{joint}, \ \forall \ t \in T \tag{7}$$

$$\psi_t^u \in \{0,1\}, \ u \in U \forall \ t \in T \tag{8}$$

$$\Psi_t^u \in \{0,1\}, \ u \in U \forall \ t \in T \tag{9}$$

$$\delta_{lt}^u \in \{0,1\}, \ \forall \ u \in U, l \in L^u, t \in T \tag{10}$$

$$x_{lt}^u \in \{0,1\}, \ \forall \ u \in U, l \in L^u, t \in T \tag{11}$$

Eq. (1) aims at maximizing the users satisfaction according to their preferences. Eq. (2) aims at minimizing the energy expense budget, which include the

charge for energy consumption and the penalization for exceeding the maximum power contracted. Eq. (3) enforces δ_{lt}^i to be one when the length of time an appliance will be on is equal or larger than the required by the user. Eq. (5) enforces ψ_j^i to be one if the user exceeds the maximum power contracted. Eq. (6) enforces Ψ_j^i to be one if the user exceeds the maximum power contracted for more than 30%. Eq. (7) enforces that the joint electric consumption by the set of users do not surpass a certain threshold maximum power. This equation is included when users are part of the same housing unit, e.g., an apartment building. Eqs. (8)-(11) establishes the binary nature of the variables.

4 The proposed simulation-optimization resolution approach for the stochastic household energy planning

Real-world data shows that considering users preferences (UP) as a deterministic parameter does not adjust to reality [15]. Users satisfaction can be modelled more accurately if uncertainty is taken into account for preferences in the model. Therefore, this article develops a resolution approach that considers this stochastic behaviour.

4.1 Bi-objective optimization

In order to handle the biobjective nature of the optimization problem presented in Section 3, a weighted sum optimization approach is applied. The weighted sum is a traditional method in the multiobjective optimization literature which has extensively been used in many applications, including for the energy household related problems [1]. Applying this approach, Eqs. (1) and Eqs. (2) are jointly optimized with Eq. (12), where w_F and w_G are the relative weights given to each criteria by the decision-maker.

$$\max H = w_F \frac{F - F^{best}}{F^{best} - F^{worst}} - w_G \frac{G - G^{best}}{G^{worst} - G^{best}} \tag{12}$$

One of the main drawbacks of this method is to know the actual best and worst values of each objective within the set of non-dominated solutions which are used for normalization (i.e., F^{best} and G^{best}, F^{worst} and G^{worst} in Eq. (12), respectively). In this work, for addressing this issue, the procedure proposed in Rossit [24] and applied in Rossit et al. [25] is used. This is a two step procedure. In the first step, the best and worst values of each objective are approximated by solving the single objective problem of each of the criteria involved. These values, which are likely to be dominated [2], are improved in the second step of the procedure. In this second phase, these best and worst values are used in the weighted sum formula (Eq. (12)) along with a biased combination of weights. This is, two different problems are solved, one problem using $w_F >> w_G > 0$ and the other problem using $w_G >> w_F > 0$. Finally, from the solutions of these last two multiobjective problems, the new best and worst values are obtained.

4.2 Sample Average Approximation method for considering stochastic users preferences

Formally, in a stochastic optimization problem with a probabilistic objective function, the expected value of this function should be optimized. In the case of the formulation described in Section 3, if parameters UP are considered stochastic, Eq. (1) should be replaced by Eq. (13).

$$e = \mathbb{E}_{\mathbf{P}} \left[F \left(\mathbf{\Delta}, \mathbf{UP} \right) \right]. \tag{13}$$

In Eq. (13), **UP** is the random vector of the stochastic users preferences and $\mathbf{\Delta}$ is the vector of decisional variables δ described in Section 3. In order to optimize Eq. (13), all the possible realizations of vector **UP** with its corresponding probability should be considered. Taking into account that the model of Section 3 uses a finite set of time slots, the set of possible realizations of **UP** is also finite. Particularly, there are $|T|^{\sum_{u \in U} |L^u|}$ realizations of this vector, each one constituting a possible scenario for the stochastic problem. For example, consider an instance in which the day is split in intervals of 30 minutes, i.e., $|T| = 48$, there two users (households) and each user has only two appliances ($|L^{u_1}| = |L^{u_2}| = 2$). Then, the number of possible scenarios would be $48^4 = 5,308,416$.

For the cases in which the large number of scenarios of real-world instances makes impractical to compute the exact expected value of Eq. (13), the expected value can be approximated with an independently and identically distributed (i.i.d.) random sample. This technique is called the "sample-path optimization" [23] or "sample average approximation" [26]. Thus, Eq. (14) is an estimator of the expected value of Eq. (13).

$$\hat{e} = \frac{1}{N} \sum_{j=1}^{N} F \left(\mathbf{\Delta}, \mathbf{UP^j} \right) \tag{14}$$

As aforementioned, the set of values $UP^1, ..., UP^N$, is an i.i.d. random sample of N realizations of the stochastic vector parameter **UP**. The optimization problem obtained when Eq. (14) is used instead of Eq. (13), is the sample average approximation optimization problem (hereafter SAA) and can be solved deterministically with commercial solvers. Clearly, the solution of the SAA problem depends on the realizations **UP** that are included in the random sample. Moreover, the larger the size of the sample (N), the smaller is the difference between Eq. (13) and its estimator Eq. (14). Particularly when $N \to \infty$, $\hat{e} \to e$ [14].

Different samples of size N (i.e., different set of realizations of the stochastic vector parameter **UP**) will shape different forms of Eq. (14). Therefore, the algorithms based on sample average solve the SAA problem several times with different samples [14, 27] and then select the most promising solution according to some predefined criteria as the final solution.

In this article the procedure proposed in Norkin et al. [21] and implemented in Verweij et al. [27] is applied. This is described as follows. Let $\hat{e}_N^1, \hat{e}_N^2, ..., \hat{e}_N^M$ be the values of Eq. (14) when solving M SAA problems, each one with a different sample of size N. Moreover, considered that $\hat{s}_N^1, \hat{s}_N^2, ..., \hat{s}_N^M$ are the solution (values of decision values) obtained when each of the aforementioned M SAA problems. An intuitive criteria for selecting the best solution among the M possibilities, would be to pick the solution with the best $\hat{e}_N$ value. A more sophisticated idea is to build an independent sample of size N', with $N' >> N$, and evaluate the solutions using this sample. Then, select the solution with the best value as it is expressed in Eq. (15) for a maximization problem.

$$\hat{s}_N^* \in \arg\max\{\hat{e}_{N'}(\hat{s}_N) : \hat{s}_N \in \hat{s}_N^1, \hat{s}_N^2, ..., \hat{s}_N^M\} \tag{15}$$

This idea takes advantage from the fact that even though using the large sample size N' for the optimization phase can be very time consuming (specially in NP-hard problems as the one addressed in this paper), using it for just for evaluation of the objective function Eq. (14) can be achievable in reasonable computing time [14].

5 Computational Experiments

This section describes the instances and methodology used for the evaluation of the proposed approach, and reports quantitative and qualitative results.

5.1 Problem instances

The instances construction is based on information from the REDD dataset [15]. As performed in Colacurcio et al. [7], instances with different sizes were considered. One of the key parameters to estimate was the users preferences. For estimating this parameter, information about the power consumption of the selected appliances on each household was analyzed. This involved cleaning the data from comparatively very small power consumption which are related to stand-by consumption of each appliance, for example, small screen leds. After this, for each combination of user and appliance, a probability of usage for each time slot was estimated (p_{lt}^u). With this probability, M instances were constructed for each sample size N as is described in Section 5.2. Additionally, from REDD dataset the mean power consumption of each appliance in KW (P_l^u) and the duration of the average time of utilization of each appliance (D_l^u) were estimated. When performing this noticeable differences were identified during the weekend, a behaviour that is usual for household users [8]. Therefore the instances were classified in weekdays and weekends.

Parameters E^u (maximum electric power contracted for each household) and C_t were obtained from the website of the Electric Company of Montevideo, Uruguay (`https://portal.ute.com.uy/`). Two instances size were considering, each one with two variations: weekdays (wd) and weekend (we):

– small ($s.wd$ and $s.we$). It has one household with seven deferrable appliances.
– large ($l.wd$ and $l.we$). It has two households with six and seven deferrable appliances respectively.

In the instances that corresponds to the small size Eq. (7) is not used since there is only one household and, thus, Eqs. (5) and (6) are enough for limiting the maximum consumed energy.

5.2 Experiment design

After some preliminary experimentation, the following sample sizes were chosen N = 50,200,500, 1000, 2000, 3000 and 10000. Within each sample size, the number of independent samples (M) was set to 100. The evaluation sample size (N') was set to 100000. The estimation of the ideal and nadir value for the weighted sum function were estimated with the procedure introduced in Section 4.1. This is performed within each N value. Additionally, five different weights configurations are used for exploring different trade-off between energy cost and user satisfaction (w_f,w_g): (0.99,0.01), (0.25, 0.75), (0.5, 0.5), (0.75, 0.25) and (0.01, 0.99). The SAA problems were solved with Gurobi [9] through Pyomo as modelling language [11].

Algorithm 1 Schema of a the Simulation-optimization (SO) approach.

initialize $SO(p^u_{lt}, N, M, \alpha, \beta)$
initialize list S of size M
for $m \leftarrow 0, m++, m \leq M$ **do**
  for $n \leftarrow 0, n++, n \leq N$ **do**
    for all $u \in U$ **do**
      for all $l \in L^u$ **do**
        for all $t \in T$ **do**
          initialize $t \leftarrow random(0, 1)$
          if $t \leq p^u_{lt}$ **then** $UP^u_{lt} = 1$
          else $UP^u_{lt} = 0$
          end if
        end for
      end for
    end for
  end for
  $S[m] \leftarrow$ **Solve MDR**$(\alpha, \beta,$ **UP**$))$
end for
return S

5.3 Experimental results

The experimental results are reported in Tables 1-2, for the small and large instances considering weekday and weekend usage conditions, respectively. These Tables report for each instance, sample size (N) and weight vector values the following results: the mean and standard deviation of the runtime, the user

satisfaction function F evaluated over N', the mean and standard deviation of the cost function G evaluated over N' (for the M different runs), and the values of F and G of the best compromising solution, i.e., the solution that has the minimal value of function H (Eq. (12)). It should be highlighted that since the cost function G (Eq. (2)) is deterministic, it is not affected by the sample size after the optimization process. In other words, for evaluation purposes: $G^N = G^{N'}$.

All the solutions of the SAA problems were solved to optimality since Gurobi was able to find solutions with 0% MIPGap for the compact mathematical formulation presented in Section 3 in relatively short computing times. The different combinations of weights were able to effectively explore the trade-off of the problem. Something interesting is that schedules that are biased towards minimizing the cost objective (with higher values of β) are more difficult to solve for Gurobi (computing times are as much of three times higher).

As expected, in general the larger the sample size N the higher the average the user satisfaction function value, since the expected value is better approximated by Eq. (14). Additionally, another important feature is that increasing sample size N led to a remarkable reduction of the variability of the results (measured through the standard deviation). Fig. 1 exemplifies this behavior, reporting the average and standard deviation of function F for the M independent samples for the three combinations with larger α, i.e., in which F has preponderance over the cost, in the large instance for the weekday patron.

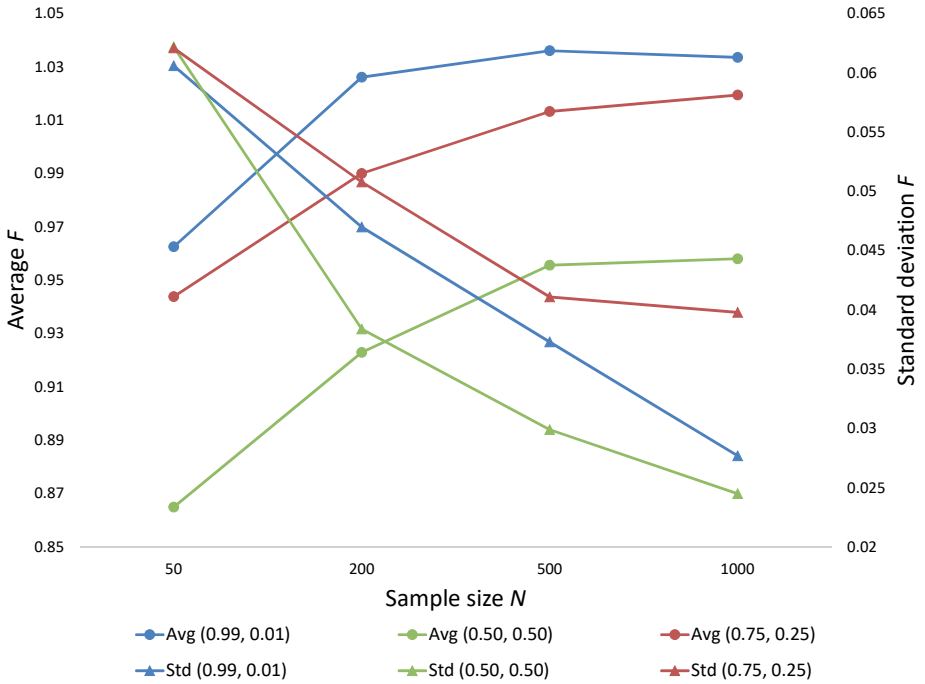

Fig. 1: Sensitivity analysis of average and standard deviation of F in l.wd instance.

6 Conclusions

This article studied the household energy planning problem, a relevant optimization problem that arises in the context of modern smart cities.

A novel bi-objective mathematical formulation of the problem was presented, accounting for uncertainty in the preferences of using each appliance. In this formulation, the aim is to schedule on a daily basis the usage of deferrable appliances while optimizing two conflicting objectives: the cost of the electricity–based on time-of-use tariff–and the users satisfaction. The users satisfaction is estimated through historical data of when (which part of the day) users prefer to use each appliance. However, since there is considerable variation of these preferences, a stochastic resolution approach was used to include the randomness of this parameter. The proposed problem was solved using the Sample Average Approximation method, which is a simulation-optimization approach that combines Monte Carlo simulation and deterministic mixed integer programming. Different real-world instances were considered and solved with different parametric combinations. The approach was able to propose different solutions that explore the trade-off between the two criteria in reasonable computing times. Particularly, for larger values of sample size the standard deviation of the results given by the method was significantly reduced.

Additionally, the initial tests performed in this work were execute in relatively small computing times even for the large instance. This shows the validity of the proposed integer mathematical formulation and the simulation-optimization approach as useful tools to perform practical load scheduling in smart homes. However, for enhancing performance of the model in a particular household, it is important to first gather specific data of that household to accurately estimate the key parameters of the model, such as the stochastic user preferences.

For future work, a crucial research line is to expand the computational experimentation. This should include using larger sample sizes and number of independent samples within each size (M) for exploring whether the accuracy of the solutions can be enhanced. Also, to study the competitiveness of the approach for larger instances in which buildings with more than two households are considered. Another way the instances can be enlarged is to include other kinds of appliances, such as non-deferrable loads, and renewable power generators within the household, e.g., solar or wind power generators.

Resumo. O uso da Tecnologia da Informação (TI) tem sido fator-chave para que empresas alcancem um nível de serviço adequado às expectativas de seus clientes, gerando um processo mais ágil e enxuto. Este artigo abordou as fragilidades nos processos de uma empresa do setor educacional cuja área de Logística ainda não emprega um sistema informatizado que auxilie no planejamento, na programação, no controle e na execução do transporte. Para tanto, analisou-se, com base em orientações técnico-teóricas relacionadas à TI e com suporte do método de tomada de decisão multicritério *Analytic Hierarchy Process* (AHP) acoplado ao modelo Benefícios, Oportunidades, Custos e Riscos (BOCR), a melhor alternativa para a seleção de um *software Transportation Management System* (TMS) considerando a realidade da empresa. A avaliação das alternativas s*oftware* próprio e *software* de mercado, foram efetuadas por uma equipe de especialistas. O resultado indicou *software* de mercado como a melhor alternativa, obteve a maior prioridade global, destacando-se como a melhor solução.

Palavras-chave: Sistema de Gerenciamento de Transportes, Fatores Críticos de Sucesso, Modelo AHP-BOCR, Empresa do Setor Educacional.

1 Introdução

O suporte de Tecnologia da Informação (TI) aplicado a diversos processos é o que tem garantido a organizações crescimento e visibilidade em um mercado cada vez mais competitivo. Assim, empresas que não lançam mão de tal suporte têm perdido oportunidades de negócio e de crescimento. De acordo com [1], as empresas devem investir em tecnologia e inovação para garantir a sua sobrevivência.

A melhoria da qualidade do serviço logístico – alcançada pela aplicação da TI – leva a maior satisfação do cliente e, desse modo, aumenta suas chances de fidelidade à empresa [2]. Considerando, portanto, que o resultado da aplicação das Tecnologias da Informação nos processos empresariais significa uma gestão mais eficaz e veloz na administração de recursos humanos e de equipamentos, é compreensível que as empresas busquem, constantemente, atualização tecnológica. Pois, como bem pontuam [3], o

crescimento das empresas, em um mundo globalizado que rompe, cada vez mais, as barreiras tempo-espaço, só se faz possível através de investimentos em tecnologia.

Assim, este estudo debruçou-se sobre uma empresa do setor educacional que não utiliza um *software* específico para o controle de informações em seu setor logístico, buscando identificar os problemas decorrentes da falta de uso de um sistema de gerenciamento de transporte (*Transporationt Management System* - TMS) e a alternativa mais adequada à organização: desenvolver um *software* próprio ou utilizar um *software* de mercado.

Por tratar-se de uma questão de integração de sistemas em uma complexa cadeia de suprimentos, compreende-se que o problema aqui levantado consiste em um problema multicritério e, portanto, deve ser abordado por meio da aplicação de um método de tomada de decisão multicritério (*Multiple Criteria Decision Making* - MCDM).

Há diversos métodos MCDM – *Analytic Hierarchy Process* (AHP), *Analytic Network Process* (ANP), *Measuring Attractiveness by a Categorical Based Evaluation Technique* (MACBETH), *Multi-Attribute Utility Theory* (MAUT), *Technique for Order Preference by Similarity to the Ideal Solution* (TOPSIS) – e cada um deles consiste em uma sistemática diferente para avaliar cada critério e como eles se correlacionam para uma avaliação geral [4]. De acordo com [4] e [5] dentre tais métodos, o mais utilizado e que permite uma análise holística das possíveis alternativas é o método AHP.

Por possuir características flexíveis e adaptáveis às necessidades do tomador de decisão e permitir um tratamento adequado, inclusive de aspectos subjetivos, esse estudo adotou o método AHP, que se baseia na definição de critérios – que neste estudo serão definidos de acordo com o modelo BOCR – e alternativas em uma estrutura hierárquica; no estabelecimento de valores a tais critérios e alternativas; na construção de uma matriz comparativa com estes valores; e, por fim, na conclusão e resolução do problema definido por meio da análise dessa matriz de comparação [6], [7], [8].

Neste contexto, o objetivo geral deste artigo foi analisar os impactos da ausência de um *software* TMS na empresa objeto de estudo e na aplicação do método AHP-BOCR para dar suporte e consistência à tomada de decisão, pela alta gestão, da melhor alternativa para a empresa na seleção desse *software*.

O artigo está organizado da seguinte forma: na Seção 2 apresenta-se a revisão da literatura, focada nos conceitos de sistema de gerenciamento de transportes, fatores críticos de sucesso para seleção e/ou implantação de sistema e método de priorização de alternativas. A Seção 3 faz referência à aplicação do AHP na seleção de sistema de gerenciamento de transportes. Finalmente, na Seção 4 estão as conclusões do trabalho, sendo seguidas pelas referências bibliográficas utilizadas neste texto.

2 Revisão da Literatura

2.1 Sistema Informatizado

Os sistemas de informação têm um papel cada vez mais importante na realização dos procedimentos logísticos nas empresas [9]. Isso porque, devido ao aumento do volume e da complexidade dos processos logísticos, os sistemas de informação são a única forma de gerenciar de maneira precisa o fluxo de produtos para os clientes.

Essa capacidade da TI em promover uma melhora significativa dos negócios empresariais também se encontra no trabalho de [2], cujas descobertas sugerem que a implementação da TI amplia diretamente a qualidade dos serviços relacionados à logística e, como consequência, auxilia na criação de competitividade entre empresas.

Uma outra função dos sistemas de TI é mediar a comunicação entre os diferentes departamentos da empresa, entre consumidores e contratados. Nesse sentido, vale a pena destacar a relação entre logística da informação e logística de transporte. A logística de transporte é frequentemente considerada um campo de pesquisa relativamente independente, que vê o transporte como a base do processo de operação logística e enfatiza o papel do transporte na conexão entre o fornecedor e o consumidor da cadeia de abastecimento [10]. Note-se também que um dos principais objetivos da logística é reduzir, constantemente, os custos dos processos logísticos, e esse objetivo aplica-se tanto ao processo de fornecimento quanto ao de distribuição – ambos relacionados à logística de transporte [11].

Portanto, a logística da informação é essencial para que tecnologias modernas sejam utilizadas de maneira eficiente na logística de transporte. Afinal, é a TI que permite que a ponte entre o fluxo de informações e a cadeia de fornecimento seja feita de maneira mais eficiente, pois é ela a responsável por integrar os dados do sistema ao transporte para o cliente com maior velocidade e exatidão, facilitando o processo, reduzindo custos e, por fim, aumentando a satisfação do consumidor.

Assim, se bem estruturado, meticulosamente planejado e equipado com a infraestrutura necessária, um sistema de TI deve ser capaz de entregar informações para todos os locais de trabalho, ao longo de todos os níveis da hierarquia organizacional da empresa, sem negligenciar nenhum dos objetivos logísticos em relação ao armazenamento de informação [12].

2.2 Sistema de Gerenciamento de Transportes

Como já exposto, as transformações tecnológicas têm exigido cada vez mais empenho das organizações no atendimento às demandas de seus clientes, que estão cada vez mais exigentes pelas possibilidades oferecidas ao dispor de um simples toque. Nesse cenário, uma empresa que necessita oferecer um produto ou um serviço, precisa fazê-lo da forma mais precisa e ágil, maximizando a qualidade e minimizando o custo.

No que tange à logística de transportes, por mais empenho que seres humanos possam oferecer nesse quadro, ele não pode ser comparado à eficiência e à agilidade de uma ferramenta tecnológica como o TMS, um dos sistemas mais utilizados em operações de logística e produção, juntamente com o *Enterprise Resource Planning* (ERP), o *Warehouse Management System* (WMS) e o *Intelligent Transportation System* (ITS) [13].

O TMS consiste em um sistema informatizado de transportes que, de acordo com [14], apresenta como principais funcionalidades o monitoramento e controle; o apoio a negociação e auditoria de frete; e o planejamento e execução. Deste modo, um TMS pode oferecer inúmeros benefícios à organização, como redução de custos, diminuição de erros e aumento na satisfação do cliente, uma vez que a ferramenta, além de conciliar diversos critérios para o cálculo das melhores alternativas, controla o fluxo de

informações através de todas as etapas de transporte, o que resulta em agilidade no atendimento das solicitações e em mais segurança, unidade e confiabilidade das informações. Esses benefícios convertem-se em vantagens competitivas, pois, como afirmam [15], a confiabilidade e a agilidade de resposta são peças centrais no dinamismo requerido pela atual conjuntura.

2.3 Fatores Críticos de Sucesso para Seleção e/ou Implantação de Sistema

Por definição, os Fatores Críticos de Sucesso - FCS [16], constituem as variáveis capazes de interferir diretamente no sucesso de projetos, ou nos objetivos, de determinada organização [17]. Os FCS devem guiar o início e o desenvolvimento do projeto em questão, sendo revisitados sempre que necessário, para que não se percam de vista os elementos que podem levar ao fracasso da empreitada [18]. Os FCS presentes na literatura [19], [20], [21], [22], [23], [24] e considerados rele-vantes à seleção e/ou implantação de um TMS no escopo do problema definido por este estudo estão relacionados na Fig. 1, com os respectivos artigos em que foram publicados.

2.4 Método de priorização de alternativas

O AHP foi criado por Thomas Saaty na década de 1970 e, hoje, é o método mais utilizado na resolução de problemas de análise multicritério por ter recebido especial atenção por parte de pesquisadores e por permitir que os tomadores de decisão em-preguem múltiplos critérios, inclusive os de natureza conflitante, de maneira quantitativa, para avaliar as opções disponíveis e, então, decidir pela melhor alternativa [25], [26]. O AHP consiste basicamente em três etapas [6]:

- Definição de uma hierarquia de decisão, a partir do estabelecimento de critérios e alternativas relacionados ao problema a ser resolvido.
- Atribuição de valores de importância para os critérios e valores de desempenho ou de preferência para as alternativas, com a construção de uma matriz.
- Revisão e síntese dos resultados.

Destaque-se que o método AHP possui dois meios para agregação das prioridades, sendo conhecidos como síntese normal e síntese ideal. Desse modo, pode-se empregar o uso da síntese normal para distribuição proporcional de recursos e/ou benefícios enquanto a síntese ideal pode ser aplicada para identificar a melhor alternativa dentro de um conjunto de alternativas distintas e sem dependência entre si [27].

O método AHP ainda permite que a sua mensuração seja realizada por meio da medição relativa ou absoluta. Na medição relativa as alternativas são comparadas aos pares e o resultado poderá sofrer alteração ou inversão dos dados finais enquanto na medição absoluta as alternativas são comparadas com um padrão de valores/desempenho pré-estabelecidos e, se combinado com a síntese ideal, garantirá a preservação do resultado [27].

A síntese ideal é indicada nas aplicações AHP se o objetivo principal é identificar a melhor alternativa. As combinações de medição absoluta com síntese ideal têm a vantagem de não permitir ordem inversa ou classificação de reversão. O método AHP exige uma seleção hierarquizada de critérios. Porém, quando a análise a ser feita é muito complexa, o mais adequado é que a estrutura adotada seja a de rede. Para tais casos, um dos critérios de decisão mais adotados é o modelo BOCR.

Com a aplicação do modelo BOCR, os critérios são organizados em pares opostos, em que B se opõe a C e O se opõe a R [7]. B e O são categorias valoradas como positivas, que remetem aos fatores que trazem consigo a certeza ou a possibilidade futura de receita/lucro, sendo que B representa os benefícios e O, as oportunidades; e C e R são categorias de importância negativa, relacionadas às possibilidades de impactos negativos, como perdas e prejuízos, sendo que C representa os custos e R, os riscos. Assim, a aplicação desse modelo permite uma análise mais complexa e proveitosa do que uma simples avaliação de custos *versus* benefícios, que não leva em consideração aspectos incertos, tantos positivos quanto negativos, da empreitada.

3 Procedimento do Método de Seleção Proposto

3.1 Objeto de Estudo

A organização objeto de estudo atua no mercado há 40 anos e suas principais atividades são: planejar, organizar, executar e supervisionar concursos, vestibulares e avaliações educacionais, a fim de selecionar pessoas por meio desses processos.

Muito embora a empresa possua um sistema de ERP (*Enterprise Resource Planning* – Sistema Integrado de Gestão Empresarial), MS Project (*Microsoft Project*) e outros sistemas que foram especificamente desenvolvidos para determinadas áreas, os processos estão apenas parcialmente imputados no sistema, não permitindo, assim, a plena utilização de toda a sua capacidade, que é a de promover a integração das atividades entre as áreas e, principalmente, fornecer a visão sistêmica de todos os processos interligados da organização.

Tendo em vista tal problemática, foram levantados, junto ao gerente e demais funcionários do setor, os impactos gerados pela falta de um sistema informatizado. Os pontos destacados estão elencados a seguir: (i) falhas de comunicação entre a área de Logística e os demais setores da empresa; (ii) desperdícios de mão de obra qualificada; (iii) sobrecarga de trabalho em determinados períodos e funcionários; (iv) desperdício de tempo com a realização de serviços manuais e de retrabalhos; (v) falta de sistema que controle o fluxo de saída e entrada de materiais; (vi) falta de sistema informatizado que seja capaz de subsidiar e dinamizar as informações necessárias; (vii) falta de sistema informatizado que seja capaz de informar: o peso e o volume do material a ser transportado por projeto, cidade e local de aplicação; modelos de roteirização, que adequariam o tipo de veículo à carga a ser transportada.

3.2 Definição de Especialistas e Aplicação do Modelo BOCR

Ao considerar as informações expostas nesta pesquisa, mostra-se relevante definir um grupo de especialistas composto por integrantes da organização, com a finalidade de se obter maior robustez na identificação, na análise e na validação dos dados levantados por este estudo. Deste modo, a composição da equipe que participou do processo de seleção foram 6 especialistas com formação nas áreas de logística empresarial (2), gestão de projetos, mestre em ciências, ciência da computação e ciências contábeis. Com 8 à 25 anos de experência na área, atuam no projeto de implantação do TMS nos cargos de gerente do projeto (1), responsáveis de TI (3), e usuários chave (2).

A seleção dos subcritérios foi baseada nos FCS (Seção 2.3) e a sua categorização foi realizada segundo o modelo BOCR. Aplicou-se essa definição para selecionar e associar adequadamente os subcritérios a cada categoria: Benefícios (B), Oportunidades (O), Custos (C) e Riscos (R). Assim, os especialistas concluíram que 12 subcritérios eram elegíveis para compor o referido estudo, os quais estão apresentados na Fig. 2.

Categorização BOCR	Código	Seleção de Subcritérios
Benefícios	B1	Avaliação de Desempenho (Monitoramento e Controle)
	B2	Reengenharia do Processo dos Negócios
	B3	Suporte da Alta Gerência
Oportunidades	O1	Composição da Equipe do Projeto
	O2	Gerenciamento de Projeto
	O3	Planejamento Estratégico (Nível de Planej. do Projeto)
Custos	C1	Negócios Apropriados & Legados dos Sistemas de TI
	C2	Suporte ao Usuário (Suporte do Fornecedor)
	C3	Treinamento e Educação do Cliente/Usuário
Riscos	R1	Customização Mínima (Alterações das Especificações)
	R2	Complexidade do Projeto
	R3	Experiência do Cliente/Usuário

Fig. 2. Seleção e categorização dos subcritérios.

4 Aplicação do Método AHP e Discussão dos Resultados

4.1 Aplicação do Método AHP

Depois de definidos critérios, subcritérios e alternativas, elaborou-se uma hierarquia para a aplicação do método AHP, apresentada e validada pela equipe de especialistas.

Por tratar-se da identificação da melhor alternativa, os especialistas estabeleceram o emprego da medição absoluta com a síntese ideal, uma vez que essa combinação não permite a ordem inversa ou classificação de reversão [28].

A Fig. 3 apresenta essa hierarquia correlacionada. No primeiro nível foram destacados os critérios: Benefícios (B), Oportunidades (O), Custos (C) e Riscos (R). No segundo nível foram elencados os subcritérios: B1; B2; B3; O1; O2; O3; C1; C2; C3; R1; R2 e R3. E, por fim, o terceiro nível compreendeu as alternativas: A1 e A2.

Após a conclusão dessa etapa, foram atribuídos valores de importância para os critérios e os subcritérios e valores de desempenho para as alternativas. Na sequência, utilizou-se o *software Excel* para a realização dos cálculos matemáticos e obtenção dos resultados de acordo com o método AHP.

Nesse estágio, iniciaram-se as comparações aos pares entre os subcritérios. Os valores de importância foram obtidos por meio de consenso dos seis especialistas participantes da pesquisa. As prioridades foram obtidas com a normalização do autovetor da matriz de comparações. As Tabelas 1, 2, 3 e 4 apresentam os resultados de prioridade para os subcritérios de cada critério Benefícios, Oportunidades, Custos e Riscos.

Observa-se na Tabela 1 que, para o critério Benefícios, o subcritério Reengenharia dos Processos de Negócios é o que possui maior índice de importância, seguidos pelos subcritérios Avaliação de Desempenho e Suporte da Alta Gerência. A razão de

consistência foi de 7% e ficou abaixo do limite tolerável de 10%. Portanto, essa matriz de julgamento pôde ser aceita.

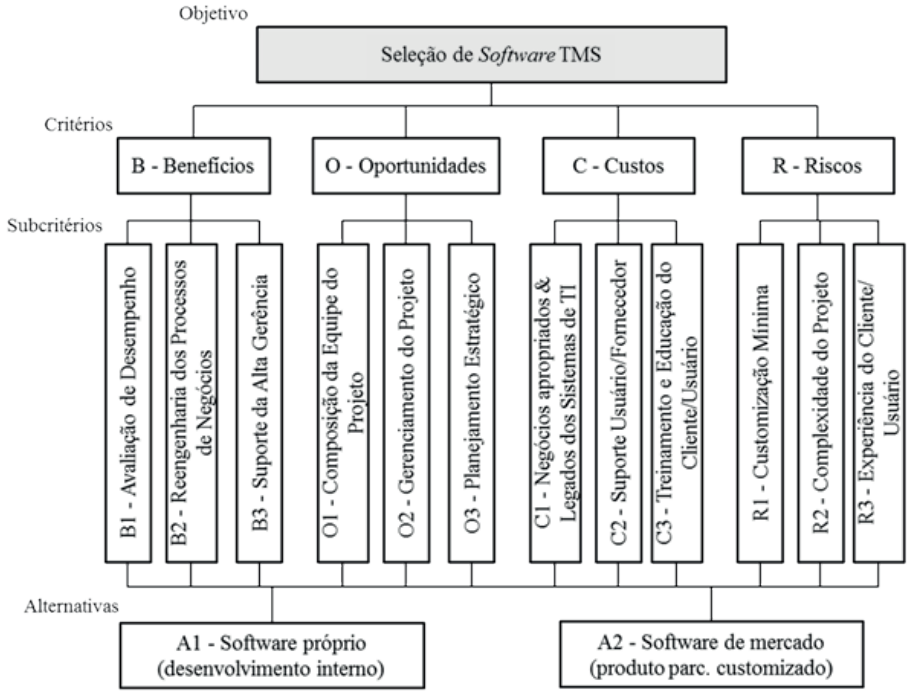

Fig. 3. Hierarquia para seleção e implantação de *software* TMS.

Tabela 1. Prioridade de subcritérios para benefícios.

	Avaliação de Desempenho	Reengenharia dos Proc. de Negócios	Suporte da Alta Gerência	Autovetor	Prioridade
Avaliação de Desempenho	**1**	1/7	3	0,8	14,9%
Reengenharia dos Proc. de Negócios	7	**1**	9	4,0	78,5%
Suporte da Alta Gerência	1/3	1/9	**1**	0,3	6,6%
Total (Soma)	**8,3**	**1,3**	**13,0**	**5,1**	**100%**

Observa-se na Tabela 2 que, para o critério Oportunidades, o subcritério Planejamento Estratégico é o que possui maior índice de importância, seguidos pelos subcritérios Composição da Equipe do Projeto e Planejamento Estratégico. A razão de

consistência foi de 7% e ficou abaixo do limite tolerável de 10%. Portanto, essa matriz de julgamento pôde ser aceita.

	Composição da Equipe do Projeto	Gerenciamento do Projeto	Planejamento Estratégico	Autovetor	Prioridade
Composição da Equipe do Projeto	**1**	3	1/7	0,8	14,9%
Gerenciamento do Projeto	1/3	**1**	1/9	0,3	6,6%
Planejamento Estratégico	7	9	**1**	4,0	78,5%
Total (Soma)	**8,3**	**13,0**	**1,3**	**5,1**	**100%**

Tabela 2. Prioridade de subcritérios para oportunidades.

Observa-se na Tabela 3 que, para o critério Custos, o subcritério Negócios Apropriados & Legados dos Sistemas de TI é o que possui maior índice de importância, seguidos pelos subcritérios Treinamento e Educação do Cliente/Usuário e Suporte ao Usuário/Fornecedor. A razão de consistência foi de 6% e ficou abaixo do limite tolerável de 10%. Portanto, essa matriz de julgamento pôde ser aceita.

Tabela 3. Prioridade de subcritérios para custos.

	Neg. Aprop. & Legados dos Sist. TI	Suporte ao Usuário/ Fornecedor	Trein. e Educação do Cliente/ Usuário	Autovetor	Prioridade
Neg. Aprop. & Legados dos Sist. TI	**1**	7	3	2,8	64,9%
Suporte ao Usuário/Fornecedor	1/7	**1**	1/5	0,3	7,2%
Trein. e Educação do Cliente/Usuário	1/3	5	**1**	1,2	27,9%
Total (Soma)	**1,5**	**13,0**	**4,2**	**4,3**	**100%**

Observa-se na Tabela 4 que, para o critério Riscos, o subcritério Complexidade do Projeto é o que possui maior índice de importância, seguidos pelos subcritérios Experiência do Cliente/Usuário e Customização Mínima. A razão de consistência foi de 6% e ficou abaixo do limite tolerável de 10%. Portanto, essa matriz de julgamento pôde ser aceita.

Tabela 4. Prioridade de subcritérios para riscos.

	Customização Mínima	Complexidade do Projeto	Experiência do Cliente/ Usuário	Autovetor	Prioridade
Customização Mínima	**1**	1/7	1/3	0,4	8,1%
Complexidade do Projeto	7	**1**	5	3,3	73,1%
Experiência do Cliente/ Usuário	3	1/5	**1**	0,8	18,8%
Total (Soma)	**11,0**	**1,3**	**6,3**	**4,5**	**100%**

Após a validação das matrizes de julgamentos, iniciou-se a análise para a definição de prioridade para cada critério BOCR. De comum acordo, os especialistas consideraram pertinente aplicar 25% de prioridade para cada critério: Benefícios, Oportunidades, Custos e Riscos. Assim, ao considerar que todos os critérios possuem a mesma prioridade de 25%, as prioridades globais foram calculadas pela multiplicação dos valores de prioridade de cada critério pelo peso dos subcritérios, por exemplo:

B1 = 0,25 . 0,149 = 3,72%, B2 = 0,25 . 0,785 = 19,63%, B3 = 0,25 . 0,066 = 1,64%

O mesmo cálculo foi aplicado aos demais subcritérios O1, O2, O3, C1, C2, C3, R1, R2 e R3. Os resultados estão dispostos na Tabela 5.

Tabela 5. Prioridade local e global.

Critérios e Subcritérios		Prioridade Local	Prioridade Global
Benefícios		**25,00%**	**25,00%**
	B1 - Avaliação de Desempenho	14,88%	3,72%
	B2 - Reengenharia dos Processos de Negócios	78,54%	19,63%
	B3 - Suporte da Alta Gerência	6,58%	1,64%
Oportunidades		**25,00%**	**25,00%**
	O1 - Composição da Equipe do Projeto	14,88%	3,72%
	O2 - Gerenciamento do Projeto	6,58%	1,64%
	O3 - Planejamento Estratégico	78,54%	19,63%
Custos		**25,00%**	**25,00%**
	C1 - Negócios Apropriados & Legados dos Sist. de TI	64,91%	16,23%
	C2 - Suporte ao Usuário/Fornecedor	7,19%	1,80%
	C3 - Treinamento e Educação do Cliente/Usuário	27,90%	6,97%
Riscos		**25,00%**	**25,00%**
	R1 - Customização Mínima	8,10%	2,02%
	R2 - Complexidade do Projeto	73,06%	18,27%
	R3 - Experiência do Cliente/Usuário	18,84%	4,71%

Ao analisar os resultados apresentados na Tabela 5, nota-se que as prioridades globais associadas a Benefícios e Oportunidades obtiveram o mesmo índice de importância (19,63%) para os subcritérios B2 e O3. Já para as prioridades globais associadas a Custos e Riscos, obtiveram um índice de importância próximo os subcritérios C1 (16,23%) e R2 (18,27%).

Em continuidade à aplicação do método AHP, a avaliação das alternativas foi realizada de modo qualitativo. Para tanto, utilizou-se a escala para medição absoluta, que contempla os níveis de qualidade e os valores de desempenho para cada um dos níveis. Assim, apresenta-se a escala para medição absoluta na Tabela 6.

Tabela 6. Escala para medição absoluta [29].

Nível	Prioridade
N1 - excelente	1,00
N2 - muito bom	0,83
N3 - entre bom e muito bom	0,67
N4 - bom	0,50
N5 - entre fraco e bom	0,25
N6 - fraco	0,00

A avaliação qualitativa das alternativas foi realizada para todos os subcritérios. Na Tabela 7, as prioridades da Tabela 6 substituem os julgamentos qualitativos.

Tabela 7. Avaliação quantitativa de *software* próprio e *software* de mercado.

Alternativas	Subcritérios											
	B1	B2	B3	O1	O2	O3	C1	C2	C3	R1	R2	R3
A1 - Software Próprio	0,83	0,83	0,50	0,50	0,67	0,67	0,67	0,67	0,83	1,00	0,50	0,83
A2 - Sotware de Mercado	0,67	0,67	0,50	0,83	0,83	1,00	0,83	0,50	0,83	0,50	1,00	0,83

As prioridades para as alternativas (Tabela 8) foram calculadas considerando o desempenho quantitativo e a prioridade global (Tabela 7), obtendo como resultado para a alternativa A1 (*Software* Próprio) 69%, exemplificado na sequência:

A1 = 0,83 × 3,72% (B1) + 0,83 × 19,63% (B2) + 0,50 × 1,64% (B3) + 0,50 × 3,72% (O1) + 0,67 × 1,64% (O2) + 0,67 × 19,63% (O3) + 0,67 × 16,23% (C1) + 0,67 × 1,80% (C2) + 0,83 × 6,97% (C3) + 1,00 × 2,02% (R1) + 0,50 × 18,27% (R2) + 0,83 × 4,71% (R3) = 0,69

O mesmo procedimento foi realizado para a obtenção do resultado da alternativa A2. Assim, a Tabela 8 expõe os resultados para as alternativas A1 – *Software* Próprio e A2 – *Software* de Mercado.

Tabela 8. Matriz de decisão - *software* próprio e *software* de mercado.

Alternativas	Subcritérios												Decisão
	B1	B2	B3	O1	O2	O3	C1	C2	C3	R1	R2	R3	
%	3,72	19,63	1,64	3,72	1,64	19,63	16,23	1,80	6,97	2,02	18,27	4,71	
A1 - Software Próprio	0,83	0,83	0,50	0,50	0,67	0,67	0,67	0,67	0,83	1,00	0,50	0,83	0,69
A2 - Sotware de Mercado	0,67	0,67	0,50	0,83	0,83	1,00	0,83	0,50	0,83	0,50	1,00	0,83	0,84

Observa-se na Tabela 8 que os subcritérios B3 (Suporte da Alta Gerência), C3 (Treinamento e Educação do Cliente/Usuário) e R3 (Experiência do Cliente/Usuário) receberam o mesmo peso de importância para ambas alternativas. Então, foi aplicado o valor de desempenho de 0,50 (N4 - bom) para o subcritério B3 e 0,83 (N2 - muito bom) para os subcritérios C3 e R3, pois os especialistas que, para essas comparações (alternativas *versus* subcritérios), deveria ser mantida uma avaliação igualitária. Assim, nota-se que a alternativa A2 (*Software* de Mercado) possui 84% de viabilidade enquanto a alternativa A1 (Software Próprio) possui 69%.

Como resultado final, a alternativa A2 destacou-se como a melhor solução e obteve, ainda, uma margem superior de 15% em relação a alternativa A1.

O resultado obtido por meio da aplicação do método AHP foi apresentado à equipe de especialistas, que pontuou a importância de se testar uma decisão com base na valoração de 50% para o critério Custos. Pois, para os especialistas, a partir do gerenciamento adequado dos Custos, pode-se obter uma avaliação mais crítica, que conduza à redução ou eliminação de desperdícios de recursos, que poderão ser convertidos em investimentos. Assim, esse critério apresenta-se mais sensível à decisão gerencial.

4.2 Discussão dos Resultados

Ao considerar o apontamento da equipe de especialistas e com o intuito de realizar o atendimento dessa nova proposta, aplicaram-se os mesmos cálculos e o resultado está apresentado, por meio de uma análise de sensibilidade, na Fig.4.

Na Fig. 4, observam-se duas linhas verticais. A linha vertical azul representa o peso inicial de 25% para o critério Custos enquanto a linha vertical verde representa a adequação proposta pelos especialistas, ou seja, a elevação do peso desse mesmo critério para 50%.

Por meio dessa representação gráfica, percebe-se que a alternativa A1 obteve elevação de 1% e que a alternativa A2 sofreu uma redução de 2%. Portanto, a alternativa A1 apresentou um resultado de 70% e a alternativa A2 de 82%. Ao analisar esse conjunto de dados e de informações, compreende-se que, independentemente das valorações para o BOCR, o resultado se manterá consistente e inalterado.

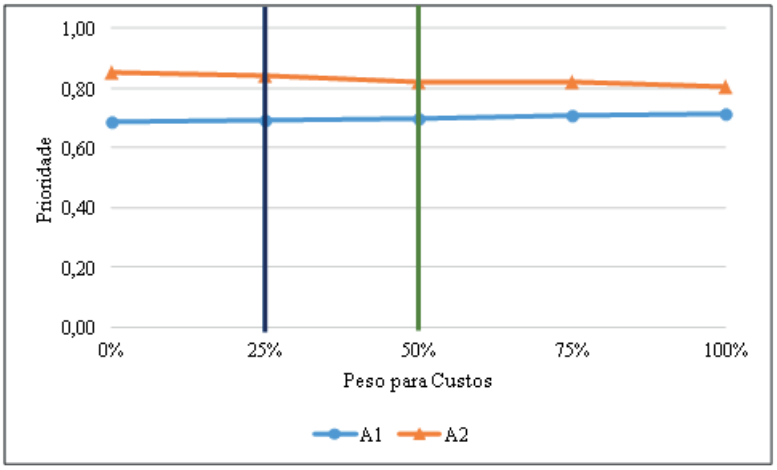

Fig. 4. Gráfico de análise de sensibilidade.

Os resultados supracitados foram apresentados, pela equipe de especialistas, ao corpo diretor da empresa, que, face à exposição, compreenderam a necessidade e os benefícios da implantação de um *software* TMS. Amparados pelos resultados consistentes apresentados pelo AHP, os diretores decidiram pela utilização do *software* de mercado, que permite a configuração de módulos e a customização de funções, de forma a atender às necessidades da empresa.

5 Conclusões

Ao considerar a complexidade da decisão e as particularidades da organização, propôs-se aplicar neste estudo o método AHP agregado ao modelo BOCR, que permitiu analisar as informações e os dados de maneira qualitativa e quantitativa, contribuindo para uma decisão imparcial e segura.

Após a apresentação dos resultados, a equipe considerou pertinente discuti-los amplamente, com o objetivo de ratificá-los. Os seguintes pontos foram suscitados: (i) a organização já possui licença e permissão para uso do módulo TMS de seu atual fornecedor de *software* ERP; (ii) a organização disporá de recursos financeiros para contratar os serviços de consultoria para a implantação do sistema e possíveis customizações de telas e relatórios; (iii) será alocado um especialista da TI para acompanhar todo o processo de implantação e parametrização do sistema, bem como para prover treinamentos; (iv) os analistas de desenvolvimento interno poderão, sempre que necessário, realizar customizações de telas e relatórios e, ainda, desenvolver melhorias no sistema após a sua implantação; (v) a organização dará continuidade ao investimento tecnológico para o desenvolvimento e suporte da área de Logística, avaliando a necessidade de agregar *softwares* complementares ao TMS, como: rastreadores e aplicativos *mobiles*.

Por fim, os especialistas destacaram a importância desse estudo para a empresa, uma vez que a solução para o problema em questão vinha sendo discutida há alguns anos e

diversas reuniões afins já haviam sido realizadas. A decisão, porém, sempre fora postergada pelos especialistas, considerando a dificuldade em se estabelecer critérios que: permitissem uma decisão unânime, possuíssem uma base criteriosa e não conduzissem a um resultado tendencioso. Assim, a equipe de especialistas demonstrou satisfação por colaborar, de modo ativo, na identificação da solução mais adequada para a organização, utilizando-se de uma ferramenta que conferiu, ao processo de decisão, a segurança e a confiabilidade que se fazem necessárias à resolução de problemas complexos.

Abstract.

The purpose of this paper was to develop a mathematical model to solve a multi-depot inventory routing problem (MDIRP). The objective of this optimization problem is to determine the optimal quantity of products to deliver to customers and to establish the route´s design to be followed by the vehicles in each of the depots. This was done to meet customer demand over a defined planning horizon.

In this case, the objective function was designed to minimize the costs associated with routing and, in turn, the costs of holding inventory at the customer and in the depots.

According to the literature review, the Genetic Algorithm (GA) metaheuristics was selected as a good technique to solve the problem. Several executions were started using different parameters to observe the behavior that this metaheuristic showed when the number of clients was modified.

The results of the experimentation were collected to observe for each instance, the routes that generated the best objective function. With this experimentation, the intention was to identify if the proposed algorithm could find reasonable solutions, within a reasonable computation time.

Keywords: Optimization problems, routing, planning periods, Multi-depot, Vehicle routing problem, genetic algorithm, inventory routing problems.

1 Introducción

En la actualidad, la logística es un proceso global que facilita un mejor desempeño de la actividad empresarial [1], dicho esto, tener un proceso logístico eficiente genera que una

empresa se pueda mantener posicionada en el mercado con el pasar de los días. Sin embargo, para lograr esto es necesario que se administren de manera eficiente los medios disponibles, además de tener algún tipo de planificación de lo que se debe producir para satisfacer a los clientes. Si no se hace todo esto, las empresas presentan problemas en la toma de decisiones y, por ende, se ve afectada no solo la corporación, sino los eslabones de la cadena de suministro [2]. Dicho esto, el desarrollo de soluciones al problema de planeación de rutas en el área de operaciones logísticas ha sido de gran ayuda a la hora de hacer planeaciones de pedidos, tiempo, distancias e inversión [3]. Uno de los modelos más conocidos es el problema IRP (Inventory Routing Problem), pues modela y optimiza algunas de las actividades más costosas de la cadena de suministro: el manejo de inventarios y la distribución física de productos [4]. Durante las últimas tres décadas, se introdujeron muchas variantes del modelo básico IRP. Las características que distinguen el modelo incluyen los tipos de demanda, si se trata como determinista o estocástica, además si el horizonte de planificación es el largo plazo o de corto plazo [5].

El modelo propuesto en esta investigación es una variación del modelo IRP el cual cosiste en un modelo de ruteo e inventario con múltiples depósitos (MDIRP), este modelo se acopla a las necesidades que presentan las empresas en la actualidad, ya que muchas de ellas al estar en ciudades de gran tamaño, recurren a tener varios depósitos para poder cumplir los pedidos solicitados por sus clientes.

Para este trabajo se desarrolló un modelo matemático que permite minimizar los costos de mantener inventario y los costos de transportar un producto, junto a la consideración de satisfacer la demanda de los clientes durante un periodo de tiempo determinado. Además, se selecciona la metaheurística Algoritmo genético (GA) como técnica para darle solución al modelo. Se usa el software Matlab para validar la eficiencia del modelo, todos los resultados e información que se recopilaron a lo largo de esta investigación se exponen en los resultados.

2 Formulación del modelo y método de solución

2.1 Descripción del problema

El problema abordado el problema MDIRP, que busca desde múltiples depósitos enviar las cantidades que satisfagan las demandas de los clientes en cada periodo de tiempo, considerando que así como los depósitos, los clientes tienen capacidad de almacenar inventario. La idea de problema es encontrar la solución óptima a las rutas de transporte, a las cantidades a enviar por periodo y a almacenar en cada uno, en el horizonte de la planificación, con el mínimo costo total. Para complementar la explicación del problema se realiza la siguiente descripción:

Se considera un grafo no dirigido G = (N, E), donde E hace referencia al conjunto de aristas $E\ \{(i,j)\colon i,j \in N, i \neq j\}$, N al conjunto de vértices. Se divide el conjunto N de tal manera que N= $(R \cup D)$, donde D = {1, 2, ..., d} es el conjunto de depósitos que entregan un producto al conjunto de minoristas R = {d + 1, d + 2, ..., d + i} mediante un conjunto de vehículos K={1, 2, ..k} en un horizonte de planeación T con una longitud t = {1, 2, ..., T} correspondiente a períodos de tiempo. Ahora bien, CTij representa el costo de ir desde un nodo i al nodo j, por medio de una matriz cuadrada. La capacidad de almacenamiento de todos los clientes CapC(i,t) está definida . Los vehículos también contienen una capacidad CapVk, es decir, la tasa de producción es limitada. Además, cada cliente i tiene una demanda Dit conocida en cada período t y puede ser atendida por vehículos del mismo depósito o desde diferentes (solo de ser estrictamente necesario). El nivel de inventario de cada cliente INV(i,t) no puede ser negativo.

2.2 Formulación matemática

Esta investigación aborda un modelo de programación lineal entera mixta. El objetivo del modelo es minimizar los costos generados por las actividades de transportar un producto, con la posibilidad de mantener inventario tanto en el depósito como en el cliente, satisfaciendo la demanda de cada cliente en cada período de tiempo. Dos características importantes de este problema son: (i) La demanda de un cliente en un periodo dado puede ser superior a la capacidad del vehículo, por lo tanto puede ser atendida por dos rutas diferentes en el mismo periodo. (ii) La demanda de un cliente en un periodo debe ser satisfecha, esto implica, que puede ser llevada en el mismo periodo o en los periodos previos.

2.2.1. Conjuntos

N Conjunto de todos los puntos $(R \cup D)$

R Conjunto de minoristas

D Conjunto de depósitos

T Conjunto de períodos de tiempo

K Conjunto de vehículos

2.2.2. Índices

i= {1, 2, 3…, R} Representa los clientes.

j= {1, 2, 3…, n} Representa los nodos.

d= {1, 2, …, D} Representa los Depósitos.

k= {1, 2, …, K} Representa los Vehículos.

t= {, 1, 2, …T,} Representa los Periodos.

2.2.3. Parámetros

$Dem_{i,t}$ Demanda del cliente i en el período t.

$CapC_i$ Capacidad de almacenamiento de cada cliente.

$CapV_k$ Capacidad de carga de los vehículos.

$CT_{i,j}$ Costo de transporte desde el nodo j al cliente i.

$CMI_{i,t}$ Costo de mantener inventario en el cliente i en el período t.

$CMD_{d,t}$ Costo de mantener inventario en el depósito d en el período t.

2.2.4. Variables

$Q_{i,d,k,t}$ Cantidad de producto enviado al cliente i usando el depósito d con el vehículo k en el periodo t.

$INV_{i,t}$ Inventario almacenado en el cliente i en el tiempo t

$Y_{i,j,d,k}$ Variable binaria igual a 1 si el vehículo k a partir del depósito d viaja directamente desde el vértice i al vértice j en el período t ((i, j) Ɛ N). 0 de lo contrario.

$Z_{i,d,k,t}$ Variable binaria igual a 1 si el vehículo k visita el vértice i del depósito d en el período t, 0 de lo contrario. (La variable no está definida cuando el vértice i es un depósito diferente de d, en este problema la posibilidad de visitar un depósito comenzando el recorrido desde otro uno no se considera.

F.O

$$Min\ z = \sum_{(i,j)\in N} CT_{i,j,d,k,t} * \left(\sum_{d}\sum_{k}\sum_{t} Y_{i,j,d,k,t}\right) + \sum_{i}\sum_{t} CMI_{i,t} * I_{i,t} + \sum_{t} CMI_{d,t}\left(\sum_{i}\sum_{d}\sum_{k} Q_{i,d,k,t}\right) \quad (1.1)$$

S.t:

$$\sum_{k}\sum_{d} Q_{i,d,k,t} - INV_{i,t} + INV_{i,t-1} - DEM_{i,t} = 0\,;\ \ \forall \boldsymbol{i} \in R, \forall \boldsymbol{t} > 1 \in T \tag{1.10}$$

$$INV_{i,1} = 0 \quad Q_{i,d,k,t} \geq 0 \quad INV_{i,t} \geq 0 \tag{1.11}$$

$$Y_{i,j,d,k,t} \in \{0,1\}\ Z_{i,d,k,t} \in \{0,1\} \tag{1.12}$$

Las expresiones (1.2-1.3) garantiza que se cumplan las condiciones de ruteo, La expresión (1.4) indica que el vehículo que entre sea el que sale del nodo partiendo de su depósito usando el vértice (i, j). La expresión (1.5) no permite que la capacidad del vehículo sea excedida por la cantidad a entregar al cliente por cada periodo. La expresión (1.6) indica que la cantidad de unidades a ser enviadas desde los depósitos mediante sus vehículos no puede exceder la diferencia entre la capacidad y el inventario que tiene el cliente. La expresión (1.7) imita la producción disponible en cada depósito. La expresión (1.8) elimina los subtoures, las expresiones (1.9-1.10) establecen que la demanda del período debe ser satisfecha considerando su inventario actual e incluyendo la alternativa de dejar inventario para el siguiente período. La expresión (1.11) corresponde a las condiciones de no negatividad del modelo y por último la expresión (1.12) indica las condiciones de variables binarias del modelo.

3 Método de solución: Algoritmos genéticos

El problema MDIRP está definido como un problema NP-hard, la resolución de este tipo de problemas tiene numerosas aproximaciones, siendo las técnicas metaheurísticas las más utilizadas y, entre ellas, una de la más conocidas los Algoritmos Genéticos (AG) [6].

Para incluir las consideraciones del modelo MDIRP, inicialmente se definen sus principales componentes, para esto se toma como base el trabajo realizado por [7] donde el gen corresponde a cada uno de los arcos correspondientes del modelo y el cromosoma es conjunto de posibles rutas desde el punto inicial hasta el punto final del recorrido, cada cromosoma trae consigo una posible solución de la función objetivo que para este tipo de problemas es Minimizar el Costo. La figura 1, muestra cómo se va a presentar un vector solución para una instancia de 3 Depósitos, 2 vehículos por depósito, 1 período y 12 clientes, siendo depósitos= (0.1, 0.2…. ,d) y clientes depósitos= (1, 2, 3….. ,i).

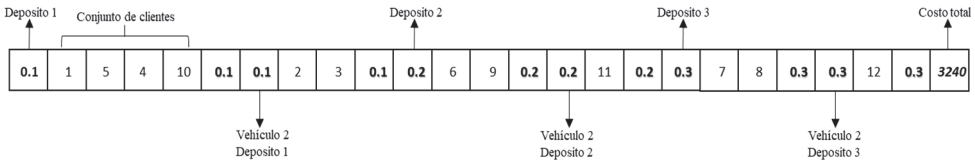

Fig. 1. Resultado Vector Solución.

A continuación, se expone como se realizan cada una de las fases del algoritmo genético para esta investigación.

3.1 Inicialización

La población inicial se genera de manera aleatoria, se origina un vector población inicial, el cual cambia para que durante la evaluación, los individuos muestren un fitness distinto. Este vector parte de la matriz de clientes, la cual a lo ancho presenta las características de estos clientes (demanda, capacidad, costos, entre otros) y a profundidad la cantidad de cromosomas que se generaron inicialmente. Cada vector población inicial corresponde a cada uno de los trozos del cubo los cuales solo contienen la lista desordenada de los clientes como se observa en la figura 2, además en este paso también se establece el vector depósitos el cual también es ordenado con base a los depósitos disponibles.

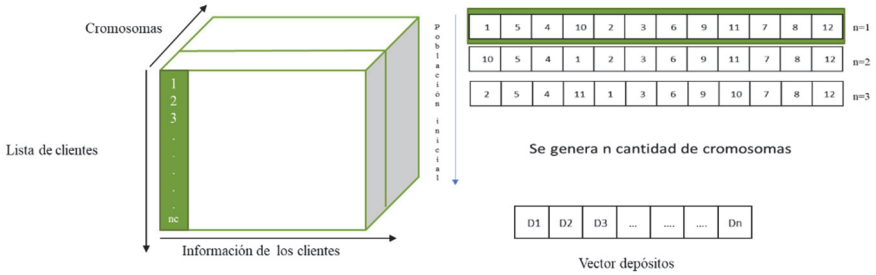

Fig. 2. Matriz de clientes y vector depósitos

3.2 Evaluación:

Se evalúa cada uno de los individuos de la población inicial asignándoles un valor según su calidad. Este valor numérico se llama fitness, y está asociado con los valores finales de costo (función objetivo).

En este punto, es necesario verificar si se cumple el criterio de parada. Si se incumple este criterio, se procede a aplicarsen los operadores genéticos, para este caso se usaron la selección y reproducción, cruce y mutación.

3.3 Selección y reproducción:

En este operador se verifican los individuos que contienen el mejor fitness, el método que se usa en este operador es la selección por torneo, la decisión radica en que este método de selección es uno de los más usados en relación con problemas de este tipo, se escogen individuos al azar de la población y entre ellos se compara el fitness reduciendo la población a la mitad, el que tenga mejor valor es el que pasa a la siguiente generación.
Una vez seleccionados los individuos mediante la selección por torneo, se procede a reproducir una cantidad de cromosomas que nunca deben superar el valor n de población inicial.

3.4 Cruce o crossover:

Cuando ya se tienen los mejores individuos (nuevos padres), se hace lo que se conoce como Crossover que consiste en mezclar el material genético. Una forma encontrada en la revisión de literatura y que se considera de las más sencillas, que se elige para este trabajo, es mediante un ‘‘One-point’’. Este consiste en elegir un punto de corte al azar para los dos individuos e intercambiar el material genético a partir de esta posición [8]. Lo anterior, se puede ver en la siguiente figura 3, la cual muestra el operador cruce con nuevos padres que contienen la mejor evaluación. Cabe indicar que se eliminan aquellos cromosomas cruzados que tienen repetido algún cliente.

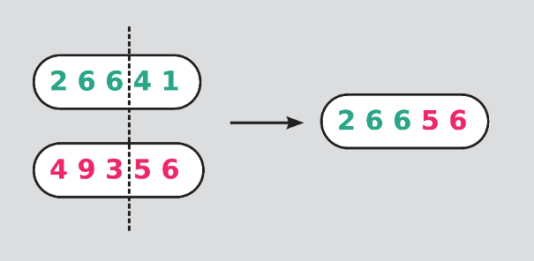

Fig. 3. Operador cruce.

3.5 Mutación:

Para realizar el último operador genético, se decide por la alternativa otorgada por [9], donde se recoge la tesis doctoral de Ruíz (2003), quien propone el uso de (SHIFT mutación), el cual demostra la superioridad y ventaja que tiene esta alternativa, sobre los otros tipos de operadores establecidos.
Inicialmente se genera un número aleatorio inicial que va de 1 hasta t, donde t representa el tamaño de la población. Este número permite identificar el individuo a mutar. Posteriormente, se tiene otro número aleatorio (0 o 1), este número hace referencia a la probabilidad de mutación, es decir, a la probabilidad de que el individuo seleccionado sea sometido a mutar. De esta manera, se comparan los 2 números aleatorios y si la probabilidad asociada al individuo es mayor o igual a la probabilidad de mutación establecida en el algoritmo, el individuo es mutado.
La estructura del operador SHIFT, es representada mediante dos fases. En la fase 1 se tiene los valores (R1, R2 y R3) siendo números aleatorios que están entre 0 y 1. R1 y R2 representan el inicio y fin del bloque del cromosoma a desplazar. R3, establece la posición del cromosoma donde se realiza el desplazamiento, esta posición no debe estar contenida dentro del bloque. Durante la fase 2, se desplaza el bloque hasta la posición R3, y se acomodan las demás posiciones del cromosoma. Ver figura 4.

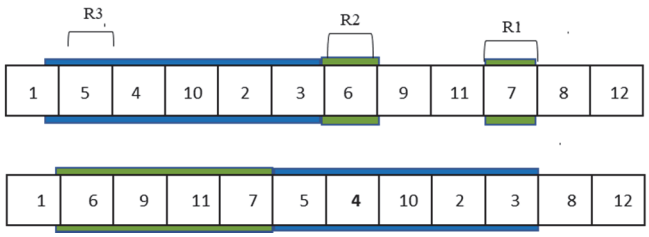

Fig. 4. Operador de mutación, nueva población.

Al tener el vector mutado nuevamente este pasa a evaluación donde se realiza la inclusión de los depósitos para la evaluación de su fitness, cada cromosoma era comparado con el anterior y así se obtiene la mejor solución de la corrida. Cabe recalcar que este proceso se realiza para un solo periodo, al ser este modelo multiperiodo el proceso del AG se realiza para cada uno de los periodos de planificación.

Una vez definido cada uno de los componentes del AG, se desarrolla este proceso en el software MATLAB. La forma gráfica que tendrá el vector solución de cada uno de los periodos de planificación de las instancias escogidas en esta investigación es la siguiente:

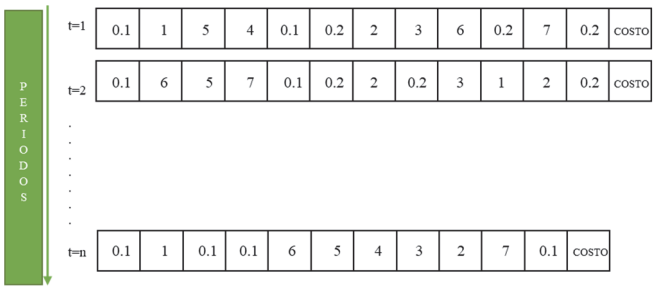

Fig. 5. Vector solución por periodos de planificación

Se usan las instancias de la literatura expuestas por [10], las cuales corresponden a un modelo IRP, y se ajustan incluyendo los costos de mantener inventario tanto en los clientes como en el proveedor, para intervalos de 5 hasta 50 clientes. Ahora bien, al ser este proyecto multidepósito multi-vehículo, se considera necesario realizar las siguientes modificaciones adicionales a las instancias:

- Se ubican los depósitos en coordenadas aleatorias pertenecientes a la posición de un cliente.
- No se dejan fijos, ni la cantidad de depósitos ni los vehículos asociados a los cientes, estos hace parte de la experimentación para observar la eficiencia de todas las posibles soluciones.
- Para generar el costo de transportar desde un punto i a j (CTij) se asocia al costo de transportar con una velocidad constantes sobre distancias euclidianas.

Y entonces sobre las anteriores, se realizan pruebas para una disponibilidad de máximo 3 depósitos por instancia para un horizonte de planificación de 3 períodos. La forma en que se expresa la estructura de los parámetros para cada una de las combinaciones posibles es la siguiente:

(# Iteraciones, # max de Vehículos disponibles, # depósitos Adicionales, # población Inicial).

Dado que las instancias escogidas provienen de un modelo con un único depósito, donde para este trabajo los depósitos adicionales se añadieron de manera aleatoria en alguna posición perteneciente a algún cliente, en la estructura del parámetro solo se verá reflejado la cantidad de depósitos adicionales, es decir, si la cantidad de depósitos totales es 3, en la estructura del parámetro aparecerá el valor de 2.

Las instancias se nombran para 5 clientes abs1n5 hasta llegar a la de mayor cantidad de clientes abs1n50, la forma de nombrar cada prueba consiste en incluir al final (. #prueba),

Estimating the Dynamic Impact of COVID-19 State-level Mobility Interventions in Brazil

Abstract. The Social distancing and quarantine are considered the so far most effective policy to prevent an increasing contagion of COVID-19. While the economic impact from the implementation of this strategy is evident, empirical assessments to measure the disease outbreak's impact are still scarce. The first results reported in this assessment aim at quantifying this prospect. Data over time and over 27 Brazilian federations in 5 regions provided by Google's COVID-19 Community Mobility Reports and classified by place categories (Retail and Recreation, Grocery and Pharmacy, Parks, Transit Stations, Work-places, and Residences) are autoregressed on the COVID-19 incidence in Brazil using Generalized Linear Poisson Regression to measure the dynamic impact of mobility on each socioeconomic category. The assessment provides estimations for the time gap between contagion and data disclosure for public authorities' decision-making, first estimations regarding the propagation R_0 and R_0^+ in Brazil, and the mobility impact and marginal contribution for each place categories. The most critical cities in Brazil based on Optimized Hotspots Analysis are investigated with a brief discussion on the effects of population density and the Carnival in São Paulo and Rio de Janeiro. Suggestions for local planning based on the results are reported in conclusion.

Keywords: COVID-19, Mobility Interventions, Generalized Linear Estimations, Geographic Information Systems, Spatial Correlation, Contagion Mapping.

1 Introduction

Since the World Health Organization (WHO) announcement declaring the novel coronavirus outbreak a pandemic, Brazil has increased the number of confirmed cases. On February 26, 2020, the first case of the Severe Acute Respiratory Syndrome Coronavirus 2, aka COVID-19, was confirmed in São Paulo. Because of seasonal differences (e.g., winter compared to summer) and cultural differences (e.g., smoking habits), and because Brazil has a much bigger vulnerable population exposed to a wider set of tropical infectious diseases, resulting in a higher acquired immunity, many authorities had great expectations the outbreak would not be as aggressive

compared to Europe. The skepticism of public authorities on the outbreak proved wrong. No more than 93 days after the first case, the country reported 438,238 confirmed cases and 26,754 deaths, making Brazil the second country with the most confirmed cases in the world [1], [2], leading the World Health Organization to declare Brazil as the new epicenter of the coronavirus outbreak. In July, the country reached more than 1.8 million confirmed cases and more than 70 thousand deaths.

The outbreak brought many uncertainties about allocating hospitalization resources [3] economic prospects and intervention policies [4]. Social Distancing, Quarantine, and Isolation are assumed to be the most efficient strategies to reduce the exponential epidemic growth jeopardizing health systems in vaccines' absence. Most mobility sanctions and social distancing measures to combat the Coronavirus in Brazil began in the week from March 15 in several states. Gradually, schools and universities were closed, gyms, cinemas, theaters and museums opening were forbidden, civil servants and public employees moved to home office working and, in some localities such as São Paulo, retail and non-essential services were closed. Despite all efforts, the rate of social isolation has been below the ideal.

One of the many reasons is the Federal Government's recurrent position downgrading the benefits of state-level mobility interventions. According to Ajzenman, Cavalcanti & Da Mata [5], who investigated geographic location data from 60 million mobile phones combined with voting information of 2018 national elections, social distancing and quarantines are significantly reduced in pro-government localities after Brazil's president dismissing the risks associated with the COVID-19 pandemic and publicly and emphatically advise people to rebel against state mobility interventions.

Despite ongoing guidelines from the World Health Organization, scholars, scientists, and experts worldwide in order to contain an exponential spread, suggesting social isolation has been continuously dividing opinions around the world when they are weighted against economic prospects. The different interpretations of the current trade-off between economic development and the health systems' stability can be attributed to a lack of feasible evaluations. While the closing business impact is evident in the unemployment rate for many sectors of the economic activity, the mobility impact in the disease propagation is not as straightforward. This conflict of interest culminated in the minister of health's demission on April 16 and an unprecedented political crisis.

The first results reported in this research aim to contribute to this discussion, providing estimates for the dynamic mobility impact considering different economic place categories, estimates for the R0, and R0+ to aid policymakers' strategic planning. The spatial incidence in Brazil's most critical areas is investigated through optimized hot spots analysis, questioning the potential determinants and government responses to the crisis. The methodology and criteria associated with the model choice are described in the next section.

2 Methodology

There is an average time lag of three weeks from the initial contamination to the data curation and disclosure by health authorities in Brazil. This is because it takes from one to two weeks to manifest the most severe symptoms that would lead to testing, and from one to two weeks for the testing results. This reasoning has statistical support in this assessment. We have performed a series of modeling considering time lags of 1, 2 and 3 weeks for new and total cases and for the percentage mobility in six place categories: retail and recreation, grocery and pharmacy, parks, transit stations, workplaces or residences. Data were provided by Google [6] COVID-19 Community Mobility Reports and by Brazil [1] Ministry of Health epidemiological report. Georeferenced data at the federative level were obtained from Cota [7] COVID-19 repository.

Combining these variables in additive and multiplicative interactions for different probability distribution families (e.g. Gaussian, Gamma, Poisson) and different link functions (e.g. Identity, Inverse and Log) offered interesting results for choosing the most appropriate model. This choice was made based on three criteria: (1) statistical support, (2) parsimony and, (3) quality of data/parameters to the empirical knowledge. Models presenting 3 weeks time lag had a higher number of statistically significant variables and interactions (measured by the p-values). Parsimony, measured by the Akaike [8] Information Criterion (AIC), refers to the trade-off between representativeness and simplicity of a model. The third criterion is an assumption based on specialized knowledge in order to avoid poor quality inputs. General Linear Models with Poisson multiplicative interactions sustained the best adherence to these criteria.

Poisson regression models have been used to determine associations of the COVID-19 and environmental, meteorological and ecological factors, including population density, temperature, solar radiation, air quality and meteorological variables [9], [10], [11], [12], [13]. Zhang, Ma, and Wang [14] employed a segmented Poisson model to analyze the available daily new cases data of the COVID-19 outbreaks in the six countries, considering the governments' interventions (stay-at-home advises/orders, lockdowns, quarantines and social distancing). Agosto and Giudici [15], [16], investigated the contagion dynamics of the COVID-19, which can heavily impact health, economics and finance, using a Poisson model autoregressed on daily new observed cases. Furthermore, Ahmed [17] carried out studies using Poisson regression analysis to quantify patients' delays and the health system and identify their associated factors.

Autoregressed models with exogenous determinants are common for public policy, laws and sanctions evaluations [18]. Following a similar approach, and based on the decision criteria for choosing the most appropriate model, the number of new coronavirus cases is autoregressed to the number of new cases preceding 3 weeks and re-

gressed to the interaction of COVID-19 base (the total number of cases up to the 3 weeks lag) with the place mobility variables. Formally:

$$\ln \lambda_i = X\beta \;\; \therefore \;\; y_i = e^{X\beta} \,|y_i \sim Poisson\,(\lambda_i) \forall\, i = 1,2,3,\dots,n \qquad \textbf{(1)}$$

Where: $X\beta$ is the linear predictor $(b_0 + \prod_{j=1}^{7} b_j x_i)\, \forall\, i = 1,2,3,\dots,n$, with 120 multiplicative interactions, such that:

b_0 = coefficient for the effect of COVID-19 new cases 3 weeks before (the R_0^+)
b_1 = coefficient for the effect of COVID-19 cases reported 3 weeks before (the R_0)
b_2 = coefficient for the effect of retail and recreation mobility reported 3 weeks before
b_3 = coefficient for the effect of grocery and pharmacy mobility 3 weeks before
b_4 = coefficient for the effect of parks mobility reported 3 weeks before
b_5 = coefficient for the effect of transit stations mobility reported 3 weeks before
b_6 = coefficient for the effect of workplaces mobility reported 3 weeks before
b_7 = coefficient for the effect of residences mobility reported 3 weeks before

Low mobility levels is expected to have a positive effect on reducing disease propagation, considering the place categories. The log link function $(\ln \lambda_i)$ in the Poisson GLM is appropriate in this modelling for keeping non-negative the projection λ when the mobility regressors X or coefficients β is expected to have negative values. Likewise, higher mobility is expected to contribute to increasing transmission.

The week from March 14 was considered as a reference for counting the initial seed of cases. This is the week 15 from the 27 federations disclosed the first cases, and most of the state-level mobility sanctions were first implemented. The initial seed of cases works as a baseline to control the autoregressive covariate's empirical estimation in this dynamic relationship. In addition, it works to identify the first week of significant macro data to model the phenomenon. Some federations have cases prior to the designed initial week. The northern states of Pernambuco (2 cases on March 12), Rio Grande do Norte (1 case on March 13), Alagoas (1 case on March 08), and Bahia (1 case on March 06) are some instances. The bigger seed of initial cases is for São Paulo, which had their first case on February 26, away before any other federation, counting 56 new cases along the weeks until March 14, and 340 new cases in the first week from March 14, resulting in a seed of 396 initial cases.

3 Assessment and Discussion

Table 1 reports the main results. The coefficient sign represents the overall data relation of that specific base or place category with COVID-19 propagation (new cases). Two places categories exhibit a negative relation with COVID-19 (Retail and Recreation and Workplaces). This can be interpreted as a spurious correlation problem: the same weeks an aggressive mobility reduction was observed in business, civic and cultural activities due to sanctions aiming at closing malls, shops, commercial centers, theaters, stadiums, outdoor events, service units and public administrations

coincide with the COVID-19 exponential increase in Brazil. We cannot attribute, however, this increase to the mobility reduction in these places. This leads to believe correlation does not imply causation for these categories considering Brazil as a whole. This prospect may not be true for smaller disaggregated data on regions, states or municipalities.

Another evidence is the exponential coefficient for these places categories. The exponential coefficient (Exp. Coeff.) is a proxy for how much new cases respond, on average, to cases and to mobility changes three weeks before. The estimates for retail and recreation and workplaces are small (0.135 and 0.788, respectively) compared to other estimates such as transit stations (2.232) and residences (2.463), despite the very significant p-values. The very high exponential coefficient for Grocery and Pharmacy is another instance of spurious data correlation in this case. The same weeks supermarkets, grocery stores and pharmacies have experienced a considerable demand increase coincide with the COVID-19 exponential increase in Brazil. Nevertheless, we have no additional evidence to attribute COVID-19 exponential increase to the mobility increase in these places, leading to believe correlation does not imply causation for this category either, considering Brazil as a whole.

The exponential coefficients cannot be interpreted as additive predictors individually because of the multiple interaction modelling structures. Nevertheless, they provide a notion of overall importance each base or place mobility has on new cases of COVID-19. For a more empirical quantitative measure of the mobility impact, we provide the marginal contribution estimates. In this dynamic modelling, estimates for the R0, R0+ and for the mobility impact of each place category change along the time and along the regions and states. For each week and for each region we have a different marginal contribution. The marginal contributions reported in Table 1 are estimations for the individual effect of each variable on the number of new coronavirus cases from May 9 to May 16, 2020. These are obtained by adding one unit change to the base of cases (new cases or total) or by adding 0.001% mobility change to the place category (retail and recreation, grocery and pharmacy, parks, transit stations, workplaces or residences), keeping everything else constant, them investigating the potential increase or decrease in the prediction for COVID-19. Statistical support is measured by the p-values.

[1] Marginal Contribution (Impact) in the cases from May 9 to May 16, 2020 (third week of May).

[2] Estimates for a marginal increment of one additional COVID-19 case and 0.001% additional mobility.

[3] Significance Scores: '***' 0.001 ≤ p-value; '**' 0.01 ≤ p-value < 0.001; '*' 0.05 ≤ p-value < 0.01.

Estimates for the R0 and R0+ varies according to the week and region. For the third week of May we can assume each new case three weeks before was responsible, on average, for 7.49 new cases. The mobility increase in Grocery and Pharmacy and Workplaces had a negative effect on new cases, whereas the mobility increase in Retail & Recreation, Parks, Transit Stations and Residences had a positive effect. The positive effect of mobility changes in residential areas can be attributed to favelas and poor communities' vulnerability. Despite the pandemic, Baile funk parties, *peladas* (pick-up soccer games) and many other forms of social organization are reported in many peripheries and informal urban settlements.

Some estimates according to the different regions (north, northeast, center west, southeast and south) are reported in Tables 2, 3, 4, 5 and 6. Figures illustrate the spatial concentration. When disaggregating the country data into small datasets, there is a lack of significant sample for each region. Therefore, most estimation for the mobility impact and contagion does not have statistical support. For this reason, this information is omitted in the Tables. We expect to provide more comfortable estimates by integrating more massive datasets in the forthcoming months. The most significant impacts are mobility in workplaces for the southeast region, parks for the center-west, residential areas in the northeast and retail and recreation in the north region. The estimates refer to a 1% marginal change.

The most critical cities are evaluated using Optimized Hot Spots Analysis. This methodology offers Getis-Ord [19] statistic for each location that indicates where cities with either high or low COVID-19 cases cluster spatially. The objective is to assess the COVID-19 intensity through cities. We question whether potential mobility contributions to eventual hot spots could indicate a spatial concentration of municipalities composing the input features aggregating the COVID-19 occurrences. A similar analysis can be accessed in Menezes et al. [20] and Nepomuceno & Costa [21] investigating the spatial concentration of crime in the urban space. In this case, each of these geographic locations' total occurrences are the analyzed field in the analysis. Figure 7 presents the visualization.

Figure 7. COVID-19 Optimized Hot Spots in Brazil

The hot spot cluster for 99% confidence is composed of the metropolitan areas of the capitals Manaus in the north, Ceará in the northeast, São Paulo and Rio de Janeiro in the southeast. In addition to a great incidence, these cities are surrounded by other

cities of high COVID-19 incidence. The impact on the health system is summed to a higher probability of contagion in these areas, which makes this significant spatial association critical and requires urgent attention by the public authorities.

Rio de Janeiro and São Paulo have the second and third highest population density, and the fifth and second capitals with the highest population density. Ceará has the capital with the highest population density in Brazil. This information combined with the airline hubs for international flights in these capitals can explain, at least partially, the high initial incidence and fast spread of COVID-19.

Another factor that may explain the current critical scenario for those cities is originated in the Community Transmission and can related to the most popular Brazilian festival: the Carnival. Community Transmission is characterized when authorities are unable to trace the source of the infection. The states of São Paulo (SP) and Rio de Janeiro (RJ) have the first community transmission officially reported on March 13, which according to our specifications, can be traced back to the last week of February reserved to Carnival holidays. During the Carnival week, all places categories in São Paulo and Rio de Janeiro had a negative mobility change, with an exemption on Parks and Residential areas which are the places concentrating Street Carnival and parades.

4 Conclusion

Brazil's COVID-19 response has been one of the most controversial in the world. If by one hand state governments and municipalities efforts follow international protocols and recommendations, on the other, there is a big question about the federal administration's institutional preparedness, which constantly jeopardizes the prospects of mobility sanctions, social distancing, and quarantine campaigns. The first results reported in this assessment aim at contributing to this discussion. In particular, reducing mobility in residential areas and retail places is a challenge local authorities should prioritize due to their high potential. The absence of the state in favelas can make longer the trade-off between the economy and health. Unquarantine planning based on the individual impact of these place categories and the interaction with external localities can be an interesting avenue to anticipate developing the first communities free from the pandemic. Lastly, the question on model selection for the best representation of data is expected to be addressed with robust statistical tests in future works.

Abstract. Com a Revolução Industrial, os processos de produção sofreram mudanças. Sendo assim, as empresas focaram no desenvolvimento de novos produtos, procurando obter maior rendimento com menos desperdícios, adotando práticas *lean*. Além disso, com o objetivo de produzir com consciência, adotaram práticas *green*. Com a aplicação de práticas *lean* e *green* as empresas conseguem reduzir a quantidade de resíduos, melhorar a utilização de recursos e aumentar a competitividade. Para as PMEs a aplicação desses conceitos é mais complexa, devido à quantidade limitada de recursos disponíveis. O objetivo desse trabalho é analisar a maturidade das metodologias *lean* e *green* no processo de desenvolvimento de produtos em PMEs brasileiras e japonesas. A metodologia é multicriterial, aliando o método Processo de Análise Hierárquica (fase 1- priorização de critérios) e TOPSIS 2-*Tuple* (fase 2 – hierarquização das 18 facilitadores *lean-green*). A pesquisa compreende três PMEs japonesas e três brasileiras, do setor metalmecânico e com foco no desenvolvimento de produto. Os resultados esperados para o método TOPSIS 2-*Tuple* são que o contexto japonês esteja com as metodologias *lean* e *green* mais avançadas que o contexto brasileiro, visto que foi onde surgiu a metodologia *lean* e está sendo utilizada há mais tempo, permitindo maturidade maior nas empresas. O método AHP (fase 1 da pesquisa) quando aplicado com especialistas dos dois países apresentou divergência de hierarquização sobre quais as características mais relevantes nas empresas. Para os japoneses, a incidência de inovação é a característica principal, já para brasileiros, a característica mais determinante é o domínio da alta gerência nos processos.

Keywords: Desenvolvimento de Produtos *Lean,* Desenvolvimento de Produtos *Green,* Desenvolvimento de Novos Produtos

1 Introdução

No século XVIII, com a Revolução Industrial, os processos produtivos deixaram de ser manufaturados para se tornarem fabris [39]. Com esse novo paradigma produtivo aumentou a competitividade entre as empresas. Para suprir as necessidades e visando conquistar mercado consumidor, as empresas foram obrigadas a passar por fases de inovação bruscas. Isso ocorreu, pois a vantagem competitiva está ligada à necessidade das empresas inovarem e aprenderem com a inovação [37].

Para conseguir conciliar a evolução, oriunda da revolução, com os restritos recursos é importante que eles sejam bem aproveitados, de maneira a obter rendimento máximo [8]. Tendo em vista esses aspectos, o desenvolvimento de novos produtos (NPD) está atrelado ao conceito de que se deve produzir com consciência, satisfazendo as necessidades dos clientes no presente, porém sem comprometer a capacidade de recursos para as gerações futuras suprirem as delas [30].

Para que o uso desses recursos ocorra de forma harmônica, há pilares sociais, econômicos e ambientais que balizam o desenvolvimento de produtos de uma forma sustentável. Ainda, é importante atentar-se ao fato que a sustentabilidade é um processo iterativo, o que implica em várias perspectivas e disciplina para sua aplicação e manutenção no médio e longo prazo [9].

Tendo em vista a quantidade limitada de recursos naturais, as empresas devem prezar para que todo o recurso disponível na empresa seja bem utilizado, evitando todo tipo de desperdício. Nesse sentido, para atingir o objetivo de maior rendimento com menos desperdícios, as empresas passaram a adotar o conceito de *Lean Manufacturing* (produção enxuta), tendo como origem o Sistema Toyota de Produção. Os princípios *Lean* são amplamente disseminados como meio para a eliminação de resíduos, proposição de valor e melhoria contínua no desenvolvimento de produtos [23].

Conforme exposto, para que as empresas tenham bom desempenho no campo de desenvolvimento de produtos, faz-se necessário o conhecimento e aplicação de métodos sustentáveis e de produção enxuta. De acordo com Oliveira [30] o NPD apresenta um conjunto de operações que influencia nos processos de manufatura, ciclo de vida dos produtos e adoção dos aspectos *lean* e *green* nas empresas.

O desenvolvimento de produto, atualmente, não se restringe apenas à funcionalidade técnica, mas sim equilibrando conceitos sustentáveis e enxutos como forma de garantir o crescimento da empresa e a manutenção dela no mercado [14]. Com base nos princípios do *lean* e do *green*, o NPD deve reduzir a quantidade de resíduos nas empresas, visando melhor utilização dos recursos produtivos [17] para aumentar a competitividade da empresa frente ao mercado. Além disso, o desperdício de recursos pode comprometer os aspectos financeiros das empresas [13].

Os facilitadores do *lean* e do *green* apresentam importância estratégica no NPD, uma vez que ambos os conceitos são aplicados visando reduzir custos, contribuir para a otimização e alcançar a sustentabilidade. Apesar dessa sinergia encontrada entre os conceitos, há uma lacuna na literatura onde a maioria dos estudos encontrados concentram-se em estudar o desenvolvimento individual de produtos com foco no *green* ou no *lean* [21]. Ainda, facilitam a alta competitividade da empresa no mercado [18]. Por fim, a literatura apresenta poucos estudos sobre o NPD em PMEs, gerando questionamentos sobre os processos de desenvolvimento de produtos que foram desenvolvidos e formalizados para empresas de grande porte, se podem ser transferíveis para pequenas empresas sem perdas [22].

O presente trabalho tem por objetivo analisar qual o nível de maturidade se encontram as PMEs avaliadas nas metodologias *lean* e *green* em dois contextos distintos (Brasil e Japão), além de encontrar quais os facilitadores desses conceitos que são realmente aplicados nas PMEs. O estudo tem duas fases, sendo que nesse artigo é

apresentada a fase 1- priorização de critérios para PMEs, sendo que a fase 2 está em fase de coleta e estará finalizada para a versão estendida após a realização do evento.

2 Referencial Teórico

O desenvolvimento de novos produtos (NPD) consiste em um conjunto de atividades, a partir das quais é possível exprimir as necessidades do mercado e dos clientes, fazendo um de tecnologias e estratégias competitivas. Ainda, está envolvido com todo o ciclo de vida do produto, desde a concepção do projeto até a descontinuidade dele no mercado [10], [22] e [33].

A introdução de novos produtos no mercado é a inovação pura [26]. Essa inovação é vital para o crescimento econômico das empresas, bem como para a formação de novas plantas e para o enfrentamento de novos desafios [40]. Além disso, para aumentar a competitividade e alcançar melhoria em termos de custo, qualidade e tempo, diferentes conceitos de gerenciamento foram estabelecidos na prática comercial [10]. Dentre esses conceitos estão as metodologias *lean* e *green*.

O *lean* enfatiza o desperdício em operações que não agregam valor aos produtos, enquanto o *green* objetiva seleção de materiais e a maximização do seu uso, como boas práticas de reutilização e reciclagem [18]. Apesar de poucos estudos conciliarem a implementação prática dos conceitos *lean* e *green* simultaneamente no desenvolvimento de produtos, ambos têm semelhanças de interesses e podem apresentar sucesso maior se aplicados em conjunto.

O *lean* é uma filosofia que define os meios para melhorar a otimização do sistema de produção [38]. Os princípios do *lean* são amplamente disseminados e aplicados como forma de eliminar resíduos, proposição de valor e melhoria contínua no processo de NPD [24]. Essa aplicação do *lean* no NPD foi nomeado de Desenvolvimento de Produtos *Lean* (LPD).

As empresas que adotam o LPD buscam eficiência e eficácia. A eficiência é buscada minimizando a variabilidade interna e externa e reduzindo todas as formas de desperdício nos fluxos de informação e produção. Já a eficácia é obtida aumentando a qualidade e o valor do produto sob a perspectiva do cliente [25]. Algumas práticas *lean* que potencializam o NPD, são: engenharia simultânea, modularização, envolvimento cliente e fornecedor e design para capacidade de fabricação. Essas práticas podem melhorar o processo de NPD e auxiliar no gerenciamento do portfólio de produtos [23].

Atualmente, as empresas buscam atingir seus objetivos no NPD não apenas por meio de processos eficientes, mas também mais produtivos e com operações sustentáveis. Essa busca por operações sustentáveis surgiu motivada, pela escassez de recursos, pressão internacional e órgãos nacionais adotando regulamentos ambientais [35].

Dessa forma, para um empresa ser *green,* ou seguir a linha de desenvolvimento de produtos *green* é simultaneamente uma oportunidade e uma necessidade [7]. Os principais objetivos do design sustentável de produtos são a redução do uso e emissão de recursos de um produto para o meio ambiente, bem como melhorar o desempenho socioeconômico ao longo do ciclo de vida do produto [11].

Dessa forma, o desenvolvimento de produtos *green* (GPD) deve contemplar uma abordagens na inovação, estratégias sustentáveis e metas e a incorporação formal de requisitos ambientais e por fim implementando ferramentas sustentáveis e personalizadas, além de integrar aspectos ambientais no gerenciamento de projetos [2].

A orientação para sustentabilidade pode ser incorporada pelas PMEs através do conhecimento associado ao nível de experiência e capacidade, tanto no aspecto estratégico como operacional [19].

As pequenas e médias empresas (PME) representam parte substancial da atividade econômica, em termos de números de empresa e do produto interno bruto (PIB) em praticamente todos os países do mundo [1]. No Japão, as PMEs representam cerca de 99,7% de todas as empresas, compondo 70,2% dos empregos e seus funcionários constituem 80% dos eleitores do país [6]. Já no Brasil as PMEs são responsáveis por, aproximadamente 60% da força de trabalho e 42% da massa salarial [4].

3 Metodologia

A pesquisa é delimitada a dois contextos distintos: PMEs do Japão, representando os países desenvolvidos e do Brasil, representando os países em desenvolvimento. As PMEs escolhidas apresentam atividade de NPD no setor metal mecânico em seus processos fabris.

Para o embasamento teórico foi realizado uma revisão sistemática da literatura, apoiada no método *Proknow-C* que foi desenvolvido para analisar quantitativamente artigos com prestígio científico. Esse método permite encontrar um portfólio relevante e alinhado com os eixos de pesquisa [43].

Durante a revisão, foram buscados artigos que tivessem relação com os eixos temáticos da pesquisa: *lean*, *green*, Pequenas e Médias Empresas e Desenvolvimento de Novos Produtos. Dentro desses eixos estão as palavras chave que foram buscadas nas bases científicas: *Green, Sustainable, Environment, Ecodesign, Lean, Kaizen, Six Sigmas, SME, Small and medium enterprises, Japanese small and medium enterprises, Developing Countries x Developed Countries, New product development, Product design, Comparative studies*. Todas as palavras chave foram escritas em inglês para que retornassem mais artigos sobre o assunto. A combinatória de palavras-chave a serem pesquisadas foi a permutação entre as palavras de todos os eixos de pesquisas, utilizando "*and*" entre as palavras de eixos distintos.

Para a busca pelos artigos foram utilizadas as bases científicas *Scopus* e *Science Direct* e delimitado a pesquisa entre os anos de 2014 a 2019, visando obter apenas artigos com informações atuais, visto que essa pesquisa iniciou em março de 2019, porém com uma margem de cinco anos para que a quantidade de documentos encontradas seja relevante para a realização do estudo. Como resultado final da pesquisa, foram selecionados 18 artigos, conforme pode ser conferido na Tabela 1. Esse portfólio bibliográfico permitiu que fossem definidos os critérios (características das PMEs) e as alternativas (facilitadores do *lean-green*), além de auxiliar no embasamento para conhecer as metodologias aplicadas nessa pesquisa.

Fonte: Autores

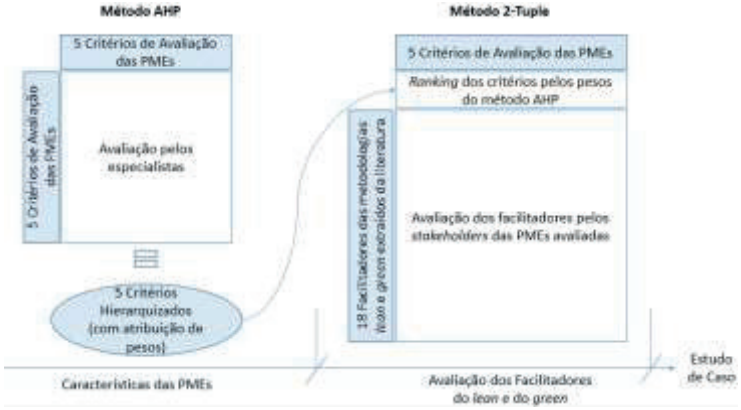
A ideia central a ser desenvolvida nesse trabalho é analisar o quão aplicados estão os princípios das metodologias *lean* e *green* nas PMEs japonesas e brasileiras, analisando quais são os facilitadores mais utilizadas e eficientes para atingimento da maturidade das empresas nesses conceitos dentro do NPD. A coleta de dados nos dois países serve como base para comparação do desenvolvimento deles.

Essa análise irá ocorrer fazendo uso de metodologia multicriterial. Serão aplicados dois métodos multicriteriais combinados: AHP (fase 1) e TOPSIS 2-*Tuple* (fase 2). Esses métodos servem de auxílio na tomada de decisões. Eles possuem etapas genéricas, na qual constam a escolha dos critérios de avaliação, alternativas sobre os

critérios de avaliação, analisar e definir qual a melhor alternativa, sendo ela a mais próxima do ideal [31].

A metodologia de coleta de dados acontecerá em duas etapas distintas. Sendo que, a primeira inclui entrevista com os especialista em PMEs para atribuição dos pesos de cada um dos critérios, hierarquizando as características mais relevantes. Os dados serão coletados a partir de uma planilha eletrônica. A segunda etapa, consiste na entrevista com as pessoas responsáveis pelo NPD nas PMEs selecionadas para o estudo. Nessa etapa serão relacionados cada uma das alternativas (facilitadores do *lean* e do *green*) com os critérios (características das PMEs), atribuindo graus de aplicabilidade dentro da empresa. Os dados nessa fase da pesquisa serão coletados a partir do uso de formulários eletrônicos.

Os critérios representam as características das PMEs, buscados na literatura [12], [29], [30] e adaptados ao contexto o qual busca-se compreender: 1 – Flexibilidade (Estrutura e fluxo de informações flexíveis, resposta rápida às mudanças ambientais, plana com poucas camadas de gerenciamento, resistência insignificante à mudança, alta gerência próxima ao ponto de entrega e muito visível, proporcionando mudanças rápidas, se necessário), 2 – Dificuldade no NPD (Falha em compreender a importância do projeto do produto e baixo grau de formalização), 3 – Inovação (Alta incidência de inovação e criatividade individual incentivada), 4 – Recursos limitados (Pessoas, tempo para realizar inovação e financiamento limitados), 5 – Autoridade (Gerente comandando todas as atividades da empresa sem conhecimento adequado).



As alternativas são os facilitadores do *lean* e *green* buscadas na literatura [30], sendo elas: Melhoria Contínua (A forma como as melhorias ocorrem não deve ser abrupta e pontual, mas sim longitudinal e gradativa), Transferência de conhecimento entre projetos (As equipes podem usar a experiência acumulada das melhores práticas de projetos anteriores para projetar novos produtos), Definir Valor e Fluxo de Valor (No NPD, iterações sucessivas e coordenadas se traduzem em valor. O mapeamento de fluxo de valor é um método de sucesso aplicado em pequenas empresas), Ferramentas de ecodesign e capacidade dinâmicas (design para o meio ambiente, eliminação de resíduos e recursos dinâmicos verdes), Conhecimento e Aprendizagem (Conhecimento e aprendizagem estão associados à capacidade das organizações de reter conhecimento tácito para aplicá-lo em suas operações de NPD), Avaliação do Ciclo de Vida (Integra as questões ambientais com os efeitos dos produtos, desde a fabricação até o descarte final, Seleção de materiais (Consequências de uma correta determinação dos materiais influenciam as operações de reciclagem e descarte no ambiente natural), Padronização de Processos (Consiste em padronizar todas as atividades periódicas), Gestão da variedade de produto (Consiste na padronização de peças, módulos e subconjuntos), Prototipagem rápida, avaliações e testes (Usada para validar tanto os problemas geométricos quanto os modos de falha de alguns componentes), Controle Baseado em Conjuntos (No controle do plano baseado na responsabilidade individual, os gestores definem os marcos, enquanto a equipe do projeto é autônoma para programar seus fluxos de trabalho, estimar a duração das atividades e dar feedback aos gestores sobre a viabilidade da proposta horários), Engenharia Baseada em Conjuntos (Considera conjuntos de projetos e soluções ao longo do desenvolvimento, descartando, sob múltiplos critérios, aquelas soluções que são inferiores às demais), Engenharia

Simultânea (As etapas do NPD são executadas sequencialmente, sendo que a próxima etapa inicia antes do término da atual), Especialização de Engenharia e Nivelamento de Carga de Trabalho (Os engenheiros da equipe do projeto devem permanecer em suas áreas de especialização), Integração de Fornecedores (Os fornecedores estão ligados à equipe do projeto), Gerente de Projetos Forte (O engenheiro chefe é o responsável pela definição do valor), Redução de Resíduos (Melhor aproveitamento dos recursos), Análise de Impactos Ambientais (Analisa os materiais utilizados no desenvolvimento do produto, de forma que não apresentem nenhum risco ambiental quando forem descartados ao final de sua vida útil).

O presente trabalho tem como base o artigo elaborado por Oliveira *et al.* [30]. As alternativas passaram por um refinamento de acordo com a mudança de cenário e a perspectiva do estudo comparativo. Os critérios também foram refinados e são alternados entre critérios de custo, aqueles que tem característica negativa e critérios de benefício, que possuem características positivas.

A Figura 1 apresenta a fase multicritério, na qual são desenvolvidos os métodos AHP para determinação dos pesos dos critérios de avaliação das PMEs e o método de variável linguística TOPSIS 2-Tuple, no qual a alta direção ou o responsável pelo NPD da empresa avaliam o quanto os facilitadores listados estão implantados nas PMEs.

Figura 1 - Modelo de avaliação para as operações de NPD nas PMEs.

Fonte: Adaptado de Oliveira [30]

No método AHP é feita a comparação dos critérios aos pares. Os elementos a serem comparados são dispostos em uma matriz *n*x*n* onde serão realizadas as correspondências. Na diagonal principal os elementos são iguais a um e os outros são recíprocos das comparações iniciais.

As comparações devem seguir a escala de Saaty [36] na qual, 1 significa que ambos elementos apresentam contribuição idêntica, 3 significa um julgamento levemente superior para um critério, 5 significa julgamento fortemente a favor de um critério, 7 significa dominância reconhecida de um critério e por fim, 9 significa dominância comprovada de um critério. Além disso tem os valores intermediários: 2, 4, 6 e 8 que podem ser utilizados caso haja a necessidade.

Para a atribuição de pesos para cada um dos critérios serão convidados especialistas da área do próprio país onde ocorrerá a pesquisa, Brasil e Japão, os quais deverão fazer a análise de prioridade utilizando o método de Processo de análise hierárquica, do inglês *Analytic Hierarchy Process* (AHP). O método AHP é considerado um método de seleção e tem como objetivo escolher em forma de hierarquia as alternativas apresentadas. A análise das alternativas ocorre par-a-par, elencando qual a melhor entre duas alternativas e quanto melhor uma que a outra. Esse método é realizado por especialistas do assunto em construir hierarquia através das respostas de especialistas, definir prioridades e verificar a consistência lógica das respostas [36].

Após a utilização do método AHP para a atribuição de pesos aos critérios acima listados, será aplicado o método de decisão multicritério de variáveis linguísticas. Esse segundo método a ser utilizado servirá para informar o grau de aplicabilidade de cada princípio nas PMEs. Esse método apresenta bons resultados para modelar e gerenciar incerteza e implica na realização de processo fazendo uso de palavras [27]. É uma ferramenta importante e que pode ser aplicado em problemas de diversas áreas para abordagem qualitativa, como recuperação de informações [15].

Porém, Herrera *et al*. [15] apresentam que se deve atentar para os termos linguísticos utilizados para que sejam simétricos, apropriados e cordiais para a aplicação. Ainda aborda sobre a grande abrangência do método que é tido como ponto forte, mas requer atenção, visto que a abrangência é muito mais que em métodos qualitativos.

Após a coleta de dados com as variáveis linguísticas, para que seja feita a análise e para facilitar os cálculos, os parâmetros linguísticos serão transformados em valores numéricos. Porém, logo após a análise, os valores são expressos de maneira linguística novamente.

O primeiro passo para a análise dos dados obtidos é estabelecer o conjunto de termos linguísticos que serão utilizados no processamento das informações. Depois, converter as variáveis linguísticas no equivalente de informação. Então é necessário identificar as soluções positivas e negativas ideais, para calcular a distância entre as alternativas até as soluções negativas e positivas ideais. Seguindo deve-se calcular a semelhança com a solução positiva ideal, calcular a variável linguística correspondente, com base no passo anterior e por fim, classificar em ordem das variáveis linguísticas.

O modelo linguístico conhecido como 2-tuple é representado na forma (s, $\propto$), onde s é um rótulo linguístico e $\propto$ é um valor numérico que representa um valor. Ainda, na questão de nomenclatura, β é o resultado de uma agregação dos índices de um conjunto de rótulos avaliados de termos linguísticos S [16].

A principal vantagem dessa representação é ter um domínio contínuo, sendo possível expressar qualquer informação no universo do discurso [44]. Para cada termo linguístico é necessário que haja um número difuso agregado [20].

Os stakeholders serão questionados através da entrevista estruturada. Para os critérios de benefício as perguntas serão da forma: “Considerando as práticas atuais em sua empresa: Qual a importância do facilitador “A1” na característica “C1” da empresa?”. Já, para os critérios de custo, as perguntas serão na forma: “Considerando as práticas atuais em sua empresa: Qual a importância do facilitador “A1” para reduzir os efeitos da característica “C2” da empresa?”.

O primeiro passo para a aplicação desse método foi estabelecer um conjunto de termos linguísticos para serem utilizados nos processamentos das informações. Tendo em vista que $S = \{s_0, \dots, s_g\}$, que $\Delta(\beta) = (S_i, \alpha)$, com $\alpha = \beta - i$ e $\alpha \in [-0{,}5, 0{,}5)$ e que $\Delta^{(-1)}(S_i, \alpha) = i + \alpha = \beta$.

Sendo que para representar cada um desses parâmetros linguísticos serão utilizados números difusos triangulares, do tipo fuzzy $\tilde{x}ij = (aij, bij, cij)$. Dessa forma, teremos as representações conforme Tabela 2:

Tabela 2 - Variável Linguística e equivalente Fuzzy

Variável Linguística	**Número *Fuzzy***
Nenhuma	0,00; 0,00; 0,17;
Muito Baixa	0,00; 0,17; 0,33;
Baixa	0,17; 0,33; 0,50;
Média	0,33; 0,50; 0,67;
Alta	0,50; 0,67; 0,83;
Muito Alta	0,67; 0,83; 1,00;
Absoluta	0,83; 1,00; 1,00;

Fonte: Autores

Após a atribuição de números difusos, eles serão normalizados para que após seja seguido o passo a passo conforme descrito acima.

Realizado a hierarquização das variáveis linguísticas para os dois casos analisados: Brasil e Japão, será realizada um estudo comparativo dos resultados de ambos para que seja possível encontrar as lições aprendidas de cada um dos países.

Os estudos comparativos ocupam lugar de destaque em pesquisas científicas, pois auxiliam em diagnósticos de problemas sociais, para o desempenho de políticas públicas e ao mesmo tempo, como parâmetro de referência para fonte de legitimação [32].

Os países, objetos de estudo, encontram-se em cenário totalmente diferentes e, analisar o nível de aderência, ou maturidade, das metodologias *lean* e *green* em cada um deles, permite que sejam observados pontos de melhorias e qual o grau de formalização do NPD nas PMEs desses países.

Para que a comparação entre dois países tão distintos ocorra de forma científica e seja, de fato, válida, as empresas escolhidas para esse trabalho atendem aos mesmos requisitos: todas as empresas classificam-se como PMEs, atuam no NPD do setor metal mecânico e utilizam potencialmente as metodologias *lean* e *green* em seus processos.

A escolha dos países para fazer parte dessa pesquisa aconteceu levando em consideração a importância de analisar cenários distintos e que se encontram em realidades econômicas diferentes para obter melhores resultados. Sendo assim, foi escolhido um país desenvolvido, o qual é o berço da metodologia *lean*, destaque em exportações e está localizado nas primeiras posições entre os países com o maior PIB: o Japão. Já o segundo país escolhido pertence à classe de países em desenvolvimento, está em constante ascensão para entrar no *ranking* de melhores PIBs e, por isso é conhecido como uma potência emergente: o Brasil.

A comparação entre os dois cenários relata tanto as diferenças quanto as semelhanças dos países estudados. Para isso, foram avaliadas e comparadas as respostas da pesquisa estruturada caso a caso, com o intuito de debater quais os facilitadores mais utilizados nas PMEs e quais as lições aprendidas das empresas Japonesas podem auxiliar as PMEs brasileiras a melhorarem o processo de NPD e aumentar o nível de aplicação e maturidade das metodologias *lean* e *green*.

Para realizar essa comparação de modo que todas as semelhanças e diferenças das empresas sejam abordadas com clareza, foi utilizado o método de escrita ponto por ponto, no qual são alternados pontos sobre um contexto e outro. Esse método permite que sejam comparadas diretamente as PMEs abordadas e possibilita que sejam discutidas todas as perguntas do questionário, avaliando as respostas de cada uma [32].

4 Resultados Preliminares e Discussão – fase 1

Esse trabalho é um refinamento de Oliveira *et al.* [30], o qual realizou uma análise da maturidade e aplicabilidade dos facilitadores do *lean* e do *green* nas PMEs brasileiras.

Os resultados esperados para essa pesquisa é que as empresas brasileiras apresentem um nível semelhante de adesão. Contudo, estima-se que haja um aumento da aplicabilidade dos facilitadores, uma vez que essas duas metodologias estão sendo cada vez mais difundidas recentemente. Já para as empresas japonesas, estima-se que o nível de aderência delas nas metodologias avaliadas seja mais elevado, uma vez que o Japão pode ser considerado o berço da metodologia *lean*. Conforme comentado anteriormente, os estudos comparativos ocupam lugar de destaque em pesquisas científicas, pois auxiliam em diagnósticos de problemas sociais, para o desempenho de políticas públicas em especial que possam ser avaliadas no contexto brasileiro.

Como refinamento para o trabalho elaborado por Oliveira *et al.* [30] apresenta-se os seguintes pontos: aumento de dois facilitadores relacionadas com a metodologia *green*, com o objetivo de equalizar a quantidade de facilitadores dos princípios *lean* e *green*; agrupamento de dois critérios com objetivos e definições semelhantes, tornando assim apenas cinco os critérios com características das PMEs; mudança dos métodos multicritérios utilizados, sendo que no trabalho de Oliveira *et al.* [30] foram utilizados AHP combinado com *Fuzzy*-TOPSIS e nesse trabalho são combinados os métodos AHP e TOPSIS *2-Tuple*. Essa troca ocorreu pois, o método TOPSIS 2-*Tuple* tem grande abrangência nas respostas, permitindo que por meio dele sejam gerenciadas as incertezas fazendo um de termos linguísticos, pode ser aplicado em várias áreas para a abordagem qualitativa, como forma de recuperação de informações [16]. Por fim, em Oliveira *et al.* [30] foi analisado o nível de maturidade das PMEs brasileiras nas metodologias *lean* e *green* e nessa pesquisa agrega-se o estudo comparativo em PMEs brasileiras e japonesas.

O instrumento e protocolo para coleta dos dados será o mesmo para ambos os países. Para o método AHP foi utilizada uma planilha eletrônica enviada aos especialistas em PMEs. Ao final do preenchimento da planilha os pesos para cada um dos critérios é calculado automaticamente. Os respondentes dessa etapa do processo são pessoas com conhecimento do contexto de PMEs, sendo que parcialmente é composto por diretores

executivos (do Inglês, Chief Executive Officer – CEO) de pequenas ou médias empresas renomadas no ramo que atuam e parcialmente é composto por professores estudiosos do assunto.

Para cada um dos países foram selecionados três especialistas em PMEs para responder a planilha responsável pela atribuição de pesos aos critérios. As qualificações de cada um dos especialistas podem ser observadas na Tabela 3 Dessa forma, foram coletadas ao todo seis respostas distintas dos especialistas que serão compiladas como forma de uniformizar o peso de cada critério, fazendo com que a métrica utilizada para posteriormente analisar os facilitadores do *lean* e do *green* nas empresas seja a mesma em ambos os países.

Tabela 3 - Especialistas e qualificações

Especialistas	Descrição das qualificações
E1 - Japão	Diretor de área de uma instituição governamental (Organização para PMEs)
E2 - Japão	Atualmente, na área acadêmica. Ex-banqueiro com anos de experiência com PMEs locais, agora CEO de uma construtora de médio porte.
E3 - Japão	Ex-CEO, com anos de experiência, de um fabricante de pequeno-médio porte.
E4 - Brasil	Analista técnica do SEBRAE atuando em programas e projetos de atendimento às pequenas e médias empresas
E5 - Brasil	Atua na área acadêmica. Pesquisadora de gestão estratégica para PMEs
E6 - Brasil	Atua em empresas e na academia. Contadora focada em administração de empresas e competitividade no mercado

Fonte: Os autores.

Na sequência, para a aplicação do método TOPSIS 2-*Tuple* (fase 2) serão utilizados formulários eletrônicos. Para cada um dos cinco critérios será elaborado um formulário distinto, sendo que todos eles apresentam o critério, a descrição e significado dele, bem como os facilitadores das metodologias *lean* e *green* e as descrições delas. Sendo organizados dessa maneira, são cinco formulários composto por 18 questões em cada um deles. As questões deverão ser respondidas de acordo com as práticas atuais dentro das empresas, para com isso validar o objetivo da pesquisa.

A coleta desses dados e o contato serão realizados por um pesquisador residente do país, tanto nas PMEs japonesas quanto nas brasileiras. Além disso, os formulários disponíveis para responder são no idioma do país em que está sendo aplicado para evitar que sejam respondidos níveis de aplicabilidade medianos por falta de entendimento do que está sendo questionado. Os formulários já estão prontos para aplicação (em português e japonês)

Todas as seis PMEs selecionadas para responder a pesquisa partilham do mesmo setor de atuação: setor metal mecânico e podem ser observadas algumas informações gerais delas na Tabela 4. Sendo que elas atendem aos requisitos de número de funcionários mínimo e máximo para serem consideradas pequenas ou médias empresas no país no qual atuam. Apesar das características básicas de todas elas serem as mesmas, há grandes diferenças na forma com o qual cada empresa é conduzida, sendo assim, possivelmente haja diferenças de aderência dos facilitadores.

Tabela 4 - Empresas selecionadas e ramo de atuação.

EMPRESAS	ÁREA DE ATUAÇÃO DAS EMPRESAS
E1 - Japão	Fabricante de corrente de metal
E2 - Japão	Fabricante de equipamentos de mecatrônica
E3 - Japão	Fabricante de materiais de cobre e metal
E4 - Brasil	Fabricante de implementos agrícolas e equipamentos rodoviários
E5 - Brasil	Fabricante de equipamentos e suprimentos para escritório, consolidada nos segmentos de automação e manufatura
E6 - Brasil	Fabricante de equipamentos industriais, projetos para fabricas de ração, manutenção industrial, engenharia de processos

Fonte: Os autores.

O método AHP foi aplicado com três especialistas de cada país, sendo que dentro do mesmo país eles residem em regiões distintas, com o intuito de avaliar o local como um todo e não baseado apenas em uma pequena região. Cada um dos respondentes avaliaram de acordo com seus conhecimentos prévios na área quais as características das PMEs que são mais importantes ou determinantes no crescimento delas.

Nas respostas dos especialistas japoneses, a característica mais determinante dentro de uma pequena ou média empresa é a alta incidência de inovação (peso 0,413), seguida pela flexibilidade da empresa em se adaptar às mudanças impostas pelo mercado (peso 0,232). Também pode ser observado que essas duas características tem peso bem superior às outras colocações. Para os respondentes brasileiro a ordem das duas primeiras características se mantém, sendo em primeiro lugar a alta incidência de inovação (peso 0,251) e seguido pela flexibilidade da empresa (peso 0,229). As respostas de brasileiros apresentaram pouca disparidade entre as colocações no *ranking*.

Os pesos atribuídos pelos especialistas podem ser observado na Tabela 5, no qual estão evidenciados separadamente os pesos atribuídos por especialistas japoneses e por especialistas brasileiros.

Tabela 5 - Resultado AHP

CRITÉRIOS	JAPÃO		BRASIL	
	MÉDIA	RANKING	MÉDIA	RANKING
C1 - Flexibilidade	0,232	**2º**	0,229	**2º**
C2 - Dificuldade no NPD	0,067	**5º**	0,179	**3º**
C3 - Inovação	0,413	**1º**	0,251	**1º**
C4 - Recursos Limitados	0,087	**4º**	0,165	**5º**
C5 - Alta Autoridade	0,200	**3º**	0,176	**4º**

Fonte: Os autores

O método TOPSIS 2-*Tuple* (fase 2) está sendo aplicado e os resultados estarão descritos na versão estendida desse artigo.

5 Conclusão

Esse trabalho apresenta 18 facilitadores do *lean* e do *green*, apresentados como as alternativas para os métodos multicritérios, sendo todas elas encontradas a partir de

revisões de literatura. A partir da aplicabilidade delas na prática é possível compreender qual o grau de maturidade das PMEs quanto às metodologias *lean* e *green*.

Os resultados da fase 1 foram satisfatórios, uma vez que foram abordados profissionais de diferentes áreas de atuação para responder ao método AHP e obtive-se resultados bem positivos com essa heterogeneidade de respondentes. As características tidas como principais, elencadas entre as duas primeiras posições, foram as mesmas em ambos os países, porém as últimas sofreram alterações de colocações.

Pode-se observar ainda que os especialistas japoneses classificam as três primeiras colocadas: Inovação, Flexibilidade e Alta autoridade, com bastante disparidade de pontuação frente às últimas colocadas. Já os especialistas brasileiros apresentam os resultados muito mais próximos uns dos outros, atribuindo importâncias semelhantes.

A fase 2 permite avaliar dentro das empresas do setor metal mecânico o quanto estão aplicados os facilitadores do *lean* e do *green*. Bem como avaliar se há práticas desenvolvidas dentro das empresas que sejam consideradas importantes e replicáveis para outras empresas. Cada uma das empresas avaliadas apresenta uma forma de gerenciamento, sendo assim, bem heterogêneas entre si.

Ainda, com esse estudo, a alta gerência pode perceber onde encontram-se os pontos fracos do NPD dentro da empresa. E, a partir disso, focar em ações que visem melhorar os pontos elencados, trazendo maior aderência aos facilitadores e metodologias do *lean* e do *green.*

Abstract. The multi-objective optimization of a direct current rotary dryer that works with pozzolan in a semi-dynamic condition is described in this article. Four objective functions are minimized using the NSGA-II algorithm, these objective functions are: (1) the pozzolan humidity at the exit of the rotary dryer, (2) the heat given off by the rotary dryer to the environment, (3) the operating costs of the production process and (4) the number of new starts of the rotary dryer. The operating parameters for the 24-hour simulation were obtained. Simulation results show that it is not recommended to interrupt the dryer operation due to the high operating costs that this generates.

Keywords: rotary dryer · multi-objective optimization · pozzolan · evolutionary computing.

Resumen La optimización multiobjetivo de un secador rotatorio de corriente directa que trabaja con puzolana en condición semi-dinámica se describe en este artículo. Cuatro funciones objetivos son minimizadas utilizando el algoritmo NSGA-II, estas funciones objetivos son: (1) la humedad de la puzolana a la salida del secador rotatorio, (2) el calor cedido por parte del secador rotatorio hacia el medio ambiente, (3) los costos operativos del proceso de producción y (4) el número de nuevos encendidos del secador rotatorio. Se obtuvo los parámetros operativos para las 24 horas de simulación y además se observó que una vez encendido el secador rotatorio no es recomendable interrumpir su operación debido a los altos costos operativos que esto genera.

Palabras claves: secador rotatorio· optimización multiobjetivo· puzolana· computación evolutiva.

1 Introducción

Este trabajo apunta a mejorar los parámetros operativos del secador rotatorio de la Industria Nacional del Cemento del Paraguay (INC), en condiciones semi-dinámicas, a fin de reducir los costos operativos, el contenido de humedad en la puzolana a la salida del secador rotatorio, la emisión de calor al medio ambiente por parte del secador y el número de paradas del secador rotatorio.

En un ambiente tradicional mono-objetivo, es decir, donde se combinan los objetivos a ser optimizados en una sola función objetivo, el problema de optimización puede reducirse a la búsqueda de un máximo o mínimo que sería la solución del problema. Por el contrario, cuando se necesitan considerar simultáneamente los diversos objetivos y estos objetivos se contraponen unos con otros por existir relaciones de compromiso, no siempre existe una única solución al problema, sino un conjunto de soluciones [1]; esto se conoce como Problema de Optimización Multiobjetivo (*Multi-Objective Optimization Problem - MOP*).

Douglas et al. [2], realizaron una simulación transitoria de un secador rotatorio que procesa cristales de azúcar y obtuvieron respuestas dinámicas de los perfiles de humedad y temperatura para el proceso teniendo como entrada una función escalón para ambos casos.

El diseño y operación de los secadores convectivos en el cual se incluye a los secadores rotatorios, fue estudiado por Kiranoudis et al. [3], evaluando los parámetros operacionales de cada secador en términos del costo anual total.

Lobato et al. [4], utilizaron técnicas de optimización multiobjetivo del tipo *Firefly Algorithm* (FA) para la estimación de parámetros de la cinética de secado y calculan los coeficientes de pérdida de calor para una planta piloto de un secador rotatorio que procesa superfosfatos.

Álvarez L. et al. [5], analizaron el diseño óptimo de los parámetros físicos característicos de un secador rotatorio que procesa puzolana, mejorando la reducción en el contenido de humedad de la puzolana en un porcentaje de hasta 6%. De este modo, se logró aumentar la capacidad de producción de una planta industrial cementera.

Miranda [6], mejoró la capacidad de producción de una planta industrial cementera boliviana, mediante el uso del software *Design Expert*, minimizando la pérdida de calor con el ambiente del secador rotatorio de puzolana y minimizando el contenido de humedad de la puzolana.

La optimización multiobjetivo de un secador rotatorio en contracorriente para el secado de fertilizantes del tipo superfosfatos simples, fue propuesto por Silveira et al. [7], donde utilizando algoritmos de Evolución Diferencial (ED) y un modelo robusto, obtuvieron las mejores condiciones de operación del secador, minimizando el calor perdido por las paredes del secador rotatorio y minimizando el contenido de humedad al final de la longitud del secador, considerando la determinación de la temperatura inicial del aire en la entrada del secador, la velocidad del aire y el flujo másico de los sólidos.

Shene et al. [8] modelaron y simularon un secador rotatorio de corriente directa que procesa pescado y soja, donde mediante un modelo distribuido obtuvieron el perfil de temperatura del aire de secado y el perfil de temperatura de los sólidos tratados, comparándolos también con los datos experimentales obtenidos en una planta piloto.

En contrapartida a los trabajos anteriores arriba descriptos, este trabajo considera por primera vez la minimización simultánea de cuatro funciones objetivo en el secado de puzolana con un secador rotatorio y en condiciones semi-dinámicas, en un contexto puramente multiobjetivo. En efecto, utilizando un MOEA (*Multi-objective Optimization Evolutionary Algorithm*) se optimiza: (1) la humedad a la salida del secador rotatorio, (2) el calor cedido al ambiente por el secador, (3) los costos operativos en el proceso de secado de la puzolana y (4) los costos de mantenimiento del secador.

En la siguiente sección se plantea formalmente el MOP y el modelado matemático en corriente directa; en la Sección 3 se resume la metodología general y el algoritmo utilizado en la resolución del MOP. En la Sección 4 se resumen los resultados experimentales obtenidos. Por último se establecen las conclusiones y los trabajos futuros en la Sección 5.

2 Problema de optimización multiobjetivo

Formalmente, una optimización multiobjetivo (*Multi-Objective Optimization*), se refiere a la optimización (minimización o maximización) simultánea de dos o más funciones objetivos, donde los objetivos podrían entrar en conflicto unos con otros [9]. El problema de optimización se establece como sigue:

$$Optimizar \quad F(x) = [f_1(x), f_2(x), ..., f_n(x)] \tag{1}$$

Sujeto a:

$$g_i(x) \leq 0 \qquad i = 1, 2, ..., n_i \tag{2}$$

$$h_i(x) = 0 \qquad i = 1, 2, ..., n_e \tag{3}$$

$$x_l \leq x \leq x_u \tag{4}$$

donde n representa al número de funciones objetivos a ser optimizados simultáneamente, x es un vector de m variables de decisión (continuos o discretos) con valores límites; *lower* (x_l) y *upper* (x_u), mientras que n_i y n_e son el número de restricciones en forma de inecuaciones e igualdades, respectivamente.

El espacio factible, Ω es un conjunto de vectores de x que satisfacen todas las restricciones de (2) a (4). La imagen de los vectores de $x \in \Omega$ crean el espacio objetivo simbolizado con la letra Λ [10].

Dominancia Pareto:

Sean $\mathbf{A}, \mathbf{B} \in \Omega$, se dice que $\mathbf{A}$ domina a $\mathbf{B}$ si $\mathbf{A}$ es igual o mejor a $\mathbf{B}$ en todos los objetivos y estrictamente mejor en al menos un objetivo. En este caso, se dice que existe dominancia de $\mathbf{A}$ respecto a $\mathbf{B}$ lo que se denota como $\mathbf{A} \succ \mathbf{B}$ ($\mathbf{A}$ es mejor que $\mathbf{B}$) [11].

Un vector $x^* \in \Omega$ en la región factible es Pareto óptimo [9, 12], si no existe otro vector factible $x \in \Omega$ que pudiera mejorar alguna función objetivo sin causar el detrimento simultáneo en al menos otra función objetivo. Las soluciones Pareto óptimas también se denominan soluciones no dominadas. El conjunto de soluciones no dominadas se conoce como conjunto Pareto (P) y su imagen en el espacio objetivo Λ se denomina Frente Pareto (FP).

2.1 Modelado matemático del secado en corriente directa en estado semi-dinámico

Las siguientes consideraciones se establecen para presentar el modelo semi-dinámico del secador rotatorio en corriente directa [3, 12]:

- se considera que el secador y el quemador operan en estado semi-dinámico, teniendo en cuenta la variación de la temperatura ambiente a lo largo de un día y la variación de la demanda de puzolana;
- ninguna propiedad varía con la posición en el volumen de control (modelo concentrado);
- se considera a la entalpía prácticamente independiente de la presión;
- se considera que la reacción de combustión del biofuel es completa en el quemador;
- para el cálculo del calor cedido por el secador a los alrededores sólo se considera el término convectivo, despreciándose los aportes de conducción de calor y de radiación.

El esquema del proceso a estudiar se muestra en la Figura 1, en donde se puede visualizar que la unidad del proceso de secado consta de dos unidades, un quemador y un secador rotatorio. En el quemador ingresa biofuel conjuntamente con aire húmedo en corriente directa, se produce la combustión, que se considera completa y los gases de combustión que salen del quemador ingresan al secador rotatorio de corriente directa acompañado con la puzolana húmeda. En esta unidad se produce la transferencia de calor y masa así, en el secado parte de la humedad de la puzolana se evapora y pasa a la fase vapor que finalmente forma parte de los gases de escape. Entonces, del secador rotatorio salen: la puzolana seca, que es el producto principal en este proceso y los gases de escape, que se devuelven a la atmósfera.

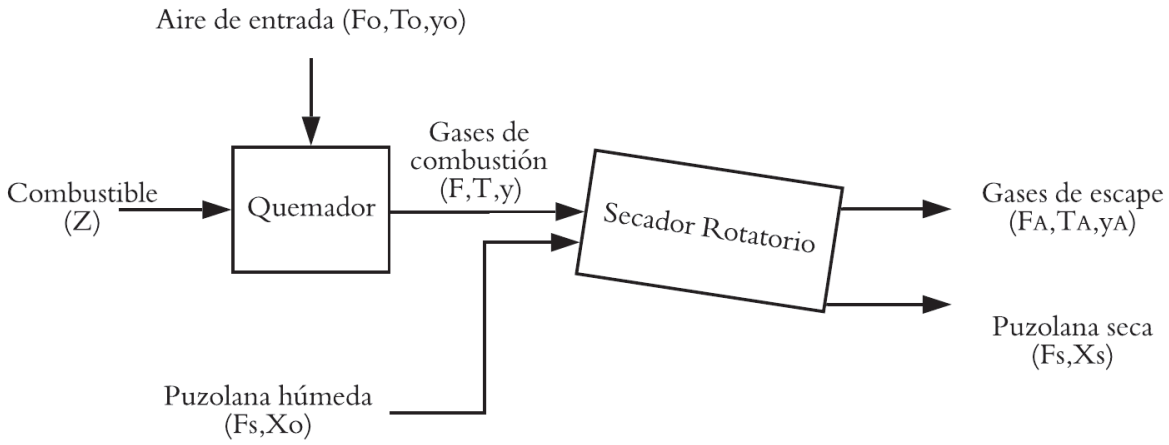

Fig. 1. Diagrama del secador y el quemador de la unidad del proceso de secado.

2.2 Objetivos de la optimización multiobjetivo en corriente directa

Humedad de la puzolana a la salida del secador (f_1): La humedad de la puzolana a la salida del secador debe ser mínima para que la operación de molienda (operación que sigue al secado en una planta cementera) no se vea dificultada.

El balance de materia en el quemador se detalla a continuación, asumiendo que el combustible usado es un biofuel, hidrocarburo con un calor de combustión igual a ΔH_f [kJ/kg] y una fracción de hidrógeno C_H [kg/kg] y que la reacción química de combustión es [12]:

$$C + O_2 \rightarrow CO_2 \tag{5}$$

$$H_2 + \frac{1}{2}O_2 \rightarrow H_2O \tag{6}$$

Se producen entonces, $9C_H$ [Kg] de vapor de agua por [Kg] de combustible [12], esto es:

$$R_w = 9C_H Z \tag{7}$$

donde:

R_w: Velocidad de producción de agua, $[kg/s]$.

El balance total de materia y de agua sobre el quemador se obtiene aplicando las siguientes relaciones [3, 12]:

$$F(1 + y) = F_o(1 + y_o) + Z \tag{8}$$

$$Fy = F_o y_o + R_w \tag{9}$$

donde:

F: Caudal másico de los gases de combustión salida del quemador, $[kg/s]$.
F_o: Caudal másico del aire de entrada al quemador, $[kg/s]$.
y: Humedad de los gases de combustión en la entrada del secador, $[kg/kg\ AS]$.
y_o: Humedad absoluta del aire en la entrada del quemador, $[kg/kg\ AS]$.
Z: Caudal másico del combustible, $[kg/s]$.

Se asume que los gases de combustión tienen las mismas propiedades físicas que el aire, por lo tanto el balance de energía en el quemador queda como [12]:

$$F(1+y)Cp_a(T - T_o) = Z\Delta Hf \tag{10}$$

donde:

Cp_a: Calor específico de los gases de combustión, $[kJ/kg°\mathrm{C}]$.
ΔH_f: Calor de combustión, $[kJ/kg]$.
T: Temperatura de entrada de los gases de combustión al secador, $[°C]$.
T_o: Temperatura ambiente, $[°C]$.

Aplicando un balance de materia total en el secador rotatorio, se obtiene la siguiente relación matemática para la humedad de salida de la puzolana [3, 12]:

$$f_1 = X_o - \frac{F}{F_s}(y_a - y) \tag{11}$$

donde:

f_1: Humedad de la puzolana a la salida del secador rotatorio, $[kg/kg]$.
F_s: Caudal másico de puzolana sólida en el secador rotatorio, $[kg/s]$.
X_o: Humedad de la puzolana en la entrada del secador, $[kg/kg]$.
y_a: Humedad de los gases de combustión en la salida del secador, $[kg/kg\ AS]$.

Calor cedido por el secador rotatorio al ambiente (f_2): El calor cedido por el secador rotatorio al ambiente debe ser minimizado debido a tres motivos: (1) optimizar el calor cedido por el combustible para el secado de la puzolana, (2) disminuir el impacto térmico al ambiente, (3) mejorar los parámetros operativos, considerando que estas son variables independientes del problema planteado.

El calor que pierde el secador rotatorio es debido a mecanismos convectivos principalmente, y está dado por la siguiente relación matemática [2]:

$$f_2 = KF^m \pi DL(T - T_o)b_i \tag{12}$$

donde:

D: Diámetro del secador, [m].
f_2: Calor cedido por el secador rotatorio hacia el ambiente, $[w]$.
K: Constante del proceso obtenido experimentalmente, $[W/m^{2\circ}\ C]$.
L: Longitud del secador, [m].
m: Constante adimensional del proceso de secado.
b_i: Número binario que puede valer 0 o 1, según el secador esté apagado o prendido respectivamente en el intervalo i.

Costos operativos (f_3): Los costos operativos considerados en este trabajo incluyen al costo de la energía eléctrica consumida por el secador rotatorio y el costo del combustible, en este caso biofuel usado en el quemador, por lo que no se consideran como variables a otros costos como los salarios de los funcionarios que operan en el sector de secado. Un factor importante es el costo de la energía eléctrica en la estructura tarifaria de la misma [1]. Existe diferencia de precios, denominada tarifa diferenciada, que para el presente trabajo se considera como sigue:

- tarifa barata (C_{ef}): de 0 a 17 hs, y de 22 a 24 hs., denominado horario fuera de punta de carga;
- tarifa cara (C_{ep}): de 17 a 22 hs., llamado horario de punta de carga.

El costo operativo está determinado por la siguiente ecuación [1, 3, 12]:

$$f_3 = qN_iD(M+W)C_{ei}t_{op}bi + ZC_{zi}t_{op}bi \tag{13}$$

donde:
C_{ei}: Costo de la energía eléctrica en el i-ésimo intervalo, $[US\$/KWh]$.
C_{zi}: Costo unitario del combustible,$[US\$/KWh]$.
f_3: Costo operativo total, $[US\$]$.
M: Masa de puzolana en el secador rotatorio, $[kg]$.
N_i: Velocidad de rotación en el i-ésimo intervalo, [rpm].
q: Coeficiente adimensional para la función de costos operativos.
t_{op}: Tiempo operativo, $[s]$.
W: Masa del secador rotatorio, $[kg]$.

Costo de mantenimiento del secador rotatorio (f_4): El costo de mantenimiento es igual o inclusive más importante que los costos operativos [1]. Se introduce el concepto de número de encendidos del secador rotatorio como una forma de medir el costo de mantenimiento. Es decir, se mide de forma indirecta el costo de mantenimiento del secador por medio del número de veces que ha sido encendido. A mayor número de encendidos, mayor costo de mantenimiento. Un encendido se considera como tal solo en el caso que el secador rotatorio haya estado apagada en el intervalo de tiempo anterior [1].

Si el secador rotatorio ya estaba encendido en el intervalo anterior y continúa estándolo o se apaga en el intervalo siguiente, no constituye un encendido. Para determinar el número total de encendidos f_4 simplemente se cuenta el número de encendidos en cada intervalo y a esto se suma la mitad del número de encendidos entre el primer y el último intervalo; esto último, de manera a considerar los encendidos que hubieran entre el día anterior y el actual, suponiendo cierta periodicidad en las programaciones. Lo explicado anteriormente puede ser expresado como:

$$f_4 = \sum_{i=1}^{24} \left\| max\left\{0; (b_i - b_{i-1})\right\}\right\|_1 + \frac{\left\| max\left\{0; (b_1 - b_{24})\right\}\right\|_1}{2} \tag{14}$$

2.3 Planteamiento matemático del problema formulado

Minimizar $\boldsymbol{y=f(x)}=[f_1(x),f_2(x),f_3(x),f_4(x)]^T$
donde:

f_1 : humedad de la puzolana a la salida del secador rotatorio; ver ecuación (11).
f_2 : calor cedido por el secador rotatorio al ambiente; ver ecuación (12).
f_3 : costos operativos; ver ecuación (13).
f_4 : número de encendidos del secador rotatorio, ver ecuación (14).
$\mathbf{y} \in R^4$;

$\mathbf{x}= [x_1; x_2; x_3; x_4; x_5] \in R^5$, es el vector de las variables independientes, también denominado variables manipulables, donde:

$x_1 = N \in R$, representa la velocidad de rotación en rpm;
$x_2 = T \in R$, representa la tempertaura de los gases de combustión en la entrada del secador rotatorio en °C;
$x_3 = Z \in R$, representa el caudal másico de combustible en la entrada del quemador, en kg/s;
$x_4 = F_o \in R$, representa el caudal másico de aire en la entrada del quemador en kg/s.
$x_5 = b_i \in \{0, 1\}$ es un número binario representa al estado apagado o encendido del secador en el intervalo i.

sujeto a: $x_l \leq x \leq x_u$
donde:

$x_l = [1; 600; 0.1; 10; 0]$
$x_u = [10; 900; 1; 1000; 1]$

3 Metodología

El modelo en estado semi-dinámico pretende determinar el conjunto de soluciones Pareto óptimos $\mathbf{P}$, minimizando la función objetivo $y = f(x)$ y considerando la variación de la temperatura ambiente y la variación de la demanda de puzolana, en cuyo caso se requiere volver a correr el algoritmo de optimización para cada hora del día.

Variación de la temperatura ambiente En la Figura 2 se presenta la variación de la temperatura ambiente considerada como ejemplo, a lo largo de un periodo de 24 horas. Ésta puede obtenerse a través de los datos del pronóstico del tiempo provistos por la Dirección de Meteorología e Hidrología[3] (DMH).

[3] http://www.meteorologia.gov.py/, consultado el 03/12/2019 a las 15:39 hs

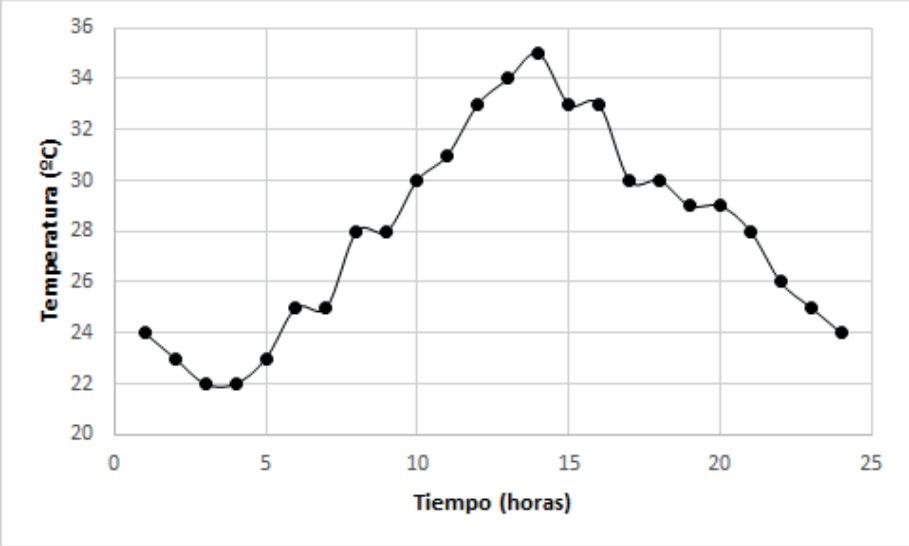

Fig. 2. Variación de la temperatura ambiente en un día (Fuente: Elaboración propia).

Variación de la demanda de puzolana Empíricamente, en la INC se realiza la distribución de la demanda en función de la temperatura ambiente, es decir; los horarios en donde es mayor la temperatura ambiente conviene aumentar la carga del secador de puzolana, y a lo largo de las 24 horas satisfacer la demanda total diaria establecida por el Departamento de Producción.

La variación de la demanda sigue una distribución estocástica, es decir, expresadas según funciones de probabilidad [14]. Matemáticamente, la demanda dentro de las 24 horas se puede expresar como:

$$\sum_{k=1}^{24} Fs_k = Fs_T \tag{15}$$

donde:

k: intervalo de optimización de 1 hora.
Fs_k: Demanda de puzolana en el intervalo $k - ésimo$, en Kg/h.
Fs_T: Demanda total de puzolana seca, en Kg/h.

Si cada demanda en un $k - ésimo$ intervalo de tiempo es función lineal a la temperatura ambiente en dicho instante, entonces:

$$\begin{aligned} Fs_1 &= \beta To_1 \\ Fs_2 &= \beta To_2 \\ &\dots \\ Fs_{24} &= \beta To_{24} \end{aligned} \tag{16}$$

De las ecuaciones (15) y (16), se obtiene el coeficiente de proporcionalidad β, como sigue:

$$\beta = \frac{Fs_T}{\sum_{k=1}^{24} To_k} \tag{17}$$

donde:

β: Coeficiente de proporcionalidad.

To_k: Temperatura ambiente en el $k-ésimo$ intervalo de tiempo, en $°C$.

Para satisfacer por ejemplo, una demanda diaria de 840 toneladas de puzolana y siguiendo la distribución de la temperatura ambiente dada en la Figura 2, el valor puntual de $\beta \approx$1254. En este caso la distribución de la demanda se muestra en la Figura 3.

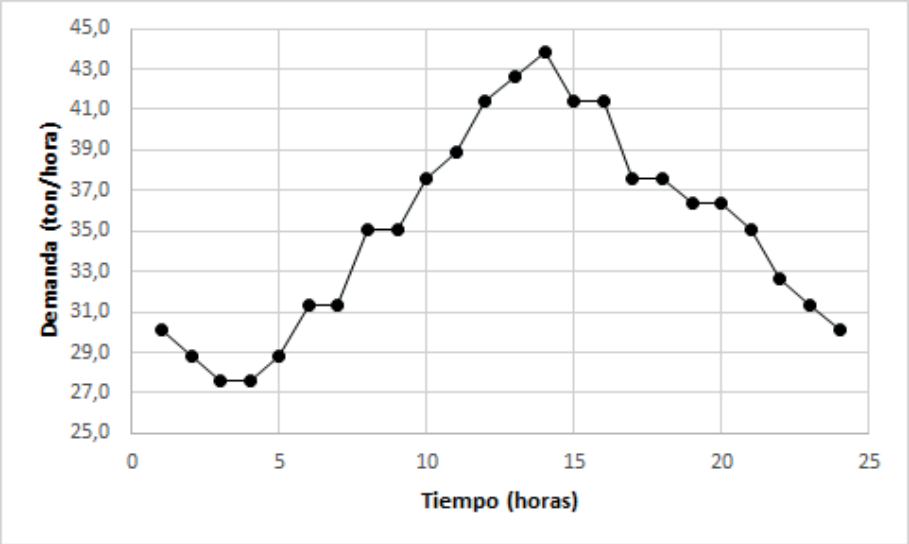

Fig. 3. Variación de la demanda en un día (Fuente: Elaboración propia).

Se tendrán en total 24 simulaciones, 1 simulación para cada hora del día.

El algoritmo utilizado para obtener los datos experimentales que se muestran a continuación es el NSGA-II [13], con un número de generaciones igual a 400, y un tamaño de población igual a 200.

Se utilizó el software Matlab $R2020a$, y un ordenador con un procesador AMD E1-200 APU con Radeon (TM) DD Graphics, 1000 MHz con 2 procesadores lógicos y memoria de 4 GByte.

4 Resultados

En la Tabla 1 se presentan los datos utilizados en las simulaciones presentadas para un proceso semi-dinámico de un día (24 horas).

Tabla 1. Datos del proceso de secado en estado semi-dinámico

Parámetro	Valor
D (m)	2
L (m)	15
U ($W/m^2\ ^\circ C$)	28.36
$T_o(^\circ C)$	según Fig. 2
q	1
Ce (US$/W)	$7*10^{-5}$
Cz (US$/W)	$5*10^{-5}$
M (kg)	1000
W (kg)	10000
C_H (kg/kg)	0.106
ΔH_f (kJ/kg)	$15*10^6$
Cp_a(kJ/kg$^\circ C$)	1180
y_o (kg/kgAS)	0.01
X_o (kg/kg)	1
ΔH_V (kJ/kg)	$2.5*10^6$
F_s (kg/s)	según Fig. 3

En la Figura 4 se muestran los resultados obtenidos para los periodos de simulación de t=1h a t=24h para la optimización multiobjetivo realizada, utilizando coordenadas paralelas. Para cada corrida se obtienen 224 conjuntos Pareto y cada conjunto Pareto tiene varias familias (subconjuntos) de soluciones. En las poli-líneas azules de la Figura 4 se minimizan las funciones objetivos de humedad a la salida del secador rotatorio (f_1) y de costos de mantenimiento (f_4). Por otro lado, en la Figura 4 se puede ver otra familia de soluciones representado por las poli-líneas de color naranja, en donde se minimizan preferentemente las funciones objetivo de emisión de calor al ambiente f_2 y los costos operativos f_3.

Un operador de la INC al ingresar a su turno de trabajo debe ingresar al ordenador (donde se tiene instalado el algoritmo de optimización multiobjetivo) las proyecciones por hora de la temperatura ambiente T_o y de la demanda F_s para lo que dure su jornada laboral. El ordenador le proporcionará como información de salida: la velocidad angular a la cual debe mantener el secador rotatorio x_1, la temperatura a la cual deben ingresar los gases de combustión al secador rotatorio x_2, el caudal másico del fuel-oil que debe ingresar al quemador x_3, el flujo másico del aire de entrada x_4 y si debe o no apagar el secador rotatorio x_5. Si existe alguna perturbación en la temperatura ambiente o en la demanda de la puzolana durante la jornada laboral, el operador deberá volver a ingresar estos nuevos datos al ordenador y ajustar las variables de decisión (x) del proceso.

Cabe destacar que los mejores resultados realizan 0 nuevos encendidos una vez que el secador entra en marcha, minimizando los altos costos de mantenimiento.

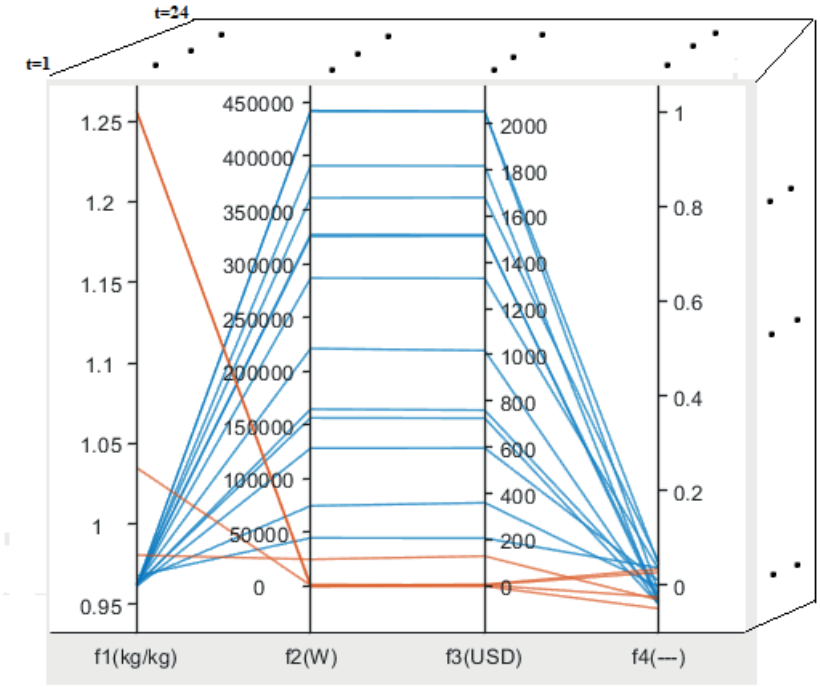

Fig. 4. Esquema de los resultados obtenidos en la optimización multiobjetivo en coordenadas paralelas.

5 Conclusión y trabajos futuros

Se obtuvo los parámetros operativos del secador rotatorio en condiciones semi-dinámicas para las 24 horas de simulación. Una vez encendido el secador rotatorio, se comprobó que no es recomendable apagarlo pues aumenta excesivamente los costos de mantenimiento.

Para trabajos futuros se recomienda analizar el modelo dinámico real, en donde en cualquier momento del día puede ocurrir una perturbación en la demanda o en la temperatura ambiente.

Abstract. En este trabajo se determinaron experimentalmente las propiedades más relevantes de granos de maíz (coeficiente de restitución, coeficiente de fricción, módulo de Young, densidad, ángulo de reposo) y se calibró el coeficiente de fricción intergranular para poder simular la rotura del maíz en el software Rocky DEM (ESSS). Además, se realizó un estudio de sensibilidad para determinar los parámetros del modelo de rotura, cuyos resultados representan adecuadamente al caso de estudio. La calibración se llevó a cabo replicando en Rocky DEM ensayos de medición del ángulo de reposo y se obtuvo un coeficiente de fricción intergranular de 0.31.

Keywords: DEM, calibración, molienda.

1 Introducción

La molienda de material particulado es una operación que reviste gran importancia a nivel industrial. Se estima que el 60% de los productos manufacturados se presentan en forma de polvo o requieren algún tipo de procesamiento de partículas [1]. A pesar de esto, la complejidad de su modelado y la falta de ecuaciones que describan adecuadamente su comportamiento, los torna ineficientes, dificultando su escalado y control.

El resultado de la molienda está determinado por las propiedades del material, el equipo utilizado y las condiciones operativas. Los enfoques tradicionales, basados en balances de energía, no tienen la capacidad de representar los fenómenos que ocurren en los sistemas de partículas. Por este motivo, el modelado por elementos discretos (DEM) ha cobrado gran importancia en la resolución de este tipo de problemáticas.

Las propiedades físicas del material son esenciales para estudiar su comportamiento y para una adecuada simulación en software DEM. Estas propiedades pueden medirse a escala de partícula (micro propiedades) o a granel (macro propiedades). Entre las micro propiedades se encuentran tamaño y forma de partícula, densidad de partícula, módulo de Young y coeficiente de Poisson del material, coeficiente de restitución (partícula-partícula

y partícula-entorno) y coeficiente de fricción (partícula-partícula y partícula-entorno); y entre las macro propiedades, la densidad a granel, el ángulo de fricción interna, el ángulo de dilatación y el ángulo de reposo. Es importante destacar que las macro propiedades no se pueden especificar como parámetros de entrada en un modelo DEM, sino que deben ser correctamente predichas mediante simulaciones de arreglos de partículas que presenten el mismo comportamiento que el material físico. Usualmente, las propiedades necesarias como parámetros de entrada de los modelos DEM se obtienen mediante ensayos experimentales o, en el caso que no sea posible medirlas directamente, deben calibrarse. Para ello, se realizan experimentos de laboratorio que permiten medir una propiedad específica del material a granel (i.e., ángulo de reposo, densidad a granel). El experimento luego se replica numéricamente siguiendo la configuración y los procedimientos de laboratorio lo más cercano a la realidad posible (experimento virtual). Los valores de los parámetros de entrada de DEM se cambian iterativamente hasta que el valor simulado de la propiedad a granel coincida con el resultado medido.

En este trabajo, se determinaron las propiedades físicas del maíz, principal componente en la industria de alimentos balanceados, y se simuló en el software Rocky DEM (ESSS).

1.1 Método de elementos discretos (DEM)

El método de elementos discretos consiste en modelar un material granulado como partículas individuales que interactúan entre sí y con su entorno. Utiliza sofisticadas técnicas numéricas para resolver las leyes de movimiento de Newton y se basa en la mecánica de contacto para predecir la fragmentación y trayectoria de las partículas tras una colisión. La dirección del movimiento y la velocidad se calculan en intervalos discretos, describiendo el proceso con elevado nivel de detalle [2][3]. En este trabajo, las simulaciones DEM se realizaron en el software Rocky DEM (ESSS), el cual posee capacidades únicas, tales como su modelado del proceso de rotura y la posibilidad de combinar diferentes formas y tamaños para crear conjuntos de partículas únicos y cercanos a la realidad, en vez de los típicos grupos de esferas que se encuentran en otros programas DEM [4].

Tal como se mencionó, para definir el modelo de contacto, la simulación en Rocky requiere un conjunto de parámetros de colisión y propiedades del material que deben determinarse cuidadosamente para obtener resultados acertados.

1.2 Módulo de Young

El módulo de Young es una propiedad que describe la rigidez de un material. Refleja la relación entre el esfuerzo y la deformación que experimenta el material al ser sometido a una carga externa, en una dirección dada [5]. Su determinación se realiza con partículas individuales, aplicando ecuaciones de contacto y teniendo en cuenta las características del equipo de compresión, que deben ajustarse a la forma y tipo de material particulado [6].

1.3 Representación de las partículas en DEM

Para llevar a cabo simulaciones cuyos resultados sean representativos del comportamiento real, las propiedades de las partículas virtuales deben aproximarse de la manera más cercana posible a aquellas propias del material. Una de estas propiedades es la forma. Debido a la irregularidad de los materiales granulados, se suele recurrir a formas simplificadas para representarlos. El modelado más sencillo corresponde al uso de esferas, cuyo tiempo de cómputo suele ser reducido pero los resultados que se obtienen son de baja fiabilidad.

1.4 Coeficiente de fricción partícula/entorno

Cuando se tiene dos superficies en contacto, y una de ellas se pone en movimiento o comienza a deslizarse, se genera una fuerza que se opone a este desplazamiento. El coeficiente de fricción es la propiedad que relaciona la fuerza de fricción y la fuerza normal, y es uno de los parámetros básicos requeridos en las simulaciones DEM.

1.5 Ángulo de reposo estático

El ángulo de reposo se define como el ángulo máximo en el cual una pila de material particulado se encuentra inmóvil sobre una superficie plana. El material empieza a fluir en ángulos mayores, mientras que en ángulos menores se mantiene estable. Suele variar entre 25º para partículas cuasi esféricas y 45º para partículas muy irregulares [7].

1.6 Coeficiente de restitución partícula/entorno e intergranular

El coeficiente de restitución de una partícula se define como la relación absoluta entre las velocidades antes y después de una colisión. Representa el grado de conservación de la energía cinética tras la colisión, ya sea entre la partícula y el entorno, o entre partículas. Se trata de uno de los parámetros fundamentales en el modelado DEM, que ayuda a predecir el comportamiento de las partículas después de una colisión dentro un sistema.

1.7 Coeficiente de fricción intergranular

El coeficiente de fricción intergranular ofrece una medida de la resistencia que presentan las partículas al movimiento, al ponerse en contacto unas con otras. Este parámetro es complejo de ser determinado experimentalmente, por lo que suele ser calibrado mediante replicación de ensayos de otros experimentos, ajustando el valor en el software DEM hasta llegar a resultados similares a los experimentales.

1.8 Parámetros de rotura

Los parámetros que afectan la rotura son inherentes a cada modelo. Para ajustarlos, se deben implementar experimentos de rotura de las partículas individuales y realizar simulaciones variando los parámetros hasta obtener resultados adecuados. Rocky DEM cuenta con el modelo de rotura desarrollado por Tavares et al. [10], el cual se describe a continuación:
a) Acumulación de daño luego de un impacto sin rotura. Las energías específicas de fractura de partícula en sucesivos eventos de carga pueden cuantificarse con la expresión:

$$E_n = E_{n-1}(1 - D_n^*) \quad (1)$$

siendo D_n^* el daño sostenido en el n-ésimo ciclo de carga, igual a:

$$D_n^* = \left[\frac{2\gamma}{(2\gamma - 5D_n^* + 5)} \frac{E_{k,n}}{E_{n-1}}\right]^{\frac{2\gamma}{5}} \quad (2)$$

donde γ es el coeficiente de acumulación de daño, cuya determinación es compleja.
b) Fragmentación de la partícula. La distribución de tamaño generada por los impactos de energía específica $E_{k,n}$ sobre partículas de una misma clase se calcula estimando la fracción del material que pasa a 1/10 del tamaño original de partícula (t_{10}):

$$t_{10} = A\left[1 - exp\left(-\frac{b' E_{k,n}}{E}\right)\right] \quad (3)$$

donde A y b' son parámetros del modelo y E es la energía específica de fractura de las partículas que se rompen con una energía de impacto $E_{k,n}$.
Al volverse más finas las partículas, se vuelven también más duras y se incrementa su energía específica de fractura. La siguiente expresión se utiliza para describir esta variación:

$$E_{50} = E_\infty \left[1 + \left(\frac{d_0}{L}\right)^{\varphi}\right] \quad (4)$$

donde d_0, E_∞ y φ son parámetros del modelo que se ajustan con datos experimentales y L es el tamaño representativo de las partículas, todos ellos varían mucho con el material.
c) Distribución de la energía específica de fractura. La ecuación (5) define la distribución de la energía específica de fractura como:

$$P_0(E) = \frac{1}{2}\left[1 + erf\left(\frac{\ln E^* - ln E_{50}}{\sqrt{2\sigma^2}}\right)\right] \quad (5)$$

donde σ^2 es la varianza de la distribución normal logarítmica de energías de fractura, E_{50} es la energía específica media de fractura y E^* es la energía específica relativa de fractura:

$$E^* = \frac{E_{max} E}{E_{max} - E} \quad (6)$$

donde E_{max} es la energía específica de fractura por sobre la cual todas las partículas se rompen en un solo impacto.

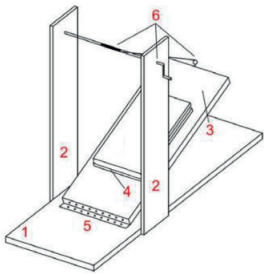
2 Metodología

2.1 Medición de la densidad y el módulo de Young

La densidad de los granos fue determinada mediante picnometría, utilizando agua como líquido de referencia. Para determinar el módulo de Young se realizaron ensayos de

compresión empleando un texturómetro (TA Instruments). El mismo consiste en una celda que aplica tensión de manera controlada a muestras sólidas, midiendo su perfil completo de deformación. Se utilizó un cabezal cilíndrico y se calculó el módulo Y con la ecuación (7):

$$Y = \frac{P(1-\mu^2)}{2aD} \tag{7}$$



donde P es la carga, μ es el coeficiente de Poisson, para el cual se utilizó un valor de 0.4 extraído de literatura [16], a es el radio de la celda, y D es el desplazamiento de la misma.

2.2 Distribución de tamaño y forma de partícula

Para determinar la distribución de tamaño de los granos, se utilizó el software de análisis de imagen *ImageJ*, el cual permite determinar dimensiones tales como el perímetro y la superficie de cada cara. Se tomaron fotografías de una muestra representativa de granos de maíz y se obtuvieron las dimensiones correspondientes. Con estos datos se calculó la distribución de tamaño en masa en función del diámetro de esfera equivalente.

2.3 Determinación de los coeficientes de fricción

El coeficiente de fricción partícula-entorno se determinó mediante un ensayo de deslizamiento utilizando un equipo construido ad-hoc (Figura 1). Este cuenta con un plano inclinable, sobre el que se fija una placa del material de entorno elegido (plástico y metal), permitiendo determinar el instante y el ángulo para el cual comienza el deslizamiento.

1. Plataforma horizontal
2. Columnas laterales.
3. Plataforma inclinable.
4. Lámina/s del material de entorno.
5. Bisagra.
6. Mecanismo de elevación.

Fig. 1. Esquema del equipo utilizado para determinar el coeficiente de fricción.

Luego de posicionar una partícula (germen hacia arriba o hacia abajo), el plano fue inclinado hasta observar el deslizamiento de la misma. Los ensayos se replicaron 40 veces y se registraron con una cámara de alta precisión, para luego procesar las grabaciones en el software de análisis de video *Tracker* e identificar el instante exacto en el que se inició el movimiento. El ángulo de inclinación (θ_ω) se obtuvo mediante el programa *ImageJ* y se calculó el coeficiente de fricción (μ_ω) utilizando la ecuación (8):

$$\mu_\omega = \tan(\theta_\omega) \tag{8}$$

2.4 Medición del ángulo de reposo estático

Para determinar el ángulo de reposo se emplearon dos métodos. El primero consistió en llenar un embudo plástico, que luego se vació sobre una superficie del material elegido. En el segundo caso, se llenó un cilindro de PVC y luego se elevó a velocidad constante accionando un eje conectado a un motor para su vaciado. En ambos métodos, el ángulo se determinó procesando imágenes de las pilas formadas (Figura 2) con *ImageJ*.

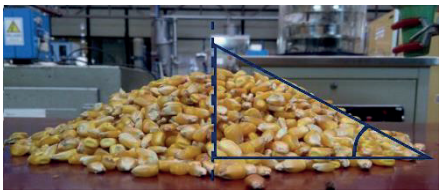


Fig. 2. Medición experimental del ángulo de reposo de granos de maíz a partir del método del embudo.

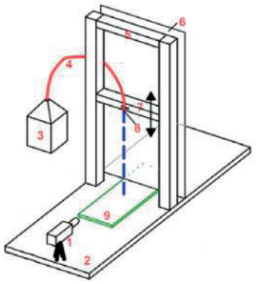
2.5 Determinación del coeficiente de restitución



El coeficiente de restitución partícula/entorno se determinó a partir de ensayos de caída libre. Se empleó un equipo construido ad-hoc (Figura 3) que permite generar colisiones controladas entre la partícula y una placa del material entorno elegido (madera, plástico o metal). Cada colisión fue registrada con una cámara de alta precisión, para luego determinar la altura alcanzada por la partícula utilizando el software *Tracker*. A partir de estos datos se calculó el coeficiente de restitución (e) aplicando la ecuación (9):

$$e = \frac{v_{1-}v_2}{u_{1-}u_2} \tag{9}$$

donde u y v son las velocidades inmediatamente antes y después del impacto, y los subíndices 1 y 2 identifican a los elementos involucrados. Considerando que el subíndice 1 hace referencia a la partícula y el subíndice 2 a la superficie plana, las velocidades u_2 y v_2 pueden considerarse nulas y asumir que la energía correspondiente se conserva. Entonces, el coeficiente de restitución e puede calcularse mediante la ecuación (10):

$$e = \frac{v_1}{u_1} = \sqrt{\frac{H_1}{H_0}} \tag{10}$$

donde H_1 y H_0 son la altura máxima y la altura inicial de la partícula en la colisión.

6. Placa de fondo.
7. Barra móvil.
8. Partícula muestra.
9. Placa del material entorno.

Fig. 3. Esquema del equipo utilizado para determinar el coeficiente de restitución.

Por otro lado, el coeficiente de restitución intergranular e_a se determinó mediante el método del doble péndulo, utilizando el mismo equipo. Este método permite generar una colisión controlada entre dos partículas pendiendo de hilos a una altura dada [9].

El procedimiento consistió en suspender una partícula A a una altura h_{A1}, formando un ángulo α_{A1}, y dejar que caiga de modo que colisione con la partícula B, suspendida a una altura h_{A2} en un ángulo nulo. Después de la colisión, la transferencia de energía acelera la partícula B y esta se balancea hasta un ángulo de desviación α_{B2}. Las colisiones se registraron con la cámara digital de alta precisión y luego se analizaron con el software Tracker para identificar los ángulos correspondientes. Finalmente, se calculó el coeficiente de restitución empleando la ecuación (11):

$$e_a = \sqrt{\frac{1 - cos(\alpha_{A2} + \alpha_{B2})}{1 - cos\alpha_{A1}}} \tag{11}$$

donde α_{A1} y α_{A2} son el ángulo de desviación inicial y el ángulo máximo que corresponden a la partícula A, mientras que α_{B2} es el ángulo de desviación máximo de la partícula B.

2.6 Calibración del coeficiente de fricción intergranular

El coeficiente de fricción maíz-maíz se calibró replicando en Rocky DEM los dos ensayos de medición del ángulo de reposo. Primero, se realizaron simulaciones para ajustar los parámetros generales y la configuración del sistema. Luego, se llevaron a cabo sucesivas simulaciones modificando el coeficiente hasta lograr que los ángulos resultantes fueran semejantes a los experimentales. Tras calibrar el coeficiente con ambos sistemas, se repitieron las simulaciones intercambiando los valores obtenidos para verificar su validez y elegir el más adecuado.

2.7 Estudio de sensibilidad de los parámetros de rotura

Se realizaron ensayos de rotura de granos individuales de maíz, empleando el texturómetro descripto en la sección 2.1. Este ensayo se implementó en Rocky DEM a fin de ajustar los parámetros del modelo de Tavares [10]. El software requiere la definición por parte del usuario de los siguientes parámetros ya mencionados: σ^2, E_{max}/E_{50}, E_{min}, E_{∞}, d_0, γ, φ, A, b', así como también el modelo de distribución de fragmentos generados.

Se analizaron los valores de los parámetros desconocidos y sus rangos para diferentes materiales en la bibliografía. Una vez identificados, se procedió a realizar sucesivas iteraciones, modificando el valor de un parámetro por vez (análisis de sensibilidad). Luego, se realizaron simulaciones combinando variaciones de los parámetros de interés simultáneamente. Finalmente, se analizaron los resultados y se identificó el conjunto de parámetros que brinda resultados más cercanos a los experimentales (ajuste de parámetros).

3 Resultados

3.1 Forma de partícula y distribución de tamaño en masa

Debido a que los granos de maíz poseen una forma irregular, se deben modelar con formas aproximadas para poder implementar en el programa de DEM los fenómenos y procesos que los involucran. Tras de evaluar diversas geometrías ofrecidas por el programa, se optó por emplear el *Polyhedron* (Figura 4). En simulaciones preliminares, se comprobó que al utilizar esta partícula el tiempo de cómputo es razonable y los resultados que se obtienen son adecuados. Luego se procedió a determinar la distribución de tamaño de partícula (PSD) para incorporarla en el programa. La PSD se calculó utilizando datos experimentales.

Rocky DEM ofrece diferentes alternativas para definir el tamaño de la partícula. Se optó por el diámetro de esfera equivalente, debido a que su cálculo es simple y brinda buenos resultados. El mismo fue calculado a partir del volumen de un paralelepípedo virtual con el espesor, alto y largo de los granos, determinándose una PSD de ocho clases (Tabla 1).

Tabla 1. Distribución de tamaño en masa.

Diámetro (mm)	% Acumulado	Diámetro (mm)	% Acumulado
7.11	0.36%	9.97	72.50%
7.68	4.21%	10.55	92.99%
8.26	13.49%	11.12	96.87%
8.83	27.32%	11.70	100.00%
9.40	50.45%		

El programa genera partículas cuyo volumen es aquel correspondiente a una esfera del mismo diámetro equivalente. Este hecho permite modificar libremente los parámetros que

definen las dimensiones de las partículas sin afectar la masa de cada grano. Se ajustó el *Vertical Aspect Ratio* y el *Horizontal Aspect Ratio* de modo tal que la altura y ancho de la partícula coincidan con los valores experimentales. Se definió el número de esquinas y el grado supercuadrático teniendo en cuenta, además de la forma real de la partícula, la facilidad de cómputo. En la Tabla 2 se presentan los valores finales de los parámetros:

Tabla 2. Parámetros de forma de las partículas simuladas en Rocky DEM.

Relación de aspecto vertical	Relación de aspecto horizontal	Número de esquinas	Grado supercuadrático
1.60	0.70	60	10

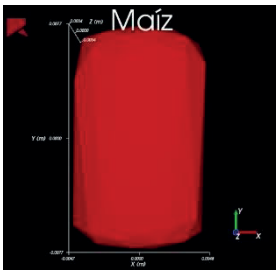

Fig. 4: *Polyhedron* con las propiedades finales.

3.2 Densidad y módulo de Young

Para determinar la densidad del maíz mediante picnometría, se realizaron 10 repeticiones y se promediaron los resultados. El valor experimental resultante es de 1231 kg/m^3 el cual es similar a aquellos valores reportados en la bibliografía para granos de maíz [6], [11].

En cuanto al módulo de Young, este se determinó promediando los resultados de 20 repeticiones de los ensayos de compresión, empleando 20 muestras diferentes. El valor promedio obtenido es de 16.91 MPa, el cual es cercano al rango reportado en la bibliografía [11], [12], [13]. En la Tabla 3 se detallan los resultados finales de cada experiencia.

Tabla 3. Propiedades del maíz obtenidas experimentalmente.

	Densidad (kg/ m^3)	Módulo de Young (MPa)
Media	1231.09	16.91
Coeficiente de variación	3.92%	7.96%

3.3 Coeficiente de fricción μ_ω

En la Tabla 4 se presentan los resultados obtenidos mediante los ensayos de deslizamiento.

Tabla 4. Coeficientes de fricción obtenidos experimentalmente.

	μ_ω maíz/metal	μ_ω maíz/plástico
Media	0.419	0.637
Coeficiente de variación	16.35%	30.05%

Se obtuvo un valor promedio global de 0.419 para el coeficiente de fricción maíz/metal. Este valor es próximo al de 0.476 reportado por Chung et al. [15]. Por otro lado, el valor promedio hallado para el coeficiente de fricción maíz/plástico es de 0.637. Este valor se encuentra dentro del rango reportado en la bibliografía para distintos tipos de plástico [15].

Para calcular los coeficientes, se promediaron todos los resultados conjuntamente, ya que no se evidenció una variación relacionada con la posición de los granos.

3.4 Ángulo de reposo

Para determinar el ángulo de reposo se realizaron 10 repeticiones de cada uno de los ensayos y se promediaron los resultados. En la Tabla 5 se presentan los resultados finales.

Tabla 5. Ángulos de reposo del maíz obtenidos experimentalmente.

	Angulo de reposo (°) –embudo	Angulo de reposo (°) –cilindro
Media	29.96	17.61
Coeficiente de variación	3.81%	7.50%

En el caso del método del embudo, se obtuvo un valor promedio de ángulo de reposo estático de 29.70°. Este valor se encuentra en el rango usual reportado en la bibliografía para diferentes tipos de granos [13], [16].

En el caso del método del cilindro, el valor promedio resultante es de 17.95°. Este valor es considerablemente menor al obtenido mediante el primer método y, a su vez, es similar al valor de 18.11° hallado mediante el mismo método por Shi et al. [17].

3.5 Coeficiente de restitución *e*

A partir de los resultados de los ensayos de caída, se calcularon los tres coeficientes de restitución partícula/entorno. En la Tabla 6 se presentan los valores obtenidos.

Tabla 6. Coeficientes de restitución obtenidos experimentalmente.

	e maíz/madera	e maíz/plástico	e maíz/metal
Media	0.550	0.517	0.457
Coeficiente de variación	26.04%	18.01%	26.64%

El valor promedio de coeficiente de restitución más elevado resultó ser el correspondiente al sistema maíz/madera, mientras que el valor más bajo se obtuvo con el sistema maíz/metal. Este último, si bien es inferior al valor de 0.61 reportado en la bibliografía [6], resulta razonable para el sistema de trabajo. Por otro lado, el coeficiente de restitución intergranular resultante fue de 0.95. Dado que este valor resulta demasiado alto comparado con reportados en la literatura y que su determinación experimental es compleja, se decidió descartar el valor medido y tomar el reportado por Gonzalez-Montellano et al. [6]

3.6 Calibración del coeficiente de fricción intergranular

La medición experimental de esta micro propiedad para granos de maíz, que presentan tamaños y formas irregulares, resulta poco precisa. Es por ello que se decidió calibrar el coeficiente de fricción intergranular. Se realizaron diversas simulaciones modificando no solo este parámetro, sino también parámetros generales del *solver* para la resolución de los modelos de contacto elegidos.

El tiempo de cómputo promedio en las simulaciones preliminares del ensayo del embudo era de 38 h. Para disminuir este tiempo, se modificó el valor de *Softening Factor*, un parámetro que, si bien reduce efectivamente la duración de las simulaciones, afecta el comportamiento de las partículas a partir de un cierto valor. El valor por defecto del *Softening Factor* es 1, pudiendo tomar valores entre 1 y 0.0001. Empleando un valor de 0.1 se logró reducir el tiempo requerido a 12 h manteniendo resultados similares de ángulo de reposo aunque con ciertas variaciones, aceptables, en el comportamiento de las partículas.

Por otro lado, se observó que las partículas, al terminar de caer por el embudo, continuaban deslizándose hasta el final de la simulación, independientemente del tiempo final elegido para la prueba. Esto dificultó la medición del ángulo de reposo ya que su valor variaba con el tiempo. Es por esto que se procedió a manipular el *Damping Ratio*, un factor de amortiguamiento que modifica las oscilaciones presentes en este tipo de pruebas. El valor por defecto del parámetro es cero, por lo que se realizaron simulaciones variando el mismo en un rango de 0.1 a 0.4. Con un *Damping Ratio* de 0.3 se logró reducir considerablemente la variación del ángulo de reposo en el tiempo, logrando una reproducción de la simulación similar al experimento real.

Una vez ajustados los parámetros, se efectuaron múltiples simulaciones modificando sólo el coeficiente de fricción. En la Tabla 7 se resumen los resultados de algunas de estas simulaciones. El ángulo de reposo obtenido experimentalmente es de 29.7°, por lo que el valor de coeficiente de fricción de 0.31 brinda los resultados más cercanos a la realidad.

Empleando los mismos ajustes efectuados para el sistema del embudo, se implementó el ensayo de ángulo de reposo con el cilindro. Se verificó que los resultados al usar diferentes valores de *Damping Ratio* y *Softening Factor* fueran apropiados y se procedió a simular variando el coeficiente de fricción. En la Tabla 7 se presentan resultados seleccionados de las simulaciones finales. El ángulo de reposo experimental correspondiente al ensayo del cilindro es de 17.9°, por lo tanto, el coeficiente de fricción calibrado para este sistema es de 0.25. Las simulaciones, en ambos sistemas, evidenciaron que el ángulo de reposo aumenta al incrementarse el coeficiente de fricción, cumpliendo con lo esperado.

Tabla 7. Valores de ángulo de reposo obtenidos con diferentes coeficientes de fricción intergranular utilizando el embudo y el cilindro.

Sistema del embudo		Sistema del cilindro	
Coeficiente de Fricción	Angulo de Reposo (°)	Coeficiente de Fricción	Angulo de Reposo (°)
0.32	30.16	0.17	14.43
0.315	30.82	0.22	17.09
0.31	29.41	0.25	17.99

Por último, a fin de verificar los resultados, se utilizó el coeficiente de fricción de 0.31 en el sistema del cilindro y se obtuvo un ángulo de reposo de aproximadamente 23°, un valor 30% mayor que el experimental. En cambio, empleando el valor de 0.25 en el sistema del embudo, resultó que las partículas no terminan de caer quedando atascadas en el cuello del embudo, lo cual no es representativo de la realidad. Es por ello que se consideró como resultado final de la calibración el valor de 0.31.

La Figura 5 muestra imágenes de los sistemas simulados en el programa.

Fig. 5. Implementación del experimento de medición de ángulo de reposo en Rocky DEM con el sistema del embudo (izq.) y con el sistema del cilindro (der.).

3.7 Estudio de sensibilidad de parámetros de rotura

En primer lugar, se analizó el efecto de los diferentes parámetros del modelo de Tavares, identificando aquellos que más efecto generan sobre la rotura. Luego, se implementó en Rocky DEM el experimento de rotura de granos individuales realizado en el texturómetro, utilizando los parámetros y propiedades del material medidos y calibrados previamente. Las simulaciones de calibración de los parámetros de rotura se describen a continuación.

Usualmente, el parámetro E_{min} mantiene el valor predeterminado de 1. Por lo tanto, se verificó que variar su magnitud no afecta los resultados de las simulaciones. Asimismo, modificar el parámetro E_{∞} tampoco altera los resultados de la rotura, ya que no influye en la forma en que se rompe la partícula. Se observó que aumentar el valor de E_{∞} retrasa el momento en el cual ocurre la rotura, ya que implica más energía para romper la partícula. Finalmente, se optó por mantener los valores predeterminados de estos parámetros.

En cuanto a los parámetros d_0 y σ^2, al modificar sus valores se observó que no influyen perceptiblemente en la rotura ni en el tiempo que tardan las simulaciones. Nuevamente, se decidió conservar los valores por defecto de ambos.

Por otro lado, se realizaron simulaciones con diversos valores de φ y se comprobó que este parámetro no afecta la forma en que se rompe la partícula. Sin embargo, para valores superiores o iguales a 1 la rotura no ocurre, por lo que se mantuvo el valor de 0.45.

Tras definir los parámetros mencionados, se efectuaron simulaciones modificando valores de A y b', dos parámetros relacionados directamente con la fragmentación. En la Figura 6 se muestra la variación del número de fragmentos generados en la rotura en función de A, y en la Figura 7, el mismo análisis en función de b'.

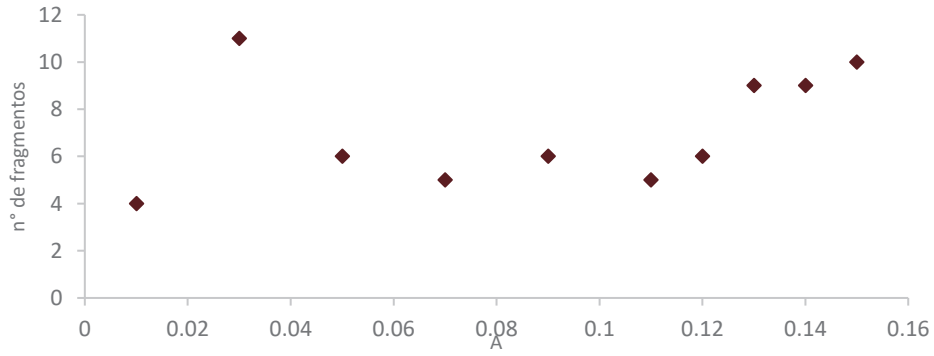

Fig. 6. Variación del número de fragmentos en función del parámetro A.

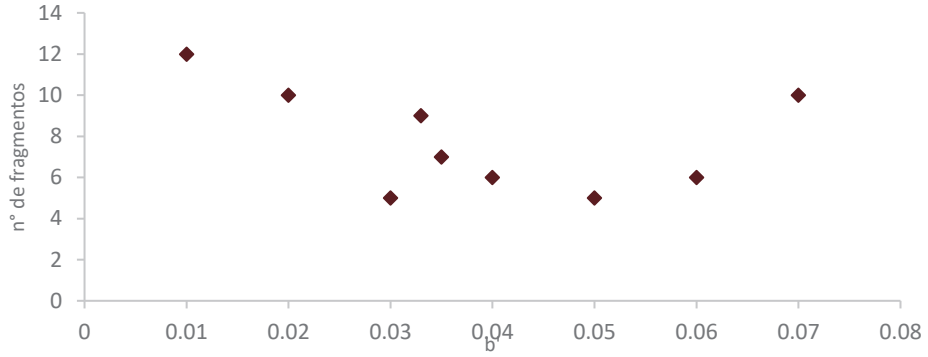

Fig. 7. Número de fragmentos en función del parámetro b'.

Se puede observar que el número de fragmentos tiende a aumentar al incrementarse el valor de A, lo que se corresponde con la definición del parámetro. El valor de b' no guarda relación con la cantidad de fragmentos, la cual oscila, e incluso varía al repetir una misma simulación. Debido a esto, se decidió mantenerlo en su valor predeterminado de 0.033.

En la mayor parte de los ensayos experimentales de rotura del maíz, se obtuvieron dos fragmentos de tamaño similar. Tal como se observa del análisis de sensibilidad, al simular esta experiencia en Rocky DEM, el número de fragmentos obtenidos siempre fue mayor. Utilizando un valor de A de 0.01, sin embargo, se logró que la partícula se fragmente en cuatro, lo cual es relativamente cercano a la realidad y se consideró aceptable considerando que el modelo de rotura implementado en Rocky se encuentra desarrollado para múltiples partículas en simultáneo y no la rotura individual como el caso de estudio.

4 Conclusiones

La determinación de las propiedades de los granos de maíz (densidad, módulo de Young ángulo de reposo, coeficiente de fricción partícula/entorno, coeficiente de restitución partícula/entorno) se logró exitosamente mediante el diseño y construcción de dispositivos experimentales, obteniendo valores cercanos a los reportados en la literatura. Además, se pudo obtener una distribución de tamaño de partícula adecuada e identificar una forma geométrica aproximada apropiada para representar los granos de maíz en Rocky DEM.

Por otro lado, se llevó a cabo la implementación de las experiencias de ángulo de reposo y de rotura de una partícula para la calibración de los parámetros restantes. Se logró calibrar el coeficiente de fricción intergranular, obteniéndose un valor de 0.31 para el caso de estudio, que permite reproducir exitosamente el comportamiento real del material. Por último, tras realizar un análisis de sensibilidad detallado, se consiguió ajustar los parámetros del modelo de rotura de Tavares que reproducen de manera aceptable la rotura individual de granos de maíz observada experimentalmente.

Abstract. The Coronavirus SARS-CoV-2 (COVID-19) emerged by December 2019, in Wuhan, China; it was reported and, a few months after, in the most of countries we are living a pandemic of an (almost) unknown disease never observed before. For this reason, the importance of a good measurement on the counting of observed cases has a crucial role. This work addresses the time-lagged effect problem via Bayesian analysis supported by a stochastic discrete-event simulation to give an answer to the truthfulness of the data and to validate the obtained results in terms of proportions based on an expected result in the particular case of Spain. Obtained results show that the reported data is untruthful and can make wrong any analysis, but even when the simulating results are as we expected they might be wrong in terms of absolute numbers. However, the most important knowledge we get is related to the fact that the disease might be considered under control because it is more likely that a person gets recover than She/He dies.

Keywords: Bayesian analysis · Stochastic simulation · COVID-19

1 Introduction

The Coronavirus SARS-CoV-2 (COVID-19) emerged by December 2019, in Wuhan, China. It was reported and, a few months after, in the most of countries we are living a pandemic of an (almost) unknown disease never observed before. Despite the drastic, large-scale containment measures promptly implemented by the Chinese government, in a matter of a few weeks the disease had spread well outside China, reaching countries in all parts of the globe [4] resulting in human and economical crisis in most of them.

To decrease the damage associated with COVID-19, public health and infection control measures are urgently required to limit the global spread of the disease [18], but till now the ongoing pandemic seems not to be overcame unless a vaccine appears. However, the saying: *you cannot manage what you do not*

* The author is grateful for partial support from ANID Beca Magíster en el Extranjero, Becas Chile, Folio 73201112.

measure, and, therefore, the importance of a well measurement on the counting of observed cases has a crucial role. On this way, the World Health Organization (WHO) [21] has published that the number of real infected individuals are between 10 and 20% of the real ones. Even so, Ioannidis [7] reviews and comments the possibility of a problem that spread even faster than the pandemic, the reliability on data; which results on a clear issue that makes models useless.

So, how COVID-19 pandemic behaves throughout time? this question might be the most important to find an answer for (as soon as possible) in the last time. On this way, it is important to anticipate the number of new cases on a daily-basis to take care about healthcare systems as well as the budget to dedicate to this disease. Several authors has been addresses this question using different models, but the most used has been those ones with dynamic nature such as the Susceptible-Exposed-Infected-Removed (SEIR) model [13,5], Susceptible Un-quanrantined infected, Quarantined Infected, Confirmed infected (SUQC) model [25], Susceptible Exposed Infected Isolated with treatment Removed (SEIJR) model [16,14], Exponential growth model [24,9], Stochastic simulations of outbreak trajectories [15] and Hierarchical models [3]. Nevertheless, despite of the possibility of working with non-reliable data approximations to transition rates, in the case of dynamic models, as the infection rate, mortality rate and recovery rate has been computed.

This study aims to merge prior knowledge generated at the moment, using the particular case of the observed data in Spain gathered from the Github repository associated with the interactive dashboard hosted by the Center for Systems Science and Engineering (CSSE) at Johns Hopkins University, Baltimore, USA [8], to know the real number of confirmed cases that would be by using Bayesian Analysis assuming the counting cases behave as a Poisson process to fit the necessary parameters to make a simulation throughout Discrete Markov Chains within a specific period.

This work is organized as follows: Section 2 establishes the time-lagged effect problem performing a descriptive analysis of the data and then makes the statement of the problem under study. Section 3 shows a Bayesian approach to fit the necessary random variables considering a hypothesis test on the lagged time effect. Section 4 addresses the truthfulness of the data via a stochastic discrete-event simulation to give an answer to the truthfulness of the data and to validate the obtained results in terms of proportions based on an expected result. Finally, Section 5 gives the main insights we found and propose to escalate the problem under study.

2 The time-lagged effect problem

In this section, we perform a descriptive analysis of the counting of each kind of cases in order to motivate the discussion and the way we model the situation that apparently we see. Then, we formally declare the variables in the situation and the equation that support the behaviour through dynamic modelling in its discrete version.

2.1 Descriptive analysis

From the considered data source, we can recognize that there was an inflexion point before and after a lock-down was established in most of the countries which take that measure. In the particular case of Spain, the lock-down policy was taken in March 14th, and as far as we know the expected effect of this measure was around two weeks after that, by March 28th, an inflexion point must appear on the counting. Motivated on this *belief*, we will work with the data corresponding to March and April given two main reasons: i) these months correspond to the most chaotic in term of how the counting was conducted, and also in this particular country, the beginning of the pandemic; and ii) to consider a larger period would add noise related to the effect of the lock-down on how the disease spread. Fig. 1 shows the counting in both months by each kind of case, Confirmed, Recovered and Death cases and two vertical lines that indicate both the day at lock-down was and the expected effect.

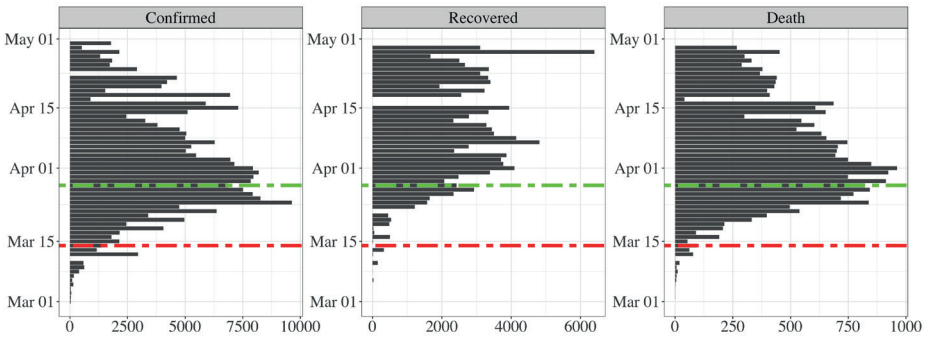

Fig. 1: Counting during March and April by each kind of case, Confirmed, Recovered and Death cases. The vertical lines indicate the day at the lock-down was implemented (March 14th, in red) and at the day its expected effect was (March 28th, in green).

It is clear to see that the counting for each kind of case, the so-called curves, do not follow a strict pattern, which can be explained, discarding the lock-down, by the manner, the authorities performed the counting. It affects directly on the Confirmed cases and therefore on Recovered and Death cases, which would show a similar -proportional- pattern after a time to recover or to die.

The later mentioned effect can be supported numerically by the descriptive statistics shown in Table 1. In the case of Confirmed cases, we see that the counting from March to April did not change as much as Recovered and Death cases, where they were (almost) four and two times greater, respectively. However, two simple ways to recognize this effect could be:

– Taking into account that a person must be a Confirmed case before be a Recovered or Death case, if we move these two counting curves some days,

they should fit with the counting related to Confirmed cases, which often happens.
– The sum of Recovered and Death cases is lower than the sum of Confirmed cases during the period we are working with.

this informal evidence allows us to motivate the problem formally.

Table 1: Descriptive statistics of the COVID-19 pandemic behaviour during March and April of 2020. Total number of Confirmed, Recovered and Death cases are 225,166, 112,048 and 24,543 people, respectively.

	Confirmed		Recovered		Death	
	March	April	March	April	March	April
Count	104,034.00	121,132.00	22,645.00	89,403.00	9,387.00	15,156.00
Q1	286.50	1,909.25	0.00	2,517.25	7.00	369.75
Mean	3,355.94	4,037.73	730.48	2,980.10	302.81	505.20
Median	2,162.00	4,423.00	53.00	3,256.00	94.00	489.00
Q3	6,621.50	5,425.25	1,396.00	3,655.25	628.50	679.00
SD	3,256.35	2,238.22	1,050.14	1,346.84	344.78	222.43

2.2 Statement of the problem

These so-called curves are dependent on each other where Recovered and Death cases are lagging product of the Confirmed cases, and thereby from another of non-infected people, the Health people.

The problem under study could be characterized by a dynamic modelling point of view. From now on, we will consider four possible states at which people are at certain time t: i) Health, are the people who have never been positive to the disease before; ii) Confirmed, are the people who currently give positive to the disease; iii) Recovered, are the people who are healthy once they gave positive before; and iv) Death, are the people who have died due to the disease. On this way, it is possible to state the following *Once a person is a Confirmed case there are two possible transitions after a certain elapsed time, that person will get recover or will die*, this situation is such as Fig. 2 shows with their respective transitions.

Formally, we can recognize that curves could be characterized by using Poisson processes with different intensities and elapsed times to change from one state to another. Let's denote the set of states $\mathcal{I}$ and the number of people at time t in each state $N_i(t)$, $\forall i \in \mathcal{I}$. Then, we propose that the number of people $N_i(t)$ is defined by a Poisson process with parameter $\lambda_i t_i$, where λ_i represents the number of new cases (in people per day), intensities from now on, and t_i represents the elapsed time necessary to change from one state to another one, $\forall i \in \mathcal{I}$.

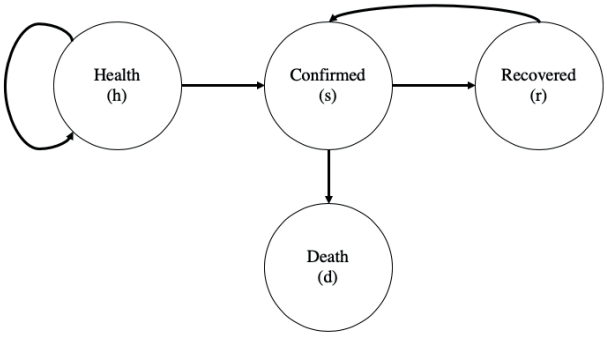

Fig. 2: A general illustration of the dynamic model considering the possibility of the population can get sick again. The states of the model indicate in which category the person is at a certain time t and where She/He from, which is indicated by the arrows.

Thus, considering the elapsed time to get recover or to die as t_r and t_d, respectively, we can define the Poisson processes as Definition 1 shows.

Definition 1 (*Structural equations*). *Let's consider a person who incubates the disease in t_s days. She/He will get recover or die after t_r or t_d days, respectively. Also, be $Y_i(t_i)$ the cumulative number of cases within a certain days in $[t; t + t_i]$, $i \in \mathcal{I}$. Thus, we can define the total number of Recovered and Death cases depending on the Confirmed cases as follows:*

- $Y_r(t_r) = N_r(t + t_r) - N_s(t)$, *defines the number of total Recovered cases in* $[t; t + t_r]$ *such that* $Y_r(t_r) \sim Poisson(\lambda_r t_r)$.
- $Y_d(t_d) = N_d(t + t_d) - N_s(t)$, *defines the number of total Death cases in* $[t; t + t_d]$ *such that* $Y_d(t_d) \sim Poisson(\lambda_d t_d)$.

thus, the equivalence between Confirmed, Recovered and Death cases is given by

$$Y_s(t + t_s) = Y_r(t + t_r) + Y_d(t + t_d) \tag{1}$$

where $Y_s(t + t_s) \sim Poisson(\lambda_s t_s)$ *with parameter* $\lambda_s t_s$ *such that* $\lambda_s t_s = \lambda_r t_r + \lambda_d t_d$.

Finally, since a person is different from each other, both the number of new cases λ_i and the elapsed time necessary to change from one state to another one t_i are not fixed parameters, but random variables. Fig. 3 shows the idea behind Definition 1 where, without loss of generality, the distribution is a smoothed one of the number of people in each state $N_i(t)$ throughout t. Also, it shows distribution at certain day t without the time-lagged effect, where it is expected that the Confirmed cases are equal to the sum over Recovered and Death cases.

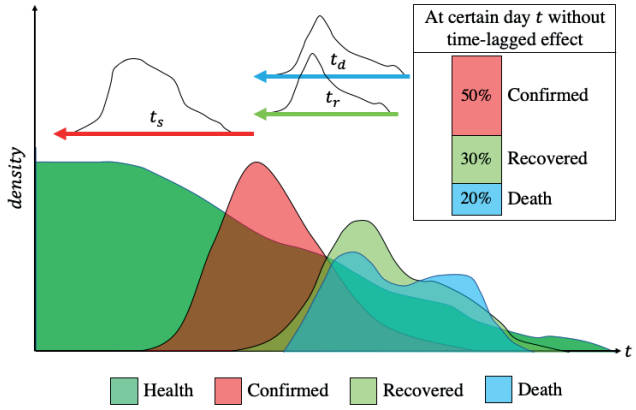

Fig. 3: Illustration of the problem under study. We consider four possible states, where the sum on specific states must be equal to the precedent states, e.g. the density curve that represents the Health people must be equal to the sum over the other density curves without the time-lagged effects t_s, t_r, t_r; which also are random variables.

3 Bayesian analysis

In this section, we propose a way to overcome the variable fitting via Bayesian Analysis using the package RStan [19]. We state the prior distribution for the later mentioned parameters and perform an interesting hypothesis test related to whether the number of days to change from Confirmed state to another are equal.

3.1 Prior distributions

As we state in Definition 1 before, the parameters that are involved in Expression (1) are random variables, and to fit them we propose a Bayesian way. On this way, we need to provide priors distributions which draw the knowledge at the moment. These could be obtained from our own knowledge or using other novel researches who also addresses similar problems from an epidemiological point of view.

The case of the intensities (λ_i) is highly dependent on the policies and at which moment they were implemented, so we adopt the knowledge based on how we believe the curves grow throughout time in these two months. Consequently, as intensities represent the number of people in each state at certain day t, it makes sense to think in a Gamma distribution.

On the other hand, the response against the disease has been studied by several authors which report what they found. The literature review shows that the elapsed times t_i distribute as a Gamma for each one of them. The incubation time, t_s, is a Gamma with mean 6.5 days and standard deviation of 2.6 days

[22,2]; the elapsed time to get recover, t_r, is a Gamma with mean 10 days but can be up to 14 or 21 days [17]; and the elapsed time to die, t_d, is a Gamma with mean 20 days and standard deviation equal to 10 days [22].

We use such parameterization of the Gamma distribution with expectation defined by $\mathbb{E}(x) = \alpha/\beta$ and variance $Var(x) = \alpha/\beta^2$; where α and β parameters, obtained by solving a system of equation, are shown in Table 2.

Table 2: Parameters that define the Gamma distribution based on the prior knowledge for each random variable to fit.

	λ_s	λ_r	λ_d	t_s	t_r	t_d
α	250	122.50	2.50	26.20	5.00	126.49
β	4.03	0.50	6.32	4.03	0.50	6.32

3.2 Posterior distributions

Once we already state the prior distributions, we can get the posterior distributions that will show the merge between the prior knowledge and the data. Table 3 shows descriptive statistics from the obtained results, where the $\hat{R}$ statistic shows the fitting process was successfully achieved, and the confidence intervals are not too large respect to the mean. These results are saying that:

- The incubation time, t_s, is about 18 days but can be between 16 and 19 days. The elapsed time to get recover, t_r, is about 11 days but can be up to 9 and 13 days. The elapsed time to die, t_d is 20 days with possibilities to find cases from 17 to 23 days.
- The number of daily Confirmed cases, λ_s is in mean 5,888. The number of daily Recovered cases, λ_r is 3,500. The number of daily Death cases, λ_r is 521.

Table 3: Descriptive statistics for fitted posterior distribution. Notice that the mean and percentile values have been truncated to enhance their interpretation. The $\hat{R}$ statistic shows the fitting process was successfully achieved.

	Mean	Error	5%	95%	$\hat{R}$
t_s	18	0.03	16	19	1.00
t_r	11	0.04	9	13	1.00
t_d	20	0.06	17	23	1.00
λ_s	5,888	306.86	5398	6408	1.00
λ_r	3,500	308.45	2993	4008	1.00
λ_d	521	1.65	452	607	1.00

A graphical analysis of the obtained results can be carried out to see the effects of the selected data which are set out in Fig. 4. It shows the density plot for each posterior distribution. In this, it is possible to distinguish that, although the prior distributions for the elapsed times are evidence from other works, and might be considered informative ones due to their short variances, the data change the landscape in its favour. The most important insight of the results is such a person who gave positive to the disease, it is more likely that She/He gets recover due to a temporal reason. Also, the number of daily Confirmed cases is greater than the Recovered cases which are greater than the Death cases.

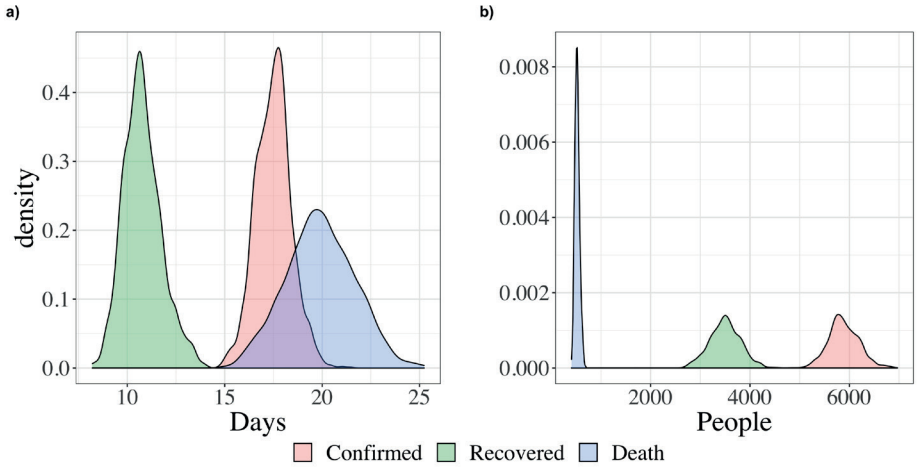

Fig. 4: Density plot for each posterior distribution of elapsed times and intensities. **a)** shows the number of days to change from one state to another and **b)** shows the number of daily cases in mean.

3.3 Differences on the elapsed times in the transitions from Confirmed cases

An interesting and useful question corresponds to check some conditions of the dynamic, in this particular case whether the number of days to change from Confirmed state to another are equal, in other words, whether the elapsed time to get recover (t_r) is equal to the elapsed time to die (t_d). Taking into account the Definition 1, it is equivalent to the hypothesis test given by

$$H_1 : Y_s(t + t_s) \sim Poisson(\lambda_r t_r + \lambda_d t_d)$$
$$H_2 : Y_s(t + t_s) \sim Poisson((\lambda_r + \lambda_d)t)$$

where the probability of each hypothesis to be true is

$$Pr(H_i|y) = \frac{\pi(H_i)Pr(y|H_i)}{Pr(y)} \tag{2}$$

again, as we are working from a Bayesian point of view, we need a prior probability for each one of the hypothesis.

The literature review did not reveal an answer for this question, but the Bayesian point of view allow us to state a non-informative probability to give to the data an important role. Thus, we use the most non-informative probability, 50%. Doing so, the hypothesis test does not support any of them, indeed the probability to be true for each hypothesis is equal to 50%, it means that there is no difference on the elapsed times in the transitions from Confirmed cases and it is completely at random.

4 Stochastic discrete-event simulation

At the moment, we have proposed the equation and parameters that would enable us to analyze the behaviour of the pandemic. Nevertheless, a crucial question arises and it is still an open problem to overcome. Are we working with (un)truthful data?. We show an approach based on a stochastic discrete-event simulation using Markov Chains to give an answer and validate the results obtained previously as an underlying product.

4.1 State equations

First of all, following the dynamic such as we showed in Section 2 and considering the elements given in Definition 1, we can establish a stochastic Markov Chain and the state equations that define it to address a discrete-time simulation.

Let $x_{i,j}(t)$ be the transition rate from state i to state j at time t and $N_i(t)$ be the people in state i at time t, $\forall i, j \in \mathcal{I}$. Thus, for a certain time $t \geq max\{t_r, t_d\}$, the elapsed time to get recover or to die, respectively, the state equations are defined by:

$$N_h(t+1) = x_{h,h}(t)N_h(t) - x_{h,s}(t)N_h(t-t_s) \tag{3}$$

$$\begin{aligned} N_s(t+1) = {} & x_{h,s}(t)N_h(t-t_s) + x_{r,s}(t)N_r(t-t_s) \\ & - x_{s,r}(t)N_s(t-t_r) - x_{s,d}(t)N_s(t-t_d) \end{aligned} \tag{4}$$

$$N_r(t+1) = x_{s,r}(t)N_s(t-t_r) - x_{r,s}(t)N_r(t-t_s) \tag{5}$$

$$N_d(t+1) = x_{s,d}(t)N_s(t-t_d) \tag{6}$$

this system of equations enables us to simulate the dynamic considering the whole results obtained previously. Equation (3) defines the number of people in Health state at time $(t+1)$ by considering the number of people who were in this state at time t minus the people who incubate the disease at $(t-t_s)$, i.e. since t_s days the person got infected. Equation (4) establishes that the Confirmed Cases at $(t+1)$ is equal to the people who got infected t_s days but never had been in Confirmed state before, and the people who got infected t_s days ago but those ones that at least have been in Confirmed state before, i.e. those people who incubate the disease again; minus the people who get recover since they were a

Confirmed case and the people who die. Equation (5) considers the difference between the people who get recover, taking into account that they have been considered as Confirmed cases previously, and those people who incubate the disease again after they got to recover. Finally, Equation (6) shows the Death state as and absorbing one.

4.2 Implementation, results and their validation

Algorithm 1 shows the implementation of the simulation which aims to compute the number of people at each state $i \in \mathcal{I}$ within a defined period $[t; \hat{t}]$ until the entire population incubate the disease (line 1). It works with the posterior distribution for each parameter as known data, and involve the stochastic component where it makes the intensities sampling for each state $i \in \mathcal{I}$ (line 2-3) and where it makes the difference over the elapsed times to get recover or to die according to a uniform $(0, 1)$ random number (line 4-10). Finally, it performs the simulation by using the state equation defined previously (line 11) at repeat for time $(t + 1)$ (line 12).

Algorithm 1: Stochastic discrete-event simulation

Data: Population, simulation period, posterior distribution of intensities and elapsed times, transition rates and hypothesis test probabilities.
Result: Number of people at each state within a defined period.

```
1  while Population > 0 and t ≤ t̂ do
2      for i ∈ ℐ do
3          get a sample λ̂_i from λ_i
4      get a sample t̂_s from t_s
5      u ← runif(1)
6      if |u − Pr(H_1|y)| < |u − Pr(H_2|y)| then
7          for j ∈ ℐ {s} do
8              get a sample t̂_j from t_j
9      else
10         get a sample t̂_{r+d} from t_r ∪ t_d
11     Perform the state equation
12     t ← t + 1
```

Till now, we already have the almost all parameters we need in order to carry out the later mentioned simulation except for the transition rates values and the number of people in the country. Fortunately, the last value can be obtained from the National Institute of Statistics (INE) [6]; and the transition rates have been reported in epidemiological researches. Velavan and Meyer [20] report the infection rate is 2.2% in average, whereas Anastassopoulou et al. [1] get it is between 1.9% and 1.92%. Zhonghua Liu Xing Bing Xue Za Zhi [26]

shows that the mortality rate is equal to 0.3% among the health workers who have become infected and Lai et al. [11] report it decreases from 2.5% to 2% between February 12th and February 14th, when the confirmed cases reached 66,576 globally [23]; finally Yi et al. [23] report a recovery rate of 87%. In the case of the transition rate of incubating the disease again after they got to recover, the literature review has not to evidence about it [12,10].

Thus, considering the whole data mentioned previously, including the posterior distributions for each fitted random variables, we can perform the stochastic discrete-event simulation. The obtained results for the number of people in each state are: i) Confirmed cases are 18,095,738; ii) Recovered cases are 12,048,823; and iii) Death cases are 50,056. These results are different from the reported cases. If we would take the simulation as the true number of people in each state, the reported cases would correspond to a 1.24%, 0.93% and 49.03% for Confirmed, Recovered and Death cases, respectively. However, these last results must be validated.

On this way, as we showed above in particular in Fig. 3, the expected result of the time-lagged effect problem should be such that at some day t the proportion of the cases would correspond to half for Confirmed cases and a half for the sum over Recovered and Death cases, and this must be applied on the reported cases as well as the simulating results to answer the issue related to the truthfulness of the data. Fig. 5 shows a stacked column plot of the proportion of people in each state and a dashed horizontal line is overlapped at the middle of the plot to enhance the visualization. It is to say that the reported cases do not behave as we expected, especially at the beginning, but the simulation does despite a couple of atypical counting. Therefore, based on the expected result of the time-lagged effect problem the reported cases, and thus the data, should be considered as untruthful data, whereas the simulation was performed on the right way in terms of proportion, but might be wrong in terms of absolute numbers.

5 Conclusion and future works

This work addresses the time-lagged effect problem on the COVID-19 pandemic via Bayesian analysis supported by the stochastic discrete-event simulation to give an answer to the truthfulness of the data and to validate the obtained results in terms of proportions based on an expected result. Motivated by this problem, the reported data of Spain is used as a study case. This reported data was characterized by a graphical approach and from a descriptive statistics point of view, where a simple analysis enables us to recognize the proposed problem is set up in the data.

The way we take to fit the established parameters, and therefore to perform the simulation via Markov Chain, is computationally tractable by a desktop computer. Obtained results show that the reported data is untruthful and can make wrong any analysis, but even when the simulating results are as we expected they might be wrong in terms of absolute numbers.

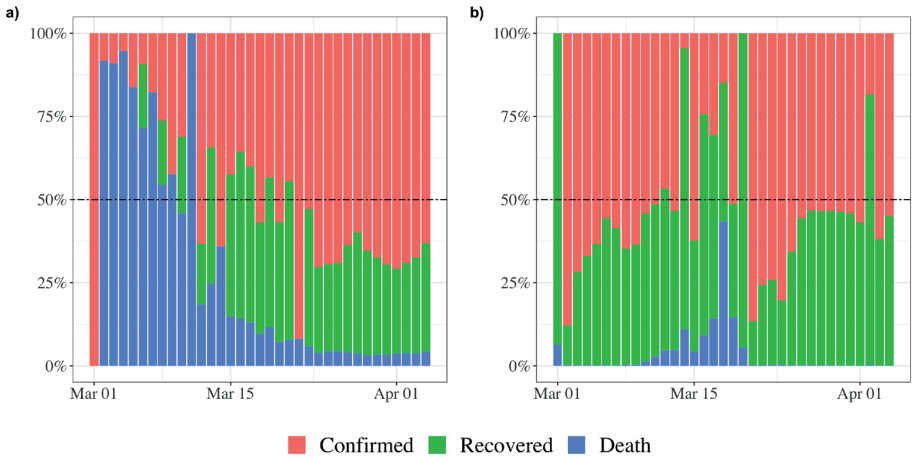

Fig. 5: Validation plot by stacked columns for the proportion of people in each state for **a)** reported cases and **b)** the simulating results. The dashed horizontal line indicates the 50% of the data to enhance the visualization.

However, despite simulating results are correct in terms of absolute numbers or not, they provide useful knowledge of the pandemic behaviour in this particular study case. The most important ones are related to the fact that the disease might be considered under control, because of it is more likely that a person gets recover than She/He dies, and it behaves differently from other countries according to related studies which are used as prior knowledge on the carried out Bayesian analysis. Nonetheless, the number of daily Confirmed cases is greater than the number of Recovered cases which is greater than the number of Death cases.

For future works, we consider making wider the period modelling the transition rates as random variables and to evaluate the effectiveness of the lock-down through a change of point analysis to find a stationary state and when it would be achieved.

Abstract. This study examines the available evidence about the state of the art of Safety Management in theory and practice applied in particular in the field of the nuclear reactors of the nuclear industry. (1) Background: During the last years, the operation of industrial facilities has advanced towards the integration of the various aspects of its management, mainly driven by the search and achievement of the highest operational performance in a competitive environment. The nuclear industry is no stranger to this movement, with the particular distinction of its main driver: safety in the operation of its facilities; (2) Methods: a systematic review to summarize and critically analyze state of the art on safety management, specialized in the management of nuclear power reactors and nuclear research reactors; (3) Results: out of 405 articles found, twenty-seven studies met the inclusion criteria for the synthesis and qualitative review, in particular, all these articles are about nuclear power reactors; (4) Conclusions: Based on the available evidence, the lack of frameworks and general models and integrators of the specific ones is the main deficiency of the area, where the conceptual, holistic or systematic models are of recent proposal and discussion.

Keywords: Nuclear, Safety, Management, Reactors

1 Introduction

Since its beginning, the nuclear industry has been a pioneer in developing and applying specific safety standards for the care of the worker, the environment, and society, integrating its own operating experience and accidents and that of the conventional industry. In these terms, this industry is considered from its technical performance as an ultra-safe macro-technical system (Amalberti, 2001).

In this sense, the academy has developed various theoretical approaches and models that explain the causes of the most relevant industrial accidents of the modern industrial

era. These approaches have been integrated into the safety requirements and recommendations of the main relevant international and national organizations and mainly by the International Atomic Energy Agency (IAEA). These approaches were systematically integrating the lessons learned in the nuclear accidents that occurred (in Nuclear Power Reactors (NPP): Three Mile Island, 1979; Chernobyl, 1989; Fukushima, 2011. And in Research Reactors (RR) RA-2, 1983. By strengthening and expanding the scope of the domain of the factors that explain an accident and/or safety performance (Acuña et al., 2020).

In particular, this paper identifies and analyzes what specific academic contributions were made during the last decade to safety management in the operation of nuclear reactors, in light of the last nuclear accident that had consequences both on the assets of its operating entity, and in society as a whole (IAEA, 2015).

One of the lessons learned by the nuclear industry from the Fukushima Daiichi nuclear accident was the need to ensure the safety of its facilities with a more integrated approach to the factors that contribute to it (IAEA, 2014; Yang, 2014; IAEA 2015). Some of them being institutional, organizational, technology management and operation factors and human factors. These are included in the stream called Safety Management.

Safety Management (SM) is a relatively new and developing area of formal and multidisciplinary study (Pillay, 2015) that comprises a set of theories and practices on decision-making, resource management, execution of activities and tasks, and the results they achieve (positive or negative), about the safety performance of an industrial asset. These positive or negative results are directly related to the care and preservation of the organization's assets and those of society as a whole and the achievement and maintenance of a certain performance. Therefore, the care and preservation of these assets imply avoiding actions that have irreversible consequences (incidents and/or accidents). This is available from the design stages of the installation and the systems that operate and manage it.

2 Methodology.

2.1 Study Design, Search Strategy and Selection Process

Having considered conducting a systematic review, to carry out the study design, we follow the guidelines proposed by Oliveira et al. (2019). For this purpose, the SM of nuclear reactors was defined as a field study or objective of the survey.

To fulfill this objective, it was decided to use both academic search engines and specialized technical search engines. In this way, the search could be reached in documents published by non-academic publishers and/or presented in specialized conferences of the nuclear industry whose procedures are not academically indexed.

The academic search engines used were Science Direct and Scopus, and the INIS (International Nuclear Information System) of IAEA was used as a technical search engine. INIS "(…) hosts one of the world's largest collections of published information on the peaceful uses of nuclear science and technology. INIS is unique and valuable

information resource, offering global coverage of nuclear literature". This search engine is widely used by academics and practitioners of the nuclear industry, so it was considered relevant.

These search engines were used for articles from peer-reviewed journals, presentations at congresses, and reports (technical documents), as the time window used the last ten full years, that is, from 2009 to 2019. This window and time filter allow us to survey the most recent publications before the Fukushima Daiichi nuclear accident that occurred in 2011 and how the lessons learned in this were incorporated into state of the art. Regarding the keywords used were: (safety management), (nuclear reactor), or (nuclear power plant). At the end of the keyword search, Zotero reference management software was used to select and record titles, abstracts, and full-text articles based on inclusion/exclusion decisions.

Studies were included if, for Scopus search:Contained the keywords "safety" and "management" and "nuclear" and (“reactor” or “plants”) on Title+Abs+Keyboards. And for INIS search: Contained the keywords "nuclear and reactor” on All Words Filter.

Studies were excluded if they: were duplicates, referring to other facilities that are not reactors (e.g., accelerators, medical centers with radiation equipment, radioisotope plants, laboratories that operate radioactive sources). And if it was focused on SM applied on an only structure, system, component, or activity of the nuclear reactor (e.g., fuel, wastes, maintenance) without a vision about the totality of the installation.

2.2 Classification criteria

Considering the preceding paragraphs and the reading and analysis of the articles, five thematic areas were defined to classify the articles according to their contributions.

Criteria to classify the articles are:

- Frameworks and Theories for Safety Management: Articles whose content presents frameworks for addressing SM issues considering the particularities of NPP or makes theoretical statements about it.
- Safety Culture: Articles whose content presents applications or interpretations about Safety Culture as contributors to the understanding or measurement of SM.
- Management systems: Articles whose content presents proposals or cases of application of Safety Management Systems (SMS) at different organizational or institutional levels of an NPP.
- Applied Safety Management: Articles whose content presents case studies, development, or application of tools to implement or measure SM in Nuclear Power Plants.
- Safety Performance: Articles whose content presents different contributions to the application of tools for the measurement or understanding of safety performance.

3 General Results.

When applying the methodology described above, a total of 27 articles were recovered. The table below (Table 1) presents the qualitative synthesis of the articles recovered.

Table 1 Characteristics and summary of documents recovered.

#	Author (year of publication)	Title See Reference List	Country	Type of Document	Thematic Area Classification
1	Hildebrand M., et al. (2009)	[1	Norway	Conference Paper - Human Factors and Ergonomics Society Annual Meeting	Applied Safety Management
2	Kavoliunas M., et al. (2009)	[2	Canada	Professional Report – SAE International	Management Systems
3	Cullen R. (2009)	[3	UK	Conference Paper - Institution of Chemical Engineers Symposium Series	Safety Culture
4	Zhai Z. (2009)	[4]	China	Conference Paper - IEEE IEEM	Frameworks and Theories for Safety Management
5	Wahlström B., Rollenhagen C. (2010)	[5]	Sweden	Conference Paper - International Conference on Operational Safety Experience and Performance of NPPs and Fuel Cycle Facilities	Frameworks and Theories for Safety Management
6	Guldenmund F. (2010)	[6]	Netherlands	Journal Paper - Journal of Risk Analysis	Safety Culture
7	International Nuclear Safety Advisor Group (2010)	[7]	Austria	Professional Report – INSAG - IAEA	Frameworks and Theories for Safety Management
8	Paradies, M. (2011)	[8]	USA	Journal Paper - Process Safety Progress	Applied Safety Management
9	Himanen, R., et al. (2012)	[9]	Finland	Journal Paper - Journal of Risk Analysis	Applied Safety Management
10	Reiman, T., Rollenhagen, C. (2012)	[10]	Sweden	Conference Paper - World congress on Ergonomics - Designing a sustainable future	Frameworks and Theories for Safety Management
11	Shan Z. (2012)	[11]	China	Conference Paper - Probabilistic Safety Assessment and Management	Management Systems
12	Wu Y. et al. (2012)	[12]	China	Conference Paper - International Conference on Automatic Control and Artificial Intelligence	Frameworks and Theories for Safety Management
13	Latorre Navarro, et al. (2013)	[13]	Mexico	Journal Paper - Journal of Safety Research	Safety Culture
14	Wahlström B., Rollenhagen C. (2014)	[14]	Netherlands	Journal Paper - Safety Science	Frameworks and Theories for Safety Management
15	Akselsson R. (2015)	[15]	Sweden	Conference Paper - Conference on Safety and Reliability of Complex Engineering Systems	Management Systems
16	Kouabenan D, et al. (2015)	[16]	France	Journal Paper - Safety Science.	Safety Culture
17	Ruimin M., et al. (2015)	[17]	China	Journal Paper - Journal of Energy Policy	Management Systems
18	Ding C, et al. (2015)	[18]	Taiwan	Journal Paper - Safety Science	Applied Safety Management
19	Saqib N., Siddiqi M. (2016)	[19]	Pakistan	Journal Paper - Safety Science	Applied Safety Management

20	N. Dechy et al. (2016)	[20]	France	Conference Paper - International Conference on Human and Organizational Aspects of Assuring Nuclear Safety	Frameworks and Theories for Safety Management
21	Vieira Neto S., et al. (2017)	[21]	Brasil	Conference Paper - International Nuclear Atlantic Conference	Applied Safety Management
22	López de Castro, et al. (2017)	[22]	Spain	Journal Paper - Journal of Accident Analysis and Prevention	Safety Culture
23	International Nuclear Safety Advisor Group (2017)	[23]	Austria	Professional Report	Frameworks and Theories for Safety Management
24	Kim J., et al. (2018)	[24]	South Korea	Journal Paper - Annals of Nuclear Energy	Applied Safety Management
25	Martínez-Córcoles M., et al. (2018)	[25]	Spain	Journal Paper - Journal of Psychologist papers.	Applied Safety Management
26	Wahlström B. (2018)	[26]	Finland	Journal Paper - Safety Science	Frameworks and Theories for Safety Management
27	Sui Y. et al. (2018)	[27]	China	Journal Paper – Journal of Cleaner Production	Management Systems

3.1 Quantitative distribution of the articles.

The thematic distribution of the articles is detailed in Table 2. In this table, it can be seen that the dominant thematic areas are “Frameworks and Theories for Safety Management” with ten papers, followed by “Applied Safety Management” with seven documents, and finally with five papers “Safety Culture” and also 5 for “Management Systems”. Regarding the distribution of the types of documents retrieved, most are concentrated on papers published in Journals with 14 papers, followed by conference papers with ten papers and finally in Professional Reports with three documents.

The journals with the most publications are Safety Science (5 papers) and Journal of Risk Analysis (2 papers), the rest of the publications (7 papers) have each been made in other Journals (Journal of Risk Analysis, of Safety Research, of Energy Policy, of Accident Analysis and Prevention, of Nuclear Energy, of Psychologist papers, of Cleaner Production). This seems to confirm the multidisciplinary nature of SM.

Regarding the Conference Papers, they do not focus on any particular topic. These being presented at different conferences: of Human Factors and Ergonomics Society Annual Meeting, of Institution of Chemical Engineers Symposium Series, of IEEE IEEM, of International Conference on Operational Safety Experience and Performance of NPPs and Fuel Cycle Facilities, of World congress on Ergonomics - Designing a sustainable future, of Probabilistic Safety Assessment and Management, of International Conference on Automatic Control and Artificial Intelligence, of Conference on Safety and Reliability of Complex Engineering Systems, of International Conference on Human and Organizational Aspects of Assuring Nuclear Safety and of International Nuclear Atlantic Conference. The professional reports 2 correspond to INSAG and 1 to SAE International.

Table 2 Thematic Distribution and Tipology of Recovered Documents

Quantitative Distribution by Thematic Area		Quantitative Distribution by Type of Document		
Thematic Area	**Total Quantity (percentage)**	**Journal Papers (percentage)**	**Conference Papers (percentage)**	**Professional Reports (percentage)**
Frameworks and Theories for Safety Management	10 (37%)	6 (32%)	2 (40%)	2 (67%)
Applied Safety Management	7 (26%)	6 (32%)	1 (20%)	0 (0%)
Safety Culture	5 (19%)	5 (26%)	0 (0%)	0 (0%)
Management Systems	5 (19%)	2 (11%)	2 (40%)	1 (33%)
Total	**27 (100%)**	**19 (100%)**	**5 (100%)**	**3 (100%)**

The temporal distribution of the documents seems to be homogeneous, and there are contributions in all thematic areas. The authors with the largest number of papers carried out or in which they had participation as the main author are Wahlström B. with a total of 3 papers (2010, 2014 and 2018) and as the second author, also with three papers to Rollenhagen C. (2010, 2012 and 2014). Finally, with two documents, *INSAG* contributed in 2010, 2017. All contribute to the theoretical field (thematic area "Frameworks or Theories of Safety Management").

The years where most papers were found were in 2009, 2012, 2015, and 2018 with four papers. For 2009 Zhai Z.; Cullen R.; Kavoulinas et al.; Hildebrand M. et al. For 2012 the papers corresponding to Reiman T. & Rollenghagen C.; Himanen R. et al.; Shan Z. and Wu Y., et al., The 2015 papers are by Kouabenan D. et al.; Akselsson R.; Ruimin Mu et al. and Ding C., et al. Finally in 2018 the works found were by the following authors, Wahlström B; Sui Y. et al.; Kim J. et al. and de Martínez-Córcoles M., et al.

The largest amount of contributions come from China with five documents, followed by Sweden with three documents. There are two documents with affiliations in Austria, Finland, Spain, the Netherlands, and France. Finally, with 1 document, they make contributions: Norway, South Korea, Mexico, Taiwan, USA, Brazil, Canada, Pakistan, and the UK.

The number of publications in China is explained by the boom and development that nuclear energy has had in that country during the last twenty years.

3.2 Content Analysis.

This section presents a brief synthesis and discussion of the recovered documents, classified in the different thematic areas. It begins with the thematic area of "Frameworks and Theories for Safety Management," in which the documents present the greatest conceptual development. From this area, it would be expected that the other areas would come off. It will continue with the thematic area of "Applied Safety Management", followed by "Safety Culture" and it will end with "Management Systems".

The research discussion goes from the more general to the more specific contributions. Also, this development will be crossed with the contribution of the main theories of safety thinking that were detailed in section 1 of the introduction.

Frameworks and Theories for Safety Management.

Wahslström & Rollenhagen (2010) in their paper "Models, Methods and tools for Safety Management" indicates that there is no integrative model that can be used to understand or describe SM without falling into a trivial representation that is useless for plant managers or reactors heads, decision-makers or senior management of a reactor operating organization. Furthermore, these authors raise the need to develop a framework or a framework model that can integrate the contributions of all or methods that explain, analyze, or describe some relevant factor in safety. This need becomes stronger when the question is asked, "What is safe enough?" because these authors still have no answer.

These same authors in 2014, take up the analysis, in their previous work, and the paper "Safety Management as a multi-level control problem". They propose to use a controlling metaphor to understand the problem of integrated and operational nuclear safety. This metaphor is useful for the design stages and their evaluation and should be adopted in the reactors' operation stage. This paper identifies the multiplicity of hierarchical levels involved in reactor safety. This multiplicity of levels and actors requires using a common language for a common understanding of the problem. For this, the metaphor of control is useful to define a conceptual framework for the identification, definition, and eventual integration of various models, also, for their input and output variables and state spaces. Finally, the authors propose to use the polycentric control design tools and the Man, Technology, Organization and Information model (MTOI) to integrate these conditioning factors of nuclear SM.

The paper "Systemic Thinking in support of SM in nuclear power plants" by Wahlström (2018), considers in the definition of the theoretical proposal of the works of Wahslström & Rollenhagen from 2010 and 2018. This authors defining a model of a Socio-technical system that can be used. The reality of an operational NPP presents dynamic interactions between the design of the operation and the practices of the operation. Each of them is feedback to the other two. For this reason, a system of systems models is required. This mode must consider the model plant states and perform an integration between hard and soft operating systems. This integration in Wahlström's words is only possible from the qualitative-quantitative systems of systems thinking "I see systemic thinking as a broad concept involving various kinds of models as well as the need for considering both entireties and details".

The Technological view of the problem, and in particular in the design stage, deals with the plant architecture from the System Breakdown Structure (SBS). In the nuclear industry, SBS is known as structures, systems, and components (SSC). And tools and techniques of safety engineering are applied to it. These results guide SM during operation.

Related to the human-related view, the design of the prevention issues is aboard from the Hazards and Consequences analysis. This analysis identifies the natural, technical, or human sources and their relationship with the different plant states. Then again, Safety engineering encompasses actions for eliminating, isolating, controlling, and mitigating these identified risks applying mainly the concept of Defense in Depth (INSAG, 1996). In that to address the model of Failures, errors and deficiencies (risk analysis) from human errors and organizational deficiencies are still difficult. In this sense, it is

convenient to consider the drivers and goals of the operating organization, the management systems involved, and the use of tools for decision support. Also, for other organizational issues, the methods of selection, education, training of personnel, the managers and leaders' behavior, and the involvement of the Stakeholders in the safety process are important. Considering this, the MTOI model seems the better way to accomplish it.

As a contribution to this vision, INSAG makes two clarifying contributions. The first, in 2011, the document "A Framework for an Integrated Risk-Informed Decision Making Process," details a methodology for the integration of operational risk from probabilistic (technology and human-related) and deterministic (technology-related) analysis. This methodology proposes a way of integrating the different approaches of the classical safety assessment. This is done by establishing requirements that focus attention on the reactor operating license holder and how to ensure that a decision made in one area does not conflict with other decisions. This proposal does not contemplate a multi-level vision in the decision-making characteristic of the operational face. Furthermore, it seems to have greater applicability to design tasks than to operational management tasks.

Meanwhile, INSAG in his document “Ensuring Robust National Nuclear Safety Systems - Institutional Strength in Depth” in 2017, he proposed a way to integrate this process and online safety analysis by merging the concept of defense in depth traditionally applied to the technological dimension of SM. This proposal considers the institutional dimension of risk and its impact at the operational level. This aspect is directly related to the lessons learned in the Fukushima accident. Likewise, with a pragmatic perspective, he presents the systemic vision proposed by Rasmussen (1997) as his main influence. In this pragmatic vision, the role of the regulatory entity and its deficiencies as an influencing factor in safety are included in the safety analysis. It also raises the need for a systemic vision of the SM problem that integrates human, organizational, and technical factors. The way to approach a Robust Nuclear Safety System as supra operational level is considering three levels. These levels are the level of the operator and holder of the operating license and its environment, the level of the regulatory body and the level of the stakeholders, and the exercise of their pressures.

Dechy et al. (2016) present a paper addressing modes of transfer of the lessons learned in industrial accidents to the nuclear industry. They were starting to wonder if all majors’ accidents have socio-technical roots (beyond technological differences). The authors identify common patterns and causes between both industries and propose two types of transfer the content issue: (a)“Knowledge of Accidents” and (b)“Culture of Accidents”. From them, and a bibliographic review identifies the so-called pathogenic organizational factors.

Finally, in this thematic area, the papers by Zhai et al. (2009) present the Event Analysis and Report System (for incidents or accidents) from 3 conceptual levels (root, nature, and surface). It states that an event is produced by socio-technical causes and a variety of factors (technical, human, and organizational) that must be integrated. This model takes some hypotheses from Reason (1997) since it proposes that: "While technical factors can be random, human and organizational factors do not appear randomly

but interact with each other through a hierarchical structure of three levels: behavior (what), contextual (where) and conceptual (how)".

The authors propose using Failure Modes and Effects Analysis (FMEA) and Probabilistic Safety Analysis (PSA) to solve the qualitative dimensions of the problem. And for the quantitative analysis, proposes to use Bayesian Belief Net (BBF), and deterministic dynamic techniques. For them, it recognizes that the greatest source of inter-certainties comes from human and organizational factors. These should be analyzed in the framework of causal analyzes based on plant operational experience. This proposal seems to consider a complete image of a relevant event for the reactor's SM. But it is a tool for analyzing causes and not postulates proactive concepts that anticipate unwanted events.

Viera-Nieto et al. (2017), in their work Soft Systems Methodology as a Systemic Approach to Nuclear SM, explores the applicability of soft systems theory to SM issues. In their work, they emphasize that this methodology is useful for modeling complex socio-technical systems. Carry out a bibliographic review and establish the necessary analyzes in this method. The analyzes are that of roles (individuals), social (cultural), and political. To these analyzes is added the description of the vision of the problem of each stakeholder. Then activity models are made from identifying the clients, actors, transformation, "Weltanschauung", Owners, and Environmental constraints. Finally, highlights the experience of applying these systems in the Brazilian nuclear system.

In 2012, Wu et al. (2012) proposed the affecting factors of SM of nuclear power based on the Interpretive Structural Modeling (ISM) methodology. This tool is used for represented relationships with a multi-level hierarchical structure visually. The results is a very conceptual model with relations between safety factors that are more compatible with applying to design SM than operational SM. It is expected not to differentiate the stages of the life cycle of a reactor. The focus on safety should be consistent between stages. If the design stage were considered as the genesis of the modeling, it would be more applicable than considering the reactor's operational actions. Therefore, the work recommends refining and expanding the model using other tools such as Fuzzy AHP.

Applied Safety Management.

In this thematic area, papers were recovered with contributions in two directions. The first is about the measurement of safety performance (Hildebrandt et al. 2009), (Himanen et al. 2012), (Saquib et al. 2016), and (Martinez-Córcoles et al. 2018). The second concerning the development of tools to measure levels or degrees of SM (Ding et al. 2015), (Paradies, 2011) and (Kim et al. 2018).

As mentioned, several authors discuss the measurement of safety and performance. Saquib et al. (2016) reflect on the consistency of the use of various safety performance indicators. This consistency is questionable when these indicators are measured to calculate a single comprehensive and strategic indicator. Within the framework of this strategic safety indicator, the weighting of these different operational indicators has different impacts. That impact depends on the independence of the input data and how

those data are independent of each other when they affect multiple indicators. To inhibit these unwanted effects, he proposes an objective equation.

Meanwhile, Martínez-Córcoles et al. (2018) state that the literature on safety behavior is scarce. Similarly, the definition of safety performance should be narrowed. To this end, it carries out a bibliographic review focused on measuring human factor safety in the nuclear industry context. He highlights his observation on safety compliance in terms of how prescriptive regulation appears to be in this industry. He attributes this to potential hazard by the understand of safety performance through relating risk, safety engagement, and safety compliance.

Hildebrandt et al. (2009) et al., discuss the need to modernize the Human Reliability Assessment (HRA) in the context of SM. For this purpose, the use and formation of communities of practice are proposed. From this, they propose a "living" HRA that takes as input the results of these communities of practice. Recognize the value of HRA as part of the Probabilistic Safety Analysis (PRA) of a nuclear power plant. It also identifies the need to develop methods that contemplate the cognitive dimensions of the operators.

Himanen et al. (2012) describe the regulatory requirements of the nuclear industry in Finland. This was done for four operational nuclear power plants. Describe how the PRA development process contributes to SM practices in the prevention of severe accidents. This is due to the need to define probabilistic safety criteria. This includes the frequency of core damage, a risk metric in nuclear safety. As the three levels for PRA was applied, the Finnish NPP operating institution gained mastery over these and other risk-informed applications.

Paradies (2011) qualitatively, compares the results of military nuclear reactors used for propulsion with reactors operated by civil organizations used to electricity generation. Given the exceptional safety record of the United States Navy reactor process, the author wonders how much this influences the military safety process. To answer this question, compare the philosophy of the US Navy with the process SM of the Chemical Process Center and its safety guidelines. In his analysis, the author identifies that there are many gaps between them. The gaps are identified in the difference in rigor posed by the military management model compared to the civilian one. That rigor seems to contribute to better safety results.

Ding (2015) develops a model to identify hidden factors and risk determinants in the nuclear power plant's operation. To do this, he analyzes the failure records of 342 pumps from a large nuclear power plant with a period of 28 years. To do this, use the Latent Growth Modeling (LGM) method. The author postulates hypotheses based on a bibliographic review and the characteristics of the expected failures of the different types of pumps. Using the mathematical model, he confirms four of his five hypotheses. Their contribution seems to be that identifying the factors contributing to risk in SM is always an unfinished task due to hidden factors.

Kim (2018), in his article "Development of a quantitative resilience model for nuclear power plants", is the first author to present the results of the application of the theoretical proposals of Hollnagel et al. (2006). This proposed model takes as input the lessons learned from Fukushima and the French electricity company's experience. To do this, resistance is defined based on the relationship of performance variables such as

Anticipation, Adaptation, Collective Functioning, and Robustness. To develop the quantitative model, 222 event reports from 2003 to 2016 are used. Finally, validate your model through statistical analysis, with data from 26 nuclear power plants. They argue that this model is complementary to classical nuclear safety analyzes results, both probabilistic and deterministic.Given the recent nature of this model, it is convenient to apply and validate it in other nuclear power plants in countries with cultures other than Korean.

Safety Culture.

In this thematic area, papers were recovered with contributions in 2 directions. The first concerning the discussion and utility of the concept of Safety Culture (Guldemund, 2010) and (Cullen, 2009). The second with the measurement of the safety climate as a proxy for the Culture of Safety of the organization (Latorre Navarro et al. 2013), (Kouabenan, et al. 2015), and (López de Castro et al. 2017).

Guldemun (2010), in his article "(Mis) understanding Safety Culture and Its Relationship to Safety Management," criticizes the treatment that academics and practitioners have given to the concept of Safety Culture (SC). His strongest statement is that "the culture concept is deprived of much of its depth and subtlety, and is morphed into a grab bag of behavioral and other visible characteristics, without reference to the meaning these characteristics might have and often infused with normative overtones."

In this sense, he performs a bibliographic review comparing SC's concept according to the components and layers that each author postulates. To link the SC to SM, he inspects how the SC assessment contributes to nuclear safety assessments,

The treatment of SC as the main basis for the study of nuclear safety is addressed by Cullen (2009). In his paper, he presents a practical way of internalizing the concept of the safety processes of a plant. When presenting the description of perception in the different processes, the differences in the vision of the participants in each one are shown. It concludes on the need to take actions to achieve a common understanding of SC's implications in all processes.

Another aspect of the academic application that was revealed about SC is its application to understand and measure the safety climate of the nuclear reactor's operating organization. In this sense, Latorre Navarro et al. (2013) present the development of a questionnaire and a standardized scale to be able to understand the nuclear safety climate in an NPP in Spain. He correlated these concepts with formal safety practices such as written procedures, and observable variables such as safety behavior and time pressure. Finally, he validates its results using factor analysis.

Koabenan et al. in 2015 argue that the safety climate is the key variable to explain the perceived risk and the involvement in safety on the part of the front-line managers of 2 French NPPs. To do this, it conducts questionnaires in the field to 63 managers. Their results are analyzed by SSPS software using Chronbach's Alpha test. The hypothesis is confirmed by its results. As a particular observation, they find that employees' safety behavior has almost no influence from managers. While the direct supervisors of the activities are influential in the perception of safety, in this sense, the paper by Castro et al. (2017) presents a similar work, carrying out a comparative study on the perception of daily safety by applying a Safety Culture Enactment Questionnaire to the staff of

two Spanish NPPs. They use Confirmatory Factor Analysis to validate the consistency of the results and conclude that it is a valid tool for measuring safety culture.

Management Systems.

Papers with contributions in 2 directions were recovered in this thematic area. The first concern is conceptual discussions on applications of management systems Kavouliunas, et al. (2009) and Akselsson (2015). The second, with the implementation of management systems for safety in China Shan (2012), Ruimin, et al. (2015), Sui (2018).

For the discussion of the management systems' applications, Akselson (2015) recognizes that the requirements for these systems are relatively new and are in development. It also recognizes that there are no mature systems in the industry, particularly in NPPs. It still takes a lot of effort to have cadres of highly trained managers in the new vision of SM applied trough a management system.

On the other hand, it addresses the discussion about the indicators. It is necessary to propose indicators that can capture subtle and little obvious behaviors, deviations, or events that initiate accidents. Meanwhile, Kavouliunas (2009) establishes that nuclear SMS require developing a structured risk management process. The risks come not only from technological failures but from the interaction of technology with the man. This author recommends as imperative to develop objective decision-making mechanisms based on NPP data and risk. For this, developments must be made that integrate the probabilistic, deterministic, and quantifiable elements.

For experience in the implementation of management systems for safety in China, Ruimin (2015), in his paper "China's approach to nuclear safety - From the perspective of policy and institutional system," details the country's nuclear safety policy. This is reinforced because mechanisms that prioritize it are established from the political and institutional perspectives. Laws, institutions, ministries, and organizations aligned on a single priority. In this work, all the interventions of these elements are mapped during the life cycle of the numerous NPPs that are operational and under development.

Shan (2012) presents the experiences gained by the China General Nuclear Program Group based on the proposals of the National Regulatory Commission of the USA. To do this, they developed a Reactor Supervision Process. A system independent of the classic already implemented. This new system considers an implementation based on risk management and structured on three levels: the unit level, the site level, and the multi-site level.

Finally, Sui (2018) details the experience gained in implementing a SMS in an NPP in eastern China. This implementation was leveraged by the development of a computer system that made it possible to standardize data processing for decision-making.

4 Discussion and Future Research.

After the Fukushima Daichii accident, there is agreement on the risk factors and causes of nuclear accidents. These factors are technological, human, organizational, and institutional (which includes the regulatory). On the other hand, the models revealed in this paper for the thematic area of Frameworks and theories of SM still cover

spaces that are too abstract and somewhat distant from those of technological safety engineering. No postulates are observed that relate physical variables of the plant and the "soft" variables of safety. In this sense, the concept of Safety Culture (a strong and useful concept) seems to become a free interpretation of each author that is diffuse or lax.

It is observed that these approaches require a complex process of internalization within each organization, and it would be advisable to review their scope and definition ontologically. On the other hand, as it is a discipline proclaimed as multidisciplinary, the application of tools from the theoretical field of SM to the practical field is wide but much unconnected in its results and many other times inconclusive. There is a research opportunity in addressing the question of what and how much is safe for the nuclear industry.

Regarding the recovered documents, 27 documents relevant to NPP were obtained, but none for nuclear research reactors. Although there was an accident in this type of reactor (RA-2, 1982) and there are currently more than 100 such reactors in operation, this object of study does not seem to arouse interest in the academy. Perhaps it is because both the risks, magnitudes, objectives, and interests are quite different for NPP and RR. Regarding the academic treatment revealed on SMS applied to the nuclear industry, there is no evidence of common features among them (framework, architecture, principles). In this sense, there is a theoretical gap in the consolidation of a specialized methodological framework that contemplates the treatment of the risk inherent in this industry.

As Wahlström (2010) stated, it is necessary to propose a framework that allows integrating all the models, meta-models, and concepts that were presented. For this, the proposal of Wahlström & Rollenhagen (2014) about assuming the metacentric of polycentric control and INSAG (2017) and Wahlström (2018) of implementing the systems system vision and the MTOI model seem to be the most appropriate to integrate them. Likewise, this proposal would allow a priori to be able to use as inputs the results of mature nuclear safety engineering tools in the nuclear industry and High Reliable Organizations.

5 Conclusions

SM was contextualized in the history of safety thinking and the causes of nuclear accidents and major industrial accidents.

The state of the art of SM for nuclear reactors was systematically surveyed. Science Direct, Scopus, and INIS were used to this end, and 27 academic articles and professional reports were retrieved. From this, the actual academic scope of nuclear SM has been identified. According to the methodology proposed by Olivera et al. (2019). Finally, the findings were critically discussed, and new lines of research were recommended.

Acknowledgments

This work was partially financially supported by the Universidad Nacional de Cuyo nº 80020180100498UN. We thank Dr. Carlos Gho and Mr. Fabricio Brollo for his support and Mr. Nicolas Dechy of IRSN, France, and Ms. Mariela Grinberg of CNEA Nuclear Safety Department for their expert comments.

Resumo. Quando se pensa em diferencial estratégico para melhorar a competitividade de um negócio, quase sempre os processos de S&OP (*Sales and Operations Planning*) e sua evolução, o IBP (*Integrated Business Planning*), estão em pauta. Estes processos, descrevem como os negócios devem criar e integrar seus planos estratégicos (vendas, marketing, desenvolvimento, fabricação, logística e finanças) para gerenciar o negócio e ao mesmo tempo, equilibrar o que está sendo produzido com que está sendo vendido. Este artigo apresenta uma pesquisa sobre como os processos de S&OP e IBP podem melhorar o fluxo de trabalho em um banco privado do Brasil, bem como podem ser usados em empresas ou departamentos do setor de serviços, e não só em empresas do setor industrial, setor precursor onde o S&OP foi utilizado pela primeira vez. O método de pesquisa adotado foi o de pesquisa-ação tendo sido realizada uma coleta de dados de departamentos específicos do banco privado e, até o momento, foram sugeridas algumas mudanças nos fluxos de trabalho. Na próxima etapa deste trabalho, será utilizado um modelo de maturidade de S&OP/IBP, com intuito de identificar novas oportunidades de melhoria nos processos do banco privado e medir os resultados destas melhorias.

Palavras-chave: Banco, Planejamento Integrado de Negócios, Planejamento de Vendas e Operações, Serviço.

1 Introdução

Num mercado cada vez mais concorrido, o alinhamento dos processos com os objetivos estratégicos da empresa é requisito mínimo para atingimento do sucesso nas empresas quando se pensa no longo prazo [1].

Cada área funcional de uma organização tende a influenciar os processos de modo a atingir os objetivos e resultados que lhes são atribuídos como meta. Quando ocorre um desalinhamento das métricas para avaliação do resultado entre as funções, é natural que haja uma intensificação dos conflitos. Por exemplo, se a meta da área de vendas é o

faturamento, é natural que a previsão de vendas seja superestimada para garantir a disponibilidade de produtos.

Dados os interesses divergentes, a importância da colaboração e a integração na tomada de decisão entre as áreas funcionais, a introdução do S&OP (*Sales and Operations Planning*) ou Planejamento de Vendas e Operações, nas empresas é de grande valia, na medida em que a finalidade deste processo é justamente desdobrar o plano estratégico da empresa em planos táticos integrados para as diferentes áreas [2].

As empresas que têm os processos de S&OP implantados em seus fluxos de trabalho em relação as empresas que não têm, apresentam os resultados mostrados na Fig. 1.

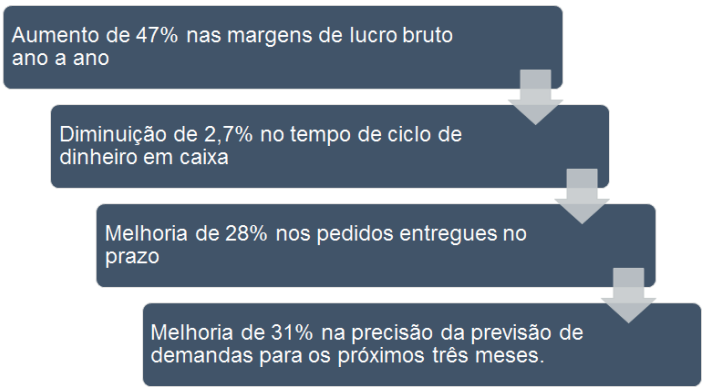

Fig. 1. Benefícios da implantação do S&OP nas empresas. Fonte: [3].

Os benefícios dos processos de S&OP podem reduzir de forma significativa os custos, aumentar a agilidade, melhorar o relacionamento com cliente e aumentar os lucros das empresas A sistemática preconizada pelo S&OP envolve três abordagens distintos tais como planejamento executivo, planejamento tático e planejamento estratégico [3].

A etapa de planejamento estratégico também recebe a denominação de IBP (*Integrated Business Planning*) ou Planejamento Integrado de Negócios. Porém, há quem defenda que o IBP abrange também as atividades do planejamento executivo e tático em sua finalidade [3]. Cenários hipotéticos podem ser criados para simular projeções financeiras, planejar futuros investimentos e até mesmo, comparar possíveis estratégias de atuação por meio de métricas volumétricas e financeiras.

Analisando-se o IBP, sua principal finalidade é garantir o alinhamento contínuo entre os planos de demanda, estoque, suprimento e fabricação, maximizar o desempenho operacional e atender os objetivos financeiros. O IBP é uma nova arma de competição para os responsáveis pela cadeia de suprimentos das empresas na batalha para direcionar e maximizar as decisões de negócios para o planejamento de curto e longo prazo. O IBP pode abranger todos os horizontes de tempo dentro do S&OP.

Neste contexto, o principal objetivo neste artigo foi avaliar e propor a implantação do IBP no fluxo de trabalho atual dos departamentos específicos de um banco privado

brasileiro, seguindo o procedimento previamente estabelecido pelos processos de S&OP.

O artigo está organizado da seguinte forma: na Seção 2 apresenta-se a revisão da literatura, focada nos conceitos de S&OP e IBP. A Seção 3 faz referência ao método de pesquisa. Na Seção 4 apresenta-se proposta de implantação do IBP. Finalmente na Sessão 5 estão as conclusões parciais do trabalho, bem como as próximas etapas a serem realizadas, sendo seguidas pelas referências bibliográficas utilizadas neste texto.

2 Revisão da Literatura

2.1 Sales and Operations Planning

S&OP é um processo para desenvolver planos táticos que forneçam à administração, a capacidade de direcionar estrategicamente seus negócios para obter vantagem competitiva no mercado. O S&OP integra todos os planos de negócios (vendas, marketing, desenvolvimento, fabricação, logística e financeiro) para criar uma cadeia de suprimentos otimizada com foco no atendimento ao cliente [4].

Cada membro da equipe multifuncional, se reúne rotineiramente para planejar e trazer para o processo de S&OP, uma perspectiva específica durante o desenvolvimento dos planos ou previsões de oferta e demanda [5].

S&OP é realizado pelo menos uma vez por mês e é revisado pela administração em um nível agregado (família de produtos). O processo deve conciliar todos os planos de oferta, demanda e novos produtos nos níveis de detalhe e agregado. Depois, vincular-se ao plano de negócios. É a declaração definitiva dos planos da empresa para o curto e médio prazo, cobrindo um horizonte suficiente para planejar recursos e apoiar o processo anual de planejamento de negócios [4].

S&OP é basicamente uma combinação de um plano mestre de produção com um planejamento de demanda. Tradicionalmente, o volume de demanda é determinado em primeiro lugar e depois, incluído no plano mestre de produção. Também é possível incluir KPIs financeiros com informações adicionais e executar análises hipotéticas para identificar alternativas de plano que produzam uma melhoria geral [6].

S&OP foi criado no final dos anos 1980 por Dick Ling e tinha como foco principal fazer o MRP II (*Manufacturing Resource Planning*) funcionar em uma única fábrica de uma empresa. Na época, o S&OP era considerado como um avanço, porque muitas empresas apresentam seus planos anuais, planos de vendas e planos de produção apartados. Existiam muitos erros nas projeções e informações desalinhadas entre os departamentos das empresas. O departamento de Finanças atuava frequentemente como arbitro entre as disputas entre os departamentos de vendas, marketing e produção [7].

A premissa do S&OP tradicional é que o atendimento ao cliente e o inventário é o "resultado final". Para gerenciar o processo, precisamos gerenciar os drivers, ou seja, demanda e fornecimento. S&OP foi um avanço para época, pois obrigou os departamentos de Vendas, Marketing e Produção, a alinharem uma vez por mês, qual seria o número de produtos a serem vendidos, produzidos e armazenados [7].

2.2 Integrated Business Planning

IBP é um modelo de melhores práticas que amplia os princípios do S&OP para um gerenciamento contínuo de processos. Ele fornece, aos tomadores de decisão da empresa, os planos estratégicos alinhados para facilitarem a decisão de como alocar os recursos críticos para satisfazer o cliente e consequentemente, aumentar a lucratividade do negócio [8]. O IBP oferece várias vantagens e benefícios competitivos para empresa, e ilustrado na Fig. 2.

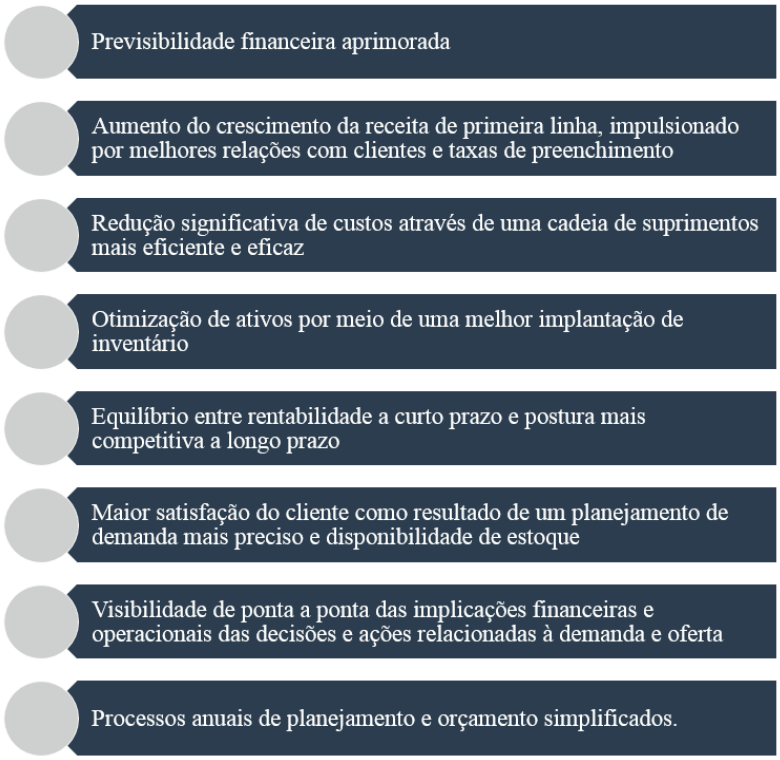

Fig. 2. Benefícios proporcionados pelo IBP implantado. Fonte: [8].

2.3 Desafios para implementação do IBP

Os principais desafios na implantação do IBP são mensurar de forma eficaz o que é necessário para o processo, bem como identificar como os recursos humanos e o gerenciamento de relacionamentos podem impactar os projetos. Para que o IBP seja implantado com sucesso, existem cinco fatores que os executivos precisam focar no processo de implantação [8]:

Comprometimento inabalável dos responsáveis pelos processos na implantação do IBP: Os executivos ou responsáveis pelos processos, devem abraçar a mudança em

primeiro lugar e depois mostrar seu comprometimento inabalável com o novo processo para todas as áreas envolvidas. Reuniões breves e individuais com todos os envolvidos pelos processos, podem ajudar a verificar sua adesão à iniciativa do IBP e alinhar seus papeis no novo fluxo.

Aproveitar tecnologias que se integrem com IBP: Uma estratégia primordial é incluir nos processos de IBP, as melhores soluções tecnológicas disponíveis no mercado. Com automação dos processos de coleta de dados, revisão de dados e divulgação de dados, isso libera recursos para análise de maiores valores. A tecnologia pode ser usada também para gerenciar prazos e fluxos de trabalho, unificar modelos de dados e integrar diferentes sistemas, e ainda, oferecer recursos avançados de planejamento e análises. Por fim, podem ser gerados de forma rápida, automática e tempo real, simulações hipotéticas de cenários que impactem a lucratividade, capacidade de produção, tempo de entrega, nível de serviço e desempenho de novos fornecedores.

Ter o argumento de mudança de processos bem definido: É crucial que os argumentos para mudança estejam bem definidos para garantir o alinhamento entre todos os envolvidos pelo processo. O sucesso depende do desenvolvimento de uma necessidade convincente de mudança com base na situação atual da empresa e nas oportunidades de mercado. Metas e objetivos do IBP precisam ser claramente articulados e definidos. O projeto deve quantificar os resultados operacionais e financeiros esperados, e identificar métricas que serão usadas para mostrar o progresso. Estabelecer um verdadeiro processo de IBP orientado por métricas é a base para maximizar a eficiência e a agilidade de qualquer organização.

Empregar procedimento comprovado para implantação do IBP: Ter um procedimento estruturado e comprovado para liderar a jornada de transformação também é crucial. Um plano formal para implementar o processo de IBP - começando com a equipe de transformação e depois envolvendo os principais interessados e líderes - deve ser desenvolvido em primeiro lugar e executado de forma eficaz à medida que as mudanças passam pelas áreas envolvidas. O plano deve ser amplo o suficiente para cobrir o planejamento, a implementação e a manutenção das mudanças. Um procedimento estruturado exige uma coleta e análise de dados rápida e eficiente, e um redesenho das estratégias, dos processos e sistemas impactados pela mudança.

Ter uma governança eficaz e manter um alto nível de energia: Ter as pessoas certas nos processos de governança de ideias, é tão importante quanto ter os processos corretos. Isso inclui a incorporação de membros de finanças, engenharia, cadeia de suprimentos, vendas, planejamento de demanda e planejamento de suprimentos, entre outros, com o conhecimento e as habilidades necessárias para gerenciar o processo de transformação do IBP. A governança deve ajudar a estabelecer controles eficientes, transparentes e livres de influências, participar de forma regular nas reuniões e apoiar as decisões tomadas como parte do processo do IBP. As partes interessadas precisam saber por que as mudanças estão acontecendo, como o trabalho delas se transformará, o que se espera delas durante e após o programa de transformação, como serão avaliadas e quais benefícios o sucesso trará para elas pessoalmente.

2.4 Modelo de Maturidade

Para avaliar o grau de maturidade que o negócio/departamento está no momento, a consultoria Oliver Wight, desenvolveu um modelo de maturidade onde ela divide o negócio em duas fases e cinco níveis de avaliação. A fase 1, demonstra se os processos de S&OP estão implantados no negócio/departamento e se existe capacidade para migração para o IBP. Na fase 2, o IBP está implementado no negócio/departamento [9]:

Fase 1, nível 1: Os processos de gerenciamento são desconectados. As reuniões são realizadas de forma tradicional e focadas nos assuntos que já ocorreram. O processo orçamentário anual não tem todos as informações necessárias para que as projeções futuras sejam feitas adequadamente. O negócio não apresenta objetivos e medidas em quantidades adequadas para seu gerenciamento, e ainda, as informações podem estar desalinhadas. Os indivíduos responsáveis pelos processos apresentam uma postura mais defensiva em relação a seus resultados.

Fase 1, nível 2: Os fundamentos do S&OP são aplicados parcialmente. Todas as ações têm seus responsáveis definido, métricas para serem medidas e estruturas definidas. O foco das ações é equilibrar de forma tática a demanda e a oferta. São criados indicadores para gerenciar a cadeia de suprimentos. O comportamento da equipe é voltado para o desafio, mas o trabalho em equipe quase não ocorre.

Fase1, nível 3: S&OP está implementado. O planejamento operacional e financeiro está integrado. Os indicadores operacionais estão implantados e aumentam a eficácia operacional, permitindo uma capacidade de 95% de entrega do processo. Os problemas são identificados e geram informações que subsidiam as tomadas de decisão para sua resolução. Os números do orçamento são substituídos pelos números gerados pelo S&OP. O trabalho de equipe é demonstrado durante todo o processo.

Fase 2, nível 4: IBP está implementado. O processo é continuo do gerenciamento de negócios. As estratégias são confrontadas com seus problemas e o foco é total em prioridades que tornam o negócio mais competitivo. O negócio ou departamento são constantemente analisados com intuito de gerar prioridades de melhoria e ações que corrijam os problemas encontrados. Os processos são remodelados frequentemente para atender as mudanças na estrutura organizacional, e utilizados para implantar e direcionar a proposta de valor.

Fase 2, nível 5: IBP está em um nível alto de maturidade. Todos os processos são impulsionados para otimização responsiva do negócio em busca de estratégias para melhorar o negócio. O gerenciamento de problemas e planejamento de cenários alternativos é constante para todo o negócio

2.5 Serviço de Atendimento ao Cliente

A caracterização do que seja um serviço, de forma clara e indiscutível, é muito difícil. Os autores que têm estudado o assunto muitas vezes definem o que não é serviço para, a partir daí, conceituá-lo [1].

Vê-se, pois, que na operação em serviços é necessário o encontro entre o fornecedor e o cliente. O local no qual acontece este encontro é denominado front office. O cliente recebe o serviço, o fornecedor fica frente a frente com o cliente, e todo tipo de variabilidade e novas situações podem ocorrer; enfim, onde o controle é muito difícil.

Na prestação de serviço, a presença do cliente é parte do processo. Dependendo da natureza, como reparo em um eletrodoméstico, o serviço será executado em outro local – oficina, por exemplo -, não na presença do cliente. Este local é denominado *back room* ou *back office*, cuja características são de baixo contato com o cliente, maior previsibilidade, possibilidade de padronização e melhor controle.

Ao longo de todo o desenvolvimento dos processos de fabricação de bens tangíveis, estiveram presentes, sempre de forma crescente, os serviços. Pode-se afirmar que, até meados da década de 1950, a indústria de transformação era a que mais se destacava no cenário político e econômico mundial, mas atualmente, isto não é mais verdadeiro [1].

Analisando-se a Fig. 3, tem-se a exata noção que a importância relativa da indústria no PIB (Produto Interno Bruto) nacional vem diminuindo ao longo do tempo e o setor de serviços tem crescido em relevância no Brasil [10].

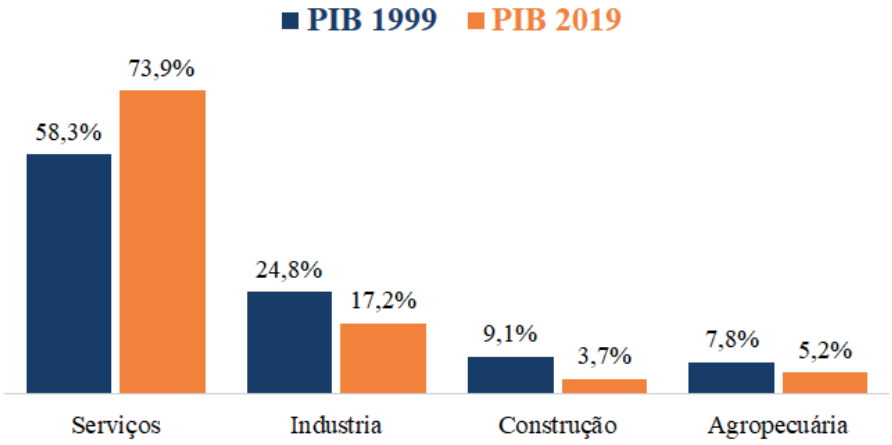

Fig. 3. PIB do Brasil divido entre os setores da economia. Fonte: [10].

Quando se fala em serviços, não se pode esquecer a quem ele é destinado. Sim, o cliente, mas quem é o cliente ou melhor o que é um cliente? Para algumas empresas, a razão de existirem. Para outras empresas, um objetivo a ser alcançado e mantido.

Historicamente houve algumas fases bem distintas quanto a produção de produtos ou serviços. Segundo [1], no início, o artesão supria as necessidades especificas de seus clientes, que ditavam com previsão a forma e as características do produto que encomendavam. Com advento da Revolução Industrial, surgiu a necessidade de padronização dos produtos e processos. Assim, o consumidor perdeu o poder de influenciar na definição dos produtos que iria consumir, ficando este com os projetistas, que, em regra, não consultavam o mercado quanto às suas necessidades.

Construir a satisfação do cliente por meio da qualidade e valor é o ponto chave do novo pensamento mercadológico. E esse pensamento parte da premissa básica de que os consumidores comprarão da empresa que entregar o maior valor. Assim, a oferta de produtos, ou serviços de maior valor, para o cliente passou a ser o diferencial que determina a vantagem competitiva em relação a outras organizações [11].

De todos os fatores capazes de determinar o sucesso de um empreendimento, ter uma boa ideia é, geralmente, considerado o mais importante, porém, atender bem o cliente é fundamental para alavancar a empresa. A sobrevivência e o sucesso de uma organização estão diretamente relacionados à sua capacidade de atender às necessidades e expectativas dos clientes, as quais devem ser identificadas e entendidas [12].

Um dos pilares da revolução digital no setor bancário é a *user experience* (experiência do usuário) e nela, os clientes passam a não mais comparar a experiência bancária somente entre os bancos, mas também com outras empresas de tecnologia e esperam mais [13].

A empresa que for realizar o serviço de atendimento ao cliente pelo modelo de telemarketing receptivo (tanto de ligações receptivas como de *backoffice*), precisará se preparar adequadamente para o volume de contatos/demandas que irá receber[14].

No caso do banco privado estudado neste trabalho, o atendimento ao cliente é feito por intermédio de um *backoffice* terceirizado. Como justificativa para tal escolha, [14] escreveu que o principal motivo é permitir que a empresa contratante do serviço, no caso o banco privado, possa focar em suas competências essenciais como emprestar dinheiro aos clientes, por exemplo.

3 Método de Pesquisa

3.1 Método de Pesquisa-ação

Para lidar com dados qualitativos da abordagem do problema desse estudo, será utilizado o método de pesquisa-ação para mapear, descrever e sugerir mudanças, se necessárias, nos processos dos departamentos do banco privado.

A pesquisa-ação é um tipo de pesquisa social com base empírica que é concebida e realizada em estreita associação com uma ação ou com a resolução de um problema coletivo e no qual os pesquisadores e o participantes representativos da situação ou do problema estão envolvidos de modo cooperativo ou participativo [15]. O detalhamento das etapas desta pesquisa pode ser observado na Fig. 4.

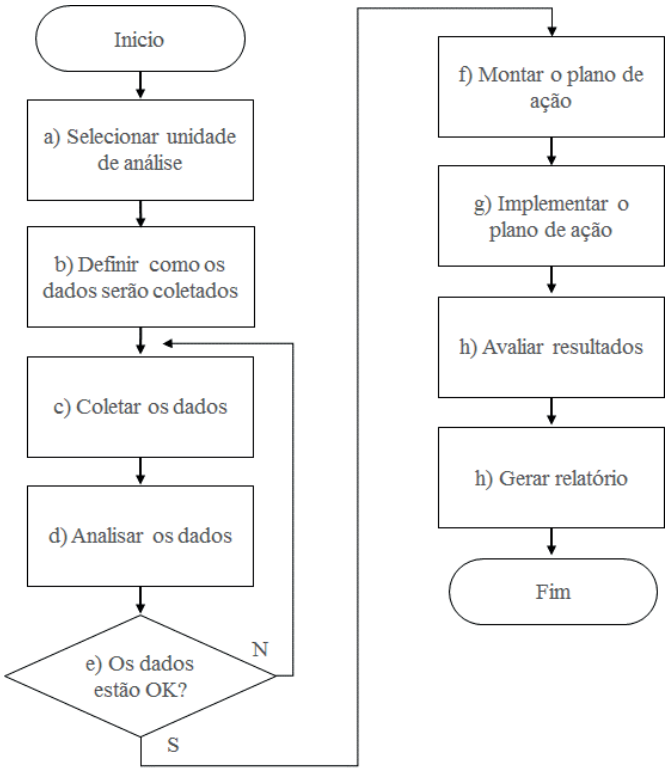

Fig. 4. Fluxograma da pesquisa

O principal foco da pesquisa-ação é a obtenção da perspectiva dos elementos que integram o objeto do estudo. Para uma abordagem mais positivista do procedimento, as variáveis devem ser controladas, as relações de causas/efeitos mapeadas e as condições de replicação da pesquisa bem detalhadas. A pesquisa-ação deve focalizar no problema real abortado no estudo, descrevendo as atividades necessárias para sua solução e relação entre os colaboradores [15].

3.2 Objeto de Estudo

Quando O banco privado deste estudo, está entre os 5 maiores bancos brasileiros e possui um grande portfólio de produtos e serviços financeiros, que são oferecidos diariamente aos seus clientes, tanto do tipo pessoa física como pessoa jurídica. Devido à grande quantidade de produtos e serviços financeiros oferecidos em seu portfólio, o banco privado é considerado do tipo misto ou múltiplo. Os principais serviços/produtos oferecidos são conta corrente, conta poupança, cartão de crédito, empréstimos/financiamentos, seguros e investimentos.

O banco privado do estudo, por ser tipo múltiplo e ter um porte muito grande (mais de 90 mil funcionários), apresenta muitos departamentos com produtos, serviços, fluxos, processos e formas de trabalhar diferentes uns dos outros, como se fossem

empresas diferentes dentro de uma mesma empresa e isto, gera um grande desafio para os gestores da alta administração. Logicamente, todos os departamentos seguem as normas pré-estabelecidas que regulamentam a atividade bancária, tanto internas como externas, mas mesmo assim, existe esse desafio a ser superado diariamente e de forma continuada pelos gestores.
Por conta da situação acima mencionada, este estudo foca no produto Empréstimos para pessoas do tipo Física e na modalidade Crédito Consignado, onde o cliente faz o empréstimo no banco e o valor da parcela é descontado diretamente de seu salário ou de sua aposentadoria [16].

Analisando os dados financeiros do banco privado, que foram publicados para os investidores após o último trimestre de 2019, foi constatado que a carteira de Crédito Consignado para pessoas física, representava 7% de todo o valor emprestado pelo banco e 20,6% de todo valor emprestado para pessoas física, mostrando sua importância para rentabilidade financeira da empresa.

4 Proposta de Implantação do IBP

4.1 Mapeamento do Fluxo de Trabalho

Para mapeamento do fluxo de trabalho deste estudo, foi utilizada a técnica de fluxograma apresentada por [17], pois, permite desenhar o fluxo de trabalho deste estudo, de forma simplificada e de fácil entendimento. O fluxograma tem como característica, apresentar poucos símbolos padronizados para sua utilização.

Através de reuniões presenciais ou por telefone com membros das equipes dos três departamentos envolvidos pelo estudo e utilizando a técnica de fluxograma, foram criados os fluxos de trabalho apresentados nas Fig. 5 e 6. O fluxograma da Fig. 5, apresenta o cenário atual dos departamentos do banco privado, que serão alvos deste estudo.

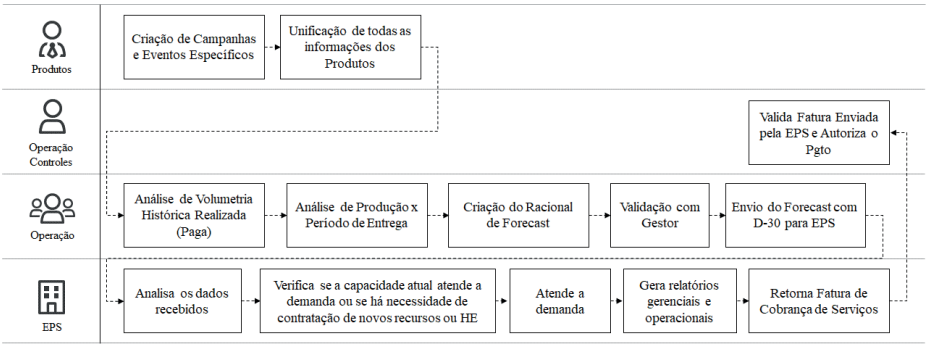

Fig. 5. Fluxograma antes intervenção do estudo

A informação inicial que compõe a previsão de demanda que é enviada para EPS, tem sua origem na área de produtos do crédito consignado, onde eram criadas todas as campanhas ou eventos para o produto. A equipe de pricing da área de produtos do crédito

consignado, era responsável por projetar e consolidar todas as volumetrias esperadas de novos contratos de crédito consignado por segmento, que o banco privado esperava adquirir por conta das campanhas ou eventos de vendas previamente agendadas e divulgadas. Esse plano ganhou o nome de carteira de clientes. Após o alinhamento, o plano era encaminhado via e-mail para os gestores e para área de operação, utilizarem os dados em suas previsões.

A área de operação com a posse do plano (carteira de clientes), analisava os dados e criava previsões que correlacionavam a volumetria histórica recebida pela EPS com a volumetria apresentada pela carteira de clientes. As previsões enviadas para EPS, eram somente dos próximos três meses. Uma vez montado o racional que seria utilizado na previsão de demanda, era realizada uma reunião com o gestor ou representante da operação para validação das volumetrias projetadas. Validados os dados, era enviado a previsão final para EPS através de e-mail e serviria para formalização oficial do plano entre o banco e a EPS.

EPS de posse da previsão enviada pelo banco, analisava a previsão e verificava se sua capacidade operacional estava adequada para atendimento da demanda. Se ela identificasse que existia um aumento ou redução da volumetria apresentada na previsão enviada pelo banco, a EPS precisava determinar se o evento é pontual (somente um ou dois meses) ou definitivo (novo padrão de volumetria média).
Se a demanda fosse alta e pontual, a EPS perguntava ao banco se podia fazer horas extras para atender a demanda, caso contrário, haveria impacto de SLA. O banco autorizando, eram feitas horas extras para atendimento da demanda. Se a demanda fosse baixa e pontual, a EPS agendava algum treinamento para o período ou dava férias para os colaboradores ou utilizava os recursos em outras esteiras de atendimento se fosse possível.

Se a demanda fosse alta e definitiva (os três meses com aumento), a EPS contratava novos recursos e solicita horas extras até que os recursos estivessem disponíveis para o atendimento. Se a demanda fosse baixa e definitiva (os três meses com redução), a EPS realocava os colaboradores para outras esteiras.

Após o atendimento da demanda e no próximo dia, a EPS disponibilizava os relatórios gerencias e operacionais para consulta. Após o fechamento do mês, a EPS informava a volumetria oficial tratada no mês e enviava a nota fiscal para o banco com todos os serviços prestados. A área de controles do crédito consignado junto com a operação, validavam a fatura e liberavam o pagamento para EPS se a cobrança estivesse correta.

No processo de mapeamento do fluxo de trabalho, foram identificados alguns itens dos processos que podem ser melhorados: falta de uma reunião de S&OP, falta de *Hard Skills* especificas de previsão de demanda, falta de métricas de gerenciamento de demanda, falta alinhamento dos planos financeiros com os planos de S&OP, prazo para envio da previsão de demanda elevado, falta de um *software* integrado de S&OP.

4.2 Proposição do processo IBP

No novo fluxo de trabalho. foram feitas mudanças para melhorar a entrega final e corrigir os problemas apontados no item anterior. Na Fig. 6, tem-se o novo fluxo de trabalho que foi implantado no banco.

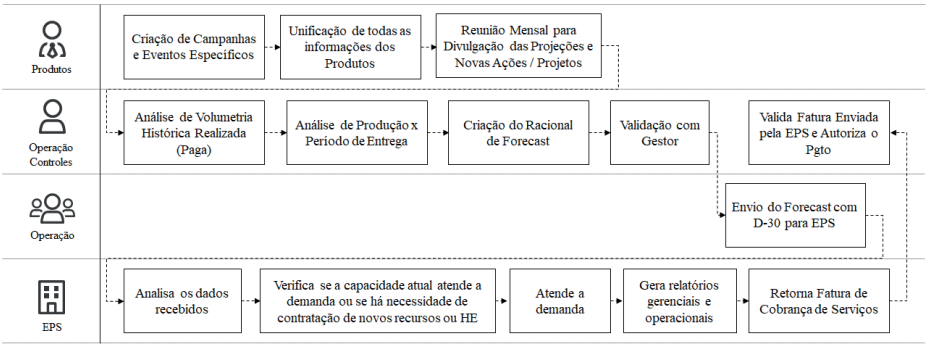

Fig. 6. Fluxograma após intervenção do estudo

Foram feitas as seguintes mudanças no fluxo de trabalho para resolver os problemas relatados:

Falta de uma reunião de S&OP: Foi alinhado com a área de pricing, que seria realizada uma reunião mensal para divulgação da previsão de carteira clientes e alinhamento das expectativas. Nessa reunião deveria ser apontado toda e qualquer informação nova sobre projetos ou eventos que poderiam impactar a demanda e se necessário, efetuar mudanças na previsão criada.

Falta de Hard Skills especificas de previsão de demanda: aqui havia duas soluções possíveis. A primeira era treinar os colaboradores em conhecimento de modelagem estatística e a segunda, era transferir a atividade para outra equipe. Foi ponderado os pontos fortes e fracos de cada uma e optou-se pela segunda alternativa, que era passar o processo para área de controles, uma vez que a área já tinha o conhecimento especifico em modelagem estatística. A única exigência era que a previsão fosse validada com os gestores da operação ou pontos focais da operação e que após a validação, a operação mandasse a previsão para EPS, por conta do relacionamento direto com eles.

Falta de métricas de gerenciamento de demanda: foi solicitado a equipe de pricing, que realizasse uma apuração do % de acuracidade dos dados que eles estavam gerando em suas previsões da carteira de clientes e de forma pontual, os dados foram gerados e houve a constatação que sua acuracidade não estava ideal (acima de 20% de erro percentual). Por enquanto, a equipe ainda não adotou o indicador como forma de balizar a qualidade das previsões, mas para as próximas reuniões, será solicitado que o indicador seja incluído em suas metas administrativas.

Falta alinhamento dos planos financeiros com os planos de S&OP: após a constatação da situação na área de controles e como o as previsões de demandas passaram a serem feitas na área, houve uma integração das previsões de volumetria de demanda com o orçamento e acompanhamento dos custos financeiros da superintendência como um todo. A criação de cenários hipotéticos de impactos financeiros foram tiveram seus tempos reduzidos por conta da informação estar integrada.

Prazo para envio da previsão de demanda elevado: como o prazo de previsão que o banco deveria enviar a projeção para EPS era de 45 dias de antecedência ao mês de trabalho e havia ainda a multa de garantia de atendimento de 90% da demanda deveria ser paga, independente do volume ser menor do que 90% da previsão formalizada, a

área de operação conseguiu negociar junto com a área de compras e a EPS, uma redução no prazo, onde o tempo de envio da previsão seria de 20 dias de antecedência ao mês de trabalho e não mais 45 dias. Por conta dessa situação, houve ganho de acuracidade na previsão de demandas por ser possível ter dados mais recentes da situação do produto e o horizonte de planejamento ser menos longo.

Falta de software integrado de S&OP: foi levado esse assunto para os gestores da operação, mas por envolver custos de licenças e mudanças de atividade, está em análise ainda.

5 Conclusões parciais e próximas etapas do trabalho

Os objetivos específicos deste estudo foram atendidos. Foi realizado o mapeamento do fluxo de trabalho entre os departamentos do banco privado e isso resultou na identificação de processos passiveis de melhorias imediata.

As mudanças implementadas, melhoraram as relações de trabalho entre as áreas, unificaram boa parte dos planos operacionais e financeiros dos departamentos, e já estão contribuindo para melhorar a margem financeira do banco privado. Mesmo assim, existem muitas oportunidades que possam ser estudas e implantadas no fluxo de trabalho.

Para próxima fase deste estudo, espera-se demonstrar a aplicação do modelo de maturidade, para medir o conhecimento das práticas de S&OP e IBP dos departamentos do banco privado, e assim, propor novas soluções para otimizar os processos e conduzir a implementação de forma consistente das melhores práticas S&OP e IBP.

Finalmente, espera-se que este estudo contribua para a comunidade acadêmica com relatos de experiências reais sobre implementação dos processos de S&OP e do IBP, em bancos privados.

Application of the AHP method to assist the strategy of bike share station positioning in the city of São Paulo

José João Manrique Franco *, Emannuell Dartora Cenzi *, Marcelo Rudek *, and Eduardo de Freitas Rocha Loures *

Pontifícia Universidade Católica do Paraná, PUCPR, Industrial and Systems Engineering Graduate Program, Curitiba, Brazil

Abstract. This article investigates the bicycle allocation strategy in a competitive market of bicycle sharing at autonomous stations. The data scientist seeks to understand the market in the shortest possible time, while the customer wants to obtain the best experience of integrated use between the different modes of transportation. The initial position of bicycle stations, the coverage area and the allocation method are investigated, and with the assessment by mobility specialists or customers, the AHP method is fed, whose results combined with the previous data are grouped into clusters to detect the best and worst bike share stations. The case study was performed with real data from a bicycle sharing network in the city of São Paulo to demonstrate the effectiveness and feasibility of the proposed solution. The results show that the proposed method was able to quickly identify the efficiency of the position of bike share stations, enabling their further optimization.

Keywords: bike share, data mining, AHP, model evaluation

1 Introduction

Around the world, bicycles are considered practical and reliable. Far from being a leisure-only option, they are currently used as a means of urban transportation where many cities face serious mobility problems. In Brazil, most cities face a scenario with serious problems where transportation by private motor vehicles causes major congestion and more pollution. Public transportation, on the other hand, offers users low connectivity, but presents an opportunity for the connection between different modes of transportation and increases the quality of user satisfaction. Seen as a strong candidate to help change perception and transportation habits over short distances, collaborative consumption through the sharing of bicycles and scooters has been gaining strength and fans. It is seen as an inexpensive, efficient and healthy way to navigate dense urban environments [14].

This work aims to analyze the strategic positioning of bicycle sharing stations with a focus on traveling between stations and other modes of public transportation using data mining techniques and the AHP decision-making method.

Collaborative consumption can be seen as a return of the old practices of sharing, collateral, rent and exchanges, which were the first forms of commerce but were abandoned with the advent of the capitalist model of production [2].

Currently the big difference is the technology that, through online platforms, smartphones and IoT devices, makes it possible to connect people to smart devices or stations powered by solar energy, GPS and RFID systems that allow better management and control of the vehicles.

The technology called IoT (Internet of Things) connects smart sensors or hardware to the internet [1]. Big Data Analytics (BDA) and the Internet of Things (IoT) are being considered the most profound transitions in technology [12] [9]. For example, in modern factories, large volumes of records and information are generated by sensors embedded in machines that are connected to solutions based on cloud processing. The main objective of adopting IoT in factories is to transform them into "smart factories", where machines and devices communicate with each other and are connected in a network [12], increasing agility and reducing costs. For some time now, research has shown how organizations that rely on collected data take advantage of information as a competitive advantage [18].

In smart cities, two items are considered essential in most analyses: the aspects of transportation and logistics with a predominantly sustainable point of view, and new technologies to facilitate the organization of activities, including data capture and analysis. Along with this change comes a growing "social pressure" from the city's public institutions on companies to design more sustainable transportation networks [6]. Thus, it is becoming clearer that it is necessary to understand and analyze the experience of consumers in e-commerce or traditional retail stores. Future logistics networks in smart cities will need to support omni-channel models. Therefore, it is essential to map the activities and the integration between various points of contact of the consumer and the brand during the shopping experience [4].

This work proposes an approach that combines the K-Means unsupervised learning method with the application of the Multi-criteria Decision Making (MCDM) method known as AHP (Analytic Hierarchy Process) to evaluate qualitative parameters in the various bike share stations in São Paulo with statistical information from 2017. In order to achieve this goal, the following is sought:

- Create a method for the quantitative analysis of bike share stations;
- Consider the role of the specialist or customers in the method;
- Use machine learning and data mining methods to compose the flow of the proposed method;
- Suggest the optimization or readjustment of stations with poor evaluation results;

AHP [15] is a method that makes it possible to deal with many decision criteria through pairwise comparisons, facilitating an assertive and personalized choice for a specific context. This method was chosen because it is a tool that is already consolidated and applied as a scientific basis containing various relevant applications and publications as in [5].

The weights generated at the end of the multi-criteria method serve to qualitatively evaluate the obtained clusters. Thus, taking the knowledge of experts and business model rules to interact directly with a machine learning algorithm. This information can help optimize docking points, making it possible to remove inefficient points, for example.

In view of the various sources used to populate the variables of the problem, a new dataset called bike_station_dataset was created, which groups information from bike share docks together with subway stations, geolocalized population information, relief information and bike paths.

2 Bike sharing worldwide

Paris and Barcelona installed their bicycle sharing system in the same year (2007), initially with few stations [10]. In 2013 there were already around 540 bike sharing programs worldwide in 50 countries with a total of more than 500 thousand bicycles, representing about 2 million trips a day in cities like Wuhan, Shanghai, Hangzhou and Taiyuan in China, as well as London, New York and Montreal [11].

Like bicycles and motorcycles, cars are used in the urban environment in what is known as door-to-door transportation. In 2012, bicycle sales exceeded car sales in 25 of the 27 European Union countries, which was economically justified due to the severe crisis there. The increase in bicycle sales was also justified by the adoption of broad public policies to encourage the use of bicycles and the construction and maintenance of bike paths.

3 Methodology

Previous studies have listed possible evaluation parameters for similar topics. For example [7] makes a similar analysis with AHP in the Mashhad region in Iran. The work gathered data from various open sources to group parameters that could be qualitatively representative to evaluate a bike share station.

For this case study the following factors are considered:

- Proximity to subway stations;
- Distance between bike share stations;
- Population of the region;
- Relief variation;
- Proximity to bike paths.

Proximity to subway stations: One of the important goals that bike share stations are solving is the "last mile" problem, a name given to the short distance to ride a bike between transit stations and home, the workplace, university, etc. [3]. It is of great importance and essential for BS systems to be integrated with other modes of transportation for the efficiency of the system as a whole, and many cities are looking for this model [17]. However, it is important to note that

efficiency and integration with different transportation models is not the only factor for the success of the BS system. In this work, information was used on the geopositioning of all subway stations in the city of São Paulo, available on Kaggle [1]. For each bike station, the nearest subway station was selected in a straight line.

Distance between bike share stations: many researchers have pointed out the importance of adequate spacing between stations [13]. In fact, the short distance to be traversed between stations is one of the keys to success. This together with a balanced distribution of stations can guarantee that everyone has the right to access the bikes [7]. From the geopositioning of the bicycle stations, a comparison of one station with the others was carried out to find out if there was a station within a close distance to integrate bicycle transportation on bike paths.

Population of the region: a study on the city of Lyon, France, shows that the population is among the important factors that affect the long-term use of bicycles by permanent users [19], as well as in Guangzhou, Chine, where 40 % of bike use comes from stations near people's homes [17]. Here, to determine population density, IBGE data was collected in the form of a statistical grid for polygons within the city of São Paulo.

Relief variation: stations at a higher altitude are less likely to be part of the users' route or to be visited. In this case study, the geotechnical chart or topographic map of the city was taken into consideration, and according to this, the highest stations are less attractive to users. It is also noted by [11] that the stations at high locations are empty of bicycles and the stations at low altitudes are full of them.

Proximity to bike paths: bearing in mind that bike paths are essential for the functioning of the bike share system, each station must be strategically positioned to integrate the stretches between public transport stations. The feeling of safety on the bike path is very important to encourage people to use bicycles [8].

For the case study in the city of São Paulo as well as other cities worldwide, the data for the factors listed above are publicly available, and the model can be applied in other locations.

Thus, with the processed and tabulated data, a dataset was generated, which will be subjected to the K-means clustering technique. This technique uses optimization to try to separate the samples into k groups of equal variance, varying the k-centroids iteratively in order to minimize the intra-cluster distance [16].

At the same time, an MCDM process was carried out using the AHP method in view of the observations made about the parameters mentioned in the literature, mainly in [7]. The weights resulting from the AHP method thus serve to evaluate the clusters obtained by the algorithm, enriching the computational operation with the information provided by specialists. The complete flow can be seen in Figure 1.

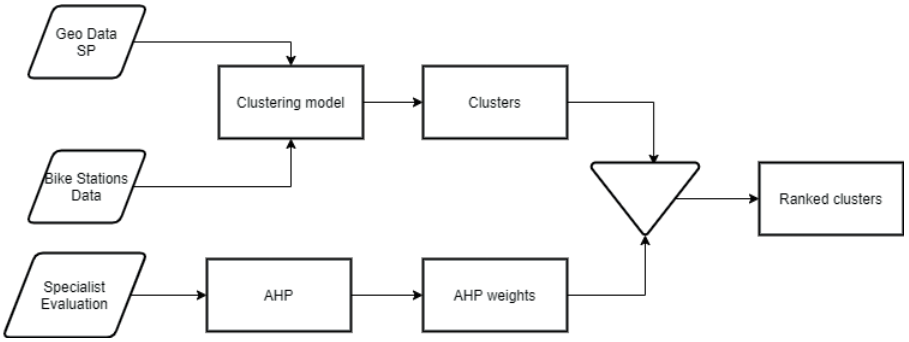

Fig. 1. Information flowchart for the proposed methodology

4 Area in analysis

The geographic area under study comprises the city of São Paulo, with an estimated population of 12,252,023 inhabitants. It is a city with a good variety of urban transportation modes such as buses, bike paths, and subway and train lines. As population density is a potentially relevant factor, this information was extracted through IBGE, which publishes granular data by census sector. Information was also collected on the relief of the city of São Paulo based on the geotechnical chart available in the city hall's open data portal.

The city of São Paulo has 473.3 kilometers of bike path, being the 6th city in the world ranking of the 50 cities with the highest mileage. For cyclists to take advantage of the modal integration, there are more than 8 thousand bike spaces in hundreds of public bicycle stands, which are installed in bus terminals, train and subway stations, and Traffic Engineering Company (CET-SP) parking lots.

There are few sources of data on bicycle stations in São Paulo, so for this study we adopted the database available on the Kaggle [2]. The dataset has a historical record of the availability of bicycles at stations in the city, and thus the bike share stations were mapped.

The bike path network [3] mapped by the city of São Paulo and the Traffic Engineering Company (CET-SP) is available free of charge in vector format. This municipal bike path network is constituted by road interventions dedicated to the exclusive circulation of bicycles. These consist of bike paths, bike lanes, shared sidewalks, and bike routes.

Subway stations are available in the Github project repository [4], as well as their respective names, geolocation, address and operating hours.

5 Results

The evaluator considered the relationship between 5 variables, which are: Proximity to subway stations; Distance between bike share stations; Population of the region; Relief variation; Proximity to bike paths. The comparisons are made in pairs to calculate priorities using the Analytical Hierarchy Process (AHP).

Table 1. Comparison between the variables analyzed by the specialist.

A - AHP priority - B			Evaluation
1	Proximity to subway stations	Distance between bike share stations	2
2	Proximity to subway stations	Population of the region	3
3	Proximity to subway stations	Relief variation	6
4	Proximity to subway stations	Proximity to bike paths	9
5	Distance between bike share stations	Population of the region	2
6	Distance between bike share stations	Relief variation	5
7	Distance between bike share stations	Proximity to bike paths	6
8	Population of the region	Relief variation	3
9	Population of the region	Proximity to bike paths	5
10	Relief variation	Proximity to bike paths	5

Given the variables, a total of 10 questions were generated for paired comparisons. The paired comparison of all criteria is made with respect to the AHP priorities, evaluating the criterion A vs. B on a scale of 1 to 9, with 1 being the same level of importance and 9 being the absolute importance of criterion A in relation to B. These are the resulting weights for the criteria based on their comparisons:

Table 2. Ranking of weights for each criterion based on the AHP method in priority order.

Variable	Priority	Rank	(+)	(-)
Proximity to subway stations	43.9 %	1	9.0 %	9.0 %
Distance between bike share stations	27.7 %	2	8.3 %	8.3 %
Population of the region	16.6 %	3	4.3 %	4.3 %
Relief variation	8.4 %	4	4.6 %	4.6 %
Proximity to bike paths	3.4 %	5	1.2 %	1.2 %

The geolocalized data obtained was grouped by the creation of a hexagonal grid with a 2 km circumscribed radius. In this way, the Population variable was grouped with a sum and the relief variation was adjusted with the average presented in each hexagon, creating a region of influence more relevant to the context of the docking stations.

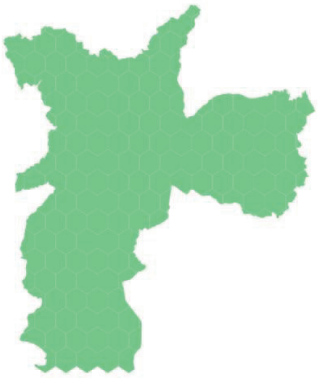

Fig. 2. Map of the city of São Paulo with the Hexagonal Grid

With the dataset already built, the clustering process continued, where several K values were tested, but what appeared to have the best performance according to the silhouette coefficient was the value 4, as can be seen in Figure 3.

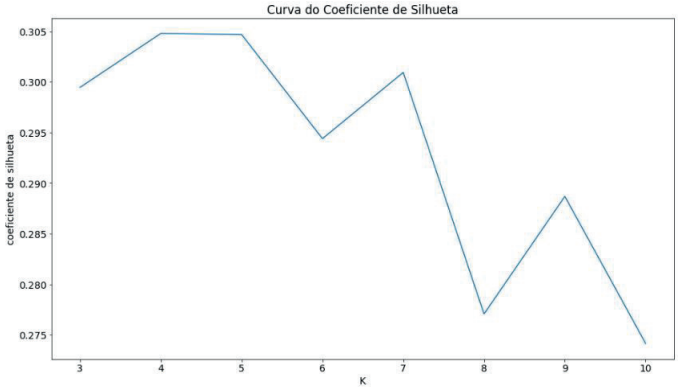

Fig. 3. Silhouette coefficient curve for the different k values

With the obtaining of k = 4 groups of stations, the determination of the product of the parameter values with the weights generated by the AHP model was carried out, inverting the module of the features whose growth implies negative consequences for the cyclist's experience. Thus, a score was obtained that allowed the comparison of the groups in a practical and simplified way, as shown in Figure 4.

It is observed in figure 4 that cluster 0 appears to present the best results, considering that all of its quartiles are above those found in the other groups.

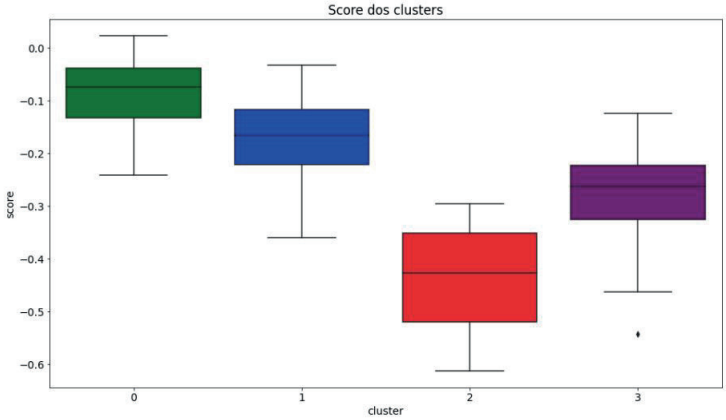

Fig. 4. Visualization of the cluster evaluation

Thus, the geographic positioning of the clusters is shown in Figure 5, using the same colors of figure 4 to identify which cluster the station belongs to. The stations in green are considered more attractive and are visibly concentrated in the more central areas, which have high population density and flow of people. In addition, these zones have stations close to each other and a good proximity to subway stations, the two most important factors pointed out by the AHP method.

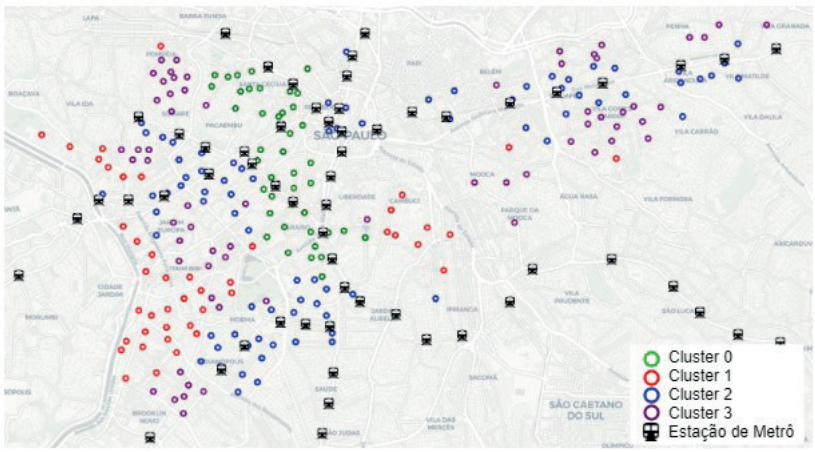

Fig. 5. Geographic location of the obtained clusters (circles) and subway stations (icon)

At the same time, it is noted that group 2 (red), which has the worst score evaluation, has a notable presence in more distant areas with greater distance between stations. It is also noticed these bike share stations are a great distance from subway stations, hindering an integration between these modes.

6 Conclusion

In view of the results achieved, it can be said that the methodology proposed in the present work achieved its objectives, carrying out a quantitative analysis of the stations with the possibility of combining this data with a qualitative view from a specialist and/or a user. The MCDM resource was combined with an unsupervised learning technique, generating groups easily distinguishable by the different distributions of their variables and by the score obtained for each variable using the AHP method.

Thus, the best and worst groups were indicated by the clusters' scores, as well as patterns that differentiate them, explaining the relevance of some of the parameters provided by the decision method, such as the distance to other stations, which penalizes more isolated stations such as those in group 2 of figure 4.

The role of the specialist or client is considered as an essential evaluator for the operation of the method, as it provides a subjective and qualitative view, in addition to the possibility of adapting to different regional and temporal contexts.

Future works can apply the proposed model in other cities around the world and propose new parameters to evaluate the stations. Further investigation with urban mobility specialists can enrich the work and bring it closer to the local reality. Tests with other methods such as PROMETHEE can also be performed.

Other analysis possibilities can arise when adding more parameters about the stations and their surroundings to create an even more robust dataset and test other types of clustering algorithms. A comparative approach with the results presented in this article can also be carried out.

Resumen. En este estudio se presentan los resultados preliminares obtenidos del análisis del flujo vehicular y su correspondiente segmentación, en determinadas intersecciones del microcentro de la ciudad de Bahía Blanca durante el primer trimestre del año 2020. Los datos generados en este trabajo son de vital importancia para, en un futuro, ser empleados en el modelado de la dispersión de las emisiones generadas por fuentes móviles en el microcentro de la ciudad de Bahía Blanca. Además, la generación de datos fidedignos contribuirá con las autoridades locales para la toma de decisiones tendientes a realizar una gestión inteligente del tránsito. Se exhibe la composición de la flota vehicular, así como también la antigüedad promedio de los vehículos motorizados que circulan por las calles evaluadas. Los datos de caracterización de la flota vehicular fueron generados mediante el análisis del material fílmico producido para este fin. Los videos examinados fueron confeccionados en el marco de nuestra investigación en cuatro puntos clave, en tres momentos del día (mañana, mediodía y tarde) en los meses de enero y marzo (pre-COVID-19) del año 2020. Esta investigación ha permitido mostrar una diferenciación en el flujo vehicular entre ambos meses en estudio siendo marzo el mayor. Además, se observó que el vehículo con más predominancia en circulación para ambos meses es el denominado sedan o automóvil particular. Finalmente, se comprobó que la antigüedad del parque automotor de la ciudad es un 17% más nuevo que el reportado a nivel nacional.

Palabras claves: Flujo vehicular, Bahía Blanca, Transporte carretero.

1 Introducción

Una ciudad inteligente es aquella que contiene múltiples atributos, la mayoría presenta cuatro características principales: sustentabilidad, calidad de vida, urbanización e inteligencia. Esta última se define como el deseo de mejorar los aspectos sociales, ambientales y económicos de la ciudad y sus habitantes. Por lo tanto, una ciudad inteligente es

aquella que posee una visión a largo plazo sobre el mejoramiento del área urbana, con el objetivo de reducir la contaminación ambiental y propiciar una mejor calidad de vida para los ciudadanos. En este aspecto, la movilidad es uno de los temas más difíciles de enfrentar en áreas metropolitanas dado que, involucra tanto aspectos ambientales como económicos [1, 2].

La movilidad de personas y bienes es fundamental para el desarrollo de las ciudades y la sociedad. El crecimiento tanto económico como poblacional conllevan un aumento significativo en la movilidad. El gran volumen y la variedad de actividades que el transporte apoya sirven para destacar el rol positivo que desempeña en nuestra sociedad. Sin embargo, el sector de transporte tiene impactos negativos tanto en el medio ambiente, en la sociedad como en la economía, tales como: generación de contaminación, congestión en las calles, alto costo de los servicios públicos de transporte local, etc. Es la presencia de estos impactos negativos lo que genera la necesidad de gestionar y supervisar eficientemente el tránsito, el cual ha aumentado en las últimas décadas. Por lo tanto, el tópico de movilidad inteligente es uno de los temas más prometedores dentro del horizonte de una ciudad inteligente, ya que podría producir grandes beneficios para mejorar la calidad de vida de casi todas las partes que conforman una ciudad [1, 3, 4].

El desarrollo de una movilidad inteligente impacta directamente en la calidad de vida de las personas que viven en las ciudades. Es por ello que si se quiere generar acciones tendientes al diseño de una movilidad inteligente es necesario estudiar el tránsito. Un primer paso en este estudio consiste en generar un análisis del flujo de tráfico, en el cual se estudian las interacciones entre las partes que lo componen como, por ejemplo: tipo de conductor, vehículos, pasajeros/vehículo, calles, señalización, etc. El objetivo es comprender cómo se mueven los distintos medios de transporte dentro de la ciudad, pudiendo detectar problemas de congestión, entre otros, y optimizar el flujo vehicular permitiendo un movimiento más eficiente de personas y vehículos. Como es sabido, el tráfico varía de un lugar a otro, difiriendo en volumen y en tipo de vehículos que circulan, por ejemplo, una calle céntrica puede tener un gran volumen de vehículos por día, siendo en su mayoría automóviles. Es por ello que la recopilación de datos permite obtener el volumen de vehículos, así como también generar una clasificación por tipo de unidad [1, 5, 6].

Las ciudades pequeñas y medianas de países sudamericanos, que sirven como intermediarias presentan un rápido crecimiento y urbanización, en algunos casos se han desarrollado de forma desmedida y sin planificación fomentando la teoría del tránsito inducido, la cual establece que el mejoramiento y expansión de la infraestructura de accesibilidad a la ciudad conduce a fomentar un mayor uso del automóvil particular. En busca de una ciudad inteligente, se debe trabajar en políticas de transporte y desarrollo urbano, con el fin de reducir los niveles de contaminación atmosférica y de ruido [7, 8, 9, 10].

El caso de estudio presentado corresponde a la ciudad de Bahía Blanca, la cual se encuentra emplazada al sudoeste de la provincia de Buenos Aires, Argentina; es un conglomerado urbano que ocupa una superficie de 2247 km^2 y cuenta con 301572 habitantes [11] (Fig. 1), debido a estas características puede ser considerada como una urbe de mediano tamaño. Además, dado que la ciudad alberga un puerto, el mayor cen-

tro petroquímico del país y un gran parque industrial puede ser catalogada como intermedia, dado que presenta los atributos de ser un nexo entre sus alrededores [12]. La ciudad de Bahía Blanca ha presentado un constante crecimiento de su área urbana, registrándose un incremento de la extensión de la ciudad del 110% entre los años 1986 - 2014, extendiéndose en diversas direcciones. Debido al significativo crecimiento económico de la ciudad se ha generado una expansión del desarrollo urbano no planificado, lo cual se relaciona con el aumento de la movilidad mediante el uso de vehículos motorizados. En una encuesta preliminar realizada por nuestro grupo de investigación se destacó que, entre el 70 y 80 por ciento de la población local, considera que el tránsito vehicular se vio incrementado en la ciudad, ocasionando un impacto negativo sobre el ambiente [10, 13, 14].

Fig. 1. Localización de la ciudad de Bahía Blanca, al sudoeste de la provincia de Buenos Aires, Argentina.

Dado que, la ciudad de Bahía Blanca pretende convertirse en una ciudad inteligente [15], consideramos que es de importancia empezar a estudiar el flujo vehicular local de manera detallada considerando la segmentación. Por lo tanto, dado que nuestra motivación es acompañar este desarrollo hacia una movilidad inteligente [16, 17], en el presente trabajo mostramos los resultados alcanzados hasta el momento acerca de la caracterización de la flota vehicular en el microcentro de la ciudad. Para lo cual se siguió una metodología de conteo y segmentación manual a través de la visualización de videos filmados en tres rangos horarios (mañana, mediodía y tarde) en un mismo día

entresemana de los meses de enero y marzo (pre-COVID-19) del año 2020, en cuatro puntos representativos del microcentro.

El objetivo principal del presente trabajo es generar datos confiables que serán en un futuro utilizados en el modelado de la dispersión de las emisiones generadas por fuentes móviles en el microcentro de la ciudad de Bahía Blanca, y contribuirán con las autoridades locales para la toma de decisiones.

2 Metodología

El estudio de la caracterización de la flota vehicular de una ciudad brinda información esencial que permite generar políticas y normativas con el fin de mejorar la movilidad. Además, una correcta segmentación del parque automotor es necesaria para estimar las emisiones locales debidas al tránsito, facilitando el control de los niveles de calidad de aire [18].

El presente trabajo se centra en el estudio de la flota vehicular (segmentación) y flujo de tránsito en cuatro puntos estratégicos del microcentro de la ciudad de Bahía Blanca. El actual análisis se realiza para dos periodos del año, en tres momentos del día: mañana, mediodía y tarde, considerando estos como los momentos de mayor tráfico. Con el fin de estudiar arterias de alta circulación en horarios pico, se seleccionan cuatro localizaciones estratégicas pudiéndose, en un futuro, analizar más. Dichos puntos se enumeran según se muestra en la Figura 2, siendo:

- Punto 1 (P1) la intersección entre calles Chiclana y Donado,
- Punto 2 (P2) la intersección entre calles Brown y Donado,
- Punto 3 (P3) la intersección entre calles Brown y O´higgins,
- Punto 4 (P4) la intersección entre calles Chiclana y O´higgins,

En cada uno de los puntos seleccionados se filmaron 3 videos cortos por día, de aproximadamente 7 cambios de semáforo por arteria, equivalentes a unos 7 minutos. En cada locación se obtuvo un video en horas de la mañana (8 am), otro al mediodía (12 pm) y un último a las 7 pm, siendo estos horarios los considerados como de mayor afluencia al microcentro de la ciudad.

La confección de los videos tuvo lugar el 7 de enero y el 9 de marzo del 2020 (pre-COVID-19). Las fechas fueron seleccionadas con el fin de presentar los cambios por estacionalidad y la actividad de un día entresemana. Como fue mencionado anteriormente el mes de enero es, en la ciudad de Bahía Blanca, un mes en el cual se produce el receso escolar y de muchas instituciones públicas, lo que conlleva una merma en el tránsito local, tal es así que el transporte público presenta bajas frecuencias de circulación. Por otro lado, en el mes de marzo comienza el ciclo lectivo escolar, así como también diversas actividades que incrementan el flujo vehicular. Esto es parte inicial de un trabajo que seguirá durante el año, con el fin de obtener una visión global de la fluctuación anual del flujo vehicular.

El material fílmico se generó con una cámara digital Samsung ST68 compacta de 16.1 Mega pixeles, obteniendo videos de resolución 720p (HD) - 1280 x 720 pixeles.

Las grabaciones fueron realizadas desde la vereda de una de las esquinas de cada intersección, la cual permitió obtener una visión completa del flujo vehicular de las dos arterias que componen el cruce (Fig. 3). Luego se procedió a realizar el conteo y segmentación del tráfico, lo que implica contar e identificar vehículos que pasan por un punto en el intervalo de tiempo del video (7 min aproximadamente), los detalles se explican en las siguientes secciones. Según la literatura este intervalo puede variar entre 24 horas por día, 365 días al año, a cinco minutos en una hora pico [19]. El conteo del tránsito es un dato base en el campo de estudio de la ingeniería del tránsito, tal es así que permite determinar el tránsito promedio diario en un determinado segmento de la calle, identificar en qué momento del día/mes/año ocurre el mayor volumen de tráfico, calcular la cantidad de kilómetros recorridos, etc. Los recuentos anuales o trimestrales permiten monitorear el nivel de congestión, evaluando si se está convirtiendo en un problema, con el fin de tomar medidas correctivas [19].

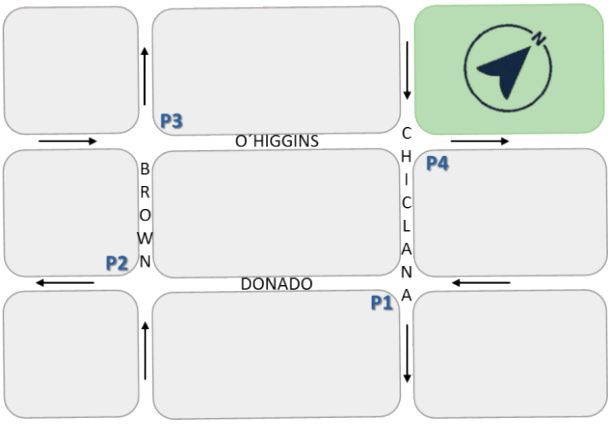

Fig. 2. Localización de las cuatro intersecciones donde se realizaron las filmaciones en el microcentro de la ciudad de Bahía Blanca, Argentina.

Fig. 3. Vista panorámica obtenida en las grabaciones de cada intersección en evaluación.

2.1 Segmentación de la flota por tipo de vehículo y análisis de la relación del flujo vehicular en cada intersección.

En la etapa inicial, los videos se observan por primera vez uno a uno, generando el conteo manual de la cantidad y tipo de vehículo que transita, obteniendo la catalogación del parque automotor en cada intersección, por día y hora. Las categorías en las cuales se desglosa la flota vehicular corresponden a: motocicletas, autos particulares (tipo sedán), camionetas, transporte de carga liviana y colectivos.

La segmentación se realiza de forma manual, dado que se pueden obtener buenos resultados con bajo margen de error, comparando resultados automatizados provenientes de softwares que detectan el largo del vehículo, lo cual en el presente trabajo no se realiza, sino que la categorización es por tipo de vehículo, permitiendo entonces un fácil reconocimiento [20].

Una vez obtenida la cantidad de unidades que contiene cada segmento, se utiliza la ecuación (1) para conseguir la cantidad de vehículos de cada categoría, que transita por cada arteria por minuto, en el día y hora especificados. Para ello se considera el tiempo que dura la filmación, el cual oscila entre 6 y 8 minutos.

$$V_{a,b} = \frac{U_{a,b}}{t_b} \tag{1}$$

Siendo:

$V_{a,b}$ la cantidad de vehículos de la categoría a que circulan por minuto por la arteria b;

$U_{a,b}$ la cantidad de unidades de la categoría a que circularon por la arteria b capturados en el video;

t_b el tiempo de duración del video, en minutos.

En esta sección se utiliza el análisis de la varianza (ANOVA simple) sobre los datos obtenidos con el fin de conocer si existen diferencias significativas del flujo vehicular primero entre los horarios de medición y segundo entre las intersecciones seleccionadas. Esto permite evaluar si el flujo en la cuadra del microcentro bahiense analizada es constante o varía significativamente. El estudio ANOVA se implementa usando el software InfoStat (http://www.infostat.com.ar/), con un p=0.05, y para las comparaciones múltiples se aplica el test de Fisher, el cual es adecuado para encontrar igualdades. Recordar que los puntos de estudio se eligieron porque tienen un comportamiento equivalente.

Como resultado de esta sección, se obtiene la categorización por tipo de vehículo en las localizaciones estudiadas, permitiendo evaluar la clase que más frecuentemente circula por cada intersección en cada horario y época.

2.2 Segmentación de la flota vehicular por antigüedad.

Una segunda visualización de las capturas filmográficas permite generar una segmentación aproximada por antigüedad, a través de la detección de la chapa patente identificatoria de cada unidad. Específicamente, en los videos se busca detectar el formato de la chapa patente, colores y forma, y en caso de ser posible la letra con la que comienza. Debido a que es muy difícil la correcta visualización del formato de la chapa

patente de las motos, estas no fueron consideradas en la segmentación, quedando entonces las categorías: autos particulares (tipo sedán), camionetas, transporte de carga liviana y colectivos.

En la Argentina, las chapas identificatorias de los vehículos han sufrido transformaciones con el paso de los años (Fig. 4). A partir del 1º de enero de 1995, se incorporó un nuevo sistema de patentamiento, el cual estableció que los dominios vehiculares estarían conformados por 3 letras iniciales y tres números, aquellos vehículos nuevos cuya inscripción inicial fuera después del 1º de enero de 1995 se le fueron otorgados dominios desde la patente *AAA-000*. En cuanto a los vehículos de modelos menores a 1995 se les solicitó el reempadronamiento de los mismos en el Registro Nacional de la Propiedad Automotor, otorgándoles los dominios a partir de *RAA-000*. Dado que, se preveía que en 2017 se alcanzaría el máximo número de combinaciones se optó por cambiar nuevamente el sistema. En 2014 se presentó una nueva patente, la cual sería única para todos los países que conforman el Mercado Común del Sur (Mercosur). Sin embargo, en la Argentina comenzó a implementarse recién en 2016 el patentamiento de vehículos nuevos, pero sin el reempadronamiento de los automotores usados que mantuvieron su patente original. Esta nueva chapa tiene características diferentes a la implementada con anterioridad dado que, cambia su forma, color y contiene una letra más, siendo del formato *AA-000-AA*.

Fig. 4. Evolución de la chapa patente de los automotores en la República Argentina desde 1964 a la actualidad.

Una vez que se generan los datos es posible hacer una estimación real de la antigüedad del parque automotor local. A su vez, puede realizarse la comparativa entre la antigüedad del parque local y lo registrado a nivel nacional, teniendo en cuenta que este estudio se restringe al microcentro de Bahía Blanca.

3 Resultados y discusiones

En esta sección se presentan los resultados obtenidos, tanto globales como segmentados por día de recolección de datos, localización y categorización seleccionadas. Cabe destacar que los resultados presentados se encuentran acotados, es decir, son representativos de dos momentos del año en tres horarios considerados de alta circulación. El fin fue obtener un primer análisis de la cantidad, antigüedad y tipo de vehículo que circula por el microcentro de la ciudad de Bahía Blanca, para avanzar en un futuro cercano con estudios más profundos.

3.1 Cantidad de unidades contabilizados en cada intersección por tipo de vehículo.

Las Figuras 5 y 6 corresponden a la cantidad de unidades de cada tipo de vehículo por intersección monitoreada, en los días y horarios seleccionados. Se puede observar en la Figura 5, correspondiente al 7 de enero de 2020, la gran predominancia del automóvil particular, entre un 60% y un 75% de los vehículos que transitaron por las intersecciones seleccionadas pertenecen a este tipo de unidades. En las esquinas denominadas P1 y P2 se puede ver que el segundo segmento mayoritario son las camionetas o pick ups, con un 10% de representatividad mientras que, en las intersecciones P3 y P4 son las motocicletas con un 14% de presencia. En la Figura 6, correspondiente al 9 de marzo de 2020, también se visualiza la gran predominancia del automóvil sedan (60-75%), seguido de las motocicletas (10-15%) y camionetas (10-12%).

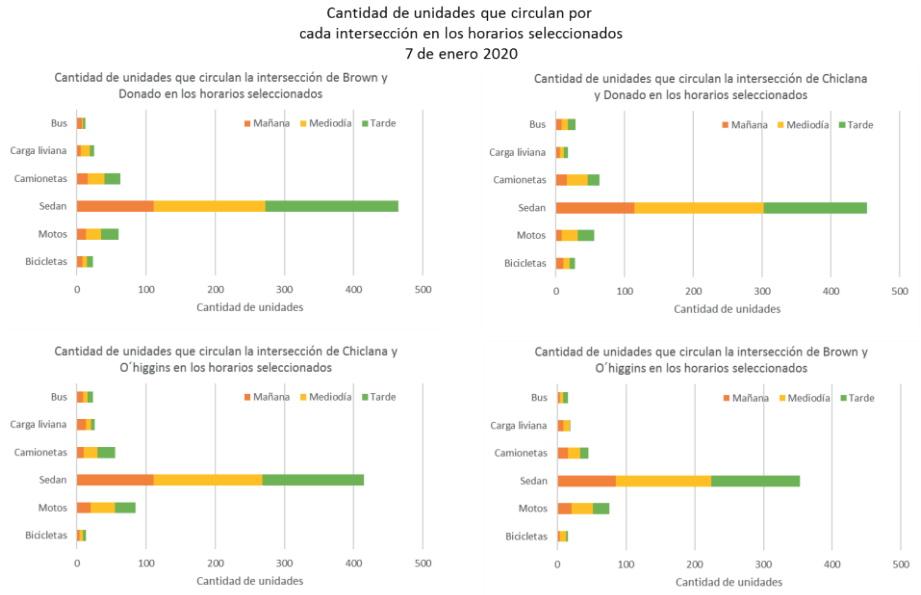

Fig. 5. Cantidad de unidades y tipo de vehículo que circularon por cada intersección seleccionada en los horarios monitoreados el día 7 de enero de 2020.

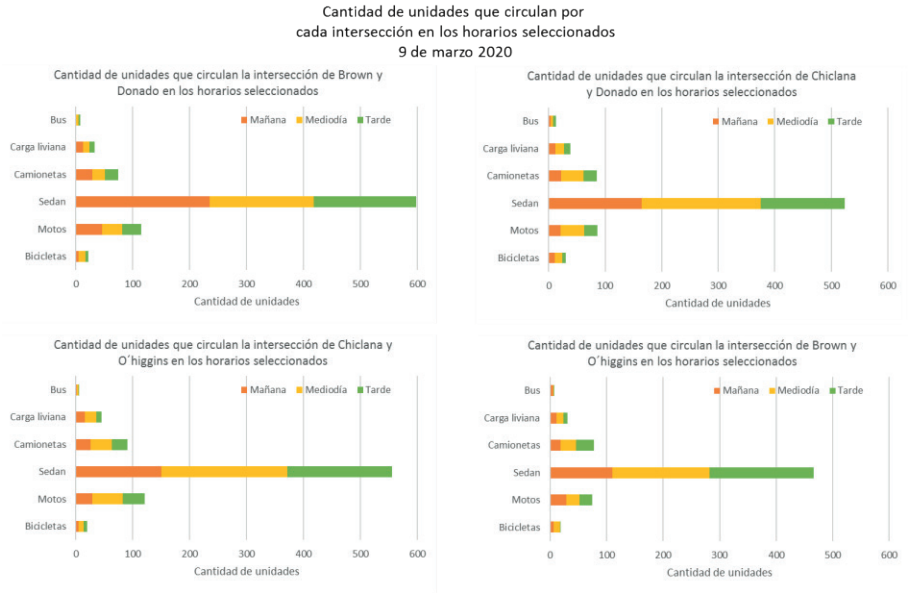

Fig. 6. Cantidad de unidades y tipo de vehículo que circularon por cada intersección seleccionada en los horarios monitoreados el día 9 de marzo de 2020.

De la comparativa entre ambas fechas podemos concluir que la tendencia es la misma en cuanto a porcentaje de cada tipo de vehículo que circula por las intersecciones estudiadas. En cada horario también se observa la misma predominancia. Es por ello, que se concluye que el automóvil particular es el vehículo que más presencia tiene en el tránsito local estudiado. No obstante, se halló una gran diferencia entre ambos periodos estudiados para el flujo vehicular en todas las categorías (Tabla 1). En enero, se obtuvo un promedio diario de 1235 automóviles tipo sedán por hora mientras que para el mes de marzo fue de 1513, lo que resulta en un incremento del 22,5%. Para la categoría motos y camionetas se contabilizó un aumento del 39% en el mes de marzo respecto de enero, mientras que para carga liviana hubo un incremento desde 65 unidades por hora a 104 (60%) para el mes de mayor actividad evaluado.

Tabla 1. Cantidad de unidades por hora promedio que transitan por el microcentro de la ciudad de Bahía Blanca en hora pico, para los meses de enero y marzo (pre-COVID-19) del 2020.

Tipo de vehículo	Cantidad de unidades por hora	
	Enero	Marzo
Sedan	1235	1513
Motos	203	280
Camionetas	166	232
Carga Liviana	65	104

3.2 Análisis de relación entre horarios e intersecciones seleccionadas.

Las Figura 7 y 8 presenta las salidas obtenidas del software InfoStat, en las cuales se muestran los resultados arrojados utilizando el método de comparación de Fisher. En la Figura 7 se visualiza la salida correspondiente al día 7 de enero de 2020 mientras que, en la Figura 8 la del 9 de marzo de 2020.

Del análisis de la salida obtenida para enero se muestra que existe una diferencia significativa entre los horarios y puntos donde se realizaron los videos. En el caso del horario evaluado se puede concluir que en el día de enero hay menos tránsito en horas de la mañana, mientras que no hay diferencias significativas entre el mediodía y la tarde. En cuanto a los sitios observados, se puede analizar que la mayor diferencia se da en el punto P3, mientras que los restantes no muestran diferencias significativas. Por otro lado, de la salida correspondiente al mes de marzo se establece que no existen diferencias significativas entre los horarios e intersecciones seleccionadas.

Fig. 8. Salida obtenida del software estadístico InfoStat para los datos del día 9 de marzo de 2020, ciudad de Bahía Blanca, usando el método de comparación de Fisher.

Además, con los datos obtenidos y haciendo uso nuevamente del método de comparación de Fisher se habilita la posibilidad de realizar un estudio entre los dos meses analizados, con el fin de visualizar si existen diferencias significativas entre los distintos horarios considerados (Fig. 9). Del análisis de la salida obtenida por InfoStat se establece que existen diferencias significativas entre los meses en estudio. Además, también se presentan contrastes entre los diferentes horarios contemplados.

Por último, se pueden utilizar los datos para generar una media total del flujo vehicular por minuto en la cuadra del microcentro bahiense analizada, para cada mes contemplado. Se obtuvo un flujo de 28,83 vehículos totales por minuto que transitan el área de estudio seleccionada para el mes de enero mientras que, para marzo la media fue de 35,71. Lo cual significa un incremento del flujo vehicular total del 24% en marzo.

3.3 Antigüedad de la flota vehicular analizada mediante la clasificación según chapa patente.

Se generó la segmentación de la flota vehicular local según el tipo de chapa patente, con el fin de presentar el análisis de la antigüedad del parque automotor de la ciudad. Para realizar este análisis se agruparon todos los datos recolectados en ambos días y en los diferentes horarios, obteniendo de esta manera una visión más global de la edad de los vehículos que transitan por los puntos seleccionados del microcentro de la ciudad de Bahía Blanca. En la Tabla 2 se presentan la cantidad de vehículos que comprenden cada segmento etario, según el recuento realizado mediante la observación de las filmaciones generadas.

Del análisis de la Tabla 2 se obtiene que el 25% de los vehículos observados que transitaron por el microcentro de la ciudad en los días y horarios seleccionados tienen menos de 4 años de antigüedad; un 71% tienen entre 4 y 20 años, restando solo un 4% para aquellas unidades mayores a 20 años.

Tabla 2. Cantidad de vehículos por tipo y antigüedad. Se contemplaron todas las unidades que registraron su paso por los puntos monitoreados –P1, P2, P3 y P4– para ambas épocas en evaluación –enero y marzo 2020–.

Tipo de vehículo	Antigüedad	Cantidad de unidades
Sedan	Menor a 4 años	895
	Entre 4 y 20 años	2809
	Mayor a 20 años	122
Pick up	Menor a 4 años	198
	Entre 4 y 20 años	327
	Mayor a 20 años	36
Carga Liviana	Menor a 4 años	57
	Entre 4 y 20 años	103
	Mayor a 20 años	8
Bus	Menor a 4 años	23
	Entre 4 y 20 años	158
	Mayor a 20 años	0

Si se realiza una comparativa entre los resultados obtenidos de antigüedad y la media nacional registrada según la Asociación de Fábricas Argentinas de Componentes (AFAC) [21], se obtiene la Figura 10. En la misma se puede visualizar que, según los datos muestreados, el parque automotor local que transita el microcentro de la ciudad de Bahía Blanca es un 17% más nuevo en comparación con la media nacional. Este resultado es coherente con lo reportado por Grassi et al [22].

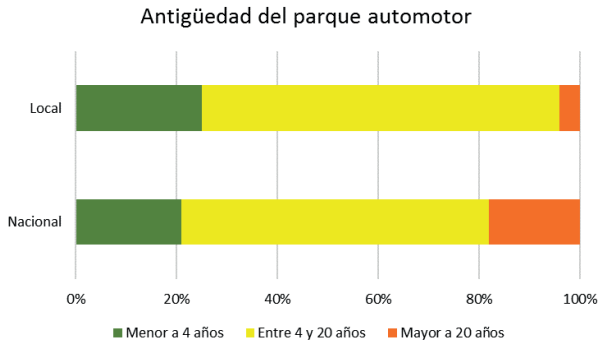

Fig. 10. Comparativa entre la antigüedad de la flota vehicular nacional y la local.

4 Conclusiones

El estudio del flujo vehicular y su categorización, realizado en la ciudad de Bahía Blanca en determinados puntos seleccionados del microcentro en enero y marzo de 2020, nos permite concluir que el vehículo con mayor predominancia en circulación es

el denominado sedan o automóvil particular. Por otro lado, pudo determinarse que en el mes de enero se encuentran algunas diferencias significativas entre los horarios e intersecciones seleccionadas, mientras que en el mes de marzo no se observan estas diferencias. Esto es coherente con el tipo de actividad de época estival de vacaciones (mes de enero) y los movimientos normales del inicio de clases (mes de marzo pre-COVID-19). En cuanto a la antigüedad del parque automotor de la ciudad se pudo determinar que el mismo es un 17% más nuevo que el reportado a nivel nacional.

La ciudad de Bahía Blanca se perfila desde la esfera gubernamental como una ciudad tendiente a convertirse en una ciudad inteligente. Para ello, el análisis del flujo vehicular exhibido en este trabajo sirve como puntapié para la implementación de una gestión inteligente del tráfico. Si en un futuro se involucraran herramientas de análisis, simulación, optimización y predicción capaces de medir el flujo vehicular se podría conseguir un volumen de datos que se usará en la implementación de modificaciones del tránsito vehicular, la semaforización y las emisiones de contaminantes. De esta manera la ciudad de Bahía Blanca se convertiría en una más agradable para vivir y transitar tanto vehicular como peatonalmente.

Lo presentado en este trabajo forma parte de un estudio mucho más amplio, de modo que se tiene previsto continuar con las filmaciones, en más momentos del año y hacerlo extensivo a otras localizaciones de la ciudad de Bahía Blanca. Si bien resulta dificultoso realizar estas tareas de modo manual, su importancia justifica el esfuerzo ya que este estudio debería ser realizado de manera permanente, con el objetivo de generar datos sobre la evolución del parque automotor local.

Agradecimientos

Agradecemos a la Comisión de Investigaciones Científicas (CIC), Provincia de Buenos Aires, por la financiación otorgada a esta investigación a través del proyecto PIT-AP-BA titulado "Logística y optimización del transporte". Adicionalmente, este trabajo fue parcialmente financiado por la Universidad Nacional del Sur (UNS), Bahía Blanca, Argentina, [PGI 24/M158], proyecto titulado “Química computacional aplicada al descubrimiento de nuevos materiales poliméricos, nuevos fármacos y a problemas ambientales”.

Resumen. La ciudad de Bahía Blanca cuenta con uno de los puertos más importantes de Argentina, así como también con gran cantidad de conexiones ferroviarias que atraviesan el ejido urbano. Por otro lado, la aeroestación civil Comandante Espora también forma parte de la ciudad, en la cual aterrizan y despegan, principalmente, vuelos comerciales de cabotaje. Tanto el transporte marítimo, como el ferroviario y aéreo son considerados fuentes móviles no carreteras de emisión de contaminantes y gases de efecto invernadero. La mayoría del transporte no carretero funciona utilizando combustible Diesel, es por ello que son considerados productores de gran cantidad de emisiones de NO_x, entre otros gases, y deben ser incluidos en los análisis preliminares de contaminación de las ciudades. Cabe destacar que un inventario de emisiones preciso y actualizado sobre el transporte no carretero es esencial, dado que, permite disponer de información confiable con el fin de ser utilizada en la mejora de las políticas de calidad de aire. Por lo tanto, el presente trabajo muestra los resultados obtenidos de la confección del inventario de emisiones del transporte no carretero de la ciudad de Bahía Blanca para el año 2018. Además, se realiza una comparativa con datos existentes del año 2013 para el tipo de transporte en estudio, concluyendo que todas las emisiones disminuyen en 2018, en concordancia con la caída de la actividad económica.

Palabras claves: Inventario de emisiones, Bahía Blanca, Transporte no carretero.

1 Introducción

Un inventario de emisiones contabiliza los gases emitidos a la atmósfera durante un período de tiempo determinado -en general un año calendario- para un territorio determinado. Es por ello que debe definirse, como punto de partida, el tipo de fuente que se va a considerar en el estudio y los contaminantes que se desean estimar [1, 2].

El caso de estudio presentado corresponde a la ciudad de Bahía Blanca para el año 2018. La urbe se encuentra emplazada al sudoeste de la provincia de Buenos Aires, Argentina, considerándose un punto estratégico que permite una relación mercantil estrecha con el centro y el sur de la región pampeana y el norte de la Patagonia, mediante múltiples conexiones viales y ferroviarias. Cuenta con un importante puerto que constituye la vinculación de la ciudad con el exterior ya que, posibilita un fluido intercambio comercial con el resto del mundo y lo convierte en la principal estación marítima de aguas profundas de la Argentina. El transporte ferroviario se encarga prioritariamente del traslado de cereales al puerto local y de productos petroquímicos con origen en la ciudad y con destino en la Ciudad Autónoma de Buenos Aires. Por otro lado, la ciudad cuenta con la aerostación civil Comandante Espora en donde operan diferentes empresas aéreas que realizan vuelos de cabotaje [3].

Dado que, la ciudad posee toda la mencionada infraestructura de transporte no carretero es de importancia mantener un inventario de emisiones actualizado. El transporte carretero como ser, automotores, camiones, etc., ha sido reconocido como una importante fuente móvil de contaminación atmosférica mientras que se le ha prestado menor atención al control de las emisiones provenientes de fuentes móviles no carreteras [4]. Nuestra línea de investigación ha contemplado ambos tipos de fuentes móviles, es por ello que en este trabajo se presentan los datos para el transporte no carretero, y pueden encontrarse los resultados obtenidos para el sector carretero en Grassi et. al. [5].

La elaboración del presente inventario de emisiones de los segmentos no carreteros contempla el transporte aéreo, marítimo y ferroviario de la ciudad de Bahía Blanca para el año 2018. Cabe destacar que un inventario de emisiones con estimaciones precisas es esencial para mejorar las políticas sobre calidad de aire. La precisión estará dada por la disponibilidad de información sobre cantidad de operaciones de cada rubro analizado, nivel de actividad y factores de emisión [6]. Para la confección se recolectó gran cantidad de información, la cual fue recopilada de fuentes bibliográficas y de las estadísticas anuales de las diferentes entidades representativas de cada tipo de transporte. Se siguieron los lineamientos del Panel Intergubernamental para el Cambio Climático (IPCC, por sus siglas en inglés) [1], así como también se consultó el Inventario Nacional de Gases de Efecto Invernadero (GEIs) de la República Argentina [2]. Cabe destacar que también se tuvo en consideración un antecedente de inventario de emisiones para la ciudad de Bahía Blanca que data del año 2013 [7], el cual fue confeccionado por un ente gubernamental que tiene a su cargo el control y monitoreo de las industrias de la ciudad y servirá para realizar una comparativa entre los dos años.

La falta de datos actualizados y fidedignos no permite tener regulaciones claras y controles fuertes sobre las emisiones de fuentes móviles no carreteras [8]. Es por ello que el objetivo de este trabajo es generar datos confiables y actualizados sobre la estimación de las emisiones generadas por este tipo de fuentes móviles de nuestra ciudad. Para esto, se evaluaron los aportes de diversos contaminantes atmosféricos y precursores, entre los que se encuentran: monóxido de carbono (CO), dióxido de azufre (SO_2), óxidos de nitrógeno (NO_x) y compuestos orgánicos volátiles distintos al metano (COVNM). Adicionalmente, se evaluaron las emisiones de dióxido de carbono (CO_2), metano (CH_4) y óxido nitroso (N_2O), considerados GEIs. El presente inventario de emisiones de fuentes móviles no carreteras constituye una herramienta para el análisis de

emisiones históricas y futuras, que resultan de utilidad en la toma de decisiones respecto a las políticas gubernamentales y su impacto.

2 Metodología y recolección de datos

Para realizar el cálculo de las emisiones de contaminantes generadas por las fuentes seleccionadas, se utilizó la metodología de factores de emisión (FEs). Un FE es un valor representativo que trata de relacionar la cantidad de un contaminante emitido a la atmósfera con una actividad asociada con dicha liberación. Estos factores se expresan como el peso del contaminante por unidad de peso, volumen, distancia, o duración de la actividad de emisión (por ejemplo, gramos de CO emitido por litro de combustible consumido por un automóvil). Éstos facilitan la estimación de las emisiones de diversas categorías de fuentes de contaminación del aire (una categoría de fuente es un sector específico de la industria o grupo de fuentes de emisión similares). En la mayoría de los casos, estos factores de emisión son simplemente promedios de todos los datos disponibles o se han desarrollado y compilado a partir de datos de prueba en las fuentes de origen, estudios de balance de materiales y/o estimaciones de ingeniería [9].
Utilizamos un procedimiento similar al presentado por el IPCC, el cual está disponible en el documento "Directrices del IPCC de 2006 para los Inventarios Nacionales de Gases de Efecto Invernadero" [10]. La ecuación general utilizada en un inventario de emisiones se define como número (1). Donde *E* corresponde a la tasa de emisión, expresada en unidades de masa por unidad de tiempo; *A* a la tasa de actividad, y *FE* al factor de emisión, expresado en masa de contaminante emitido por unidad de actividad.

$$E = A * FE \tag{1}$$

La tasa de actividad (A) seleccionada para este estudio es el volumen de combustible consumido anualmente [m^3/(año)] por cada categoría de transporte y tipo de vehículo establecida. En cuanto a los factores de emisión usados para los casos de transporte ferroviario, marítimo y aéreo se emplearon los que propone el Inventario Nacional de Emisiones de GEIs [2]. Allí se pueden encontrar los FEs para todos los contaminantes estudiados: monóxido de carbono (CO), dióxido de azufre (SO_2), óxidos de nitrógeno (NO_x) y compuestos orgánicos volátiles distintos al metano (COVNM), así como para los GEIs estudiados: dióxido de carbono (CO_2), metano (CH_4) y óxido nitroso (N_2O). Para trabajar con los FEs seleccionados se debió realizar un correcto pasaje de unidades, recurriendo a la información del Poder Calorífico Inferior (PCI) del combustible, extraído de tablas de la página web de la Secretaría de Energía de la Nación [11], y a la densidad del combustible determinada a 15 ºC según norma ASTM D - 1298/4052, extraídos de las fichas técnicas de YPF [12, 13, 14]. Los datos propios de cada tipo de transporte fueron obtenidos de las estadísticas anuales para el 2018 de cada ente representativo del rubro. Además, fueron usados diversos datos extraídos del Inventario de Emisiones Gaseosas de Fuentes Móviles – Bahía Blanca, 2013 [7]. En los siguientes apartados se presentan los datos y metodologías seguidas para cada tipo de transporte considerado.

Por último, dado que existe un inventario de emisiones del transporte no carretero de la ciudad de Bahía Blanca para el año 2013, el cual fue considerado como base de referencia para el presente estudio, se procedió a realizar una comparación contra los resultados obtenidos para el 2018. Para ello se realizó una unificación en el uso de los factores de emisión, considerando para ambos años los presentados en este trabajo.

2.1 Transporte aéreo

En esta sección se presentan los datos relacionados con las operaciones aéreas de la aeroestación civil "Comandante Espora" de Bahía Blanca, considerando solo aquellas operaciones comerciales regulares las cuales son las que están sujetas a itinerario y horario prefijado. Se detalla el número de operaciones que tuvieron lugar a lo largo del año 2018 y los datos de actividad relacionados con el consumo de combustible.

Del Anuario Estadístico 2018 [15] de la Administración Nacional de Aviación Civil Argentina se obtuvo un resumen de las operaciones aéreas comerciales realizadas en Bahía Blanca durante el año 2018. Para hacer la clasificación por tipo de aeronave se consideró que los aviones comerciales que llegan al aeropuerto corresponden a: los Embraer ERJ-190 y los Boeing 737-700 y 737-800. Según datos recolectados de la página web oficial del aeropuerto local [16], se llega a la conclusión que el 66% de los vuelos corresponden a los Embraer ERJ-190, un 26% a los Boeing 737-800 y 8% restante a los Boeing 737-700. Siguiendo con la clasificación que fue utilizada en el Inventario de Emisiones Gaseosas de Fuentes Móviles – Bahía Blanca, 2013 [7], podemos considerar a los Embraer ERJ-190 como aeronaves medianas, mientras que los Boeing serán considerados aeronaves pesadas. La cantidad de operaciones comerciales por tipo de aeronave se presenta en la Tabla 1.

Tabla 1. Cantidad de operaciones por cada tipo de aeronave durante el año 2018 en la aeroestación de Bahía Blanca.

Tipo de aeronave	Cantidad de operaciones
Aeronaves Pesadas	1769
Aeronaves Medianas	3435

Es necesario aclarar que el consumo de combustible "operativo" de una aeronave se corresponde con lo reportado por el IPCC como consumo por LTO (landing-take off), y el consumo por "rodaje" es debido al modo crucero [17]. En la Tabla 2 se presentan los datos de actividad para cada tipo de aeronave, que fueron extraídos del Inventario de Emisiones Gaseosas de Fuentes Móviles – Bahía Blanca, 2013 [7]. Luego, en la Tabla 3, se muestran los resultados del consumo total de combustible, mientras que los FEs correspondientes a la aviación comercial son enumerados en las Tablas 4 y 5.

Tabla 2. Combustible consumido en cada operación tanto en rodaje como en estado operativo por tipo de aeronave, expresada en [m^3/operación], para Bahía Banca, año 2018.

Tipo de aeronave	Consumo Operativo [m^3/operación]	Consumo en Rodaje [m^3/operación]
Aeronaves Pesadas	0,85	0,13
Aeronaves Medianas	0,45	0,07

Tabla 3. Combustible consumido anualmente por tipo de aeronave tanto en rodaje como en estado operativo, expresado en [m^3/año], para Bahía Banca, año 2018.

Tipo de aeronave	Consumo Operativo [m^3/año]	Consumo en Rodaje [m^3/año]	Consumo Total [m^3/año]
Aeronaves Pesadas	1503,96	230,02	1733,97
Aeronaves Medianas	1545,59	240,42	1786,01
TOTAL	3049,55	470,44	3519,98

Tabla 4. FEs de contaminantes basados en el tipo de combustible consumido por el transporte aéreo [kg de contaminante emitido/m^3 de combustible consumido].

Tipo de combustible	CO	NO_x	SO_2	COVNM
Aerokerosene	3,52	8,82	1,60	1,76

Tabla 5. FEs de gases de efecto invernadero basados en el consumo de combustible del transporte aéreo [kg de GEI emitido/m^3 de combustible consumido].

Tipo de combustible	CO_2	CH_4	N_2O
Aerokerosene	2522,52	0,018	0,071

Como parte de la metodología usada para el cálculo de las estimaciones de emisiones por parte del transporte aéreo se utilizó la ecuación 3.6.1 que se presenta en las "Directrices del IPCC de 2006 para los Inventarios Nacionales de GEIs" [17], la cual es mostrada en este trabajo como número (2).

$$E = Consumo\ de\ Combustible * FE \quad (2)$$

2.2 Transporte marítimo

En el presente apartado se consideran las entradas y salidas del puerto de aquellos buques de gran porte, la flota pesquera y remolcadores. En el caso de buques de gran porte (de navegación), se considera para el cálculo, el combustible consumido para la navegación en un trayecto de 10 km de entrada y 10 km de salida del puerto, más el consumo de combustible empleado en servicios durante la espera y estadía.

Los datos de cantidad de buques de navegación fueron extraídos de las estadísticas del Consorcio de Gestión del Puerto de Bahía Blanca (CGPBB) [18]. En el caso de pesqueros y remolcadores se mantuvo la misma cantidad que la utilizada en el Inventario de Emisiones Gaseosas de Fuentes Móviles – Bahía Blanca, 2013 [7], dado que este dato no se encuentra en las estadísticas mencionadas y no recibimos respuesta a las consultas sobre este dato (Tabla 6).

Tabla 6. Cantidad de embarcaciones, por tipo, durante el año 2018 en el Puerto de Bahía Blanca.

Tipo de embarcación	Cantidad
Buques de Navegación	644
Flota de Remolcadores y Pesqueros	23*

* dato tomado del año 2013

Los datos de actividad de ambas categorías fueron extraídos del Inventario de Emisiones Gaseosas de Fuentes Móviles – Bahía Blanca, 2013 [7], los mismos se presentan, de manera resumida y ordenada, en las Tablas 7, 8 y 9. Se consideró que el consumo promedio de fuel-oil para buques de gran porte es de 25 t/día, a una velocidad de 22,2 km/h. Los cálculos de consumo de combustible se realizan en base a los 20 kilómetros recorridos en entrada y salida del puerto. Además, el consumo de gas-oil empleado en servicios para los buques de navegación es de aproximadamente de 3 t/día, considerando un tiempo de espera y estadía en el puerto de 2,5 días. En el caso de la flota pesquera y de remolcadores, el consumo de gas-oil es de 200 litros/semana y se considera que el tiempo de actividad es de 48 semanas al año (4 horas por día durante los 365 días del año). Finalmente, los FEs correspondientes al transporte marítimo son enumerados en las Tablas 10 y 11.

Tabla 7. Combustible consumido por buques durante navegación, [m^3/año], para Bahía Banca, año 2018.

Tipo de Embarcación	Combustible utilizado	Embarcaciones al año	Actividad [km]	Consumo [m^3/km]	Consumo [m^3/año]
Buques de Navegación	Fuel-Oil	644	20	0,048	618,24

Tabla 8. Combustible consumido por buques durante su estadía para servicios, [m^3/año], para Bahía Banca, año 2018.

Tipo de Embarcación	Combustible utilizado	Embarcaciones al año	Estadía [días]	Consumo [m^3/día]	Consumo [m^3/año]
Buques de Navegación	Gas-Oil	644	2,5	3,41	5490,10

Tabla 9. Combustible consumido por la flota pesquera y remolcadores, [m^3/año], para Bahía Banca, año 2018.

Tipo de Embarcación	Combustible utilizado	Embarcaciones al año	Actividad [semanas]	Consumo [m^3/semana]	Consumo [m^3/año]
Pesqueros y Remolcadores	Gas-Oil	23	48	0,20	220,80

Tabla 10. FEs de contaminantes basados en el tipo de combustible consumido por el transporte marítimo [kg de contaminante emitido/m^3 de combustible consumido].

Tipo de combustible	CO	NO_x	SO_2	COVNM
Fuel – Oil	39,59	59,38	7,84	7,91
Gas – Oil	36,55	54,82	1,32	7,31

Tabla 11. FEs de gases de efecto invernadero basados en el tipo de combustible consumido por el transporte marítimo [kg de GEI emitido/m^3 de combustible consumido].

Tipo de combustible	CO_2	CH_4	N_2O
Fuel – Oil	3064,42	0,27	0,079
Gas – Oil	2708,35	0,25	0,073

La metodología usada para el cálculo de las estimaciones de emisiones por parte del transporte marítimo sigue la ecuación 3.5.1 que se presenta en las "Directrices del IPCC de 2006 para los Inventarios Nacionales de GEIs" [17], la cual es mostrada en este trabajo como número (3). Donde *a* se relaciona con el tipo de combustible consumido y *b* con el tipo de embarcación considerada.

$$E = \sum Consumo\ de\ Combustible_{a,b} * FE_{a,b} \quad (3)$$

2.3 Transporte ferroviario

Dentro de este segmento se tuvieron en cuenta los trenes de transporte de carga y de pasajeros, que circulan en un radio de 10 km de la ciudad. La información recolectada contabiliza arribos, partidas y maniobras de operaciones. Se trabajó con los datos actualizados del año 2018, para los trenes de carga y las locomotoras de maniobra. Mientras que, para los trenes de pasajeros se considera la noticia emitida por uno de los diarios locales en marzo de 2019 [19], en donde se menciona la cantidad de pasajeros y formaciones que transitan semanalmente por la ciudad. En las Tablas 12 y 13 se presentan los datos de actividad recolectados, cantidad de operaciones anuales y tiempo de funcionamiento de las locomotoras de maniobra, junto a los respectivos consumos de combustible. Además, los FEs correspondientes al transporte ferroviario son enumerados en las Tablas 14 y 15.

Tabla 12. Combustible consumido en arribos y partidas de trenes de carga y pasajeros, [m^3/año], para Bahía Banca, año 2018.

Tipo de formación	Combustible utilizado	Formaciones al año	Consumo [m^3/operación]	Consumo [m^3/año]
Tren de carga	Gas - Oil	4055	0,05	202,75
Tren de pasajeros	Gas - Oil	313	0,03	9,39

Tabla 13. Combustible consumido por locomotoras de maniobra, [m^3/año], para Bahía Banca, año 2018.

Tipo de formación	Combustible utilizado	Tiempo de funcionamiento [horas]	Consumo [m^3/hora]	Consumo [m^3/año]
Locomotora de maniobra	Gas - Oil	16506	0,013	214,58

Tabla 14. FEs de contaminantes basados en el tipo de combustible consumido por el transporte ferroviario [kg de contaminante emitido/m^3 de combustible consumido].

Tipo de combustible	CO	NO_x	SO_2	COVNM
Gas – Oil	36,55	43,86	1,32	7,31

Tabla 15. FEs de gases de efecto invernadero basados en el tipo de combustible consumido por el transporte ferroviario [kg de GEI emitido/m^3 de combustible consumido].

Tipo de combustible	CO_2	CH_4	N_2O
Gas – Oil	2708,35	0,15	1,04

Para el transporte ferroviario se seleccionó la ecuación 3.4.1 que se presenta en las "Directrices del IPCC de 2006 para los Inventarios Nacionales de GEIs" [17], la cual es presentada a continuación con el número (4). Donde j se relaciona con el tipo de combustible consumido.

$$E = \sum Consumo\ de\ Combustible_j * FE_j \quad (4)$$

3 Resultados y discusiones

Luego de realizar los cálculos correspondientes, según las metodologías presentadas previamente, se presenta en la tabla 16 el resumen de todos los resultados obtenidos por tipo de transporte y compuesto gaseoso estudiado. También se muestran los resultados de las emisiones anuales de cada contaminante (Fig. 1) y de cada gas de efecto invernadero (Fig. 2) en forma gráfica para todos los tipos de transportes.

De los resultados obtenidos puede observarse que el mayor porcentaje de gases contaminantes, en las categorías de transporte seleccionadas, corresponden a los NO_x con

un 54,33%. Seguido de las emisiones de CO (35,52%), COVNM (7,61%) y por último los SO_2 (2,53%). En cuanto a gases de efecto invernadero son predominantes las emisiones de CO_2 (99,99%). Por otro lado, se evidencia que el transporte marítimo genera el mayor aporte de todos los gases contaminantes (CO, NO_x, COVNM y SO_2) y también de los gases de efecto invernadero: CO_2 y CH_4, mientras que el ferroviario generó mayor cantidad de emisiones de N_2O para la ciudad de Bahía Blanca durante el año de estudio 2018. Esto se debe a que el transporte marítimo es el que, según lo reportado, consume mayor cantidad de combustible. Si bien la mayor proporción viene dada por el gas-oil, cabe destacar que los buques suelen quemar combustibles más pesados, como el fuel-oil, en sus motores de propulsión [4]. Es por ello que no sorprende que el transporte marítimo sea el que más aporte de emisiones genere, y que más aún las emisiones de NO_x sean las más predominantes como se ha reportado en otros lugares del mundo [20, 21, 22]. Dado que estamos analizando la contribución que tienen los diferentes tipos de transporte no carretero en la ciudad de Bahía Blanca debemos recordar que no consideramos, por ejemplo, las emisiones que los buques realizan en alta mar, sino las generadas en un pequeño recorrido de ingreso y egreso al puerto, además de la estadía en el mismo. Mas aún, debido a que la estadía se estima como 2,5 días en promedio, esta representa la mayor cantidad de emisiones.

Dado que existe un antecedente previo en la ciudad de inventario de emisiones para transporte no carretero, el cual fue considerado como base de referencia para el presente estudio, se presentan en las Figuras 3 y 4 la comparativa entre el año 2013 y el 2018 de manera gráfica mientras que, la tabla 17 contiene los resultados numéricos.

Tabla 16. Resultados finales obtenidos de emisiones de contaminantes y GEIs por tipo de transporte en la ciudad de Bahía Blanca, para el año 2018, en [t/año].

Gas contaminante o GEI	Transporte Aéreo	Transporte Marítimo	Transporte Ferroviario
CO	12,42	233,21	15,72
NO_x	31,05	349,82	18,86
COVNM	6,21	46,64	3,14
SO_2	5,63	12,42	0,57
CO_2	8.879,23	17.361,69	1164,54
CH_4	0,06	1,63	0,07
N_2O	0,25	0,47	0,45

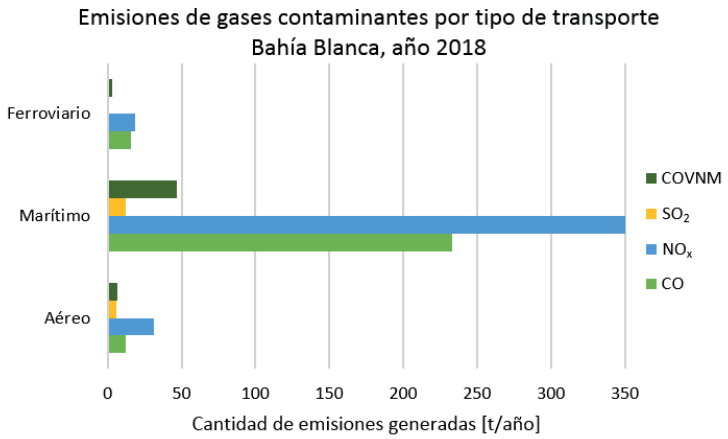

Fig. 1. Cantidad de emisiones de gases contaminantes generadas por tipo de transporte en la ciudad de Bahía Blanca, para el año 2018, en [t/año].

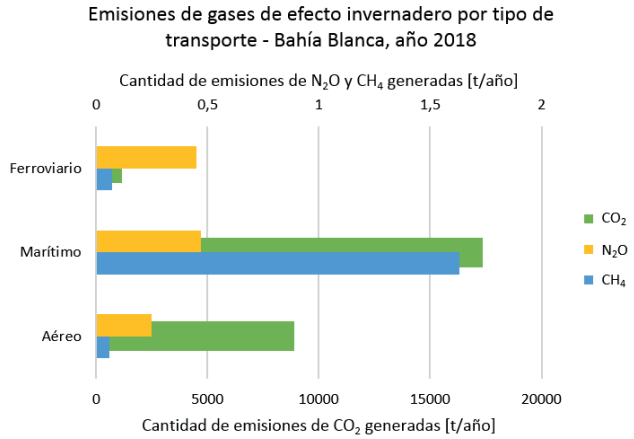

Fig. 2. Cantidad de emisiones de gases de efecto invernadero generadas por tipo de transporte en la ciudad de Bahía Blanca, para el año 2018, en [t/año].

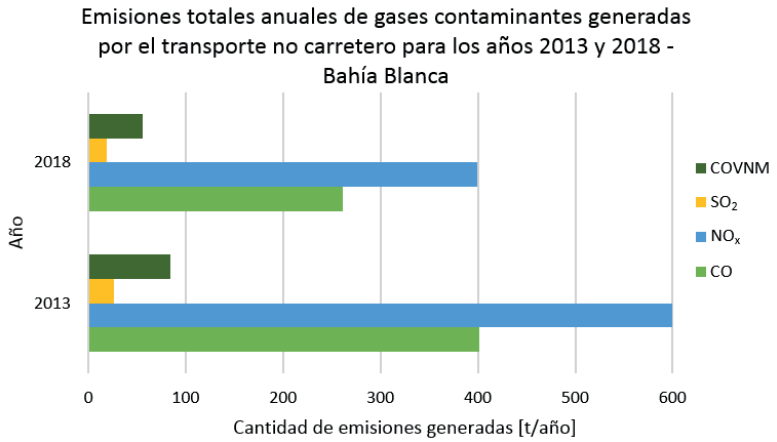

Fig. 3. Cantidad de emisiones totales anuales de los gases contaminantes estudiados para los años 2013 y 2018, englobando los tres tipos de transporte analizados en la ciudad de Bahía Blanca, en [t/año].

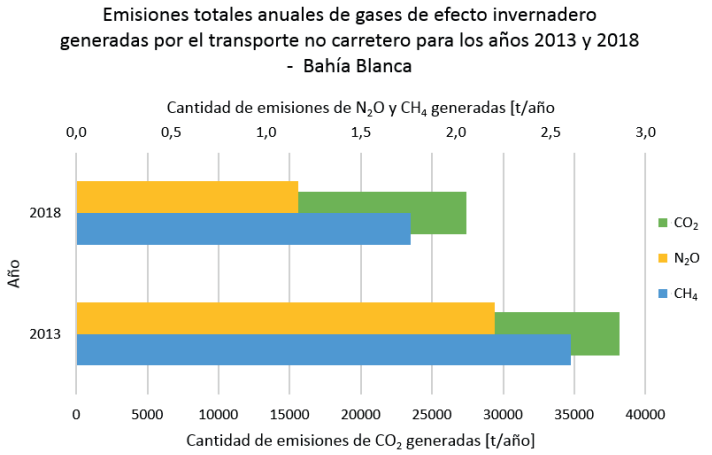

Fig. 4. Cantidad de emisiones totales anuales de los gases de efecto invernadero estudiados para los años 2013 y 2018, englobando los tres tipos de transporte analizados en la ciudad de Bahía Blanca, en [t/año].

Tabla 17. Resultados de emisiones totales de contaminantes y GEIs del segmento de transporte no carretero de la ciudad de Bahía Blanca, para los años 2013 y 2018, en [t/año].

Gas contaminante o GEI	2013	2018
CO	401,84	261,35
NO_x	599,50	399,73
COVNM	84,22	55,99
SO_2	25,93	18,62
CO_2	38163,21	27405,46
CH_4	2,60	1,76
N_2O	2,21	1,17

Cabe recordar que con el fin de llevar adelante las comparativas entre los años 2013 y 2018 se utilizaron los mismos factores de emisión para ambos periodos, con lo cual las diferencias que se presentan en los resultados están estrechamente relacionadas con los niveles de actividad y no así, con el mejoramiento tecnológico del transporte ni el combustible que se emplea. Del análisis de las gráficas comparativas entre los años 2013 y 2018 (Fig. 3 y 4) se puede ver como las emisiones de gases contaminantes y GEIs han disminuido. Las mismas se han reducido entre un 28% y un 47% (Tabla 17). Esto se debe a que han mermado todas las operaciones marítimas, ferroviarias y aéreas en la ciudad de Bahía Blanca. Tal es así que en 2013 operaron 961 buques, 5678 aviones y 9309 trenes mientras que, en 2018 se redujeron un 33% la cantidad de maniobras en el puerto, un 8,5% las operaciones en la aeroestación y 53% los movimientos de formaciones ferroviarias (Tabla 18). Esto se relaciona estrechamente con los niveles de actividad económica de la ciudad, la región y el país. Si bien se considera que el año 2013 presentó una situación de estancamiento con algunos indicios de mejoría tras la caída del nivel de actividad del 2012, 2013 fue un año en el cual la producción agrícola se ubicó por encima de los niveles promedio históricos [23, 24]. En cuanto al año 2018 se puede decir que, tanto a nivel local como nacional, ha sido un año complejo desde el punto de vista económico. Con un inicio alentador del año que terminó concluyendo en una profunda crisis económica interna para finales del 2018, lo cual se vio reflejado en "una recesión sin precedentes", según la fuente de información del Centro Regional de Estudios Económicos de Bahía Blanca Argentina (CREEBBA) [25]. Por otro lado, utilizando los datos de la serie histórica del Estimador Mensual de Actividad Económica (EMAE) reportados por el Instituto Nacional de Estadísticas y Censos (INDEC) [26], se concluye que la actividad económica del año 2018 cayó respecto del 2013 un promedio del 1,8%. Esto se ve reflejado en la merma de las operaciones del transporte local no carretero provocando una disminución en las emisiones de gases contaminantes y GEIs que reportamos en el presente trabajo.

Tabla 18. Cantidad de operaciones anuales registradas por tipo de transporte no carretero analizado para los años 2013 y 2018, Bahía Banca.

Tipo de transporte	Año	
	2013	2018
Aéreo	5678	5204
Marítimo	961	644
Ferroviario	9309	4368

4 Conclusiones

Durante el 2018 de los tipos de transporte considerados en este estudio, el sector marítimo es el de mayor generación de emisiones de gases contaminantes y de efecto invernadero en la ciudad de Bahía Blanca.

En cuanto a la comparativa entre lo reportado en 2013 y lo obtenido para 2018 se observa, que en este último periodo analizado las emisiones han sido menores, lo cual se corresponde con la disminución de cantidad de operaciones en los tres rubros investigados. Esto último puede relacionarse directamente con la caída de la actividad económica a nivel local, regional y nacional.

Cabe destacar que un inventario de emisiones preciso y actualizado sobre el transporte no carretero es esencial, dado que, permite disponer de información confiable con el fin de ser utilizada en la mejora de las políticas de calidad de aire, sumado al correspondiente estudio de transporte carretero. Este trabajo se enmarca dentro de una línea de investigación sobre contaminación atmosférica debida a fuentes móviles en la ciudad de Bahía Blanca.

Agradecimientos

Agradecemos a la Comisión de Investigaciones Científicas (CIC), Provincia de Buenos Aires, por la financiación otorgada a esta investigación a través del proyecto PIT-AP-BA titulado "Logística y optimización del transporte". Adicionalmente, este trabajo fue parcialmente financiado por la Universidad Nacional del Sur (UNS), Bahía Blanca, Argentina, [PGI 24/M158], proyecto titulado “Química computacional aplicada al descubrimiento de nuevos materiales poliméricos, nuevos fármacos y a problemas ambientales”.

Agradecemos el apoyo brindado por el personal del Comité Técnico Ejecutivo (CTE) de Bahía Blanca, especialmente por los ingenieros César Pérez, Cristian Stadler y Anabella Aiello. Reconocemos a todos los que colaboraron con la contribución de datos para este trabajo.

Summary: This article studies the uncertainty caused by the Bullwhip effect in the supply chain. The supply chain evaluated in this study is made up of a manufacturer, a distributor, and a retailer, and we studied the effect of demand between the links in the supply chain. The research uses data from the demand for Argentine automotive parts for 48 months and compares the forecast using the Holt-Winters and ARIMA methods over 4 years to minimize the Bullwhip effect.

Key Words: Bullwhip effect, Supply chain, ARIMA models, Time Series, Holt-Winters Method, Automotive Industry.

Introduction

Global markets require modern logistics chains to improve productivity and sustainable growth of international trade. In the same sense, each of the different actors in the supply chain must be coordinated to guarantee good customer service, ensuring a balance between the demand and supply chain. A simple supply chain is made up of independent organizations such as manufacturers, distributors, and retailers [1,2]. The efficiency of the supply chain can be evaluated using the total cost of services [3], the average inventory [4], and the bullwhip effect [5].

The bullwhip effect can be caused by several factors, including; demand forecast, lot order, price fluctuation, rationing measures, and shortages [6]; waiting times [7,8,9], inventory policies [10,11]; replacement policies [12,13,14]; poor control systems [15]; the number of participants in the supply chain [16]; distortion of information in the supply chain [17,18,19,20,21]; company processes [22]; capacity limits [16]; erroneous feedback perception [22]; lack of synchronization in the chain [23]; local optimization without global vision [22]; multiplier effect [15]. Also, the whip effect can be affected by members of the supply chain due to the delay of decision-

making, lack of learning and/or training, and for fear of having an empty stock [24,25,26]. Other aspects have been reported by [27].

The bullwhip effect is a phenomenon that makes administrative management of the supply chain difficult; This effect generates a growing distortion of the demand transmitted by the different agents participating in the flow management of tailor-made products from the market to the producer. In other words, the Bullwhip effect reflects increased uncertainty as orders are transmitted upstream in the supply chain; It is an amplification phenomenon of the demand between the different elements that make up a supply chain.

This article evaluates the impact that the Bullwhip effect has on a supply chain made up of a manufacturer, distributor, and retailer: specifically studying the uncertainty caused by the manufacturer due to the demand variability in each market retailer.

1.1 Demand Forecast

The whip effect makes operational management of the supply chain difficult, in particular, forecasting demand. There are several methods to determine the demand forecast transmitted from the customer to the producer. The various forecasting methods existing in the literature can be classified into the following categories:

- **Time series forecasting techniques**
- **Automatic learning models.**
- **Agent based models**
- **Control engineering models**

The time series forecasting techniques are the moving average (MA), exponential smoothing (ES), auto-regression (AR), and auto-regressive moving average (ARIMA) [28, 29, 30, 31]. These techniques minimize total cost by optimizing the optimal inventory level and the number of orders. We conducted a comparative demand forecast study using the Holt-Winters and ARIMA methods to reduce uncertainty in the supply chain.

2 Methods

Forecasting of the demand time series will be approached using the Holt-Winters method by the seasonal characteristics and the systematic component of the demand. The implementation of the Holt-Winters method is:

For the systematic component of demand [(level + trend) x seasonal factor] with periodicity p of the data. L0, T0, and seasonal factors (S1, S2,… Sp) are obtained using the static forecasting procedure. For period t, the forecast for future periods is given by:

$$F_t+1 = (L_t+T_t)(S_t+1) \text{ y } F_t+n = (L_t + nT_t)S_t+n \quad (1)$$

After observing the demand for period t + 1, the estimates for the level, trend, and seasonal factors expressed in equations (2 - 4) were revised:

$$T_t+1 = \beta(L_t+1 - L_t) + (1- \beta)T \quad (2)$$

$$L_t+1 = \alpha(D_t+1/S_t+1) + (1- \alpha)(L_t+T_t) \quad (3)$$

$$S_t+p+1 = \gamma(D_t+1/L_t+1) + (1- \gamma)S_t+1 \quad (4)$$

With α = smoothing constant for the level, β = smoothing constant for the tendency and γ = smoothing constant for the seasonal factor.

The ARIMA technique models the regular part and the seasonal part of the time series using the autoregressive component (AR) and moving averages (MA).

3 Analysis of the results

Graph (1) shows the initial descriptive analysis of the time series with a level, a trend, and a certain cyclical seasonality for the three series. This pattern is repeated as shown in figure N°1.

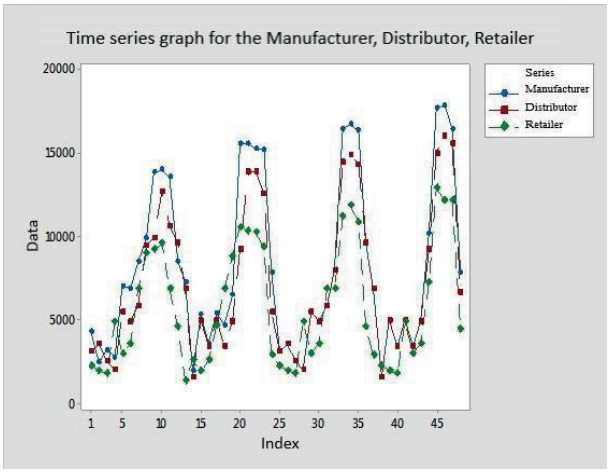

Fig. 1. Time series for the Manufacturer, Distributor, Retailer

For the Holt–Winters method, a smoothing constant was used for the α and β level in the range between (0.1-0.3). The adjustment of the parameters of this model was through simulations; the variation of the parameters had a differential of 0.01 for each iteration. Subsequently, a level of variation of the seasonal factor was determined at a range below 0.21. The best fit was achieved with the values of α = 0.21; β = 0.21, γ = 0.21 for the case of the manufacturer (figure 2).

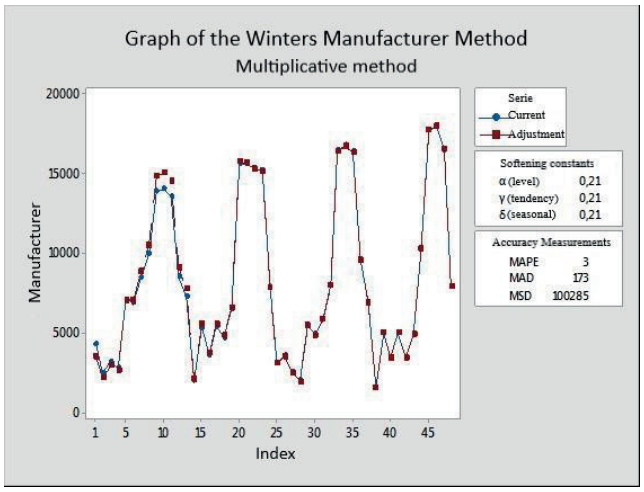

Fig. 2. Manufacturer Forecast

The forecast when using this technique obtained a mean absolute percentage error (MAPE) for the manufacturer, the distributor, and the retailer of 3%, 3%, and 2.7% respectively.

For the ARIMA analysis, the behavior of the time series was identified. The data do not have a normal distribution, as seen in figure Nº3 for the manufacturer's data.

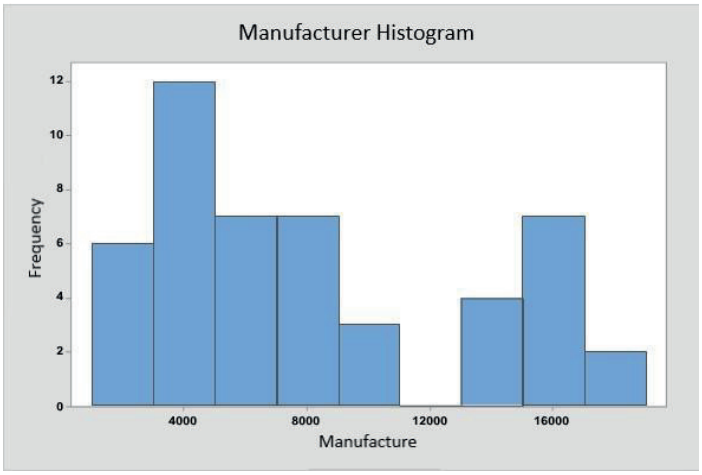

Fig. 3. Manufacturer's Histogram.

A bimodal normal distribution was observed, to carry out the transformation using the Box-Cox method, transforming the data series into a normally distributed model, with $\lambda = 0.5$.

The autocorrelation functions (ACF) and Partial autocorrelation function (PACF), have a mixed model AR and MA structure (Figures 4 and 5).

A bimodal normal distribution is observed, to make the transformation using the Box-Cox method, changing the data series into a normally distributed model, with (lambda) = 0.5.

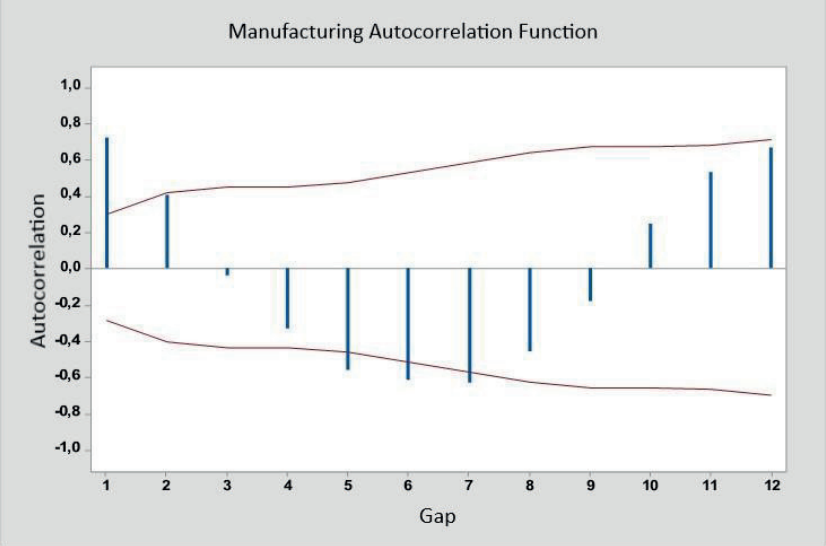

Fig. 4. ACF Producer.

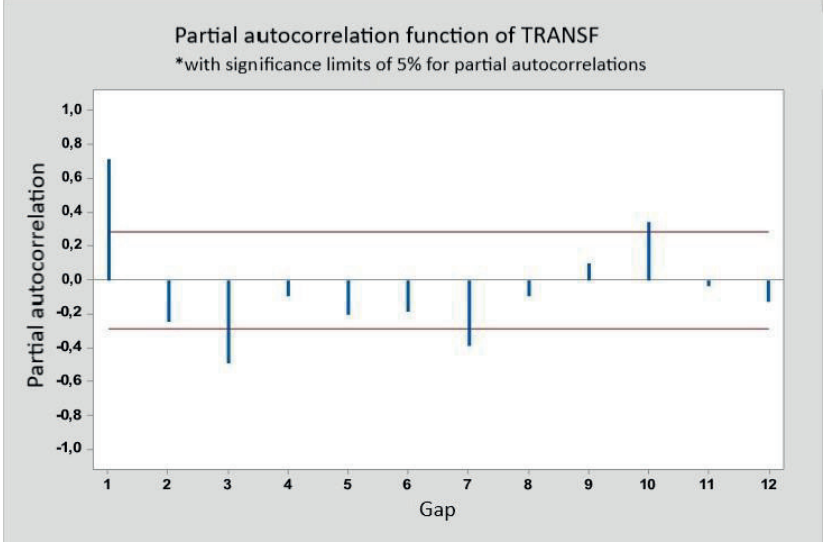

Fig. 5. PACF Producer.

Finally the following models were tested:

- ARIMA (1,0,0) x $(0,1,0)_{12}$
- ARIMA (1,0,1) x $(0,1,0)_{12}$
- ARIMA (1,0,2) x $(0,1,0)_{12}$
- ARIMA (1,0,3) x$(0,1,0)_{12}$
- ARIMA (0,0,3) x $(0,1,0)_{12}$
- ARIMA (1,1,1) x $(1,1,0)_{12}$

All models, except the last one, use the constant. Figure 6 presents the model with the best prognosis.

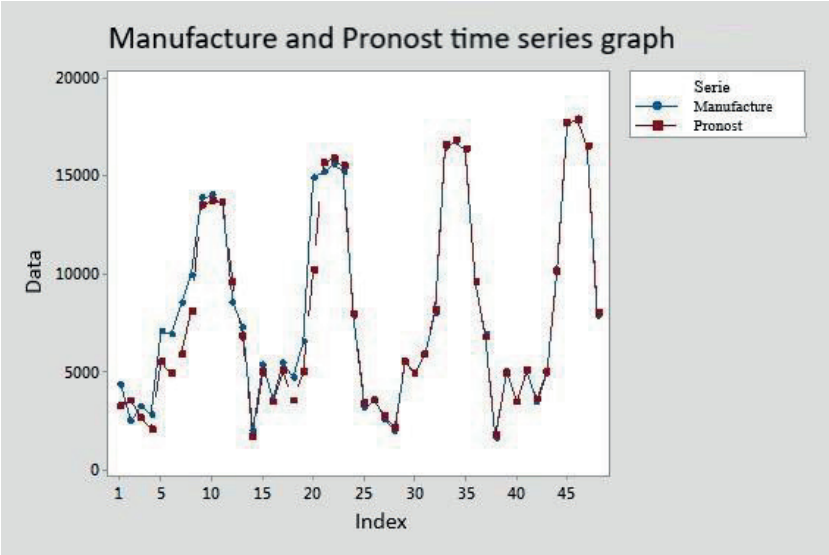

Fig. 6. Manufacturer's forecast using ARIMA model.

For the distributor and distributor series, the transformations were made using the Box-Cox method. However, no correlations were found for the time series using the ARIMA model (table 1). The time series used correspond to the demand for spare parts in the Argentine automotive industry (see annex table 2).

Table 1. The final parameters obtained by the model.

Type	Coefficient	SE Coefficient	Value T	Value P
AR 1	0.385	0.195	2.18	0.056
SAR 12	-0.974	0.102	-9.50	0.000
MA 1	0.942	0.127	.41	0.000

4. Conclusion

This study focused on minimizing the Bullwhip effect by forecasting the demands of the manufacturer, distributor, and retailer based on historical data from the argentine automotive sector. The results obtained were consistent with the theorical literature that refers to the bullwhip effect for the demands at different levels, providing the decision maker with an appropriate methodology for seasonal demands.

Two methods were used, the Holts-Winters method which obtained optimal values for α, β, and γ for the manufacturer, distributor, and retailer. The values for the three stages are $\alpha = \beta = \gamma = 0.21$, with a forecast error of less than 5%.

The ARIMA model for the manufacturer's time series was ARIMA (1,1,1) x $(1,1,0)_{12}$ without a constant end, and was validated with the T contrast test and the p-values. However, ARIMA models could not be found for the other two series after the transformations made with the Box-Cox method.

Abstract. In this paper we deal with a topic of smart grids that considers residential appliance scheduling. As nowadays being interruptible is a quality of many appliances, we analysed the possibility of interrupting the operation of the appliances to represent real-life scenarios in a more faithful way. This could lead to better decisions avoiding the operation of appliances during intervals in which the energy prices were high. We detail the methodology we used and how we generated a diverse instance set with the goal of presenting a realistic analysis. Considering various metrics, we compare the computational results obtained for our model with those belonging to the scenario without interruptions, and explain the positive impact of our incorporation.

Keywords: smart grids, demand response, day-ahead price, residential power scheduling, interruptible appliances, combinatorial optimisation

1 Introduction

In Argentina, as in the rest of the world, energy consumption is constantly rising. This demand is not just boosted by the increase in population but also by the development of new technologies and changes in the ways of living, that become more dependent on electricity.

According to the European Commission (https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:52011SC0463&from=EN), "a Smart Grid is an electricity network that can cost efficiently integrate the behaviour and actions of all users connected to it — generators, consumers and those that do both — in order to ensure economically efficient, sustainable power system with low losses and high levels of quality and security of supply and safety".

Smart grids use new technologies, such as intelligent autonomous controllers, advanced software for optimisation and data management, and bidirectional communications between the electricity companies and the user, with the aim of creating an automatised and distributed energy supply grid [1]. Smart grids allow the adaptation to the changing consumption and generation needs and combine, in a safe way, storage units and renewable energies for distributed generation.

To achieve these goals, the prediction of energy consumption and the determination of energy prices are a key component. The utility companies can have a pricing policy based on the consumption at different times of the day to indirectly control the peak energy demands of the users through a demand response (DR) program. These programs are procedures that can be applied to motivate a change in the energy consumption habits of the users, that respond to incentives such as lower energy prices.

The program implements a pricing policy that *punishes* the energy consumption during peak times, leading the user to reduce the use of appliances in periods of high demand. For this, the user must know this pricing policy beforehand. The implementation of demand response programs has shown to have a significant impact on reducing the costs [2].

Another essential task to achieve the goals of smart grids is scheduling the residential load. To optimise the electricity bill, the user must avoid using appliances in times when the energy is more expensive whenever this is possible or at least operating them at lower powers. To make decisions about residential power scheduling, optimisation algorithms that consider the user's preferences are needed.

Lately there has been plenty of research on optimisation for smart grids. The diverse models proposed, among many differences, have distinct objectives, such as minimisation of the electricity bill, social welfare maximisation, energy consumption minimisation, minimisation of the peak demand, other goals and many combinations.

In [3], distributed generation (DG) and energy storage systems (ESS) are considered and the scheduling model used has as its sole objective the minimisation of the electricity bill. The authors in [4] also consider batteries but focus on a distributed real-time algorithm that allows users to keep to themselves private information regarding their daily schedules. A genetic algorithm is developed in [5] to target energy sharing in a prosumers community.

In [6], the problem of load balancing is tackled by taking into account renewable sources and estimating the energy cost through a combination of real-time pricing (RTP) and incline block rate (IBR), which is a pricing scheme that divides the electricity price into several blocks which are more expensive for higher levels of consumption. RTP and IBR are also used as pricing schemes in [7], where the aim is to schedule household load and integrate renewable energy sources (RESs). An ESS is included and neighbouring consumers can trade surplus generation.

A plug-in hybrid electric vehicle (PHEV) works as an ESS and electricity can be sold to the power grid in [8]. The authors in [9] integrate ESSs and RESs and develop an algorithm which is a combination of a genetic algorithm and a moth-flame optimisation algorithm to minimise the energy cost, the peak-to-average ratio (PAR) and the discomfort, which is a measure of user unpleasantness due to the difference between the desired operation of the appliances and the actual one. In [10], another hybrid algorithm is developed to schedule home appliances but discomfort is not contemplated, the focus is on electricity cost and PAR.

Critical peak pricing (CPP) and RTP are used as pricing schemes. These two pricing tariffs are also used by the authors in [11], where they present a metaheuristic algorithm for controlling the residential loads with the aim of reducing the PAR, the energy consumption and the cost while considering how much time users have to wait for appliances to finish their operation.

In [12], an hour-ahead DR algorithm is proposed. Price forecasting is achieved using artificial neural networks, and decisions for appliance use are based on Reinforcement Learning (RL). RL is combined with Fuzzy Reasoning (FR) by the authors in [13], who develop a home energy management system (HEMS). Their objectives are to avoid energy consumption peaks and to minimise the electricity cost while considering user's preferences.

In this paper we deal with the problem of scheduling residential appliances under a demand response program. We consider a day-ahead pricing scheme and aim to minimise the economic cost of energy and the discomfort felt by users. Appliances are categorised into two groups. Those of the first group are delayable and the discomfort is a consequence of the time the users have to wait for the appliances to end their operation. The others have a flexible power and the discomfort is related to the difference between the actual power of operation and the one it should be. To the best of our knowledge, this paper makes many contributions to the existing literature on residential power scheduling in smart grids. Other papers use other pricing schemes or work with different models regarding possibilities (for example, interrupting appliances or not), formulations (such as using the Taguchi function) or objectives (for example, minimising energy consumption), among other differences.

The remainder of this paper is structured as follows. In Section 2 we present the model considered in [14], modified to have a choosable discretisation for the period of a day and extended to add the possibility to interrupt the operation of some appliances. The solution methodology we used is explained in Section 3, in which we design two polynomial-time algorithms and present their foundations. In Section 4 we describe the set of instances we designed to represent real-life scenarios in a more faithful way, taking into account different needs and priorities regarding the use of electric appliances. Computational results for those instances are presented in Section 5 with an analysis that considers various metrics and compares both algorithms. We finalise this paper with conclusions and ideas to continue our work, explained in Section 6.

2 Two Types Appliance Scheduling for Economic and Disconfort Minimisation With Interruptions (2TASEDMWI)

In [14], the authors present a problem that we shall call Two Types Appliance Scheduling for Economic and Disconfort Minimisation (2TASEDM). They consider an intelligent system for the purpose of assisting a user in a decision-making process regarding their use of different electric appliances. The goal is to min-

imise the discomfort felt by the user and also their electricity bill by considering certain priorities according to a desired-tradeoff.

The system knows the electricity prices p^t of consuming one kW during each interval t between two consecutive instants t and $t+1$ of a certain time window $\mathcal{T} = \{0, ..., T\}$, fixing $T = 23$ to represent each hour of a day, horizon in which the user will schedule their appliances.

In [14], the user has two types of electric appliances. Those of the first type, grouped in set $\mathcal{A}_1$, have a flexible operation time and work continuously with a fixed power. Appliances of the second type, clustered in $\mathcal{A}_2$, have a predefined working time with flexible power which may be different for each interval.

Each appliance a can operate within a certain interval $[\alpha_a,\ \beta_a)$ included in the time window $[0,\ T+1)$. An appliance $a \in \mathcal{A}_1$ must operate T_a consecutive intervals with a fixed power r_a and α_a represents the desired starting time. In contrast, as is mentioned in [14] by the authors, those with flexible power must operate during the whole interval $[\alpha_a,\ \beta_a)$ with powers between r_a^{min} and r_a^{max}.

The model proposed in [14] does not consider interrupting the operation of appliances, even when being interruptible is a quality of many appliances. This could lead to better decisions avoiding the operation of appliances during intervals in which the energy prices were high. For these reasons, we proposed a new model adding the possibility of interrupting the operation of the appliances of $\mathcal{A}_1$. We shall call this new problem 2TASEDMWI (Two Types Appliance Scheduling for Economic and Disconfort Minimisation With Interruptions).

We also think that hourly discretisation as proposed in [14] is not the most suitable one when dealing with electric appliances, given that some, such as electric ovens, have shorter operation times. Instead, we propose using a discretisation that provides greater granularity to represent real-life scenarios in a more faithful way. Such granularity will be a parameter of our algorithms and, according to the scenario to be modeled, the appropriate value will be set.

To precisely formulate the objective function, first we define some variables. For each appliance a and each interval $t \in \mathcal{T}$, we define $x_a^t \in \mathbb{R}_{\geq 0}$, the power of operation. In addition, for each appliance $a \in \mathcal{A}_1$ we shall define the variable $t_a \in \mathbb{Z}_{\geq 0}$, the ending time of operation.

As we mentioned earlier, there are two goals: the reduction of the electricity bill and the decrease in the discomfort.

The electricity bill results from the energy consumption levels and the electricity prices in each interval. It is calculated as the sum over all intervals of the product of the price and the energy used:

$$V_p = \sum_{t \in \mathcal{T}} \left(p^t \sum_{a \in \mathcal{A}_1 \cup \mathcal{A}_2} x_a^t \right) \tag{1}$$

The discomfort is different for the two types of appliances: for the first type it arises from the delay in the operation ending time with respect to the user's wish and for the second type it is related to the difference between the power used and the normal power consumption in each interval.

In the mentioned paper, the authors present an hourly discretisation and propose the following formula to model the discomfort for a certain appliance

$a \in \mathcal{A}_1$

$$V_a = \rho_a \ \big(t_a - (\alpha_a + T_a)\big)^{k_a} \tag{2}$$

where $0 < \rho_a < 1$ and $k_a \geq 1$ are real numbers related to the operational characteristics of a.

To achieve a metric that is independent of the discretisation, we incorporate a constant *iph* that represents the number of intervals included in one hour according to the chosen discretisation, so that the number of hours of delay is expressed instead of the number of intervals. We also want a greater discomfort for a bigger value of k_a, and no discomfort in the case of having no delay, so we propose the following formula:

$$V_a = \rho_a \ \Big[\ \Big(1 + \frac{t_a - (\alpha_a + T_a)}{iph}\Big)^{k_a} - 1\Big] \tag{3}$$

For appliances in $\mathcal{A}_2$, the discomfort related to their powers of operation is expressed through the Taguchi loss function [15].

In each interval t, if $\widehat{x}_a^t$ stands for the normal power consumption of a certain appliance a, $\widehat{x}_a^t \pm \Delta_a^t$ designates the extremes at which the appliance will suffer functional failure. Then, the user must take some countermeasure if the power of an appliance is $\widehat{x}_a^t + \Delta_a^t$ or $\widehat{x}_a^t - \Delta_a^t$, and its cost is denoted A_a^t.

If the parameter ω_a^t is defined as

$$\omega_a^t = \frac{A_a^t}{{\Delta_a^t}^2} \tag{4}$$

then the discomfort caused by the operation of the appliance a in the interval $t \in \{\alpha_a, ..., \beta_a - 1\}$ is formulated as

$$V_a^t = \omega_a^t \ (x_a^t - \widehat{x}_a^t)^2 \tag{5}$$

The total discomfort for an appliance $a \in \mathcal{A}_2$ is the sum of the discomfort over the operation intervals:

$$V_a = \sum_{t=\alpha_a}^{\beta_a - 1} \omega_a^t \ (x_a^t - \widehat{x}_a^t)^2 \tag{6}$$

The authors in [14] also mention that the restrictions on the powers of the appliances of $\mathcal{A}_2$ are only valid if $2 \ (\widehat{x}_a^t - r_a^{min}) \ \omega_a^t < p^t$.

The objective is to determine the values of the variables x_a^t and t_a that minimise a convex combination of the electricity bill and the discomfort. In other words, the goals have weights $\alpha_1, \ \alpha_2 \in \mathbb{R}_{\geq 0}$, $\alpha_1 + \alpha_2 = 1$, and the objective is to minimise the weighted sum.

3 Methodology for 2TASEDMWI

In the following we detail the methodology we used and provide the time complexity as well as the auxiliary space for each algorithm.

In the optimisation problem presented, each appliance can be optimised independently of the others. Also, for an appliance $a \in \mathcal{A}_2$, the optimal powers can be found independently for the different operation intervals.

We developed two algorithms for the appliances of $\mathcal{A}_1$ using dynamic programming: one prioritises the execution time at the expense of greater memory usage, while the other one restricts the memory utilised. Both make use of the fact that given the economically optimal solution for a certain possible ending time t, s_t, the one for the time $t+1$ is obtained removing the most expensive interval used in s_t and adding the interval t.

For both algorithms we consider that a solution for an appliance a is a dictionary of key-value pairs in which the keys are energy prices. For each key p, the value is a set of intervals, each with price p, in which a is active. Moreover, the solution has an economic cost which is the sum of the energy prices of the intervals in which the appliance was used.

If the implementation is done with appropriate data structures like ordered associative containers and binary search trees, efficient algorithms are obtained.

We first present the algorithm that uses less memory. Algorithm 1 assumes, without loss of generality, that $\alpha_a + T_a \leq \beta_a$ for all appliances a of the first type included in the instance being solved. If this were not the case, the instance would be infeasible.

Algorithm 1

create 2 empty solutions s and $sOpt$
totalCost $\leftarrow 0$
optimalCost $\leftarrow 0$
for $t \leftarrow \alpha_{a1} \dots \alpha_{a1} + T_{a1} - 1$ **do**
    add t to s
end for
totalCost $\leftarrow \alpha_1 * s$.economicCost $* r_{a1}$
$sOpt \leftarrow s$
optimalCost $\leftarrow$ totalCost
optimalEndingTime $\leftarrow \alpha_{a1} + T_{a1}$
for $t \leftarrow \alpha_{a1} + T_{a1} \dots \beta_{a1} - 1$ **do**
    remove from s an interval that is the most expensive among those of s
    add t to s
    totalCost $\leftarrow \alpha_1 * s$.economicCost $* r_{a1}$ + discomfort for $a1$ for finishing at $(t+1)$
    if totalCost $<$ optimalCost **then**
        optimalEndingTime $\leftarrow t + 1$
        optimalCost $\leftarrow$ totalCost
    end if
end for
for $t \leftarrow \alpha_{a1} + T_{a1} \dots optimalEndingTime - 1$ **do**
    remove from $sOpt$ an interval that is the most expensive among those of $sOpt$
    add t to $sOpt$
end for
return optimalCost and intervals of activity of $sOpt$

This algorithm can be implemented with a time complexity of

$$\mathcal{O}\Big[\Big(\sum_{i=1}^{T_a} log(i)\Big) + T_a + (\beta_a - 1 - (\alpha_a + T_a)) * (1 + log(T_a))\Big] \tag{7}$$

Considering that $T_a \leq \beta_a - \alpha_a$, a weaker bound for the time complexity is

$$\mathcal{O}\big((\beta_a - \alpha_a) * log(T_a)\big) \tag{8}$$

Regarding memory, the auxiliary space complexity is $\mathcal{O}(T_a)$.

Next we detail other algorithm, which uses more auxiliary space. It can result in lower execution times for instances where there are many appliances which share the time windows of possible operation, given that it makes use of information independent of the parameters relative to the discomfort of each appliance.

Given α_a, β_a and T_a, finding the activity intervals of optimal functioning makes it easier to find those for appliances with the same parameters of start and duration but earlier ending. This is due to the fact that during the process of solving the problem for the combination (α_a, β_a, T_a) it is possible to calculate, for each possible instant of finalisation t, the minimum economic cost and the associated activity intervals, as seen in the previous algorithm.

Therefore, given an appliance a' with parameters $\alpha_{a'} = \alpha_a$, $T_{a'} = T_a$ and $\beta_{a'} \leq \beta_a$, the possible instants of operation finalisation $t_{a'}$ between $\alpha_a + T_a$ and $\beta_{a'}$ should be examined. For each of these, the global cost would be calculated from the economic cost associated with the duration T_a and from the discomfort resulting from finishing the operation in t_a.

For this algorithm we have two dictionaries. One contains the economically optimal solution for each combination (α, t, T) of possible start of operation (α), instant of possible end of operation (t) and duration (T). The other contains the maximum t for each α and T, since from this solution we will remove and add intervals to obtain the solutions with posterior ending times.

As before, as $T_a \leq \beta_a - \alpha_a$, with an efficient implementation of this algorithm we can obtain an upper bound on the temporal complexity of

$$\mathcal{O}\big((\beta_a - \alpha_a) * T_a\big) \tag{9}$$

Even when the complexity for a single appliance is worse than the one we have for the other algorithm, the motivation for this algorithm lies in the use for scenarios with many appliances. Moreover, when the data structures already have the information stored, the complexity will be that of evaluating the costs for the $\beta_a - (\alpha_a + T_a)$ possible ending times added to that of copying the optimal solution:

$$\mathcal{O}\big((\beta_a - (\alpha_a + T_a)) + T_a\big) \tag{10}$$

For each appliance of the second type and each of its operation intervals, the total cost is a quadratic function on variable x_a^t:

$$c(x_a^t) = \alpha_1 \; p^t \; x_a^t + \alpha_2 \; \omega_a^t \; (x_a^t - \widehat{x}_a^t)^2 \tag{11}$$

where its domain is $[r_a^{min},\ r_a^{max}]$ if the restrictions for the power are active, otherwise it is $[0, +\infty)$.

We can obtain the analytical solution for the minimisation of the total cost function with constant time complexity and auxiliary space.

4 Instance set

With the goal of having bigger and more realistic instances than those presented in [14], in this paper we set $T = 143$, being able to distinguish each 10-minute interval, and we consider instances of different sizes.

First we design 3 types of houses: the house of a person that goes to work during the day, called *diurnal house*; the house of a person that goes to work during the night, named *nocturnal house*; and the house of a person that doesn't work outside the house, to which we refer to as *full day house*.

The houses have 13 schedulable appliances. The appliances of the first type are a robot vacuum (RV), a robotic pool cleaner (RP), a computer (C), a television (TV), a washing machine (WM), an iron (I), an electric stove (ES) and a water heater (WH). The appliances with a flexible power are lights (L), an air conditioner (AC), a dishwasher (DW), a treadmill (T) and an hydromassage table (HT).

The parameters of the appliances for the diurnal house, detailed in Tables 1 and 2, arise from considering that it belongs to someone who sleeps from 12 a.m. until 8 a.m. and works from 9 a.m. until 5 p.m., arriving home at 5:30 p.m. The robots are charged, preferably while the owner has breakfast just in case there are any problems, and are fully charged when the user arrives home. Then the treadmill is used from 6:30 p.m. to 6:50 p.m. After that, the clothes are washed and it is time for a massage. Between 6:30 p.m. and 9:30 p.m. dinner is cooked, and at 9 p.m. the dishwasher starts functioning. Also, from 8 p.m. until going to sleep, the user wants to use the computer and the television, iron clothes and take a shower.

For clarity purposes we choose to show the times represented by α and β instead of their respective numbers of intervals. In other words, with the selected discretisation which considers an instant every 10 minutes, for $\alpha = 48$ we show 8 a.m. We also changed the representation for the parameter T opting for the hours and minutes format.

Likewise, even though there could be different values for the parameters $\widehat{x}^t$ and ω^t throughout the day, we only show one for each parameter as it was the same during the whole operation time.

In the same way, in Tables 3, 4, 5 and 6 we present the parameters of the appliances of the nocturnal house and the full day house. For the full day house, it is reasonable to think that the operation time windows would be wider and the operation times would be greater, given that the owners spend more time in their homes than the people that leave for work. Another consequence is that their concern about the time at which they do certain activities is less than that of the people that leave for work.

Table 1. Parameters of the appliances of $\mathcal{A}_1$ considered for the diurnal house

	RV	RP	C	TV	WM	I	ES	WH
α	8 a.m.	8 a.m.	8 p.m.	8 p.m.	7 p.m.	7 p.m.	6:30 p.m.	10 p.m.
β	5 p.m.	5 p.m.	12 a.m.	12 a.m.	11:30 p.m.	9 p.m.	9:30 p.m.	11:30 p.m.

ρ	0.001	0.001	0.8	0.75	0.1	0.7	0.4	0.2
k	1.3	1.3	3	2.8	1.9	3.6	2.1	1.8

Table 2. Parameters of the appliances of $\mathcal{A}_2$ considered for the diurnal house

	L	AC	DW	T	HT
α	7:00 p.m.	6:20 p.m.	9 p.m.	6:30 p.m.	7:20 p.m.
β	12 a.m.	8:50 p.m.	10:20 p.m.	6:50 p.m.	7:50 p.m.
r^{min} (kW)	0.3	0.3	0.3	0.3	0.3
r^{max} (kW)	0.9	1.1	0.9	0.9	0.9
$\widehat{x}^t$ (kW)	0.5	0.7	0.8	0.8	0.5
ω^t (\$/kW^2)	1.6	2	0.8	1.9	1.1

We also design neighbourhoods replicating the 3 original houses and changing the parameters of their appliances. To achieve a better model of reality, 70% of the houses of the neighbourhoods are diurnal houses, 10% are nocturnal houses and 20% are full day houses.

For the diurnal and nocturnal houses, the parameters α and β can be changed at random any number of intervals up to one hour or not be changed at all, all the options are equiprobable. If α results less than 0 or greater than $|\mathcal{T}|$, it is assigned that value. The same happens for β if it is less than 1 or greater than $|\mathcal{T}| + 1$. The duration for the appliances of $\mathcal{A}_1$ may remain unchanged or be modified a certain number of intervals up to 10 minutes for every whole hour of operation of the original appliance and all the options are equiprobable. The minimum possible duration is an interval and the greatest is $|\mathcal{T}|$. In the case that after the modifications for some appliance a, the inequality $\alpha_a + T_a \leq \beta_a$ is not satisfied if $a \in \mathcal{A}_1$ or $\alpha_a \leq \beta_a$ if $a \in \mathcal{A}_2$, the parameters of the original appliance are copied to the new one.

$\widehat{x}^t$ (kW)	0.4	0.7	0.8	0.8	0.5
ω^t (\$/kW^2)	1	2	0.8	1.9	1.1

Table 5. Parameters of the appliances of $\mathcal{A}_1$ considered for the full day house

	RV	RP	C	TV	WM	I	ES	WH
α	7 a.m.	7 a.m.	4 p.m.	4 p.m.	5 p.m.	4 p.m.	6:30 p.m.	10 a.m.
β	6 p.m.	6 p.m.	12 a.m.	12 a.m.	10:30 p.m.	9 p.m.	9:30 p.m.	10:30 p.m.
T	1:40	1:40	1:30	2:10	1:20	1:20	00:50	00:40
r (kW)	1.4	0.4	0.38	0.16	0.7	1	1.20	1
ρ	0.001	0.001	0.7	0.65	0.1	0.6	0.5	0.2
k	1.15	1.15	2.7	2.4	1.75	3.3	1.9	1.6

The rest of the parameters are obtained uniformly at random as a value between 93% and 107% of the original value, with possible posterior changes to guarantee their validity. For ρ, the maximum value between the result and 0.0001 is taken, and then the minimum between that result and 0.9999. For k, it is the maximum between the result obtained and 1. For r_{min} and r_{max}, if $r_{min} > r_{max}$ then the original values are restored. Likewise, if $\widehat{x}^t < r_{min}$, r_{min} is assigned to $\widehat{x}^t$, and if $r_{max} < \widehat{x}^t$, r_{max} is assigned to $\widehat{x}^t$. Finally, for ω^t the maximum is taken between the value obtained and 0.001.

For the full day houses, the appliances are changed similarly.

For those of $\mathcal{A}_1$, α is advanced in time a certain number of intervals uniformly at random up to 2 hours (possibly 0), and analogously β is delayed. For the appliances of $\mathcal{A}_2$ the changes were up to one hour. As before, α is not less than 0 and β is not greater than $|\mathcal{T}|+1$. The activity duration of the appliances of the first type was extended some number of intervals (possibly 0) equiprobably up to 30 minutes for every whole hour of operation. If the duration of the original appliance was less than an hour, it was extended an interval for the new

Table 6. Parameters of the appliances of $\mathcal{A}_2$ considered for the full day house

	L	AC	DW	T	HT
α	6 p.m.	5:50 p.m.	8 p.m.	6 p.m.	6:40 p.m.
β	11:30 p.m.	9:20 p.m.	9:20 p.m.	6:30 p.m.	7:30 p.m.
r^{min} (kW)	0.3	0.3	0.3	0.3	0.3
r^{max} (kW)	0.9	1.1	0.9	0.9	0.9
$\widehat{x}^t$ (kW)	0.6	0.8	0.8	0.5	0.35
ω^t (\$/kW^2)	1.7	2	0.8	1.4	0.9

appliance. The final duration was the minimum between the new duration and the size of the time window of possible operation $\beta - \alpha$.

The parameter r is obtained randomly as some value between 90% and 104% of the original value. For each of the remaining parameters ρ and k, a uniform random value between 86% and 100% of the original is obtained and then we proceed as explained before to guarantee their validity.

Finally, r_{min} and r_{max} are changed as for the other types of houses. The normal power consumption $\widehat{x}^t$ is obtained as a value between 85% and 99% of the original value and we ensure it will be in the range $[r_{min},\ r_{max}]$ as we explained before. On the other hand, ω^t is fixed as the maximum between 0.001 and a value between the original ω^t and 114% of it.

We randomly generated 5 instances for each neighbourhood size, starting with 10 houses and increasing by 10 up to 500, then adding $5,000$ houses starting at $5,000$ until $50,000$ and finally augmenting from $100,000$ up to $1,000,000$ with steps of $50,000$.

Finally, we considered electricy prices characteristic of the society of Buenos Aires, Argentina. These are shown in Figure 1 and correspond to a demand-response program.

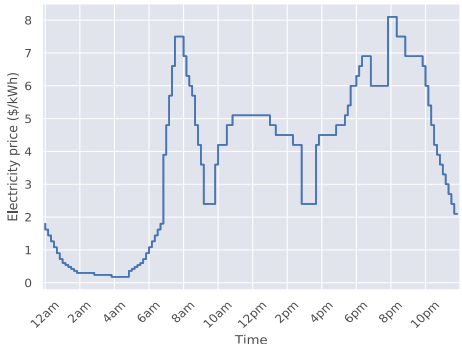

Fig. 1. Electricity prices in the different subintervals of the time window

5 Computational Results for 2TASEDMWI

In this section we compare the results obtained for the scenario with interruptions with those for the scenario without interruptions, and also for the algorithms designed.

For all the experiments presented in this paper we used a computer with *Intel Core i*7 7700, 3.60GHz and 16 GB RAM. The metrics studied were the value of the objective function, the electricity bill, the total discomfort, the peak energy demand in one interval, the peak-to-average ratio, the execution time and the memory used. For each metric we took the average of the values for the executions for the different instances with a common size.

As in [14], we consider three operation modes according to different priorities. In the first one, called "Economic" (E), the consumer only cares about the electricity bill and so we set $\alpha_1 = 1$, $\alpha_2 = 0$. In the second operation mode, the user is only concerned about discomfort and we set $\alpha_1 = 0$, $\alpha_2 = 1$, so this mode is called "Comfort" (C). In the third one, "Balance" mode (B), the user is equally worried about the electricity bill and the discomfort, resulting $\alpha_1 = \alpha_2 = \frac{1}{2}$.

In the figures shown, the continuous lines (NI) belong to the scenario with non interruptible appliances and the other lines (I) belong to the scenario with interruptible appliances. Also, because the two algorithms designed for the scenario with interruptible appliances always find the same optimal solution, all the metrics dependent on the composition of the solutions (for example, the electricity bill) and not relative to obtaining the solutions (such as the execution time) resulted equal. Moreover, the results for those metrics for the comfort mode were the same for both scenarios, something that can be verified in the plots, in which the continuous line labeled "NI - C" overlaps with the intermittent line labeled "I - C". This can be explained taking into account that in that operation mode, appliances end their operation time as soon as possible, and this is achieved starting as soon as possible and not interrupting the operation. Because of this, the analysis for these metrics when comparing both scenarios is only made for the other operation modes.

Figure 2 shows a reduction in the value of the objective function that is due almost entirely to a decrease in the electricity bill, as it can be seen in Figures 3 and 4.

Figure 5 shows that the peak energy demand increased for the balance mode for the scenario with interruptible appliances but decreased for the economic mode. This could be due to the fact that the balance mode distributed the activity between less cheaper intervals because after a certain moment, discomfort became very high.

Given that for a certain operation mode the total energy consumption is the same with and without interruptions, the differences in the peak energy demand led to differences in the PAR, as it can be observed in Figure 6. Contrary to what happens in the scenario without interruptions, in the scenario with interruptions the economic mode presents a lower peak demand that the balance mode. Even so, as it happens in the scenario without interruptions, it results in a greater PAR. Again, this can be explained by the difference in the total energy consumption for both operation modes. It should be mentioned that the increase of the PAR for the balance mode when interruptions are allowed is less than the decrease of the PAR for the economic mode.

Overall, the incorporations of interruptions is undeniably beneficial. Users, specially those with hard economic situations, would be particularly relieved by a decrease in their electricity bills.

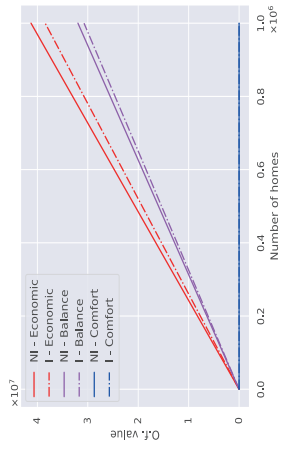

Fig. 2. Value of the objective function for each scenario

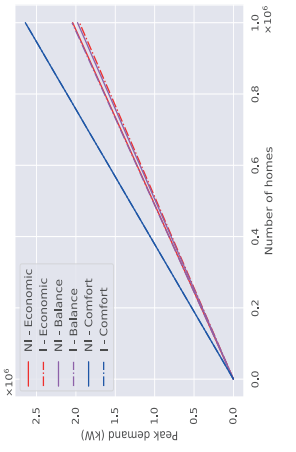

Fig. 5. Peak energy demand for each scenario

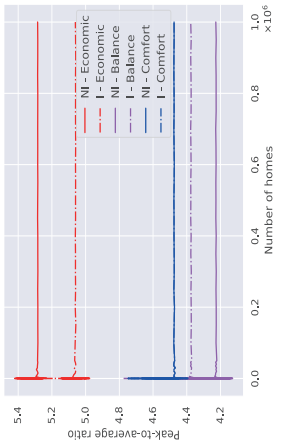

Fig. 6. PAR for each scenario

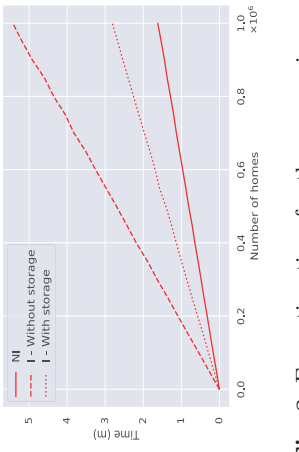

Fig. 8. Execution time for the economic mode

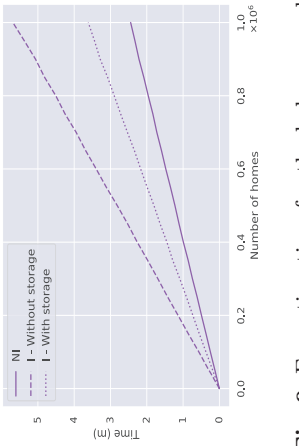

Fig. 9. Execution time for the balance mode

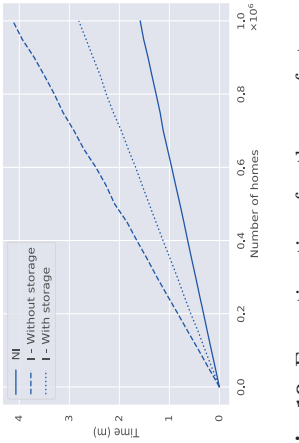

Fig. 10. Execution time for the comfort mode

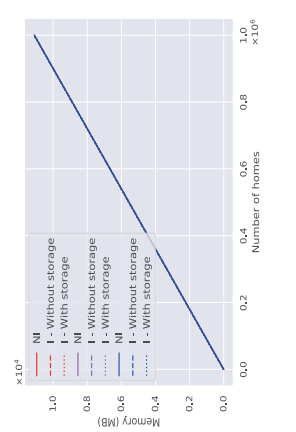

Fig. 7. Memory used for all algorithms

Regarding the algorithms, the execution times for the algorithms for the scenario with interruptions were in fact greater than those of the algorithm for the scenario without interruptions, as shown in Figures 8, 10 and 9. Even though there was a significant difference between the execution times of the algorithm for non-interruptible appliances and those of the one for interruptible appliances with less information storage, the difference was less that half when comparing the former with the algorithm for interruptible appliances with more information storage. Moreover, Figure 7 shows that the memory used was almost the same considering the sizes of the instances and the resources of most computers nowadays. It is also worth mentioning that for these computational resources the dependence with the number of homes appears to be linear.

Even though the execution times were different for the algorithm without interruptions and the algorithm with interruptions and additional data structures, this is due to two factors. One is related to the information storage on the additional data structures. Given that once completed, their sizes do not depend on the number of appliances, the contribution to the execution time would eventually be negligible when considering more homes. This is consistent with the fact that the complexity calculated for the algorithm when the information is already stored is almost the same as that for the algorithm for non-interruptible appliances. The other factor is related to the fact that storing the information to report the solution in the scenario without interruptions only consists in storing, for example, the instant of finalisation of activity of each appliance, since the operation intervals can be obtained from that. This is not true for the scenario with interruptions, which requires storing all activity intervals of each appliance.

6 Conclusions

In this paper, we decided to allow interruptions in the operation of delayable appliances because this models real-life scenarios in a more faithful way. Despite the fact that allowing interruptions proved to be advantageous regarding many metrics, the peak energy demand and the PAR worsened for the balance mode. Furthermore, the economic mode could create high peaks of energy demand as a result of choosing the cheapest intervals as operation intervals for many appliances. Even without interruptions, the confort mode could also generate energy demand peaks as a result of using excessive energy during some intervals. It would be reasonable if the electricity provider established a bound on the energy consumption for each interval to avoid oversizing the power grid, as that would not be exploited during most of the day. It becomes interesting to consider these energy consumption bounds, which are the center of our future research.

marcele.elisa@ufpe.br

Abstract. The municipal government of Caruaru (PE), Brazil, has made several efforts to control the spread of the new coronavirus (COVID-19) in the municipality. The first action was the creation of a crisis management committee. Since then, Caruaru adopted some preventive actions, such as: suspension of classes in public and private schools and universities; prohibition of local commerce activities and non-essential services; creation of digital platforms to enable the commercialization of goods and services; cleaning and disinfection of public areas; investigation of people crowding; proposition of awareness campaigns and assistance to the vulnerable population. Despite all these preventive actions and the numerous awareness campaigns, there are a large number of reports of disrespect for the actions imposed. Does the population understand the need for social distancing? Do they understand the risk of the disease? Several strategies can guide individual actions and they have a direct and real reflection on the social distancing. Therefore, this study aimed to understand the residents' perceptions of social distancing and, consequently, the resumption of economic activities in the municipality. The results show that the population understands contagion risk from COVID-19, understands the need for social distancing, and prophylactic measures to reopen the commercial activities and recognize myths of the disease. However, there is a failure to comply with the actions imposed by the municipality.

Keywords: COVID-19, Public management, Social distancing, Public health.

1 Introduction

The spread of the new coronavirus (COVID-19) forced governments to develop public policies to slow down the disease transmission and reduce overcrowding in health systems. One of the recommended strategies for all countries, regions, cities, and communities is to reduce social contacts, that is, to perform a social distancing [1].

The first suspected and confirmed case of COVID-19 in Latin America was in Brazil [2]. The COVID-19 is spreading very fast in Brazil [3], and the country is in a

crucial moment to minimize the impact of the illness on society by reducing the number of cases and, thus, preventing deaths [4].

In the state of Pernambuco (PE), Brazil, it was no different. The first COVID-19 cases registered in the state date from March 12, 2020. As a result, a series of preventives actions were adopted by both the state and municipal governments.

Caruaru is a Brazilian municipality, located in the state of Pernambuco, with an estimated population in 2019 of 361,118 people [5]. The Municipality of Caruaru published a decree nº024 on March 15 with the first actions to combat COVID-19 (Caruaru had no COVID-19 cases at this moment). Several additional decrees were proposed to limit people's circulation and crowding. On March 23, the city registered its first confirmed case of COVID-19. The municipality started to publish daily bulletins of the situation of COVID-19 in the city in April 12[6]. Fig. 1 shows the evolution of COVID-19 cases in Caruaru, where on August 09 where 5,231 cases and 256 deaths were recorded.

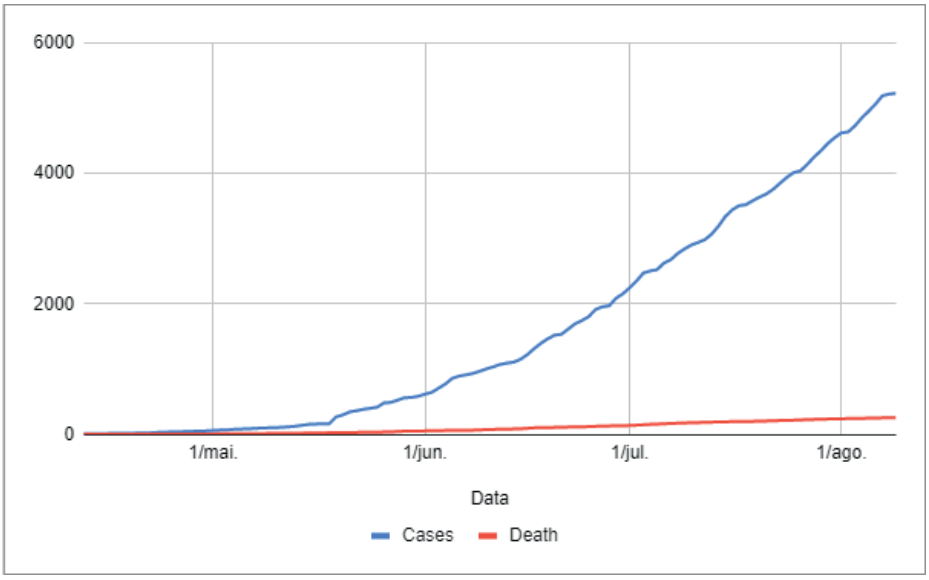

Fig. 1. Evolution of COVID-19 cases in Caruaru (PE).
Fonte: Adapted from [6].

Despite all the efforts of the municipality's management to make social distancing effective, the number of COVID-19 cases increased exponentially (see Fig.1) and several complaints of people crowding were reported in this period. Although the main objective is to save lives, the biggest conflict is about the social distancing impacts the local economy. As a result, there are countless debates about the severity of the actions adopted and what would be the right time to "loosen them up", i.e., when to a resumption of economic activities, mainly trade, since there are still no proven effective drugs or vaccine [7].

Maloney and Taskin [8] related that fear or social responsibility are the main responsible for effective voluntary individual actions of social distancing. Also, they

showed that public campaigns on protective actions (e.g. face masks), can make people feel more confident, increasing social mobility. "Therefore, it becomes crucial to understand people's worries about the pandemic and their perceptions of the effects of containment policies, so that the design of further policies and contingency actions well-informed, and a high level of compliance can be expected from the population" [7].

Therefore, this paper developed a questionnaire that was applied to residents of Caruaru (PE), in June 2020, intending to understand the public sentiment toward the actions used by policymakers for COVID-19 containment, and how they assess the risk of resumption economic activities in the municipality.

The results can help to guide the actions of the local public management, carrying out specific awareness campaigns, as well as directing actions regarding the rules for the resumption of economic activities in the municipality.

The paper was divided into four sections, the first being this introduction. Section 2 reports on materials and methods. Section 3 presents the results of the research. Finally, the discussions and conclusions are made in section 4.

2 Material and Methods

This research is characterized by survey research through a structured questionnaire. In this paper, a descriptive approach to results was used.

Also, it was assessed whether there is a correlation between the respondents' age and the observed variables. For the correlation analysis, the Kruskal-Wallis non-parametric test and Spearman's correlation were used. A significance level of 5% probability for rejection of the null hypothesis was adopted as a reference.

2.1 Research questionnaire

Questionnaires are one of the most used means of collecting data. They can contact and collect responses from a relatively large number of people in dispersed and possibly remote locations [9].

To build the questionnaire for this study, the steps recommended by [10] were followed. The questionnaire was assigned the self-administration method, i.e., the data collection instrument was conducted by the respondents themselves.

The questionnaire consists of 34 items, 06 of which are sociodemographic and 28 of specific knowledge, divided into the following categories: (1) cases of the disease and fear of contracting the COVID-19; (2) assessment of social distancing in the municipality; (3) evaluation of trade reopening actions; (4) Contagion risk assessment; (5) assessment of knowledge about COVID-19.

The final version of the questionnaire was applied in the city of Caruaru, in the state of Pernambuco, Brazil, in June 2020. Through random sampling, the questionnaire was answered by 268 residents. Considering the current population of Caruaru of 361,118 inhabitants and a confidence interval of 95%, the sampling error is 6%, our sample is close to the real representation of the population, but it is not enough for full population extrapolation.

2.2 Questionnaire analysis

The internal consistency of the questionnaire was estimated using Cronbach's alpha [11]. A value of $\alpha > 0.70$ is generally considered acceptable [12]. To calculate the Cronbach's alpha, the Statistical Package for the Social Sciences (SPSS) software version 16.0, 2007 was used.

The questionnaire had $\alpha = 0.728$, showing an acceptable internal consistency.

3 Results

3.1 Sociodemographic analysis

The demographic data of the respondents are shown in Table 1.

Table 1. Sample demographics

Variables	Percentage	Variables	Percentage
Genre		Education degree	
Male	34.33%	Incomplete elementary school	0.70%
Female	65.30%	Complete elementary school	0.40%
No answer	0.37%	Incomplete high school	0.40%
Age		Complete high school	7.80%
16 – 22	17.20%	Technician	3.70%
23 – 29	38.80%	Incomplete graduation	26.50%
30 – 39	16.80%	Graduation complete	48.50%
40 – 49	8.20%	Master's	9.70%
50 – 59	13.80%	Doctorate	1.50%
60 +	4.10%	No answer	0.70%
No answer	1.10%		

Of the respondents, 74.6% have lived in Caruaru for more than 10 years and 75% of them are graduates or are undergraduate students. From this and the data in Table 1, there is a strong indication that the respondents have the technical capacity to understand the subject reported here, as well as, know the characteristics of the municipality in question.

3.2 Specific knowledge analysis

Social distancing. An interesting fact was that 89.9% of respondents partially or strongly agree that social distancing is a necessary action in facing the COVID-19, while 82.1% believe that people are not respecting social distancing in Caruaru. They also partially or strongly disagree that economic activities return to normal as long as the virus is not controlled, thus maintaining social distancing as a preventive action.

However, analyzing the relationship of the three variables mentioned above with the respondents' age, Spearman's correlation was performed and it was found that there is a weak correlation in all cases ($r = -0.070, p = 0.254$; $r = 0.108, p = 0.080$ and $r = 0.062, p = 0.311$, respectively).

Cases of the disease and fear of contracting COVID-19. From the 268 respondents, 81.0% stated that they did not show any symptoms of COVID-19 at the time of answering the questionnaire, 15.7% said they had symptoms, but did not take the exam to confirm, while 3.4% took the exam. Of those who took the exam, only 1.5% had the diagnosis of COVID-19 confirmed. Thus 87.3% of respondents claimed to have a moderate to very high fear of contracting COVID-19. Fig.2 shows the intensity of the fear of contracting the disease by age group.

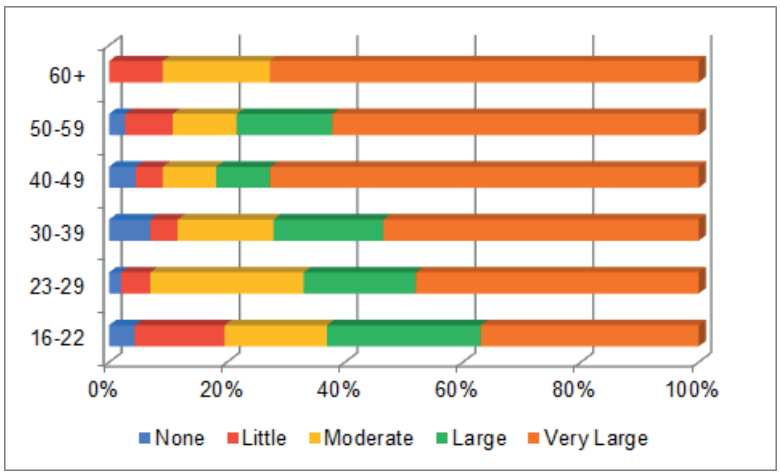

Fig. 2. Fear intensity by age group.

The Kruskal-Wallis test did not detect evidence that there is a difference of fear between the age groups ($p = 0.0889$). The Spearman's correlation also detected a low correlation, almost zero, between age and fear of contracting COVID-19 ($r = 0.024, p = 0.704$).

Reopening of trade. In a scenario of reopening of economic activities in Caruaru, before the development of a vaccine, respondents were asked to evaluate three situations of actions necessary for the reopening of commerce: (a) Use of masks by all people in commerce (employees and customers); (b) Availability and incentive for the use of disinfectants (e.g. 70% alcohol) by all; and (c) Limiting the number of people in the establishment to guarantee social distancing. The results were summarized in Table 2.

Table 2. Necessary actions for the reopening of commerce.

Scale of importance	(a)	(b)	(c)
Strongly important	88,3%	89,1%	87,2%
Partially important	7,9%	7,2%	6,4%
Neutral	0,4%	0,4%	0,4%
Little important	3,4%	3,0%	4,5%
Not important	0,0%	0,4%	1,5%

Therefore, it is noted (see Table 2) that the respondents consider the actions to be very important to enable the return of economic activities. However, there is no statistical evidence that this opinion changes according to the age group. But, a fact that deserves mentioning concerns the strong positive correlation between variables (a) and (b) ($r = 0.782, p = 0.000$) and (a) and (c) ($r = 0.723, p = 0.000$).

This indicates that the people who believe that the use of masks should be mandatory are the same ones who expect the trade to have a more hygienic environment and with restrictions on the number of people. In other words, one action alone does not seem to be sufficient for this sample.

Contagion risk assessment. Respondents were asked to assess the risk of contagion in the following situations (see Table 3):

(d) Public transport without the mandatory face mask;
(e) Public transport with the mandatory face mask;
(f) Attend shopping centers and galleries;
(g) Attend public parks and squares;
(h) Downtown, with busy streets and people without face mask;
(i) Downtown, with busy streets and people wearing face mask;
(j) Contact with close friends or family members who live in the same house;
(k) Contact with people already diagnosed and recovered from COVID-19;
(l) Unprotected contact with people working in hospitals;
(m) Contact with people who work in hospitals with appropriate protections.

Table 3. Contagion risk assessment.

Degree of risk	(d)	(e)	(f)	(g)	(h)	(i)	(j)	(k)	(l)	(m)
High	94.8%	19.1%	64.2%	36.3%	87.3%	20.9%	12.4%	22.2%	84.7%	28.0%
Medium	4.5%	63.7%	30.6%	43.1%	9.0%	61.6%	47.2%	30.5%	14.6%	53.7%
Low	0.7%	16.5%	4.9%	18.0%	2.6%	15.3%	36.3%	32.7%	0.0%	17.2%
None	0.0%	0.7%	0.4%	2.6%	1.1%	2.2%	4.1%	14.7%	0.7%	1.1%

Fig.3 shows the contagion risk assessment by age group.

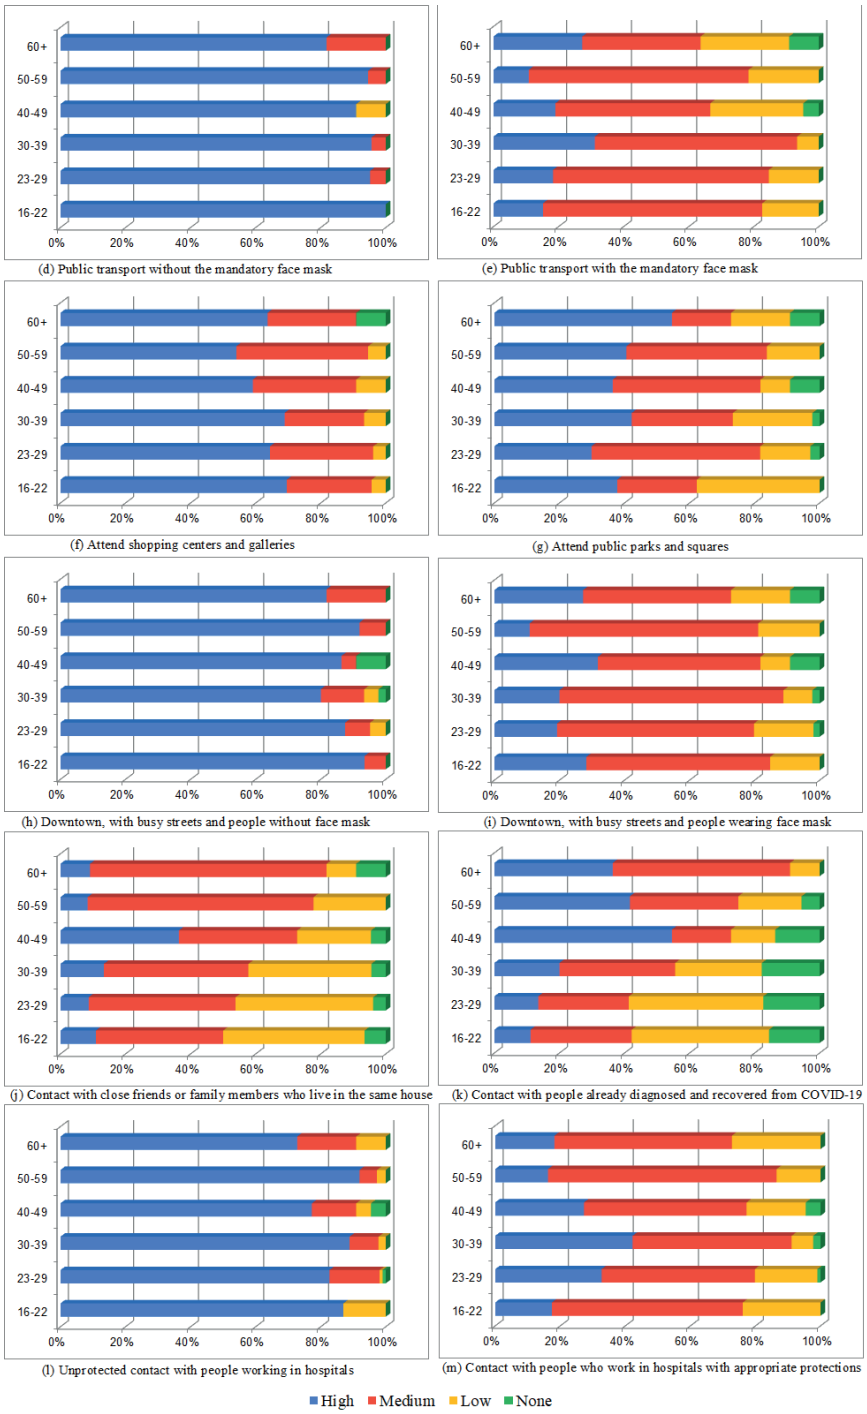

Fig. 3. A contagion risk assessment by age group.

Analyzing Table 3, it can be seen that items (d), (h) and (l) were considered to be at higher risk. Items (d) and (h) are related to overcrowding without adequate Personal Protective Equipment (PPE) and item (l) is related to the proximity of someone more likely to have contact with the disease. Another point is that respondents feel safer with the use of face masks. This fact corroborates the previous statements (Table 2).

The result, using the Kruskal-Wallis test, of the hypothesis that the perception of the risks does not differ between age groups (see Fig.3), and the correlation among age groups and the contagion risks are shown in Table 4.

Table 4. Age group *versus* contagion risks.

Contagion risks	Spearman		Kruskal-Wallis
	r	p	
(d)	-0.150*	0.015	0.450
(e)	-0.063	0.307	0.044
(f)	-0.090	0.144	0.640
(g)	0.071	0.248	0.860
(h)	-0.098	0.111	0.230
(i)	-0.072	0.242	0.500
(j)	0.172**	0.005	0.030
(k)	0.290**	0.000	0.000
(l)	-0.009	0.884	0.338
(m)	0.020	0.746	0.110

*Correlation is significant at the $p<0.05$

** Correlation is significant at the $p<0.01$

Although in all cases the correlation is weak, the Kruskal-Wallis test shows that for statements (e), (j) and (k) the null hypothesis of equality is rejected, i.e., there is statistical evidence that there may be a difference in perception among age groups about some contagion risks.

Knowledge about COVID-19. Finally, some questions were asked to assess the respondent's level of knowledge about COVID-19. The questions were (see Table 5):

(n) My city is hot and is less likely to spread COVID-19.

(o) I have a homemade recipe for flu that helps in the defense of COVID-19.

(p) The use of antibiotics is important in the defense of COVID-19.

(q) I expose myself to the sunlight every day and I absorb sufficient vitamin D in my body. So, I have protection against COVID-19.

(r) I don't trust in information on combating COVID-19 from the local government.

(s) The local recommendations to combat COVID-19 are exaggerated.

(t) Young people have no chance of contracting COVID-19.

(u) Only elderly people die from COVID-19.

Although most respondents disagreed with the statements, it is noted (see Table 5) that the fake news that circulated on social networks, as well as some statements with no scientific basis given by federal public managers, influence the population opinion. Also, 14.2% do not trust the information provided by the municipal public administration and 7.1% believe that the recommendations to combat the virus are exaggerated. Fig.4 presents these data by age group.

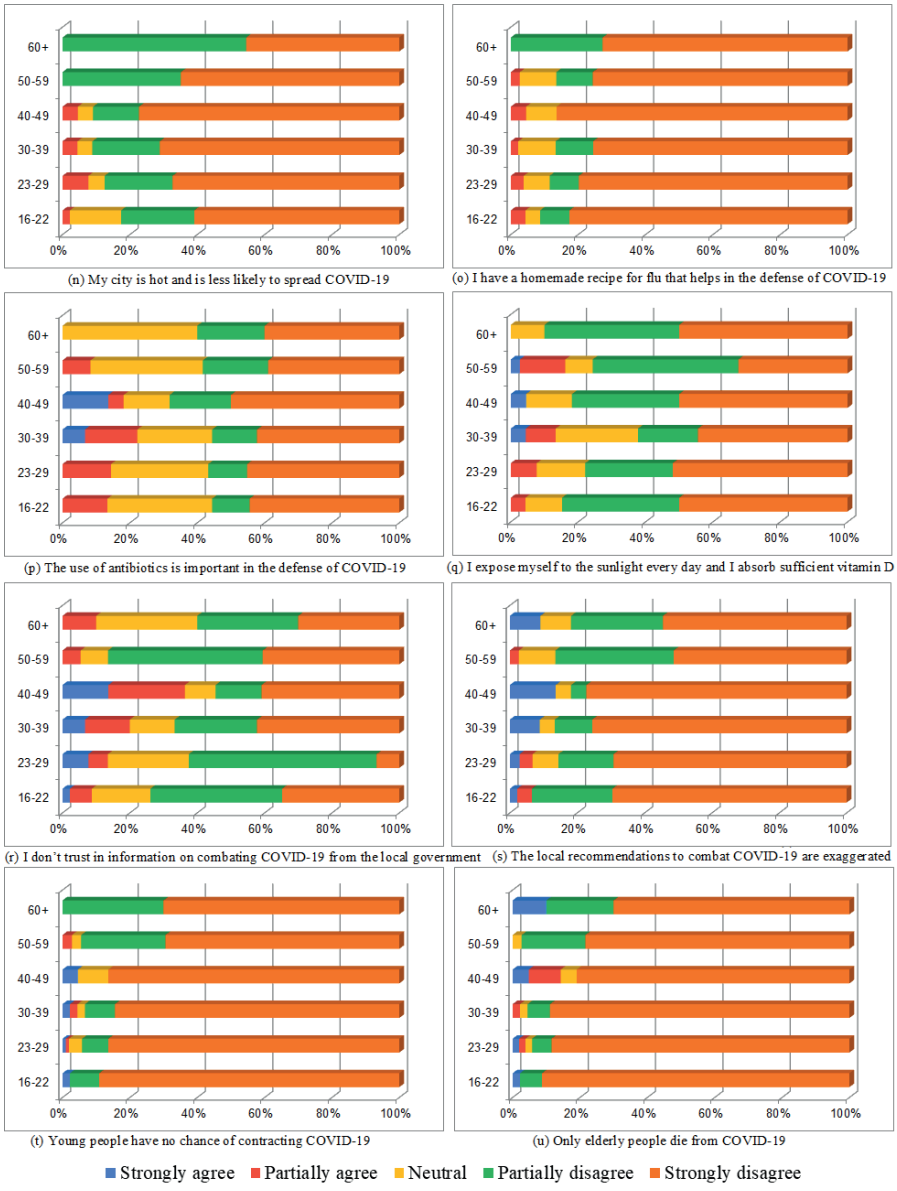

Fig. 4. Respondent's knowledge by age group.

Table 5. Respondents' knowledge

Degree of concordance	(n)	(o)	(p)	(q)	(r)	(s)	(t)	(u)
Strongly agree	2.2%	0.0%	4.5%	1.9%	5.6%	4.5%	1.5%	1.9%
Partially agree	2.2%	3.4%	9.8%	6.7%	8.6%	2.6%	1.1%	1.9%
Neutral	5.6%	7.8%	28.0%	14.6%	10.9%	6.0%	3.0%	1.9%
Partially disagree	23.1%	9.3%	13.6%	29.2%	29.2%	18.7%	10.6%	7.9%
Strongly disagree	66.8%	79.5%	43.9%	47.6%	45.7%	68.3%	83.8%	86.5%

The correlation between the age group and knowledge about COVID-19 is shown in Table 6.

Table 6. Correlations between age range and knowledge about COVID-19.

Respondents' knowledge	Spearman		Kruskal-Wallis
	r	p	
(n)	-0.044	0.474	0.570
(o)	0.050	0.422	0.620
(p)	0.007	0.909	0.890
(q)	0.102	0.097	0.220
(r)	0.032	0.604	0.230
(s)	0.110	0.073	0.320
(t)	0.177**	0.004	0.123
(u)	0.148*	0.016	0.360

*Correlation is significant at the p<0.05
** Correlation is significant at the p<0.01

All correlations were considered weak. The Kruskal-Wallis test does not demonstrate a significant difference in perception among age groups. Analyzing the pairs of alternatives, a strong positive correlation was observed between the variables (t) and (u) ($r = 0.744, p = 000$). In this research, it was observed that people disagree that only elderly people die from COVID-19 and that young people have a chance of contracting the disease, that is, they are dependent variables.

4 Conclusion

This paper presented research about the residents' perception of the Caruaru (PE) city, Brazil. A sample of 268 respondents was reached.

From the analysis of this sample, it can be concluded that the respondents expect that various preventive actions will be adopted by the trade for its reopening (e.g., mandatory use of face masks, constant cleaning, and limiting the number of people). In other words, considering just one action does not seem to be enough.

The results also show that respondents are less afraid of the COVID-19 with the use of Personal Protective Equipment (PPE) as a face mask. This corroborates the statement by [8] that stated campaigns on preventive actions encourage people to increase mobility, i.e., to come out of social distancing.

This result has some limitations. When analyzing the stratified sampling by age group, considering the last Brazilian census in 2010, it was observed that for the age groups of 30 - 39, 40 - 49 and 60 + years the sample was below of the ideal. Another limitation is about the way used to obtain the answer of the population. This limitation does not allow us to extrapolate results for all city, but give us an induction about some COVID problems.

However, it is believe that, for the municipality of Caruaru, the local public administration does not need to link specific awareness campaigns by age group, but needs to be concerned with mitigating fake news. Without clear and immediate actions to refute fake news, the COVID-19 pandemic will be much more challenging [13]. Therefore, the public authorities should increase the population's level of confidence in the information provided by municipal management. This information should be aligned with the recommendations of the World Health Organization.

Abstract. In general, qualitative intra-criterion evaluation is intuitively based on the decision makers' perceptions and knowledge. In this type of evaluation, commonly, the elicitation process uses semantic scale. This type of scale has a standardized size (e.g., 5 points), and, in many cases, it can be improper. Therefore, this paper presents a computational system based on "play cards" procedure to aid decision makers in the evaluation process in subjective criterion. This allows quantify alternatives based on their rank position, without to establish a standardized size for the scale. The main contribution is assisting decision makers with a user-friendly system in subjective criteria intra-criterion evaluation for multiple criteria subsequent evaluation.

Keywords: Decision Making, Decision support, Preference elicitation, Normalize.

1 Introduction

The decision making is in fact an integral part of everyday life, but it is also a complex activity and potentially of the most controversial, where it need to choose an alternative among a set of alternatives, as well as to choose ways of evaluate them [1]. Complex problems are generally evaluated through a multi-criteria analysis, and decision-maker's preferences are a fundamental input to any Multi-Criteria Decision Aid (MCDA) problem, so their elicitation and representation are obviously important [2].

Thus, when it comes to a multi-criteria model, two types of preferential information can be distinguished [3]: (1) Inter-criteria preferences – judgements refereed to the relative importance addressed to the information carried by each single criterion; and (2) Intra-criterion preferences – judgements refereed to relative values addressed to alternatives, representing different levels of performances in one criterion.

This paper is interested in obtaining intra-criterion preferences. In addition, this paper emphasizes also qualitative evaluation, i.e., subjective criterion, because, in this type of criterion, the decision maker's intuition, based on expertise and experience,

has great relevance due to the lack of quantitative information [4]. Many decision makers have difficulty in evaluating alternatives on subjective criterion.

In this type of evaluation is normal to make use of semantic scales, where decision maker must carry out their evaluations using a pre-defined scale. Nevertheless, this scale size may not be appropriate for decision maker's preferences, or for the set of alternatives. For these reasons, Fontana et al. [5] proposed the use of a procedure, inspired by the work of Simos [6], which uses a 'play cards' to facilitate the quantitative intra-criterion evaluation in subjective criterion. The advantages of this procedure are: (a) it is not tied to a standardized size of scale, and (b) it allows a global visualization of both the order of preference for the alternatives and the intensity of preference between them.

Therefore, since the intra-criterion subjective evaluations are made intuitively, the 'play cards' aim is transcribing this alternatives ranking mental image in order to extract information less complex as possible. Thus, this paper presents a user-friendly computational system to aid decision makers perform 'play cards' procedure to provide intra-criterion information. A normalization process different from [6] is used. This system is able to assist decision makers cognitively, speeding up the evaluation process.

The paper is organized as follows. Section 2 provides a literature overview. Section 3 explains the methodology. Section 4 showed the computational system developed. Finally, section 5 presents some concluding remarks.

2 Literature overview

Preference modelling aims to capturing stakeholder's preferences for the specific decision context. The difficulty here is that preferences cannot be considered as predetermined and stored within human mind. Instead they are modelled during the decision aid process by means of specific techniques, often as a learning procedure, enabling decision makers to think and realise their aspirations [3].

Traditionally, researchers and practitioners agreed that sound decision-making was understood to occur under only the most rational conditions. The ideal decision-maker was understood to be acting from a "cool head". That is, decisions must come from only rational, cognitive processes — emotions have no place in reasoning. Emotions were considered elusive (i.e., not easily understood, much less amenable to empirical research methods) and, thus, unfit to warrant a legitimate position in the quest for understanding ''good'' judgment processes [7].

However, the problem is that one cannot extract emotions and feelings from an understanding of the functions of the mind. Research in the neural processing of decision making reveals that a collection of neural systems dedicated to functions of reasoning and decision making (particularly decisions in personal and social domains) is the same collection of systems involved in emotion and feelings [7-8].

In this way, the measurement system of preferences should be adapted. Measurement is the process by which numbers or symbols are assigned to attributes of entities in the real world in such a way as to characterize the attributes by clearly defined

rules [9]. Thus, measurement requires: entities (objects of interest); attributes (characteristic of entities); and rules (and scales) for assigning values to the attributes [10].

Normally, according to Muravyov and Savolainen [11], the quantitative value (entities and/or attributes) are measured by ratio and/or interval scales (rule), while the qualitative value by ordinal and/or nominal scales, that are also referred to as 'soft' or 'weak' scales. These terms (nominal, ordinal, interval and ratio) are used to describe a hierarchy of measurement scales. Let's assume a scale, s, used to assign real numbers, to a set of elements, A, from observed judgments, so that for all i and j in A, $s(i) > s(j)$ if and only if i is preferred to j. The measure scale can be defined as following [11-13].

Nominal scale (NS) is characterized by some set A and equivalence relation defined on it. In other words 'nominal' scales are merely a ranking, allowing to describe variables or to designate the subject, without recourse to quantification. It is the most elementary level of representation, based on the classification and grouping of elements for the formation of distinct sets. The variables expressed in nominal scale can be compared using only the relations of equality or difference. For example, in Fig.1, there is a set A, where its elements are classified using a nominal scale containing four basic labels: symbols, consonants, vowels and numbers.

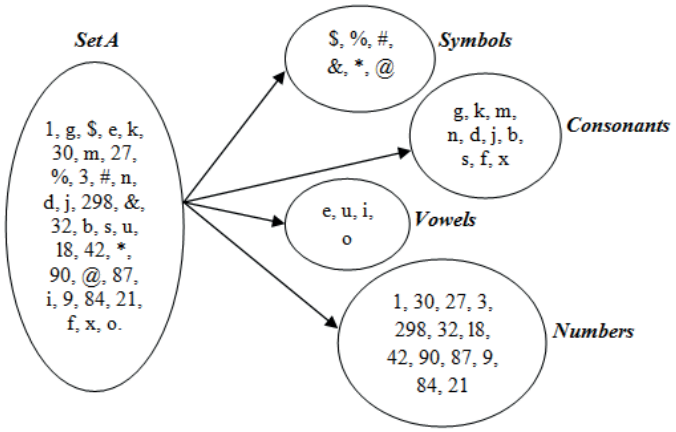

Fig. 1. An example of a nominal scale.

Ordinal scale (OS) is obtained by 'adding' a strict order relation to an equivalence relation on the same set A. Each observation is the association of the individual measured at a given class without quantifies the magnitude of the difference compared to other individuals. For example, in Fig.2, there are five labels (Very bad, Bad, Regular, Good, Very good) that establish an order to preference. Although the order is clear, there is no reference to the magnitude of the difference in preference between labels.

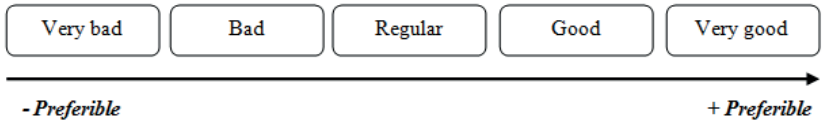

Fig. 2. An example of an ordinal scale.

Interval scale (IS) reaches a "quantitative" form of the previous scale. The zero point on an interval scale is a matter of convention or convenience. This point can be illustrated by two scales of temperature, Centigrade and Fahrenheit (see Fig.3), where there are equal intervals between values and an arbitrary zero is agreed upon for each scale. On these scales, it makes no sense to say that one value is twice or some other proportion greater than another. Interval scales involve a difference (–) instead of order (>) operator, so the set of permissible transformations for interval scales preserves relative differences.

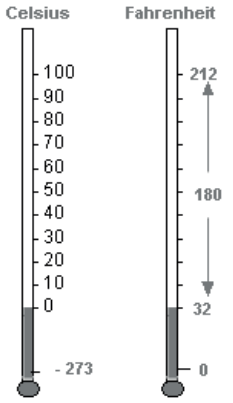

Fig. 3. An example of an interval scale.

Ratio scales (RS) are those most commonly encountered and they are possible only when there are operations for determining all four relations: equality, rank-order, equality of intervals, and equality of ratios. A ratio scale is characterized by a well-defined object whose intensity from natural zero (absolute zero) is the unit of measure. Fig.4 is a good example of a ratio scale that shows a standard of measurement and the zero is clearly the absence of value.

Fig. 4. An example of a ratio scale.

However, some multi-criteria decision methods search facilitate the elicitation process of the decision maker's preferences by using semantic rating scale, considering that the decision maker can be hesitate in assigning quantitative values on differences of attractiveness [14]. The semantic scale consist in a series of rating scales in which the decision maker is asked to give a judgment about something along an ordered dimension, usually of five until nine points, where there are two opposite ends (e.g., strong-week). It is usually used for psychological measures to assess attitudes, beliefs and preferences [15].

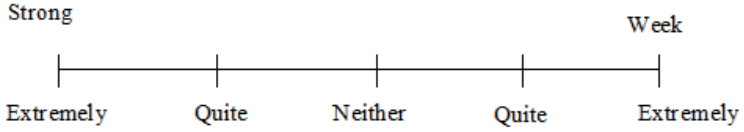

Fig. 5. An example of a semantic scale.

Some authors argue that it is an ordinal scale, others that it is possible to assign values between points, making it an interval scale, especially due to the possibility of assigning a zero point [16]. However, this scale assigns predefined values to the decision maker, and is not appropriate in some cases.

3 Methodology

The computational system developed here was based on the dynamic of 'play cards' from Simos' procedure [6], originally used to establish criteria weights. Thus, Fontana et al. [5] proposed the similar dynamic to evaluate alternatives. Briefly, the decision maker (DM) receives *n* cards of the same size with the name of each alternative and he/she receives others *n* 'white' cards. All cards must have the same size. Then, the DM should rank the cards, with the alternative names, from the worst to the best. However, the system proposed here uses the rank "from the best to the worst", because its visualization seems easier for users.

In the rank, the DM may allocate the same position when they consider the alternatives like the same importance, or insert white cards when they consider the difference between two alternatives subsequent is more than one unit u. Thus, it procedures as follows:

- No 'white' card means that the distance between two alternatives subsequent is equal to one unit *u*,
- One 'white' card means that the difference is twice u, and so on.

Suppose a set *F* with *05* alternatives, $F=\{x_1, x_2, x_3, x_4, x_5\}$, where the DM is requested to rank the alternatives on a certain subjective criterion Cr_1 according to his/her preference. DM should insert white cards always that he/she considers appropriate. Thus, one possible rank is illustrated in Fig.6.

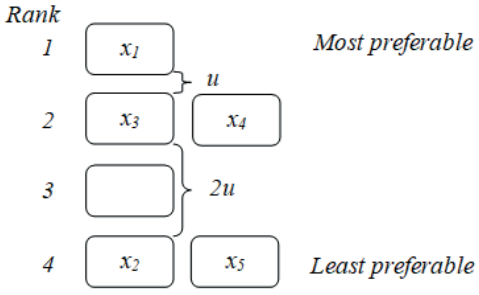

Fig. 6. Illustration of the rank given by DM ('play cards')
Source: Adapted from [17].

To sum up, it can be said that the use of 'play cards' allows to measure the decision maker's preferences through an interval scale. As described earlier, in the interval scale is defined a unit, which will be used in comparison of the alternatives from the difference between two subsequent values. Thus, the ranking visualization facilitates preferences understanding, between the alternatives differences, for DM. Therefore,

the value 'u' represents the difference existing between two subsequent positions in rank. Moreover, it cannot say that the order given by DM represents a value in ratio scale, such as the alternative x_3 is two times more important than the alternative x_2. However, it can say that there is a difference in preference between these alternatives in 2 times 'u' (which is the unit of measure adopted for the difference).

To be more precise, imagine your salary account. Independently on previous months, when you find no money, it means absolute zero (ratio scale). Now, let's considered your preference for fast food on a semantic scale: (-2) Dislike … (-1) … (0) … (+1) ... (+2) Like. The zero value does not characterize lack of taste, only that you neither love nor hate; i.e., zero does not represent absence of value.

Preferences are modeled in a qualitative way because it is hard for humans to give exact numeric values [18]. However, purely qualitative comparisons are not enough in all cases, especially when the primary attributes of interest are quantitative measures, or when outcomes differ in respect to some easily measurable quantity. For example, in standard economic models the utility of money is proportional to the logarithm of the amount of money. Quantitative comparisons also are needed when the decision requires assessing probabilistic expectations, as in maximizing expected utility. Such expectations require cardinal as opposed to ordinal measures of desirability [19].

So, after checking the position of each alternative in rank from 'play cards' procedure, there are some normalization procedures that allow it assign values on a scale, as for example, from 0 to 1. There are basically three normalization procedures, which are [20]:

- Procedure 1: $v'_j(a_i)=v_j(a_i)/[Max\ v_j(a_i)]$, it can be interpreted as a percentage of the maximum value of $v_j(a_i)$. Indicates the distance to the leading alternative.
- Procedure 2: $v'_j(a_i)=[v_j(a_i) - Min\ v_j(a_i)]/[Max\ v_j(a_i) - \text{Min}\ v_j(a_i)]$, it can be interpreted as a percentage of range $\text{Max}\ v_j(a_i) - Min\ v_j(a_i)$. It is observed that zero means only the minimum.
- Procedure 3: $v'_j(a_i)=v_j(a_i)/[\sum_i v_j(a_i)]$, it can be interpreted as a percentage of total $\sum_i v_j(a_i)$.

Proportionality is maintained in procedures 1 and 3 (ratio scale). In the second procedure (interval scale), the proportionality is not maintained, i.e., $v'_j(a_i)/v'_j(a_k)$ is not necessarily equal to $v_j(a_i)/v_j(a_k)$. Simos' procedure used procedure 1 removing the position of the white cards.

However, there is some equivalence on scales when it considers the comparison of each alternative within the same criterion, in assessing intra-criterion. In fact, the ordering of the alternatives for each criterion will be the same for any of the three normalization procedure.

According to Campello de Souza [21], it is possible to transform data that they were recorded in a particular type of numerical scale in another type of scale, since it respect the hierarchy and the basic attributes of each scale. That is, the values provided by the play cards are from an interval scale, it can save them on this scale, or transform them into an ordinal scale, if it is decision maker interest. However, to transform them into a ratio scale, it will require more information from decision makers; such information is not available in this elicitation procedure. Thus, the procedure adopted

for values normalization phase is the procedure 2. Therefore, for the case illustrated in Fig.6, the normalized values, between 0 and 100, are shown in Table 1.

Table 1. Normalized values from Procedure 2

Alternatives	Number of cards	Position	Normalized
x_1	1	1	$v'_i(x_1)=100*([4 - 1]/[4 - 1]) = 100$
x_3, x_4	2	2	$v'_i(x_3)= v'_i(x_4)= 100*([4 - 2]/[4 - 1]) \approx 66{,}67$
White	(1)	3	--------
x_2, x_5	2	4	$v'_i(x_2)=v'_i(x_5)=100*([4 - 4]/[4 - 1]) = 0$

Note that the white card receives no value, since it is interested only in the alternatives, but the position of the white card influences in the outcome of subsequent alternatives. Alternatives in the same position receive the same value.

4 Computational system developed

Computational system was developed in Java (http://www.java.com) and was named by Normalize. Access to the system in: https://sites.ufpe.br/deplog/category/produto-tecnologico/.

The system starts indicating the number of alternatives to be evaluated in the space provided in the top of the screen (see Fig.7). Then the user must click on 'Generate' for the number of suggested alternatives appears on the screen. If the number of alternative is wrong, the user can click on 'Reset' to restart. It should be clear for decision maker that the best alternative should be ranked at the top, i.e., in the first position, then the second best and so on.

Alternatives can be renamed according to the significance given by the DM. Just click once on the alternative and a window will open, which allows name change (see Fig.7). In this window, the DM may also add observations that it will help them in this process.

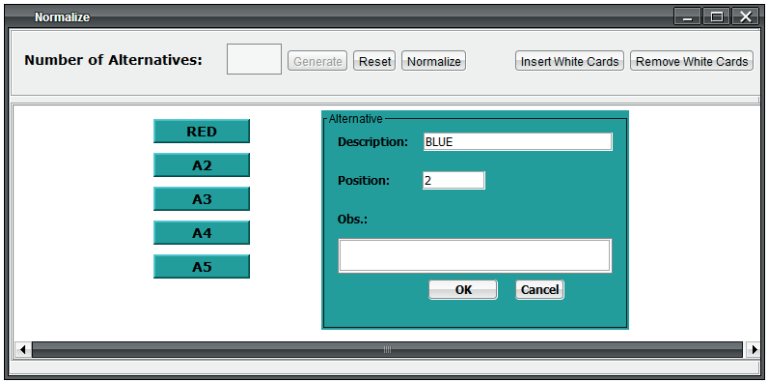

Fig. 7. Rename the alternatives.

After the initial alternatives ranking, the decision maker should ask himself/herself: "Is the distance between subsequent alternative correct?" If 'yes' the DM should click

on ‘normalize’. If ‘no’, the decision maker should insert white cards between the alternatives. For this, the DM should click on "insert white cards" and defines how many white cards want to add after some position. For example: If the DM wants two white cards between the alternatives Red and Blue, which are in positions 1 and 2, respectively, inserts position = 1 and white card = 2, as shown in Fig.8. If the DM added more ‘white cards’ than necessary, the DM can remove them by clicking on ‘Remove white cards’.

Fig. 8. Insert white cards.

At any time, the DM can change the position of the alternatives by clicking on them and modifying the information (position), as well as, if there are alternatives with equally importance, DM should be allocated on the same position. When the ranking of the alternatives satisfies the decision maker’s preferences, the DM should click on ‘normalize’. Then a table will appear with the alternatives, their position in the ranking and their normalized values, as Fig.9.

Alternative	Position	Value
RED	1	100.0
BLACK	4	40.0
BLUE	5	20.0
YELLOW	5	20.0
GREEN	6	0.0

Fig. 9. Normalization procedure.

These values are useful in comparing the intensity of preference between the alternatives. If the DM does not feel satisfied with the values shown in the table (see Fig.9), the DM can click on ‘back’ to return to the same rank (this button will appear in same place than “normalized”) or clicks on ‘reset’ and restart the process. The DM can ‘reset’ at any moment.

5 Conclusion

This paper focused on a very common problem that is the difficulty of decision-makers in evaluating alternatives on subjective criteria. This assessment is usually made intuitively, based on knowledge and experience of own decision maker. In this case, the greater the number of alternatives, the greater is the difficulty to the DM in establishes preference differences between them.

Another common problem is the use of verbal scales fixed for conducting such evaluations, since to quantitatively evaluate an alternative in a qualitative criterion is very difficult to most decision makers. For this reason, commonly, the evaluation is made by a semantic scale and, then, assigns numerical values for each label. In addition, the values range in semantic scale fixed may not be suitable for the decision maker to evaluate the alternatives properly. The ideal values range changes from decision maker to decision maker and hinder their pre-establishment.

Thus, this paper presented a computational system that performs a procedure similar to 'play cards' proposed by Simos [6] to elicit the criteria weights, but it doesn't use the same normalization process. Intuitively the DM ranks the alternatives from best to worst. The easy rank visualization facilitates the DMs to understand their preferences. In this rank, there are not restrictions as to its size, which increases the flexibility of the procedure for preferences elicitation. Each alternative position in the ranking is normalized in an interval scale, thus, the DM can apply some multi-criteria decision making method, for example.

The main contribution of this paper is the computational system developed based on play cards idea to evaluate alternatives under qualitative criteria possibility. This is a user-friendly system and it allows the elicitation procedure to be performed anywhere, with or without a facilitator presence. This system can be used in any multi-criteria problem that involves intra-criterion evaluation in subjective criteria.

This work is not intended to make a final decision. Thus, work's limitation is the fact that the developed system performs only the intra-criterion evaluation and only one criterion at a time. Advances in this system can be made to enable intra-criterion evaluation of multiple criteria, as well as inter-criteria evaluation to assist in final decision making. In addition, despite numerical transformations performed, the resulting scale is interval. Therefore, decision makers must be careful to a possible results' misuse as a ratio scale.

Mineração de processos e aprendizado de máquina aplicado ao processo de empréstimos pessoais

Pedro Antonio Boareto[1][0000-0003-3024-1772] e Silvana Pereira Detro[1][0000-0003-3383-1364]

Resumo. O processo de empréstimos é essencial para sistemas financeiros. E com a queda dos juros, tal processo ganha espaço. Processos podem ser analisados por meio da mineração de processos, que tem como objetivo a análise a partir de dados sobre a execução do processo, o que permite aprimorá-lo. Assim, esta pesquisa tem como objetivo o uso de técnicas de MP a fim de identificar melhorias para tornar esse processo competitivo em um ambiente mais tecnológico e capaz de atender uma demanda crescente. Inicialmente, foi realizada uma revisão sistemática da literatura para compreender o estado da arte da MP em ambientes financeiros. Na sequência, foi utilizada a técnica PM² a fim de compreender o registro coletado, realizar o seu tratamento, aplicar técnicas de mineração de processos e então propor melhorias. Desse modo, evidenciou-se que a MP, em sistemas bancários, é fortemente proposta junto a outras técnicas como forma de criar sistemas de previsão e identificação de fraudes. Porém, muitas vezes, não são realmente implementadas. Logo, conclui-se que o processo possui muitas oportunidades de melhorias, entre elas o desenvolvimento de técnicas que evitem que os clientes enviem documentos errados, um rearranjo das atividades entre os recursos, a eliminação da atividade "W_Handle_Leads" que não agrega valor. Como trabalhos futuros, propõe-se o desenvolvimento de um sistema de juros de empréstimos mais inteligente baseado em técnicas de aprendizagem de máquina que compreendem critérios mais sensíveis à necessidade e capacidade de pagamento do cliente.

Palavras-chave: Mineração de Processos; Business Process Management; Banco.

1 Introdução

A mineração de processos é uma área de conhecimento emergente que, com um conjunto de ferramentas, promove *insights,* baseados em fatos, que visa descobrir, analisar e melhorar os processos a partir dos dados disponíveis nos registros de eventos de sistemas [1]. Assim, [2], apresentam que 6,4% das aplicações sobre mineração de processos são destinadas a processos financeiros. Dentre tais aplicações um dos destaques é a análise do processo de empréstimos, a qual se refere a tomada de um montante de crédito, geralmente para curto ou médio prazo, por meio de um contrato junto a uma

instituição financeira, com a responsabilidade de pagamento desse valor acrescido de juros em um prazo previamente determinado.

Sua principal vantagem é a facilidade e a rapidez em conseguir o recurso desejado, até mesmo para quem já está com problemas financeiros. Entretanto, um fato histórico relevante é a crise de 2008, a qual foi motivada, essencialmente, por um abuso na concessão de empréstimos [3] o que tornou mais difícil a obtenção de empréstimos. Assim, já que tais operações não geravam mais fluxo de caixa e os bancos perdiam sua liquidez, tal cenário causou uma insegurança no mercado e os investidores passaram a retirar seu investimento de tais fundos. O que demonstrou, o grande impacto que o processo de empréstimos tem na economia e na sociedade.

Dessa forma, mesmo que gerido majoritariamente por bancos [4] a competição com emergentes instituições tecnológicas financeiras (*FinTechs)* é uma crescente ameaça para o setor [5]. Então, com a necessidade de se reinventar, técnicas modernas como modelos de aprendizagem de máquina ganham destaque. Por exemplo, [6]–[8] aplicam modelos de regressão e árvores de decisão direcionados à classificação e identificação de fraudes em sistemas de empréstimos bancários. Neste contexto, este trabalho tem como foco estudar o registro de eventos disponibilizado por uma instituição financeira, o que busca compreender seu processo e sugerir melhorias e aplicar modelos de otimização da análise de crédito para manter a competitividade desse processo no mercado. Além disso, o processo de empréstimo pode ser beneficiado com a utilização de técnicas de aprendizagem de máquina. O uso de técnicas de mineração de dados permite que o processo de negociação a respeito do valor do empréstimo seja acelerado por meio da indicação do valor máximo que pode ser ofertado ao cliente de acordo com as suas características.

2 Trabalhos correlatos

Com o intuito de compreender o estado da arte da mineração de processos, a metodologia de mapeamento sistemático da literatura desenvolvida por [9] foi utilizada. Nesta metodologia cinco etapas são desenvolvidas: (1) realiza-se a definição do escopo da pesquisa; então (2) é conduzida a pesquisa; na sequência (3) executa-se o processo de filtragem e seleção dos artigos coletados; por sua vez (4) é desenvolvido o processo de classificação dos artigos; e por fim (5) é realizado o mapeamento sistemático.

Assim, observa-se que a abordagem da mineração de processos (MP) em instituições do setor financeiro acontece de diversas formas. [10] utilizam a técnica IBUPROFEN de reestruturação destinada a modelos de processos para assegurar a garantia de qualidade nos relatórios de contas bancárias. A técnica proposta tem a função de reduzir as falhas de qualidade. Os autores afirmam que tais questões afetam seriamente a compressibilidade e a capacidade de modificação dos modelos de processos de negócios.

[11] e [12] analisam processos correlatos a *call centers* de bancos e apresentam, respectivamente, uma investigação sobre a duração de atendimentos que utiliza registros de eventos junto da lógica fuzzy a fim de compreender desvios de processo com foco na perspectiva da frequência dos dados e ao levar em conta possíveis flutuações nesse processo; e uma análise que utiliza um algoritmo *fuzzy* em um banco da Tailândia com

o intuito de compreender as interrelações no processo do atendimento ao cliente e quais problemas podem existir no sistema desenvolvido.

Questões que envolvem fraude bancária são analisadas por [6]–[8]. Os autores utilizam a MP como ferramenta auxiliar durante o processo de classificação das fraudes existentes e até mesmo no desenvolvimento de sistemas que colaboram na previsão de novas fraudes. Respectivamente, os autores fazem uma avaliação de fraude em empréstimos ao usar MP junto de analise multicritério (AHP) e lógica *fuzzy* para aumentar a acurácia da avaliação. Os autores identificaram ataques em contas de clientes através do *internet banking* ao utilizar um método de avaliação de fraude baseado em uma classificação por algoritmos de árvore de decisão e *alpha*+++.

Em empréstimos pessoais e cheque especial, além de [6] citado no parágrafo anterior, [13] aplicaram a MP como base para descoberta do processo e análise, e desenvolveram um modelo preditivo usando redes neurais para minimizar a alocação de recursos destinados a essa área. Já [14] implementam a MP, de modo exploratório e guiado, com foco na relação dos produtos de uma ou mais atividades, que visa assim, visualizar, quantificar e compreender a correlação entre as interações das atividades do processo. [15] abordam a aplicação de um modelo de MP de serviço de solicitação de empréstimo em um banco dos Países Baixos e ressaltam, em seu trabalho, como a drástica perca de precisão que a falta de dados gerada nos logs de evento é traduzida no modelo.

3 Etapas da pesquisa

Essa pesquisa, com o intuito de promover uma melhoria à instituição financeira e mantê-la competitiva em meio aos novos desafios do setor, é dividida em quatro etapas, conforme **Fig. 1**.

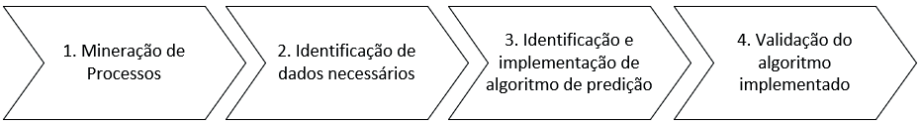

Fig 1. Etapas da pesquisa

Essas etapas compreendem, respectivamente, um projeto de MP que visa permitir uma compreensão do estado real do processo assim como compreender as melhorias que podem ser realizadas de forma pontual. Na etapa seguinte, é realizada a coleta dos dados necessários para a aplicação de algoritmos de aprendizagem de máquina que não estão presentes na primeira etapa, junto a instituição financeira. Após a coleta de dados, a próxima etapa se refere à identificação e implementação do(s) melhor(es) algoritmo(s) de predição para tal caso. E por fim, a validação da implementação e da qualidade do algoritmo junto a instituição. Este artigo refere-se à primeira etapa, a qual se aborda a aplicação da mineração de processos, a fim de identificar as principais características do processo de empréstimo de um banco.

4 PM²: Process Mining Project Methodology

Diversas metodologias foram e ainda são desenvolvidas para a aplicação da MP, tais como Process Diagnostics Method (PDM) de [16], Life-Cycle de [1] e PM²: Process Mining Project Methodology de [17]. Estas metodologias buscam uma otimização e padronização das abordagens dessa tecnologia emergente. A metodologia PM² pode ser descrita como um modelo composto por etapas. De modo que, cada uma dessas etapas possui entradas e saídas. [17] aponta que essas etapas são compostas por "objetos" de objetivos gerais, de dados e modelos. Os objetos dessa metodologia relacionados ao objetivo são *1.Perguntas de pesquisa* (derivadas dos objetivos do projeto); que são encontradas como pergunta inicial do projeto, e *2.Descobertas de performance(ex: gargalos de processo)*; e/ou *3.Descobertas de segurança(ex: inconformidades que identificam fraudes);* que ocorrem nas iterações de análise da mineração de processos, e que assim levam a *4.Ideias de melhoria* que são implementadas na etapa 6. Assim, essa metodologia pode ser organizada em seis etapas conforme **Fig. 2.**

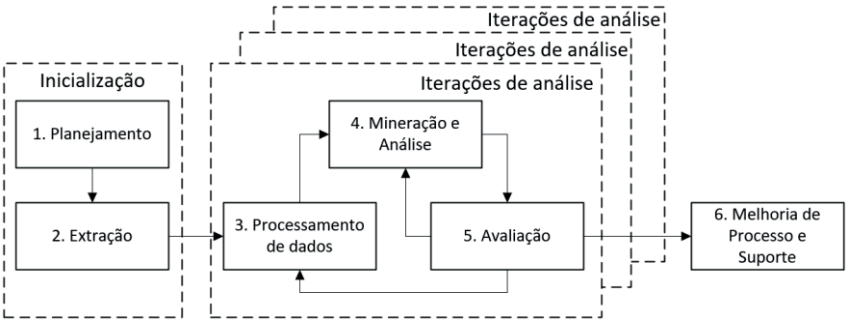

Fig 2. Metodologia PM² - adaptado de [17]

A fase de inicialização contém as etapas 1 e 2, e é composta pelas atividades (a) identificar questões de pesquisa, (b) selecionar processos de negócio, (c) determinação do escopo do projeto e (d) extração dos dados de eventos. Esta etapa tem como input os processos da organização a serem estudados e como saída os dados de evento. Na sequência, tem-se a fase de iterações de análise, compostas pelas etapas 3, 4 e 5. Nesse momento são realizadas, respectivamente, as atividades de (e) criar visões, (f) agregar eventos, (g) enriquecer logs, (h) filtrar logs, (i) descoberta de processos, (j) verificação de conformidade, (k) aprimoramento, (l) análise de processos, (m) diagnosticar, (n) verificar e (o) validar. Esta etapa recebe o *output* da fase anterior e tem como resultado, a elaboração de ideias de melhorias para o processo ou então, se necessário, de novas perguntas para uma nova fase de iteração de análises. Por fim, a etapa 6, refere-se à Melhoria de Processo e Suporte, que possui como entradas as ideias de melhoria da fase anterior e como saídas as modificações no processo. Esta etapa é composta pelas atividades de (p) implementação de melhorias e (q) suporte operacional. Esta etapa visa aplicar o projeto com intuito de modificar a execução do processo real.

5 Estudo de caso

5.1 Inicialização (Planejamento e Extração)

Para a aplicação da mineração de processos foi usada a base de dados, com informações reais e anonimizadas, fornecida por uma instituição financeira. Essa base de dados contém dois registros de eventos (*logs*) de todas as solicitações de empréstimos que aconteceram em 2016 até seu atual *status* em 2 de fevereiro de 2017. A base de dados possui 1202267 registros de eventos que são referentes a 31509 pedidos de empréstimos, bem como um arquivo com todas as 42995 ofertas criadas para esses pedidos. De modo que mais de uma oferta pode acontecer para cada solicitação. Além disso, apresenta 149 recursos (funcionários ou sistema da empresa) que operam em tais processos e atividades organizadas em 3 tipos: A (mudanças de estado da solicitação), O (Mudanças de estado da oferta) e W (eventos de processo). As informações existentes na base de dados são apresentadas na Tabela 1.

Tabela 1. Conteúdo dos logs

Base de dados	Conteúdo
Solicitação	– Valor solicitado (em euro) – (RequestedAmount) – Tipo de solicitação – (ApplicationType) – Motivo da solicitação – (LoanGoal) – Identificador – (ApplicationID)
Oferta	– Valor ofertado – (OfferedAmount) – Retirada Inicial – (FirstWithdrawlAmount) – Número de parcelas – (NumberOfTerms) – Valor da parcela – (MonthlyCost) – Score de crédito do cliente – (CreditScore) – Quem criou a oferta – (Resource) – Se a oferta foi selecionada – (Selected) – Se a oferta foi aceita – (Accepted) – Identificador – (OfferID)

A partir da compreensão do processo que é investigado e de seus elementos, foi realizada a primeira etapa da metodologia PM2, a qual se refere ao desenvolvimento das seguintes questões de pesquisa, que são a base do projeto:

1. Quais são os principais gargalos do processo?
2. Quanto tempo o processo costuma demorar e como isso pode ser melhorado?
3. Quais são os principais desvios do processo padrão? E eles são um problema?
4. Como os processos poderiam ser melhorados?

Por sua vez, as etapas (b) seleção dos processos de negócios, (c) definição do escopo da extração de dados e a (d) extração dos dados de eventos dos sistemas de negócio não serão necessárias, uma vez que essas atividades foram, respectivamente, definidas e ofertadas pela instituição financeira. Dessa forma, como *output* da inicialização, se tem

as perguntas de pesquisa e os dados de eventos para realização de processamento dos dados e mineração.

5.2 Processamento de Dados

Na etapa de processamento de dados, a atividade criação de visões (e) não é necessária, afinal o foco deste projeto é a resolução das questões de pesquisa que visa encontrar potenciais melhorias e não o desenvolvimento de pontos de vistas. Também não é necessária a etapa (f) agregação de eventos, pois tal base já possui os registros de dados na granularidade e exibição necessárias. Porém, a fim de atingir o objetivo dessa pesquisa, os *logs* de ofertas e solicitações foram, (g) enriquecidos e (h) filtrados da seguinte forma:

1. Enriquecimento no *log* das ofertas:

- $Juros = \frac{Customensal * Númerodeparcelas}{ValorOferecido}$

(1) Com essa informação, junto do score de clientes, objetivos da solicitação de empréstimos e valor solicitado é possível analisar as relações das recusas de ofertas de empréstimos;

- $\%Coletado = \frac{ColetaInicial}{ValorOferecido}$

(2) Permite a análise do comportamento do consumidor em relação aos seus objetivos com o empréstimo;

5. Filtros no *log* de solicitações:

- Seleção apenas das variantes compartilhadas por pelo menos onze casos, compondo assim, 80% de todos os casos, 5% das possíveis variantes e 74% dos eventos. Dessa forma, o número de outliers é reduzido, permitindo um maior foco no processo padrão;
- Remoção de variantes com fins de processos marcados nas atividades "A_Pending", "A_validating", "O_Sent (mail and online)", "O_Sent (online only)" e "W_Call after offers". No log de evento todas as solicitações estão marcadas com um estado "*end*" no fim de suas sequências. Assim, estes *cases* não são relevantes para uma análise do processo como um todo, portanto foram excluídos do *log* de evento.

Desse modo, com os filtros aplicados, se tem como *output* dessa etapa o *log* de eventos do processo. O *log* de solicitação de empréstimos passa a ter 44% dos casos e 36% dos eventos em relação ao seu *log* original. Por sua vez, o *log* das ofertas mantém o volume de 100% dos seus casos com adição de outras duas novas colunas de dados.

5.3 Mineração e Análise

Com o *log* de eventos filtrado e enriquecido como input para a fase de mineração e análise, é então possível, primeiramente, a descoberta do processo. Para tal, o software DISCO é utilizado. Assim, com o foco voltado para a compreensão de gargalos e melhorias de processo, foi escolhido a realização de uma análise de granularidade com 100% das atividades e dos caminhos, para compreender em que arcos ou atividades realmente estão os gargalos. Além disso, duas perspectivas foram escolhidas para a descoberta e análise do processo. Primeiramente, em relação à perspectiva de frequência, a medida baseada em casos foi selecionada por apresentar, com um maior grau de significância, o processo mais recorrente. Enquanto que, as medidas absolutas e de repetições máximas apresentariam melhor as medições de retrabalho do processo. Por sua vez, a perspectiva de tempo permite uma compreensão mais realista do processo padrão enquanto que as medidas total e mediana apresentam perspectivas melhores para análises de custo das atividades ao longo do ano e a medida de duração mínima e máxima apresentam os maiores desvios do processo.

Assim, foi possível identificar que tal processo pode ser dividido em quatro subprocessos, e extrair o mesmo para BPMN, conforme a figura a seguir. Primeiramente, o subprocesso de (1) criação da solicitação de empréstimos, seguido pela etapa de (2) negociação, responsável por definir como será o empréstimo com o cliente; então, caso necessário para a etapa de (3) validação, responsável por analisar a documentação enviada pelo cliente, e por fim a etapa de (4) decisão, responsável por definir se tal empréstimo será realizado, conforme **Fig. 3**.

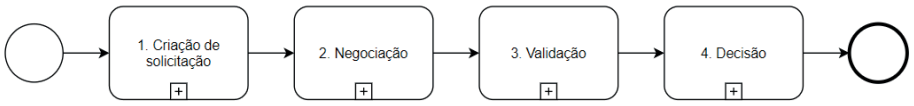

Fig. 3. Diagrama em BPMN do macroprocesso de solicitação de empréstimos

Sendo assim, é importante destacar também que tal processo possui diversos caminhos, e estes podem seguir por variantes com *loops,* que fazem o processo retornar para etapas anteriores, o que gera retrabalho. Então, com o objetivo de tornar a compreensão desse processo mais clara e entender o seu processo padrão, as três variantes mais comuns do processo (menos de 1% das variantes) responsáveis por 34% dos casos e que contêm 25% dos eventos, foram filtradas. Essas variantes de processo foram identificadas pela ferramenta DISCO e então traduzidas para BPMN através do Celonis, conforme a **fig. 4.**

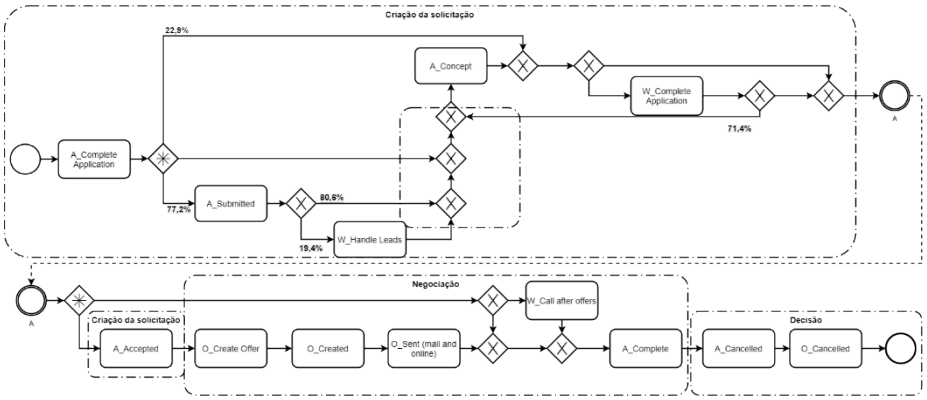

Fig. 4. Principais variantes do processo de solicitação de empréstimos – BPMN

Dessa maneira, é possível compreender que o processo de solicitação de empréstimos bancários, na perspectiva das principais variantes é composto por apenas 3 etapas. Diferente do processo completo, o subprocesso (3) Validação, responsável pela análise de fraudes e de documentos dos clientes, não acontece frequentemente. De modo que, o comportamento mais comum observado inicia com a (1) criação da aplicação ("A_Create Application"), que segue para ("A_submitted") em 77,2% das vezes, de modo que, em 21,2% dos casos realiza-se em paralelo("A_Concept"). Ou então para ("W_Complete Application") em 22,9% das ocorrências. De modo que, quando segue para ("A_submitted"), 19,4% das vezes, o processo passa por ("W_Handle leads") e o restante direciona-se diretamente para ("A_Create_Application"). Na sequência, durante as atividades de ("A_concept") e ("W_Complete Application"), o processo pode se encaminhar de uma atividade para a outra, o que acontece em 71,4% dos casos. Porém, em momento nenhum entra em *loop*, o que indica que acontece somente se necessário, e sem necessidade de retrabalhos. Então, o processo é aceito e passa pela (2) negociação ("A_Accepted" → "O_Create Offer → "O_Created" → "O_Sent (mail and online)"). Na sequência, o processo vai para "W_Call after offers" (o que acontece também em paralelo, em 65% dos casos), e então é (4) finalizado ("A_Complete" → "A_Cancellled" → "O_Canceled").

Sob outra perspectiva, através do uso do Disco, é possível notar que em nenhum dos 5895 casos que o processo padrão compreende houve retrabalhos. Entretanto, é notável que a atividade "W_Handle Leads", que acontece após "A_Submitted", o qual é específico para solicitações que começaram pela internet é utilizada em apenas 15% dos casos. Isso acontece quando alguma falha na avaliação automatizada da solicitação ocorre, o que gera a necessidade da realização de um trabalho manual pelo funcionário do banco.

Outra etapa importante para a compreensão dos processos, é a realização de uma análise descritiva dos dados disponíveis. Para isso, a ferramenta Disco disponibiliza a duração média e a frequência relativa de cada atividade. Assim, referente ao processo de solicitação de empréstimos, é possível notar que, para seu *log,* a maioria dos processos é cancelado. Em números absolutos, existem 39312 atividades somadas de "A_Complete", "A_Cancelled", "O_Cancelled" e "O_Refused". Entretanto existem

apenas 13920 casos. Ou seja, é evidente um número alto de retrabalho durante a negociação do empréstimo. Também, observa-se que 0,15% dos processos terminam como "A_Complete", enquanto que 19,9% terminam como "O_Refused" e 79,48% terminam como "A_Cancelled" ou "O_Cancelled". O que indica assim que mais de 99% das solicitações acabam sendo canceladas ou recusadas. Então, ao comparar a frequência relativa dos casos na base de solicitações de empréstimos, ao se saber que se tem 13920 pedidos de empréstimos criados e 18106 registros da atividade "O_Create Offer" criados, evidencia-se que as atividades da etapa de negociação são as atividades com maior número de retrabalho.

Sob outro prisma, a duração média de cada atividade durante o processo pode ser observada com o intuito de sinalizar as atividades que mais acontecem e/ou se repetem, e as atividades que são gargalos. Assim, é evidente que o subprocesso de validação é o mais longo, principalmente para as atividades do tipo "W". Pode-se destacar a atividade responsável por avaliar potenciais fraudes, que possui duração média de 8 dias e 11 horas, e pode chegar até 37 dias. Porém, tal atividade, acontece em apenas 0,18% dos casos. Em segundo lugar, para o caso de ser necessário ligar em busca de solicitação por documentos faltantes, é gasto em média 1 dia e 20 horas nessa atividade. Tal atividade acontece em 19,4% dos processos, e chegou a repetir em até 3 vezes no mesmo caso. E, em terceiro lugar, a atividade de validação da solicitação, tem uma duração média de 1 dia e uma hora, porém esta acontece em todo *case* que chega nessa etapa. Assim, "W_Validate application" apresenta ser o gargalo mais recorrente e mais importante a ser resolvido. Seguido por "W_Call incomplete files" e "W_Assess potencial fraud", que são atividades menos recorrentes, porém com durações ainda maiores.

Por sua vez, o subprocesso de ofertas, já citado anteriormente como parte do processo de solicitações, tem um *log* de eventos próprio, devido a sua importância. Portanto, permite uma análise específica e isolada de seus elementos. Seu modelo em BPMN é representado na **Fig. 5**.

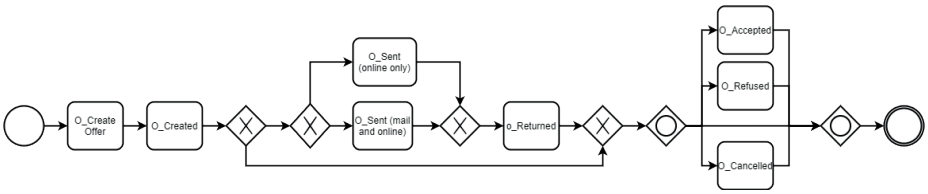

Fig. 5. Diagrama em BPMN do processo de ofertas

Este processo começa com uma criação de oferta ("O_Create Offer" e "O_Created"), que pode se direcionar para ("O_cancelled") ou realiza um processo de envio das ofertas para os clientes, por e-mail e online ("O_Sent (online and mail)") ou somente online ("O_Sent (online only)") e aguardam o retorno ("O_Returned"). Então, as ofertas podem ser canceladas ("O_Cancelled"), aceitas ("O_Accepted") ou recusadas ("O_Refused"). E, então fundamental ressaltar que esse processo possui uma complexidade menor do que o de solicitações, entretanto é mais rico em número em relação a seu conjunto de atributos disponíveis para estudo. Em relação aos gargalos, a análise da frequência relativa das atividades mostra que 88,67% das ofertas são canceladas ou

recusadas, sendo 2,93% logo após a criação da oferta. Além disso, 95% das ofertas são enviadas por e-mail e online, enquanto que apenas 5% são enviadas somente online e 21,5% das ofertas não são respondidas, tendo como última atividade o seu envio.

Também, é fundamental compreender as relações entre as variáveis disponíveis nessas bases, com o intuito de identificar possíveis causas de gargalos e melhorias de processo. Para isso, o software R, que de forma simples permite a análise de informações em grande escala, foi utilizado para realização da análise de correlação das variáveis disponíveis. Dessa forma, a **Fig. 6**, apresenta a correlação entre todas as variáveis.

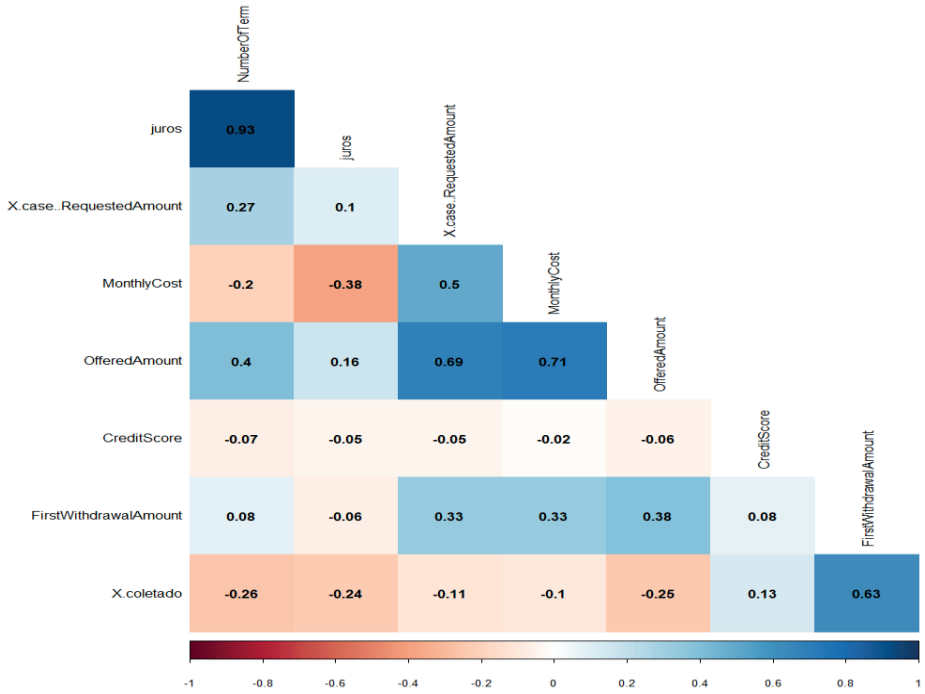

Fig 6. Correlações entre variáveis do registro de ofertas

Assim, é possível observar, primeiramente, que alguns casos como "%¨coletado" e "FirstWithdrawlAmount" não devem ser analisados juntos, pois a informação "% coletado" varia de "FirstWithdrawlAmount". Então, para esse trabalho, a relação do custo mensal e do valor ofertado (correlação mais elevada), foi analisado junto a cada uma das outras variáveis, em forma de gráfico de pontos, e suas observações com o número de parcelas e com o "% coletado" têm destaque. Dessa forma, é possível notar, que os juros aumentam na medida que a relação entre o custo mensal é menor e o valor oferecido aumenta, conforme a **Fig. 7**.

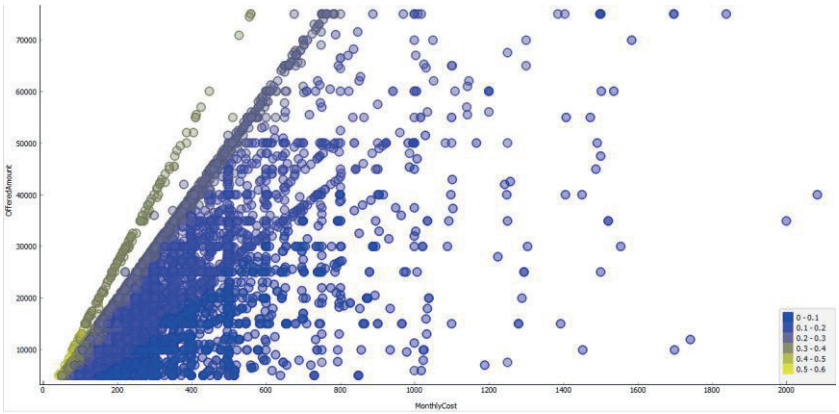

Fig 7. Relação entre custo mensal x Valor ofertado x taxa de juros

Então, nessa etapa é possível identificar como *output* para a etapa de avaliação, as etapas do processo, o que permite a compreensão a respeito do processo, quais são suas variantes e seu processo de comportamento mais comum. Por meio de uma análise descritiva das atividades, quais são as que mais demoram para execução, tanto no sentido absoluto quanto ao se levar em conta sua frequência. Além disso, a taxa de recusa e de aceites das ofertas que tal processo possui, assim como a aceitação das ofertas. E, por fim, compreender a relação entre as variáveis desse processo com o intuito de encontrar formas de melhorar o mesmo.

6 Discussão e considerações finais

Com o intuito de atender ao objetivo da pesquisa, o qual visa identificar, por meio de *logs* de eventos, os gargalos e desvios de um processo de empréstimos bancários e assim poder propor melhorias para tal processo, foi aplicada à metodologia de mineração de processos PM² de [17], no anseio de compreender os *logs* de eventos disponíveis, aplicar métodos de mineração de processos para descobrir os gargalos e desvios do processo e então ser capaz de apresentar sugestões de melhorias. Tal técnica que consiste em 6 fases e tem como objetivo responder à questão de pesquisa, possui as fases (1) planejamento do projeto, (2) extração dos logs, (3) processamento dos dados e (4) mineração e analise, realizadas no capítulo anterior. Por sua vez, a etapa (5) avaliação é desenvolvida nessa sessão e aborda a relação dos resultados da etapa anterior com as questões de mineração de processos levantadas, e dessa forma propõe ideias de melhorias.

Dessa forma, a respeito da questão "*I. Quais são os principais gargalos do processo?",* em relação ao processo geral de solicitação de empréstimos bancários, é notório que as atividades que mais atrasam o processo, quando acontecem, são as atividades relacionadas a validação da solicitação e analise de potencial fraude. Entretanto, a atividade que mais atrasa o processo, caso aconteça, não está presente em 99,8% dos casos. Sendo assim, as atividades que dizem respeito ao ato de ligar para o cliente quando documentos estão em falta e de validar a solicitação com o cliente, ocorrem em respectivamente 19,4% e 100% dos casos, e que pode inclusive ter retrabalhos,

apresentam-se como os principais gargalos desse processo, devido a sua relação entre recorrência e duração. Por sua vez, o *log* de ofertas não apresenta registros sobre os tempos das atividades e não permite uma compreensão estatística relacionada a suas durações.

Já sobre "*II. Quanto tempo o processo costuma demorar e como isso pode ser melhorado?"* A partir do registro de eventos é possível obter inferências em relação a quantidade de eventos que duraram certo período de tempo. Assim, nota-se para o *log* de solicitação de empréstimos uma duração média de 25,6 dias, com uma amplitude de 1,6 até 169 dias, enquanto que a mediana está em 30,8 dias e a maior densidade de casos se concentra entre 30,4 e 32,3 dias com 30,5% dos casos. De modo que, tal processo pode ser melhorado a partir da redução do tempo de espera que tal processo possui, afinal 79,3% dos casos possuem um tempo de espera maior do que 24 horas e 8% possuem um tempo de espera maior do que uma semana útil. O *log* de ofertas não apresenta registros de tempos durações, impossibilitando tal análise.

A questão, "*III. Quais são os principais desvios do processo padrão? E eles são um problema?"* A atividade "W_Handle Leads", acontece em 15% dos casos. Esta, é executada quando o sistema não é capaz de processar a submissão independentemente, fazendo com que um operador necessite lidar manualmente com tal submissão. Portanto, tal atividade é um processo corretivo e deve ser resolvido e eliminado.

Por sua vez, em relação a questão "I*V. Como os processos poderiam ser melhorados?"* as seguintes melhorias são sugeridas:

- A partir da pergunta um, é notável uma melhoria ao garantir que os documentos sejam entregues corretamente. Tal melhoria pode ser realizada a partir da configuração de uma interface de usuário que se preocupe com a experiência do mesmo e que, de forma intuitiva e amigável, oriente o cliente a preencher corretamente os dados necessários para seu tipo específico de solicitação. Além disso, pode contar com *machine learning* para mapeamento de arquivos que valide a qualidade dos anexos inseridos;
- Já, com a pergunta é notável a redução dos tempos de espera com a finalidade de minimizar os gargalos e aumentar o índice de ofertas aceitas por meio de uma realocação das atividades entre os operadores. Afinal, são notórios grandes valores de tempo de espera durante as atividades, e também que os recursos (operadores) não realizam tempos totais de trabalho de forma igualitária.
- A partir da pergunta três, a da exclusão da atividade "W_Handle Leads", que executa um papel puramente corretivo no processo é notável. Esta, pode ser executada a partir de um estudo aprofundado dessa atividade e de suas correlatas.
- Através das **fig. 6 e 7** nota-se a possibilidade do desenvolvimento de um sistema de juros e parcelamento mais flexível e inteligente com algoritmos que permitam avaliações e predições mais completas e sensíveis em relação a capacidade e forma de pagamento que visa maximizar a conversão do número de propostas aceitas.

Portanto, o trabalho realizado apresenta que o processo de empréstimos é essencial para os sistemas financeiros. De modo que, mesmo com o novo desafio do setor,

relacionado a concorrência com as emergentes *FinTechs*. O processo estudado apresenta uma série de potenciais melhorias, conforme citado acima, que podem ajudar a instituição, a qual o *log* pertente, a se manter ou ainda se destacar no mercado. Tais melhorias, que podem ser desde correções de *loops* do processo ou eliminação de atividades desnecessárias e até mesmo desenvolvimento de formas de comunicação mais assertivas com os clientes, são implementadas na sexta e última etapa da mineração de processos, que diz respeito a melhoria de processos. Entretanto, essa etapa não cabe no escopo desse trabalho e, portanto, tais melhorias se direcionam como sugestões de trabalhos futuros.

Assim, como sequência desse trabalho, será necessário a identificação de todas as variáveis coletadas durante a etapa de criação de solicitação e negociação junto a instituição financeira, já que não fornecidas integralmente nesses *logs*. E dessa forma, mapear quais são as variáveis mais capazes de predizerem valores e parcelas que são propostos em empréstimos junto aos clientes. Então, com essa informação, identificar o melhor algoritmo de aprendizagem de máquina, implementa-lo nesse processo, e por fim, realizar uma atividade de validação da qualidade desse projeto junto a instituição financeira

Abstract. The accelerated growth of the population and the consumption of goods produce a sustained increase in the generation of solid waste. In this paper, we present a case study of a Colombian company dedicated to collection, transportation, and final disposal of solid waste. The associated problem consists of optimizing the fleet and arrival times of the vehicles at the waste unloading destination to reduce possible congestion in the system and avoid collapse inside the discharge facility. The methodology used comprises two stages. The first one consists of a mathematical programming model through which the optimal fleet size is found. In the second stage, a heuristic algorithm is used to sequence the collection micro routes to be carried out by each vehicle during the week. The result obtained reveal a reduction between 10% and 30% of current fleet and sequencing that allows increasing the number of daily trips made by each vehicle.

Keywords: solid waste collection, optimization, heuristic.

1 Introduction

The world generates 2010 million tonnes of solid waste annually, its generation increases as the population growth, economic development is promoted [1], standard of living improves, and consumptions habits change [2]. Solid waste generates from unwanted or discarded materials at the end of its life cycle, comes from domestic, commercial, institutional, and industrial consumption [3]. Waste come mainly from organic matter which represent the highest percentage of generated waste and the remaining fraction comes from metals, glass, plastics, papers [1], leather, rubbers, batteries, textiles, and construction materials [4].

Globally, developed countries are the generators of 34% of waste [5]. Latin America generates on average, one kilogram of solid waste per inhabitant per day representing around 10% of the generation of solid waste worldwide. Colombia generates approximately 6% of this waste, which equals to 12 million tonnes per year. The high generation of these waste and the low level of reusing and recycling of them leads to saturation

in landfills and facilities to dispose and treat them generating a negative impact on the environment and the society [6].

Solid waste management involves the processes of generation, separation and onsite storage, collection, transfer and transport, processing, recovering and final disposal [7]. Collection and transport represent between 60% - 80% of the total cost of solid waste management [8, 9]. These processes include the activities of collecting and transporting solid waste to a destination that may be a landfill, a material processing of treatment facility or waste transfer station (WTS) [2]. Particularly, a WTS is a place within an urban area where the transfer of solid waste of compactor vehicles to others vehicles with greater load capacity is carried out, which are in charge of transporting the waste to the sanitary landfill located on the outskirts of the city.

In the city of Medellín (Colombia) a new WTS will be installed through which the operation of the service can be improved with respect to activities such as the collection, transport, and transfer of solid waste. This brings benefits at an environmental and social level. In addition, this allows the operation to be more efficient generating a reduction in costs. The operation of these facilities depends on the proper management of the municipalities, who oversee generating strategies for proper management and of defining possible areas of location [10].

The WTS generates positive impacts related to the compactor vehicle fleet, such as the reduction in travel times to landfills and unproductive times, at the same time, allowing a reduction in the operating costs [11]. In this order of ideas, this work addresses the case study of a Colombian company dedicated to providing the collection, transportation, and final disposal of solid waste. We present a mathematical programming model to determine the optimal fleet size and a heuristic algorithm built to sequence the micro routes that each vehicle will serve during the week.

The remaining of this paper is structured as follows. Section 2 contains a literature review about applications of operations research and optimization in solid waste collection. Section 3 presents the description and formulation of the mathematical models developed to determine the optimal fleet size and sequence of the collection micro routes. Section 4 also presents a heuristic algorithm to schedule the micro routes. Section 5 presents the results of the case study. Finally, Section 6 concludes and present the major findings of the case study as well as future work opportunities.

2 Literature Review

Operational research has been successfully applied in planning of solid waste collection systems for decision making at the strategic, tactical, and operational levels. In the practice, location models have been used to locate landfills, WTS [12] and containers in residential areas [13]. Additionally, it has been used to take tactical frequency assignment and zoning decisions [14, 15] such as operational routing decisions [16] and personnel assignment [17]. The interested reader is referred to [18] for a recent review focused on the location of facilities (landfills and WTS) and other strategic and tactical decisions (zoning, frequency allocation, fleet composition, etc.). Furthermore, in [8] the authors presented a review focused on the routing of collection vehicles.

In Colombia, operational research has been used for the planning of solid waste collection systems for residential waste, hazardous waste, and recycling. For example, in [19] the location of landfills with potential for future expansion was studied to address the problem caused by the number of landfills that have reached the end of their useful life in Colombia and other emerging countries. Using a multiobjective optimization model, the authors of this work explore the trade-off between operating costs and environmental risk for a Colombian case in the center of the region Valle del Cauca. Similarly, in [20] the location of WTS for the collection of hazardous hospital waste is studied with a bio-objective optimization model that is solved with a genetic algorithm.

Recently, the interest for the use of waste in the framework of circular economy projects such as waste-to-energy or industrial symbiosis has opened new opportunities for the application of optimization models and heuristic solution methods. For example, the one presented in [21] where sugar cane residues are used for energy cogeneration and those presented in [22, 23] that addressed the design of collection routes for the reuse/recycling of residues.

Particularly, to determine the fleet size in the collection of solid waste, the possibility of making multiple trips with the same vehicle in one day arises as an interesting planning option. This characteristic results in the vehicle routing problem with time windows and multiple trips like the one studied in [24]. In this work, the authors initially generate the routes with a vehicle routing problem with time windows and in a second stage they group them into trips made by the same compactor vehicle to minimize the fleet size. Unlike the work presented in [24], in our case, the modification of the collection micro routes is not possible. The only possible modification for these routes is to change the collection day to reduce the number of vehicles needed and better balance the amount of waste collected per day.

Likewise, in [25] the scheduling of waste collection routes was studied in a similar context in which the collection routes are fixed. In a real application carried out in the city of Porto Alegre (Brazil), the aim is to minimize collection costs which include fixed (fleet) and variable costs associated with the routes. Although this problem can be efficiently solved in some cases, the objective of balancing the waste that reaches the transfer and recycling facilities force the authors of this study to resort to heuristic methods inspired on the generalized assignment problem. In our case study, heuristic methods are also used to program the routes on a particular day. However, we considered an (alternative) objective function that has been studied previously in the literature in the so called *truck allocation problem* [8]. This is the minimization of the number of routes that arrive at the WTS in each hour to prevent queuing and the collapse in the internal operation.

In the next section, we describe the two-phase procedure for route scheduling used for the redesign of the solid waste collection operation in the city of Medellín motivated by the entry in operation of a new WTS.

3 Mathematical Model

WTS's allow the discharge of compactor vehicle waste to larger capacity containers or vehicles, this prevents compactor vehicles from traveling to landfills. The introduction of WTS generates a reduction in travel times and an increase in the number of trips that compactors can make to collect waste (known as micro routes in this context). For a city that has defined the micro routes in which the operation is carried out, an implementation of a facility like this leads to a reduction in the vehicle fleet and savings in operating costs. Therefore, through the application of mathematical programming techniques, we developed mathematical models to determinate the optimal size of the compactor vehicle fleet and the sequence of micro routes that must be served by each vehicle during the week.

3.1 Determination of vehicle fleet size

The determination of the fleet size was formulated as a lexicographic bi-objective optimization model, that finds the number of vehicles necessary to provide the service and, additionally, seek to balance the amount of tonnes collected during each day by these compactor vehicles. These objectives were combined lexicographically defining the reduction of the fleet size as a maximum priority objective.

Given a set M = {1,2, …,$|M||$} of micro routes in which the urban solid waste collection service is provided at a given frequency F = {1,2, …,$|F|$}, each element of F represents a possible combinations of days D = {Monday, Tuesday, …,$|D|$} that must be visited. To determine the number of compactor vehicles, the variable Y corresponds to the maximum number of vehicles scheduled in a day. The variable X_{ij} takes the value of one if the micro route $i \in M$ is assigned to a a vehicle at frequency $j \in F$ and zero otherwise. Additionally, the binary variable C_i is equal to one if the micro route $i \in M$ changes frequency in the new planning and zero otherwise. The variable W_k indicates the amount of tonnes of waste collected on day $k \in D$. Finally, variables W_{min} and W_{max} represent the minimum and maximum amount of tonnes of solid waste collected. Using theses variables, the optimization model is formulated as follows:

$$Min \;\; Y + \epsilon(W_{máx} - W_{mín}) \tag{1}$$

Subject to:

$$\sum_{j\in F} X_{ij} = 1 \;\; \forall i \in M \tag{2}$$

$$\sum_{j\in F} n_j X_{ij} = r_i \;\; \forall i \in M \tag{3}$$

$$\frac{1}{dv}\sum_{i\in M}\sum_{j\in F} v_{kj} X_{ij}(d_i + \max[t_i^{ET}, t_i^{BO}] + f_i + tET + tBO) \leq Y \;\; \forall k \in D \tag{4}$$

$$\sum_{i\in M}\sum_{j\in F} tn_i X_{ij} v_{kj} = W_k \;\; \forall k \in D \tag{5}$$

$$W_{min} \leq W_k \leq W_{max} \quad (6)$$

$$C_i \geq 1 - X_{ij} \quad \forall i \in M, j = freq_i \quad (7)$$

$$\sum_{i \in M} C_i \leq mc \quad (8)$$

$$Y \in Z^+ \quad (9)$$

$$X_{ij} \in \{0,1\} \ \forall i \in M, j \in F \quad (10)$$

$$C_i \in \{0,1\} \ \forall i \in M \quad (11)$$

$$W_k > 0 \ \forall k \in D \quad (12)$$

$$W_{min}, W_{max} > 0 \quad (13)$$

The first term of the objective function (1) seeks to minimize the number of compactor vehicles, taking into account that this value will cover all micro routes, while the second part (multiplied by a very small number ϵ) minimizes (lexicographically) the difference between the minimum and maximum tonnes collected throughout the days of the week, so that a balance in the tonnes collected daily is achieved. Constraints in (2) and (3) guarantee that a micro route will only be assigned to a vehicle on a frequency that is compatible and that this frequency in turn will be compatible with the number of weekly collections in which the micro route must be visited (r_i). Expressions (4) ensures that there is sufficient fleet availability to serve all the micro routes, given the start times of the operation in the micro routes (from the WTS t_i^{ET} or the depot of the compactors vehicles t_i^{BO}), the duration of the micro route (d_i), the completion time of the operation (in the WTS f_i or in the depot tBO), the unloading time in the WTS (tET) and the daily availability of the vehicles (dv). Constraints in (5) accumulated each day the tonnes of the micro routes (tn_i) assigned to frequencies that include this specific day of the week (parameter $v_{kj} = 1$). The minimum and maximum amount of waste collected in the week is defined through constraints in (6). Additionally, expressions (7) and (8) count and control the number of micro routes that change in their frequency (with a maximum value mc), taking into account that they can only be changed for those that include the same number of weekly visits (n_j) in constraints (3) and considering the current assignment of each micro route ($freq$). Finally, expressions (9), (10), (11), (12), (13) define the domain of the decision variables.

3.2 Micro route sequencing

In this work micro route sequencing is understood as the assignment and scheduling of the micro routes to be carried out by vehicles in such a way that their arrival at the WTS to discharge the waste is balanced during the day. Therefore, a second optimization model was developed to make decisions regarding the time at which each micro route will be carried out and to define which of the vehicles will carry it out.

Along this line, the objective function is responsible for minimizing the number of compactor vehicles that arrive at the WTS each hour of the day. In this model, variables

T_{iv} and F_{iv} indicate the hours in which the vehicle $v \in V$ starts and ends the collection in the micro route, respectively. The binary variable L_{ih} takes the value of one if the collection of the micro route $i \in M$ ends in the hour $h \in H$ and zero otherwise. The variable S_{iv}, also binary, takes the value of one if the vehicle $v \in V$ performs the micro route $i \in M$ and zero when it does not. Furthermore, the binary variable P_{im} indicates if the vehicle $v \in V$ performs the micro route $i \in M$ before the micro route $m \in M$ ($P_{im} = 1$), and ($P_{im} = 0$) if not. Finally, the variable Nr refers to the maximum number of micro routes completed in one hour of the day. The following optimization model (inspired by parallel machine sequencing [26]) was formulated for micro route sequencing using the above described variables.

$$Min\ Nr \tag{14}$$

Subject to:

$$\sum_{v \in V} S_{iv} = 1 \ \ \forall i \in M \tag{15}$$

$$\sum_{i \in M} S_{iv} \leq rm \ \ \forall v \in V \tag{16}$$

$$S_{iv} \sum_{z \in Z} hi_z \, zn_{iz} \leq T_{iv} \ \ \forall i \in M, v \in V \tag{17}$$

$$S_{iv} \sum_{z \in Z} hf_z \, zn_{iz} \geq T_{iv} + \max[t_i^{ET}, t_i^{BO}] + d_i \ \ \forall i \in M, v \in V \tag{18}$$

$$F_{iv} = T_{iv} + d_i + \max[t_i^{ET}, t_i^{BO}] + f_i + tET \tag{19}$$

$$F_{iv} \leq L_{ih} hd \ \ \forall i \in M, v \in V, h \in H \tag{20}$$

$$\sum_{i \in M} L_{ih} \leq Nr \ \ \forall h \in H \tag{21}$$

$$F_{iv} \leq T_{mv} + K(1 - P_{im}) \ \forall i \in M,\ m \in M,\ v \in V \mid i \neq m \tag{22}$$

$$F_{mv} \leq T_{iv} + KP_{im} \ \forall i \in M,\ m \in M,\ v \in V \mid i \neq m \tag{23}$$

$$\sum_{i \in M} (d_i + \max[t_i^{ET}, t_i^{BO}] + f_i + tET) S_{iv} + ntBO \leq dv \ \ \forall v \in V \tag{24}$$

$$Nr \geq 0 \tag{25}$$

$$T_{iv}, F_{iv} \geq 0 \ \ \forall i \in M, v \in V \tag{26}$$

$$L_{ih} \in \{0,1\} \ \ \forall i \in M, h \in H \tag{27}$$

$$S_{iv} \in \{0,1\} \ \ \forall i \in M, v \in V \tag{28}$$

$$P_{im} \in \{0,1\} \ \ \forall i \in M, m \in M \tag{29}$$

The objective function (14) minimizes the number of routes that are completed at any hour of the day. Subject to constraints (15) that guarantee that a micro route is only assigned to one vehicle. During the day, a compactor vehicle may have assigned at most rm micro routes, which is ensured by expressions (16), these micro routes must be completed in the available operating time for the vehicles, the remaining time is dedicated to preventive maintenance. The group of constraints (17) and (18) ensure thar the

operation of the micro routes is carried out within the time windows (with start time hi_z and end time hf_z) established for the zone to which they belong (zn_{iz}=1). Expressions in (19) relates the variables corresponding to the time when a vehicle starts and ends the micro route, this indicates that a vehicle ends a micro route when it performs the collection operation and makes the respective discharge in the WTS of the solid waste that was collected. Likewise, constraints (20) and (21) count and control the termination of micro routes and indicate that the time at which a vehicle ends a micro route must not exceed twenty four hours a day (hd). Expressions (22) and (23) guarantee that two micro routes will not be programmed at the same time for the same vehicle, each vehicle is in charge of starting a micro route and completing it in order to start the collection in the next micro route, to ensure this these constraints include a large real number K to ensure that only one of the constraints is activated. The time that a compactor vehicle can operate during the day is given by constraints in (24), which considers the operating times in the micro routes, the discharge of solid waste at the WTS at the end of each working duty (carried out twice a two day to change the crew of the compactor, which means that two trips are made to the depot $ntBO$). Finally, expressions (25), (26), (27), (28) and (29) define the domain of the decision variables.

4 Sequencing heuristic

Given the number of micro routes programmed per day (more than 100) and the number of compactor vehicles involved in the operation (between 80 and 103), the direct use of model (14) – (29) is not possible. In particular, given the complexity of the model to assign the micro routes (mainly the time windows of zones and the daily availability of the vehicles), a commercial optimizer was not able to find a feasible solution in reasonable times.

Therefore, for the scheduling of the micro routes that the vehicles must perform every day, a heuristic algorithm was developed under the logic of the parallel machine sequencing problem [26], composed of a randomized construction phase and an improvement phase that tries to balance the number of routes that finish at each hour of the day. The implementation of the two phases assigns the micro routes to the vehicles in such a way as to balance their arrival at the unloading facilities (WTS) in order to avoid congestion that may be generated inside this facility. The randomized construction phase consists of assigning the micro routes to the vehicles, considering the possible routes that it can take. For this case study, in a duty, a compactor vehicle can perform two routes. The first has as its starting point the depot, which is the place where these compactors start and end the operation. The second route departs from the WTS, this is carried out only if the vehicle has made its first micro route and has the possibility of making a second route without exceeding the working day. The general flow diagram of this phase is shown in Fig. 1.

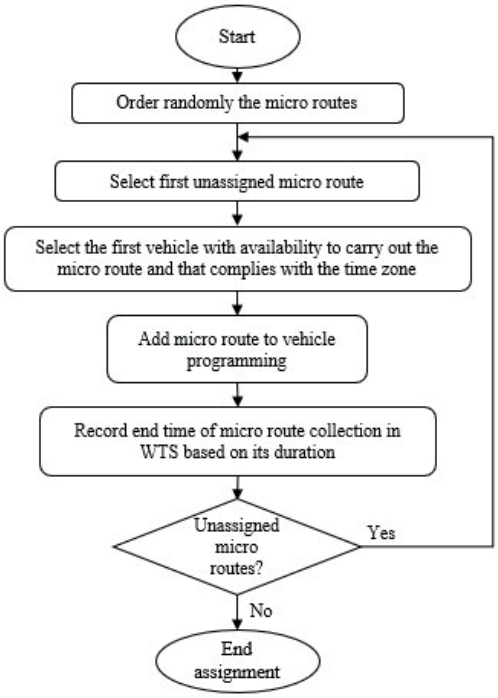

Fig. 1. General scheme of the randomized construction phase for the allocation of the micro routes to the compactor vehicles.

The improvement phase aims at achieving a better balance in the arrival of vehicles at the WTS, the objective is to minimize the number of vehicles that arrive per hour at the facility. Through the local search moves *change of start time* in the collection of the micro routes and *exchange of the visit order* in the micro routes of the same vehicle, the results obtained in the construction phase are improved, that is, a better balance is obtained. Taking the number of vehicles that arrive per hour at the WTS, the improvement phase is performed if an improving solution is found. Within these two moves, the change of start time move analyzes systematically the effect of displacing (in up to three 30 minutes steps forward or backward) the start time of the first route of each compactor vehicle that is involved in the critical time zone (i.e., $h^* = argmax_{h\in H}\{\sum_{i\in M} L_{ih}\}$, the one that determines the maximum number of vehicles that enter the WTS at a given time). When this first move fails to improve the solution, *the move exchange of the visit order* systematically exchanges the order of the micro routes of vehicles arriving in the critical time zone to search for further improvements.

The improvement phase ends when a local optimum is found, that is, and improved result that reduces the number of vehicles arriving per hour at the WTS and none of the two moves is able to improve it further (i.e., a local optimum for the two improvement procedures). When finished, the best balance obtained with the heuristic is reported. This phase is shown in Fig. 2.

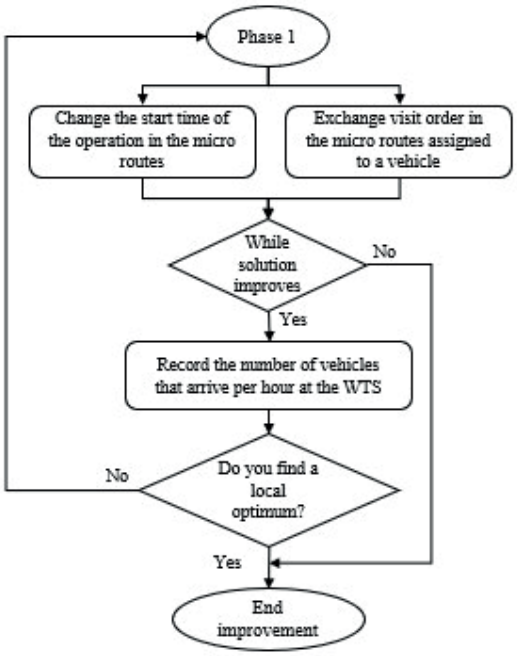

Fig. 2. General scheme of the improvement phase in the balance the arrival of compactor vehicles to the WTS.

5 Results

The proposed mathematical models were implemented in the Xpress Optimization Software using its Mosel Language. The data used come from the historical records of a Colombian company dedicated to the collection and treatment of solid waste, these data were recorded between 2019 and 2020. The results obtained for both models include the projection of growth of the tonnes of solid waste generated in the city for the period 2023 to 2038.

The heuristic procedure for the assignment of micro routes and to balance the arrival of compactor vehicles at the WTS, was implemented in Visual Basic for Applications (VBA) for Excel [27]. To evaluate the performance inside the new WTS using the determined compactor vehicle fleet size and the proposed micro routes scheduling, we used a discrete event simulation model implemented in the Flexsim Software.

Through the model developed to determine the optimal fleet size that considers the effective operating times of the vehicles during the collection of solid waste, we obtained a reduction in the number of compactor vehicles between 10% and 30% with respect to the fleet that currently is under operation. This reduction is due to the decrease in time (about 40%) dedicated to the transport of solid waste with the new WTS. Being closer to the micro routes when unloading waste, allows compactor vehicles to carry out more trips during the day compared to those performed today to the landfill

without the WTS. Fig. 3 illustrates the number of compactor vehicles that are necessary to carry out the collection in the micro routes in the years following the startup of the WTS and considering the projected volumes of solid waste for these years. This quantity considers the fleet with which the micro routes scheduling was performed by the heuristic procedure for model (14) – (29). In some cases, more vehicles were used when compared to those found with the initial mathematical model (1) – (13). Time windows constraints in the zones of the city made not possible to program all the micro routes with the initially determined fleet size. For instance, to ensure feasibility of the second model an increase of 4% of the initial fleet size was needed for the first projected year.

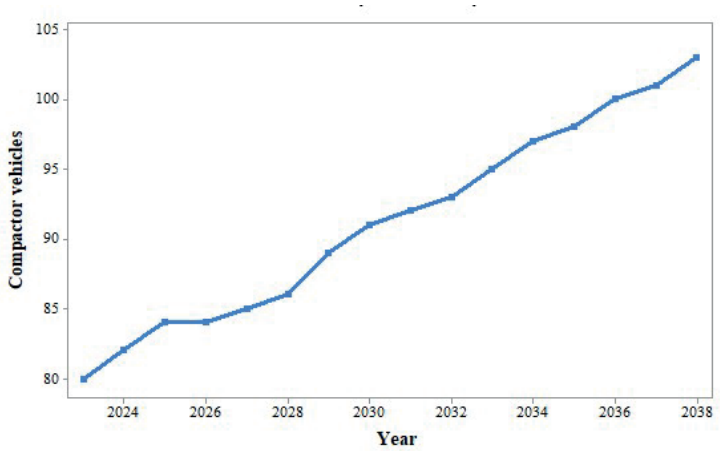

Fig. 3. Compactor vehicle fleet size projection.

When considering a change in the frequencies of the micro routes, a better balance of the tonnes collected daily was obtained. With only a 10% change in frequency of the micro routes, a difference of less than one tonne of collected waste is achieved between the days of the week (i.e., the difference between the day of greatest collection and the day of least collection). It should be noted that in the initial situation (with current frequencies) this range is 121 tonnes. The better balance of the collected waste brings a 4% reduction in the fleet size.

The results obtained with the heuristic for the first projected year, in which the WTS will have started its operation, will be discussed. With the first phase, corresponding to the randomized construction, the arrival of vehicles at the WTS are represented in Fig. 4. The critical hour occurs in the afternoon, in which 29 vehicles finish 12.3% of the micro routes and enter the WTS to carry out the respective discharge of solid waste, during this hour the queue generated inside the WTS increases since all vehicles go through internal unloading operations in which only one vehicle at a time is allowed. With the implementation of the first randomized construction phase, approximately 17% of vehicles can carry out between one and two micro routes per day. For the operation in the new WTS, it is not profitable to operate a vehicle to make only one or two trips as they are currently used to transport and unload solid waste in a landfill located outside the city. However, in the results obtained we show that the randomization of

the micro routes is an influencing factor in the allocation and may be one of the reasons why some vehicles do not reach more than two micro routes. In this case it is ideal, that they can complete up to four micro routes daily. This objective is achieved after the improvement phase.

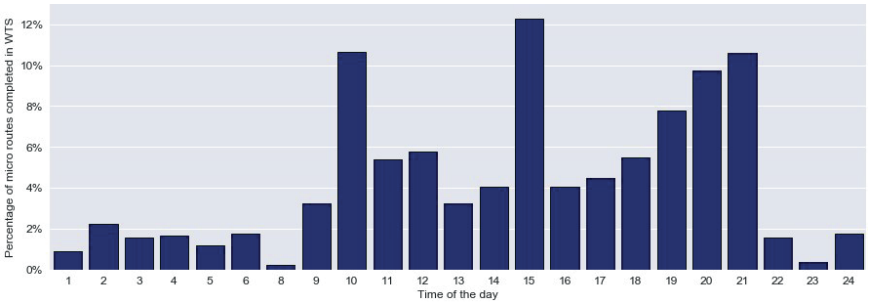

Fig. 4. Behavior in the arrival of compactor vehicles to the WTS after the collection of waste in the micro routes under the application of the randomized construction phase.

By implementing both phases of the heuristic, the results indicate that 6.5% of the vehicles will carry out only two micro routes a day and the remaining percentage will be in charge of collecting solid waste for three or four micro routes. This indicates that approximately 94% of vehicles will collect between three and four micro routes daily. Under this scenario, the percentage of vehicles arriving at the WTS at the critical hour decreases by approximately 14%. In Fig. 5, the result obtained with the implementation of the two phases of the heuristic can be seen, in this case, for the critical hour, the vehicles discharge (on average) the waste of 10.3% of the micro routes served daily.

The comparison of figures 4 and 5, reveals that by means of the randomized assignment and the improvements phase implemented in the heuristic, it was possible to obtain a better balance in the arrival of vehicles at the WTS at critical times. Furthermore, with the reduction in arrival times at the new facility the vehicles have a greater use since they perform a greater number of micro routes that exceeds the trips currently made by each compactor.

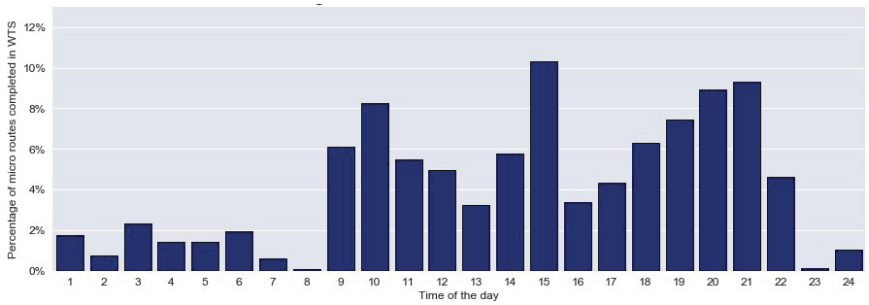

Fig. 5. Behavior of the arrival of compactor vehicles at the WTS after the collection of waste in the micro routes under the application of the randomized construction and improvement phases.

The use of a discrete event simulation model made it possible to evaluate the performance inside the facility, considering the best balance of vehicle arrival at the WTS. For this facility to be operationally viable, in addition to the arrival of vehicles, come other elements must be taken into account: the waste discharge points, the amount of resources for internal and external use to transport the waste to the landfill, the parking slots for these resources and defined locations for scales, porter's lodge and other necessary spaces for the operation.

Different scenarios were proposed considering the variation of the resources that will be used in the WTS. Table 1 shows the results obtained from this variation. The queue analyzed corresponds to the one formed before the entrance scale for the compactor vehicles, this is a critical queue and its formation depends on the availability of unloading points, trailers and internal trucks, if at a given moment none is available or the scale is busy, a queue will begin to form inside the WTS.

Trailers	External trucks	Internal trucks	Compactor vehicles			
			Maximum queue	Average queue	Average time in queue (minutes)	Average time in WTS (minutes)
21	18	4	35	3	20	40
29	18	4	18	2	15	35
35	20	5	12	0.5	2	23
40	20	5	12	0.17	2	22

Table 1. Simulation results.

For the case study, the different scenarios and the capacity of the future facility were analyzed to determine the amount of resources required. Due to the queues allowed in the system, we determined that the continuous operation of the WTS requires 35 trailers and for these vehicles the corresponding parking slots should be considered since they have to wait while they pass to the unloading points.

6 Conclusions

In this paper we present the mathematical models developed to support the tactical decision making of the solid waste collection and transportation operation by a Colombian company. The first mathematical model determines the optimal fleet size of the compactor vehicle to cover the total number of micro routes in the years following the entry into operation of a new WTS. The second model was developed to schedule the service of micro routes during the working week. However, due to its complexity, it was not possible to find a feasible solution with a commercial optimizer in a reasonable time for this model. Therefore, the scheduling of the micro routes was performed using a heuristic algorithm composed of two phases. The first phase consists of a randomized construction heuristic that assigns micro routes to the compactor vehicle while keeping the time windows of the zones and the available operating hours of the vehicles. The second phase improve the initial assignment in order to balance the arrival of vehicles at the WTS using two moves (that change of start time of the micro routes of a vehicle or exchange the order in which they are performed).

Through the application of these models, a reduction between 10% and 30% of the vehicle fleet was obtained for the projected years (years following the entry in operation of the WTS) with respected to the fleet size that the company operates currently. In our scenarios of analysis, these compactor vehicles manage to cover all the micro routes and more than 90% carry out between three and four micro routes daily.

A future study could consider the routing of compactor vehicles in such a way as to reduce the times of completion of the micro routes and, therefore, reduce the fleet size. Likewise, the effect of the change in the frequencies of the micro routes could be considered to know its impact on the programming of the micro routes and on the determination of the fleet size. Furthermore, the scheduling of working hours for the crews of the vehicles could be included in the assignment of micro routes to vehicles. This to better include the labor legislation that regulates the assignment of personnel to the operation and their well-being.

Abstract. We applied a modeling tool for linking molecular architecture of low-density polyethylene produced in high-pressure tubular reactors to linear viscoelastic behavior. The modeling approach applies a rheological model based on the reptation theory to connect molecular structure, in terms of molecular weight distribution, to the shear viscosity flow curve. The model is validated against experimental data of low-density polyethylene produced in an industrial reactor.

Keywords: Low-Density Polyethylene, Tubular Reactor, Rheology, Mathematical Model.

1 Introduction

Low-density polyethylene (LDPE) is widely used in many modern applications due to its versatile end-use properties. One of the most widely used production technologies is radical polymerization in high-pressure tubular reactors. This polymerization process produces polymer chains with a relatively broad molecular weight distribution (MWD) and many branches, both long (LCB) and short (SCB). The characterization of the polymer molecular structure helps industrial practitioners find its correlation with the process operating conditions, such as temperature or pressure. Furthermore, it has been established that the chain microstructure controls the end-use properties of polyolefins, including their rheological behavior. Taking advantage of this fact, different grades of LDPE can be obtained, each of which may be engineered to meet special processing and end-use needs.

Linear viscoelastic parameters, such as the relaxation modulus (G), dynamic moduli (G', G'') and the complex viscosity (η^*) are commonly used to characterize polymer melts. They are measured under low-frequency rotational tests, which ensures that the rheological response is due only to the molecular architecture of the polymer. de Gennes [1] and Doi and Edwards [2] where the first to propose a detailed molecular model for predicting these rheological properties for well entangled linear polymer melts in terms of the MWD. The theory of double reptation of Tsenoglou [3] and des

Cloizeaux [4] is usually applied together with reptation concepts. This last author proposed a model called time-dependent diffusion reptation (TDD). Several authors have used the TDD model in conjunction with a double reptation (DR) model obtaining excellent results for linear and slightly branched polyethylene [5].

In this work, the MWD of LDPE produced in a high-pressure tubular reactor, obtained from a high-fidelity reactor model previously developed by the authors [6], was used as input for a rheological model which applies the TDD with DR model. Parameters of the rheological model were fitted against experimental data of the rheological properties. Close agreement with the experimental information was obtained, showing that these models may be extended to polymers with higher levels of branching.

2 Rheological Model

According to the TDD with DR model, the relaxation modulus $G(t)$ of a well entangled linear polymer melt can be estimated as the contribution of a reptation modulus $G_{Rept}(t)$ and a Rouse modulus $G_{Rouse}(t)$:

$$G(t) = G_{Rept}(t) + G_{Rouse}(t) \tag{1}$$

The first one is related to the MWD through the following mixing rule, which weights contributions from various chain lengths and their mutual interactions:

$$G_{Rept}(t) = G_N^0 \left(\int_{Me}^{\infty} \left[F_{TDD}(t,M) \right]^{1/\beta} w(M) dM \right)^{\beta} \tag{2}$$

In this equation, G_N^0 is the plateau modulus, $w(M)$ is the weight fraction of chains having molecular weight M, Me is the molecular weight between entanglements, and F_{TDD} is the relaxation function of polymer chains of molecular weight M in the melt at time t. Exponent β was set to 2 according to the double reptation theory [3]. According to the TDD model, function F_{TDD} is defined as:

$$F_{TDD}(t,M) = \left(\frac{8}{\pi^2} \sum_{p\ odd} \frac{1}{p^2} \exp\left(-p^2 U(t,M)\right) \right)^{\beta} \tag{3}$$

Function $U(t,M)$ in this equation consists of two terms: the first one represents relaxation by reptation as expressed previously by Doi and Edwards [2], the second one represents contributions by fluctuations of the tube length around its equilibrium value.

$$U(t,M) = \frac{t}{\tau_{rept}} + \frac{M^*}{M} g\left(\frac{M\ t}{M^*\ \tau_{rept}} \right) \tag{4}$$

$$g\left(\frac{M\ t}{M^*\tau_{rept}} \right) = -\left(\frac{M\ t}{M^*\tau_{rept}} \right) + \left(\frac{M\ t}{M^*\tau_{rept}} \right)^{0.5} \left[\left(\frac{M\ t}{M^*\tau_{rept}} \right) + \left(\pi \left(\frac{M\ t}{M^*\tau_{rept}} \right) \right)^{0.5} + \pi \right]^{0.5} \tag{5}$$

$$\tau_{rept} = K_{rept} M^3 \tag{6}$$

When M is below Me, the relaxation process occurs through monomer friction and is described by the Rouse mechanism. For entangled polymers with $M > Me$, relaxation processes that are faster than the reptation time are also described by the Rouse process. This is represented by:

$$F_{Rouse}(t,M) = \sum_{p=N}^{\infty} \frac{1}{N} \exp\left(\frac{-p^2 t}{\tau_{Rouse}(M)}\right) + \frac{1}{3}\sum_{p=1}^{N} \frac{1}{N} \exp\left(\frac{-p^2 t}{\tau_{Rouse}(M)}\right) \quad (7)$$

$$\tau_{Rouse} = K_{Rouse} M^2 \quad (8)$$

Here $N = M/M_e$ is the number of entanglements per chain. The Rouse modulus is then obtained using a linear mixing rule:

$$G_{Rouse}(t) = G_N^0 \left(\int_{Me}^{\infty} F_{Rouse}(t,M) w(M) dM \right) \quad (9)$$

Once the relaxation modulus of the melt is estimated through eq. (1), it is used to predict the storage and loss moduli G' and G'' employing the Schwarzl [7] relations. Finally, the complex viscosity η^* is estimated as a function of the frequency ω ($\omega = 1/t$):

$$\left|\eta^*(\omega)\right| = \frac{1}{\omega}\left(G'(\omega)^2 + G''(\omega)^2\right)^{1/2} \quad (10)$$

The polymer molecular structure input for the rheological model is the MWD ($w(M)$). The rheological model involves three parameters to be determined: M^*, K_{rept} and K_{Rouse}.

3 Results and Discussion

The above theoretical model was implemented in gPROMS ModelBuilder software. The MWD of an LDPE grade obtained by simulation using a high-fidelity model developed previously [6], was used as input for the rheological model. The LCB content, also calculated by the high-fidelity model, was relatively low, which makes the proposed rheological model suitable. The plateau modulus G_N^0 was estimated using the literature value of Me = 1500 g/mol [8]. Parameter β was set at 2 as explained previously. The remaining parameters were fitted against experimental data of complex viscosity corresponding to a given LDPE grade, obtaining as a result $K_{rept} = 2E^{-9}$, $K_{rouse} = 2.28E^{-7}$ and $M^* = 70000$.

Figure 1 shows experimental data of the complex viscosity η^* as a function of ω, obtained at 180°C, 200°C and 220°C and subsequently unified at 190°C using the time-temperature superposition principle. It can be seen that the predicted curve is in good agreement with experimental data. Figure 2 displays the storage G' and loss G'' moduli.

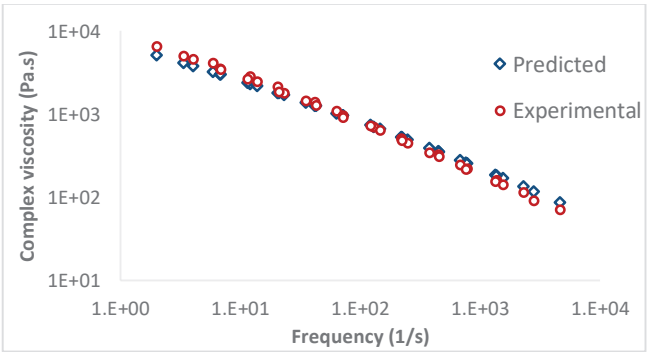

Fig. 1. Experimental and predicted complex viscosity curve of LDPE at 190°C.

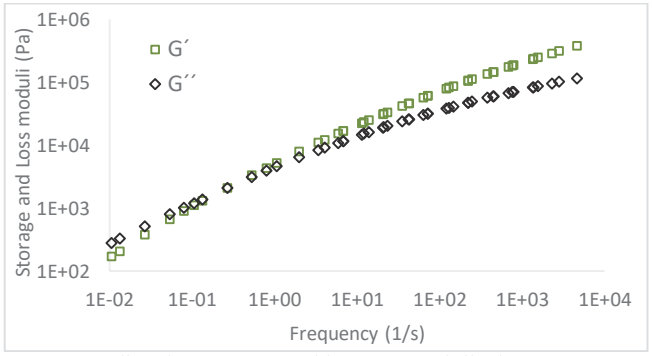

Fig. 2. Predicted storage G´ and loss G´´ moduli of LDPE.

4 Conclusion

A mathematical model for the prediction of rheological properties such as the relaxation modulus (G), dynamic moduli (G', G'') and the complex viscosity (η^*) of LDPE as a function of its MWD was applied. This model represents a useful tool to connect polymer production conditions with rheological end-use properties. For example, the complex viscosity curve could be subsequently used to predict end-use properties such as the polymer melt index, a quality control parameter very useful for polymer producers.

Abstract. This paper aims to select the best propellant for the Patrol Ships (NPa) Grajaú class, making use of an Operational Research tool, the Holtrop-Mennen method. To enable this study, parameters and information obtained through consultations with equipment manuals, acquisition contracts and visits on board the NPa were used. After data collection, a comparative analysis was made between many types of conventional Series B propellers, varying several parameters, such as the number of blades, step/diameter and area ratios, in order to choose the one that, when integrated into the propulsion system, could meet the demands of the ship understudy, especially concerning the required thrust, efficiency and cavitation criterion. As a result, the two-blade propellant was considered more indicated to be used, notably because it presented the lowest occurrence of cavitation. This article represents great relevance for academia and society, because the methodology presented in this paper can be used in several situations, aiming at increasing efficiency and sustainability in naval propellants.

Keywords: Efficiency, Sustainability, Propellant, Cavitation, Operational Research.

1 Introduction

The "Grajaú" class patrol ships (NPa) were designed to have around 200 tons of displacement. They are employed in coastal patrol of Brazilian Jurisdictional Waters (AJB), towing maneuvers and refueling at sea. The class has 12 ships, built in English or Brazilian shipyards, having passed 15 years between the construction of the prototype and the last ship of the class. The first ship of the class was incorporated into the Brazilian Navy (MB) on December 1, 1993.

With the current situation of MB, which has been facing several budget cuts, it is necessary to operate the means efficiently, aiming at the use of available resources in

the best possible way, avoiding waste. Therefore, a well-designed and integrated propulsive system is of importance, as it is responsible for the generation of movement of the vessel and the consequent fulfillment of its mission.

In this context, Operational Research (OR) emerges as an excellent tool to solve the proposed problem - increasing efficiency. The term Operational Research appeared in 1939 during World War II but was little known and nothing studied [1]. The evolution of the OR happened even after the First Industrial Revolution, where the first problems began to arise. The tools provided by the OR offer the same solution that a decision-maker could reach through intuition and that such tools can be approached through deterministic models of mathematical programming [2].

The use of the OR is justified by the fact that it is a science composed of numerous techniques and models intrinsically related to the optimization of systems, and can be considered an optimization tool par excellence [3]. The brazilian academic production focused on military problems, especially naval ones, has not had much expressiveness, or dissemination, in the field of the OR and efficiency, to meet the potential of use in MB [4].

This paper aims to select a propellant that, integrated with the other components of the Propulsion System of the NPa Grajaú, provides the necessary thrust to the ship as efficiently as possible. Therefore, the main contribution of this study is presenting an efficiency analysis in a Brazilian Navy ship, which can be replicated to other civil and military vessels, contributing to raise the energy efficiency of the propulsive systems and consequently increase in environmental and economic sustainability.

2 Methodological Procedures

Initially, the components of the Propulsion System of NPa Grajaú were described, based on data contained in the equipment manuals, information collected from the acquisition contract and onboard the ships. It is noteworthy that, after data collection, the parameters not obtained, because they are confidential, were estimated.

Then, a comparative analysis was made between two, three and four-blade Series B-series propellers, varying their area ratios using KT-KQ-J diagrams. For this, the Holtrop-Mennen method [5] was used, which provides the total resistance to the feed and buoyancy required.

Finally, we analyzed cavitation criteria and evaluated the results obtained, with the consequent selection of the propellant considered the most suitable for the full fulfillment of the mission of the NPa Grajaú.

The first step in selecting a vessel's propulsion system is to estimate its forward strength. There are a few ways to obtain this estimate of advance resistance. In this work, the Holtrop-Mennen method was used. The method provides a prediction of the components of surface ships total resistance and is widely used at ships initial design stage for estimating the resistance [6].

2.1 Literature Review

The first step in selecting a vessel's propulsion system is to estimate its Effective Horse Power (EHP). There are a few ways to obtain this estimate of ship resistance. In this section, the important parameters for the proposed analysis will be described.

Ship Resistance (R_T). Consists of the sum of forces acting on the vessel when it sails at a given speed. Its estimation allows us to determine the power required for the displacement of the ship [7]. The most common solutions for calculating R_T are tank tests with scale models and the application of statistical methods. Academically it is common to use the statistical method Holtrop-Mennen, developed by [5].

Effective Horse Power (EHP). EHP comprises the power required to overcome the R_T to the movement for a given service speed (V_S). [8]. The equation for obtaining it is described in section 2.2.

Propeller. The most common type of propellant in naval propulsion systems is the helix, which is located at the stern of the vessel and has the function of converting torque into thrust, allowing the ship to overcome the ship resistance [9].

Diameter (D). The propeller diameter is equivalent to the diameter of the disc area. In theory, the larger the diameter, the greater the increase in efficiency, however, its specification depends on the space available at the stern of the vessel [10].

The cavitation phenomenon is also a preponderant aspect in the choice of diameter, because when there is the excessive velocity at the ends of the blade, there may be cavitation in it [11].

Pitch (P). The helix pitch is defined as the pitch of the blade section cut to 0.7 of the propeller radius. It is the displacement in the forward direction when the thruster performs a full turn. As well as the diameter, the pitch is selected according to the values available by the manufacturer. In most cases, there is a wide variety of options, which provides selection in favor of maximum efficiency [10].

Design Diagrams. The propeller performance is defined by testing with small-scale models. The results of the tests carried out in open water, that is, without the presence of the hull-propellant interface, compose a database represented in the form of performance diagrams [11]. Thus, some non-dimensional coefficients are calculated based on the helix parameters, which are: Torque coefficient (K_Q), Thrust coefficient (K_T) and the Advance number (J), which the mathematical formulations for obtaining these parameters will be addressed below.

The K_T and K_Q dimensional coefficients as a function of J, when analyzed graphically, conventionally provide an estimate of the propeller efficiency [12]. Fig. 1 shows a typical performance diagram of a propeller.

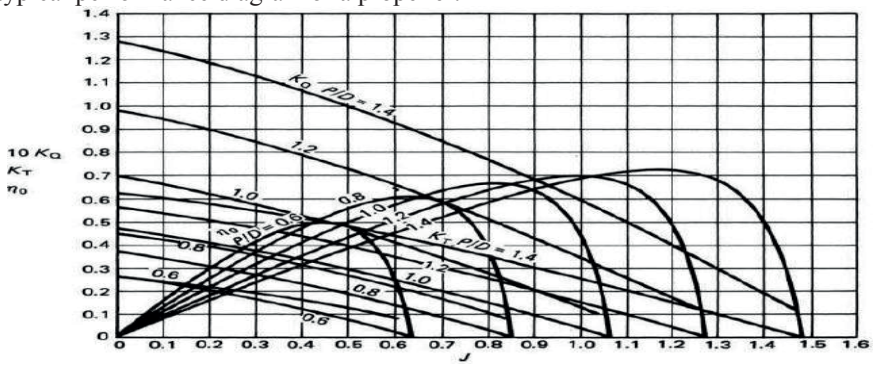

Fig. 1. KT-KQ-J diagram [11].

2.2 Hull-Propeller-Engine Integration

The presence of the hull induces disturbances to the flow around the propellant due to the separation of the flow and the formation of the trach. As a result, there is increased ship resistance and the difference between the average flow velocity around the propeller and the displacement speed of the vessel itself [13].

Thus, to estimate the thrust power and the ship speed necessary to anticipate these phenomena, certain coefficients deducted should be established by testing with similar vessels or by empirical and statistical methods. Such factors are known as the reduction of propellant power coefficient (t) and wake fraction coefficient (w).

Once these factors are determined, the thrust power (T) can be calculated by (1) [14]. R_T is obtained through the Holtrop-Mennen method, which will be introduced in chapter 3.

$$T = \frac{R_T}{1-t} \tag{1}$$

The advance speed propeller (V_a) is obtained through the relationship between the Service Speed (V_s) demanded by the V_s and w, according to (2).

$$Va = Vs(1-w) \tag{2}$$

The first parameter related to the hull-propeller interaction is defined from the hull efficiency (η_H), which consists of the ratio between the EHP and the Thrust Horse Power (THP), shown in (3)

$$\eta_H = \frac{EHP}{THP} = \frac{(R_T . V_S)}{(T.V_a)} \tag{3}$$

It is also possible to rewrite this equation through (4) [15].

$$\eta_H = \frac{(1-t)}{(1-w)} \tag{4}$$

Thus, it is possible to deduce the rotation propellant (n) as a function of (J, Va and D, defined according to (5) [15]:

$$n = \frac{Va}{J.D} \tag{5}$$

According to the resulting n value, it is possible to calculate the torque (Q) value that must be supplied to the propeller (6), as well as the Thrust (T) supplied by it (7) if operated in open water [16]. The K_Q coefficient value is graphically established from the performance curves of the propellant, considering the operation J.

$$Q = KQ.\rho.n_{hélice}^2.D^5 \tag{6}$$

$$T = KT.\rho.n_{hélice}^2.D^4 \tag{7}$$

However, the torque required by the propellant when it operates at the stern of the hull is different from the Q value, established for open water. The correction of this value refers to the Relative Rotating Efficiency (η_{RR}), specified in (8).

$$\eta_{RR} = \frac{Q_0}{Q_{hélice}} \tag{8}$$

2.3 Engine-Propeller Integration

The engine-propeller integration process aims to select the most suitable engine for the project so that it supplies torque to the propellant and has the best performance, i.e. the lowest fuel consumption [13]. For this selection, in possession of the required torque values (Q_{OPE}) and the propeller rotation of operation (n_{OPE}), the necessary power to be delivered to the propeller (W_{AP}) is determined, as indicated in (9) [15].

$$W_{AP} = 2\pi.Q_{OPE}.n_{OPE} \tag{9}$$

However, the power that the engine must provide to the propellant is given according to the transmission system efficiency, shown through (10)

$$W_{ENGINE} = \frac{W_{AP}}{\eta_T} \tag{10}$$

2.4 Cavitation criterion

When a propeller moves rapidly in water, the pressure in the adjacent liquid falls proportionally to the square of the local flow velocity. If local pressure falls below the vapor pressure of the surrounding liquid, small bubbles or vapor cavities are formed. Then, the flow decreases behind the object and these small cavities are collapsed with very high explosive force. If the cavitation area is large enough, it will alter the characteristics of the propeller, causing decreased thrust, torque change, damage to the propeller material (corrosion and erosion), strong excitation and vibration noises [12].

To obtain the cavitation criterion $\sigma_{0.7R}$, using the Relative speed V_R at 0.7 of the radius and the pressure on the propellant centerline (11):

$$\sigma_{0,7R} = \frac{p_0 - p_v + \rho g h}{\frac{1}{2}.\rho.(V_a{}^2 + (0,7\pi ND)^2)} \quad (11)$$

Considering the approximate values, it is possible to obtain (12):

$$\sigma_{0,7R} = \frac{188,2 + 19,62h}{V_a{}^2 + n^2 D^2} \quad (12)$$

Where h is the water column above the axis line (m), D is the propellant diameter (m) and n is the thruster rotation (RPS).

Also, the τc coefficient, which expresses the average thrust load on the propellant blades, must be calculated (13):

$$\tau_c = \frac{T/A_P}{\frac{1}{2}.\rho.(V_R)^2} \quad (13)$$

Where T is the thrust (KN), A_P is the projected blade area (m²) and V_R is given by $V_R{}^2 = V_a{}^2 + (0.7\pi nD)^2$. The projected area can be calculated by (14):

$$A_P \backsim A_D.\left(1,067 - 0,229.{}^{P}/_{D}\right) \quad (14)$$

2.5 NPa Grajaú Propulsion System Data

The propulsion system provided by MTU consists of a Main Combustion Engine (MCP) model MTU 16B 396 TB 94, with 16 cylinders in "V" and a maximum power of 2460 KW (2100 rpm). The reduction ratio is 3.074:1 through a gear coupling. The propellant is a B-series propeller with a diameter of 1.65m.

2.6 Holtrop-Mennen method

The method is a power prediction methodology based on a regression analysis of random model and full-scale test data. The method had been adjusted to test results obtained in some specific cases for many combinations of main dimensions and form coefficients.

The performance prediction models are typically used for the calculation of bare hull resistance, appendage resistance and propeller characteristic [17]. For conventional ships, the Holtrop-Mennen method is applicable to a wide variety of ship types. The method has been widely used to obtain resistance from the ship [18]–[20].

3 Comparative analysis of propellants

In this section will be made the comparative analysis of propellers with 2, 3, and 4 blades, area ratios of 1.05, 0.7, and 0.55 respectively, aiming to select the propellers that provide the necessary thrust for the ship to demand its service speed (12 knots) with the highest possible efficiency, besides being evaluated the occurrence of cavitation.

3.1 NPa Grajaú Propulsion System Data

To determine the ship resistance with greater precision, the values calculated through the Calculation Spreadsheet of the Holtrop-Mennen method were used. As their formulas are valid for typical forms of merchant ships, the results for other forms, such as a military ship, tend to be incoherent. For this reason, the ship was considered with only 1 propellant, parallel draught, and the coefficients of the waterline and master section were approximated to typical values of forms similar to NPa Grajaú (Fig. 2).

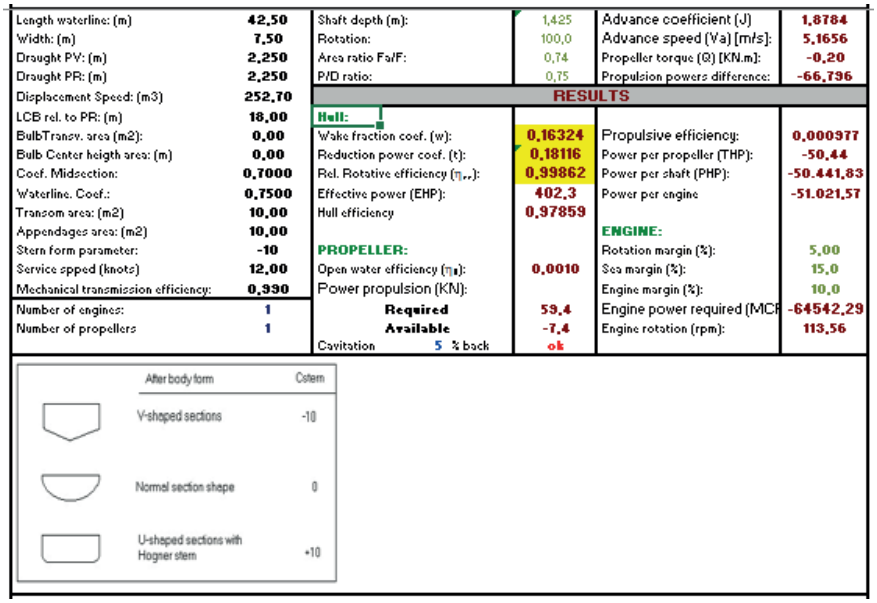

Fig.2. Holtrop-Mennen spreadsheet interface after entering the input data.

The results obtained by the method were: the SHIP resistance (RT) for the SPEED of 12 knots is 48.6 KN; t equal to 0.18829; w equal to 0.16816. Since t is known, it is possible to obtain the required T VALUE by (1). Thus, the result for T is 60 KN.

For the proposed analysis, we selected the propellers that provide the thrust necessary for the ship to demand its V_S (12 knots) as efficiently as possible. The propeller diameter will be considered 1.65m. For the two-blade propeller, all step-by-step calculations will be performed. The other blade configurations and area ratios will have their results presented in section 4.

3.2 Two-blade propeller with area ratio 1.05

To obtain the data related to this propellant, the design diagram for 2-blade propellers, area ratio of 1.05 and pitch/diameter ratio ranging from 0.5 to 1.4 was analyzed.

Table 1 summarizes the values found in the K_T-K_Q-J diagram. K_T and K_Q coefficients were used (6) and (7).

Table 1. Analysis of the K_T-K_Q-J diagram for the 2-blade propellant and area ratio 1.05.

T (KN)	K_T	*n (RPS)*	RPM	J	P/D	η_0 *(%)*
60	0,21937	6	360	0,50505	0,9	44
60	0,27083	5,4	324	0,56116	0,85	48
60	0,31590	5	300	0,60606	1,15	52
60	0,49359	4	240	0,75757	0,95	54

The highest efficiency was 54%, for the rotation of 240 RPM and P/D ratio 0.95.

Break Horse Power (BHP) calculation. Now the BHP power that must be supplied by the MCP will be calculated so that the propeller considered the most efficient can provide the thrust needed for the ship to reach the service speed.

First, EHP and THP are calculated using (15) and (16).

$$\mathrm{EHP} = \mathrm{R_T}.\mathrm{V_S} \tag{15}$$

$$\mathrm{THP} = \mathrm{T}.\mathrm{V_a} \tag{16}$$

After performing the calculations, EHP = 291.6 KW and THP = 300 KW. With the value of THP, it is possible to find DHP, by using (17).

$$\mathrm{DHP} = \frac{\mathrm{THP}}{\eta_0} \tag{17}$$

The value of DHP = 517.24 KW is found. From this point on, the sea (20%), operational (10%) and engine rotation (10%) margins will be introduced. To facilitate calculations, the powers will be used, as below:

To facilitate calculations, the powers will be used, as below:

BHP_1 = DHP

BHP_2 = BHP_1 after the seashore is applied.

BHP_3 = BHP_2 after the operating margin of the engine is applied.

BHP_4 = BHP_3 after the engine speed margin is applied.

When the 20% sea margin is applied in DHP, BHP_2 equal to 620.7 KW is obtained. With the value of BHP_2, it is possible to obtain the value of RPM_2, through (18).

$$\frac{BHP_2}{BHP_1} = \left(\frac{RPM_2}{RPM_1}\right)^3 \tag{18}$$

So RPM_2 = 255 RPM. When the operating margin is applied, BHP_3 is equal to 682.8 KW. Using (18), the value of RPM_3 = 263.3 RPM is found.

Applying the rotation margin, the RPM_4 value is equal to 289.6 KW. Finally, it is found the value of BHP_4 equal to 908.8 KW, power that must be supplied by the MCP so that the propeller under analysis can provide the thrust required for the ship to demand the service speed of 12 knots. Using (18) once again, the engine RPM is equal to 890 RPM.

3.3 Three-Blade Propeller with Area Ratio 0.7

To obtain the data related to this propellant, the diagram for three-blade propellers, an area ratio of 0.7 and pitch/diameter ratio ranging from 0.5 to 1.4 was analyzed. The highest efficiency is 54%, for a P/D ratio of 0.8.

3.4 Four-Blade Propeller with Area Ratio 0.55

To obtain the data related to this propellant, the diagram for four-blade propellers, area ratio of 0.55 and pitch/diameter ratio ranging from 0.5 to 1.4 was analyzed. The highest efficiency is 53% and P/D ratio of 0.75.

3.5 Analysis of cavitation occurrence in the propellers

Considering that the occurrence of cavitation in military ship thrusters is quite harmful, the Burril diagram will be used to evaluate cavitation in the thrusters considered the most efficient for each configuration of the number of blades and ratio of areas.
For this analysis, the two input parameters in the Burril diagram should be found, using (11), (12), (13) and (14). Figure 3 and Table 2 present the results for the three propellers considered the most efficient operating at the service speed.

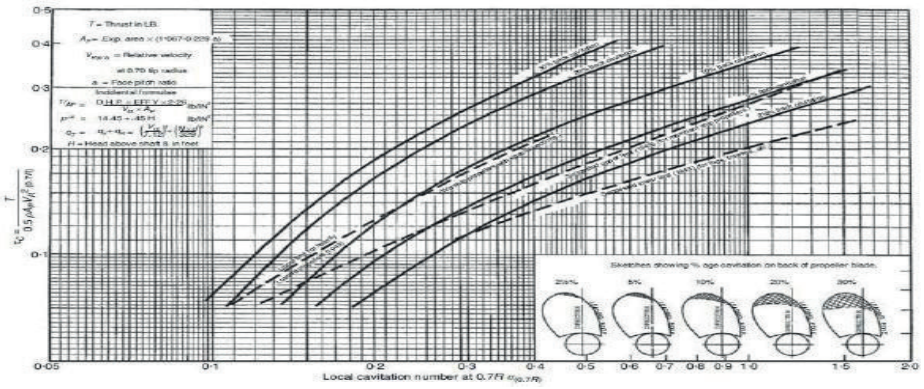

Fig.3. Burril diagram.

Table 2. Analysis of cavitation criteria for the most efficient propellers.

Propel-lant	Va (m/s)	P/A	AE /A0	T (N)	N (RPS)	RPM (propeller)	σ (0.7R)	τ_c	Cavita-tion
2 blades	5	0,95	1,05	60000	4	240	0,9	0,26	Below 2.5%
3 blades	5	0,8	0,7	60000	4	240	0,9	0,37	Above 10%

4 blades	5	0,75	0,55	60000	4	240	0,9	0,47	Above 10%

4 Analysis of Results

Evaluating the results for each propellant analyzed separately, it was possible to observe that, as the rotation decreases, the efficiency in open water increased. This occurred for all propellers, regardless of the number of blades and area ratios.

Table 3 summarizes the data of the propellants considered the most efficient for each configuration of the number of blades and area ratios previously evaluated.

Table 3. Most efficient propellants for each configuration of number of blades and area ratios.

Propellant	V_S (Knots)	P/A	A/A_0	T (N)	n (RPS)	RPM (propeller)	K_T	J	η_0 (%)
2 blades	12	0,95	1,05	60000	4	240	0,219	0,505	54
3 blades	12	0,8	0,7	60000	4	240	0,270	0,561	54
4 blades	12	0,75	0,55	60000	4	240	0,315	0,606	53

It was verified that all the maximum efficiencies found were very close because the increase in efficiency resulting from the decrease in the number of blades was counterbalanced by the decrease in the area ratios, which would tend to cause the performance of the thrusters to decrease.

It is concluded that it is not possible to state which propellant is most suitable for the NPa Grajaú if only the performance of each propeller is taken into account. Analyzing now the integration of the propellers with the MCP, table 4 is reached.

Table 4. Integration of each propeller with the MCP, operating at the service speed.

Propellant	T (N)	η_0 (%)	N (RPS)	RPM propeller	EHP	THP	DHP	BHP	RPM engine
2 blades	60000	54	4	240	291.600	3.000.000	555,5	976,1	890,2236
3 blades	60000	54	4	240	291.600	3.000.000	555,5	976,1	890,2236
4 blades	60000	53	4	240	291.600	3.000.000	566,1	994,5	890,2236

It is possible to observe that all propellants require the same MCP rotation to provide the thrust necessary for the ship to demand the service speed. It is verified that the MCP of the ship is fully able to provide the thrust required for all the propellers analyzed.

Analyzing the cavitation criteria, shown in the table 2, it is verified that the two-blade propellant has the lowest cavitation level. After the three proposed analyses, considering the efficiencies and the parameters of hull-propeller-engine integration were very similar for all the propellants analyzed, the two-blade propellant was considered the most suitable for the NPa Grajaú, as it has the lowest cavitation index among all of them.

Given the above, the propellant selected for the NPa Grajaú was the two-blade propeller, area ratio 1.05 and P/D ratio equal to 0.95.

5 Conclusion

The objectives of this paper were achieved, considering that, after all the analyses and calculations performed, it was possible to select a propellant that met all the requirements stipulated for the ship, concerning the required thrust, integration with the MCP and cavitation criteria.

The methodology presented in this paper can be used in several naval propulsion systems, aiming to increase propulsive efficiency, contributing greatly to the economy of resources and the preservation of the environment.

One factor that offered some limitation to the analysis proposed in this work was the use of the Holtrop-Mennen method, which is not indicated for unconventional forms, as is the case of military ships. However, since most of the parameters of these ships are confidential, there was no other alternative for performing the calculations. Even with this limitation, the results obtained with the estimates were satisfactory.

In cases such as this work, in which the shape of the ship under study is outside the scope of the Holtrop-Mennen method, some other methods, such as CFD (Computational Fluids Dynamics), which uses finite element method for calculations, solving equations that represent the behavior of the flow of a fluid in a domain with certain boundary conditions [21]. Another way to improve the analysis would be to obtain the hydrostatic tables of the ship.

Future researches could address analyses of ship's propulsive systems with ostentatious parameters, which would bring the results very close to reality. Another suggestion would be to design the propulsive system as a whole, which would make the analysis much more interesting and complex.

Abstract. This paper aims to verify the feasibility of using waterjet propulsion in Brazilian Navy (MB) ships, in view of the limitation that conventional propulsion presents mainly in regions of low depth and difficult maneuverability, such as riverside and wetlands. For this, Operational Research (OR) was used, through the Holtrop-Mennen method, to compare the efficiencies of waterjet and conventional propulsion, operating in three velocity ranges: 12, 21 and 35 knots. In addition, the main energy and operational characteristics of the waterjet propulsion system were studied, highlighting its advantages and disadvantages and some cases of waterjet application in military ships were exemplified, evaluating the feasibility of implementing this type of propulsion in other MB ships. The results show that waterjet is more efficient than conventional propulsion for vessels that spend high speeds, especially in riverside and Pantanal operations, and this characteristic can be very useful to MB, contributing to the increase of inspection capacity in the Brazilian Jurisdictional Waters (AJB). Therefore, this article represents great relevance for academia and society, as it presents a methodology that allows verifying which type of propulsion is most efficient, which can be used by civil and military naval sectors, aiming to choose the most appropriate type of propulsion to achieve its objectives.

Keywords: Efficiency analysis, Waterjet propulsion, Military application.

1 Introduction

The Brazilian Navy (MB) has as the main mission the guarantee of national sovereignty in Brazilian Jurisdictional Waters (AJB). For this, the means employed must be modern, versatile, robust and efficient. It was identified a difficulty in fulfilling this mission,

especially in riverside and wetlands, where the small depths and the presence of logs and debris in the water represent risks to the integrity of traditional outboard engines, which limits surveillance in these regions.

Such limitations in the supervision by MB naturally tend to increase the number of illegal actions in these areas, especially with regard to smuggling, illicit fishing and drug trafficking. Thus, the implementation of propulsion systems that will resolve these limitations would be a very useful way to improve the operating conditions of surveillance vessels in these sensitive regions, which would greatly increase the ability to fulfill their missions.

Nowadays, some more advanced types of propulsion, such as waterjet, gain enormous relevance because they offer advantages in terms of versatility and speed spent in regions of difficult maneuverability. In addition to the operational aspects, the efficiency in fuel consumption is of great importance, given the difficult situation in which the Brazilian economy is located and, consequently, MB, which has been facing several budget cuts in recent years.

Taking into account that conventional propulsion has proven not to offer good efficiency at high speeds [1], it is necessary to carry out feasibility studies for the implementation of alternative propulsion types, which offer better performance concerning fuel consumption in this operating condition.

Given the above, this paper aims to verify the feasibility of installing waterjet propulsion in MB's small, medium and large vessels, evaluating the advantages and disadvantages of this system when compared to conventional propulsion.

The article is divided in 5 parts. In section 2, the description of waterjet propulsion is made, addressing physical and thermodynamic principles. Then, in section 3, the main operational and technical characteristics of the use of waterjet propulsion are studied. Besides, it will be presented its use in ships of foreign Navies and also in small vessels of MB and some relevant data regarding the construction project of the National Corvette. In section 4, the methodology is described and a comparative analysis between conventional propulsion and waterjet propulsion is performed, highlighting the aspects concerning efficiency under different operating conditions and advantages of one in relation to the other. Finally, in section 5, the article is concluded.

2 Background

In this section the waterjet propulsion system is described, as well as its physical and thermodynamic aspects are detailed.

2.1 Literature Review

The waterjet is a marine propulsion device in which water is supplied to an internal pump that adds energy to the fluid and expels it from the stern of the vessel at high speed [2]. The concept of waterjet propulsion dates back to 1661 when Toogood and Hays first proposed this form of propulsion. Its use in the intervening years has been confined mainly to small high-speed pleasure craft and working boat situations where high maneuverability is necessary [3].

It is observed that the waterjet started to be used in medium and even large vessels, which was possible due to the considerable increase in the propelling unit sizes by waterjet. The reason for the comparatively smaller use of the waterjet compared to the conventional propeller is that this was generally considered simpler, lighter and more efficient. However, the introduction of more efficient pumps, in addition to the need for higher speed vessels are the main reasons for the rapid growth of the waterjet [3].

2.2 Description of the waterjet propulsion system

A waterjet installation mounted on the stern can be divided into four components: the inlet, pump, nozzle and steering device. The main component is the pump, which produces the jet at the nozzle outlet. In general, the stator basin and nozzle are integrated into one piece. The combination of the pump unit and nozzle is considered as waterjet pump. The system of ducts connected to the pump is called input [4]. The waterjet illustrated in Fig. 1 shows a built-in inlet duct, used, for example, on fast ferries and high-speed motor yachts.

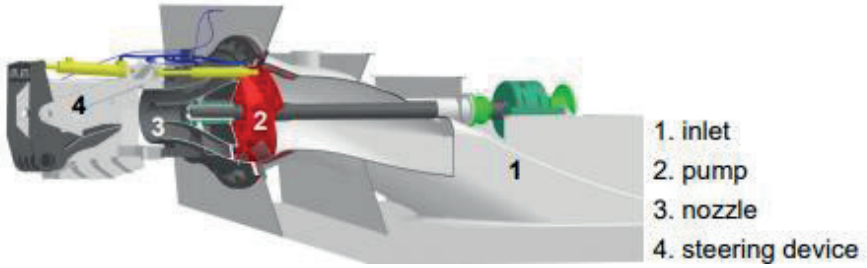

Fig. 1. Three-dimensional view of a waterjet installation [4].

In addition to the inline input, the inputs of type "ram" and "scoop" are mentioned, which have an opening that is more or less perpendicular to the direction of the flow, while the entrance opening mounted on the wall is parallel to the flow. Above the nozzle, there is a steering device, which can divert the jet of water in order to create steering and reversing forces. There are also facilities for deflection of the jet, constituting the option of reversal, useful for operating with machines in reverse or even for quick stop maneuvers [5].

The principle of operation of the waterjet is similar to that of jet aircraft turbines. The water from the underside of the vessel is aspirated, pressurized and thrown back at high speed. This forces the boat to move forward, creating movement. Its functioning is based on Newton's third law: "The whole force of action corresponds to a reaction force of the same intensity and contrary direction". The steering system works by directing the water jet sideways. Similarly, it can activate the reverser to get machines in reverse. It is a propulsion system that eliminates reversors, long shafts, propellers and rudders.

2.3 Physical and thermodynamic principles of waterjet

As a basis for considering the principles of waterjet propulsion, fig. 2 can be taken as a reference, showing an idealized waterjet system.

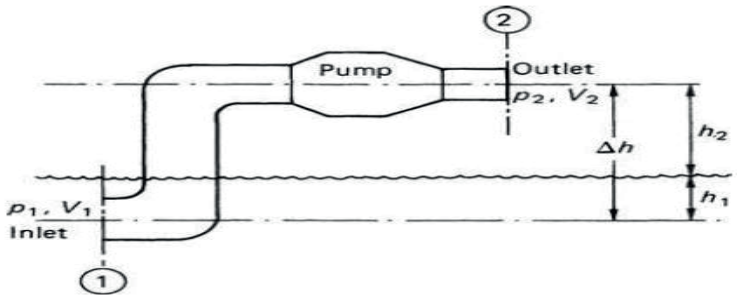

Fig. 2. Idealized waterjet system [3].

Based on this diagram, it is assumed that the water enters the system with velocity V_1 and leaves with a different velocity V_2 through a nozzle of area A_2. The water mass flow by the water jet is then given by (1) [6]:

$$\dot{m} = \rho A_2 V_2 \tag{1}$$

Where ρ is the density of water. Thus, the increase in the rate of moment change of water passing through the waterjet is given by (2):

$$\mathbf{\rho A_2 V_2 (V_2 - V_1)} \tag{2}$$

Because the force is equal to the rate of moment change, the thrust (T) produced by the system is given by (3):

$$\mathbf{T = \rho A_2 V_2 (V_2 - V_1)} \tag{3}$$

And the propulsion power (P_T) is given by (4):

$$\mathbf{P_T = TV_S = \dot{m} V_S (V_2 - V_1)} \tag{4}$$

Where V_S is the speed of the ship. Now, to derive a useful expression for the power required to drive the waterjet system it is necessary to resort to the general energy equation of the mechanical fluid and to apply this between the input and output of the unit (5):

$$\mathbf{\frac{p_1}{\rho g} + \frac{V_1^2}{2g} + H_p = \frac{p_2}{\rho g} + \frac{V_2^2}{2g} + \Delta h + h_{loss}} \tag{5}$$

Where H_p is the portion associated with the potential energy supplied to the system by the waterjet pump; $\mathbf{\Delta}_h$ is the load loss between the inlet and outlet of the waterjet

(i.e. = h_1 - h_2); h_{loss} is the portion associated with the load losses of the flow by the system and also the load loss in the pump.

In the case of the difference between the inlet and outlet of the waterjet system, it should be noted that this will be a variable between the initial conditions and navigation conditions. The term of loss, h_{perda}, is associated with frictional losses that occur during the flow passage through the curves of the ducts and the various system obstructions that can prevent the flow during its passage through the unit.

For practical purposes, we can assume that p_2 is constant above the waterline, given that the altitudes involved and their effect on ambient pressure are small. With this, equation 5 can be rewritten as (6):

$$\mathbf{H_P} = \frac{\mathbf{V_2^2 - V_1^2}}{\mathbf{2g}} + \mathbf{h_2} + \mathbf{h}_{loss} \tag{6}$$

Now the energy transferred to the water by the pump can be expressed in terms of energy per unit of time as $\dot{m}\mathbf{gH_P}$, which, from (6) leads to (7):

$$\mathrm{P_{pump}} = \dot{m}\left[\frac{1}{2}(\mathrm{V_2^2} - \mathrm{V_1^2}) + \mathrm{g(h_2 + h_{loss})}\right] \tag{7}$$

Thus, it is possible to calculate the efficiency in open water equivalent of the waterjet, which can be defined from (4) and (7), being the ratio between the thrust power and the delivered power, as follows (8):

$$\boldsymbol{\eta_0} = \frac{\mathbf{V_S(V_2 - V_1)}}{\left[\frac{1}{2}(\mathbf{V_2^2 - V_1^2}) + \mathbf{g(h_2 + h_{loss})}\right]} \tag{8}$$

By analogy with the propellers, the efficiency of the waterjet pump can be expressed as (9) [7]:

$$\boldsymbol{\eta_{pump}} = \frac{\boldsymbol{\Phi\psi}}{\mathbf{2\pi K_Q}} \tag{9}$$

Where φ and $\boldsymbol{\psi}$ are the flow and energy transfer coefficients, defined respectively by (10) (11):

$$\boldsymbol{\Phi} = \frac{\mathbf{Q}}{\mathbf{ND^3}} \tag{10}$$

$$\boldsymbol{\psi} = \frac{\mathbf{gH}}{\mathbf{N^2D^2}} \tag{11}$$

Where K_Q is the normal torque coefficient of the conventional propeller.

Given that the pump value is higher for a jet of water than a propeller, this is not the basis on which the comparison should be made. An appropriate comparison can only be made in terms of the quasi-propellant coefficient, which for the propeller, includes the hull and relative rotating efficiency. For the waterjet, (8) should be observed, as well an appropriate hull coefficient covering the effect of the waterjet.

One good solution is using a parametric model for the description of the behavior of the waterjet-hull set, which allows the separate identification of the interaction between

the terms that interfere in the mutual relationship between the waterjet and the hull of the ship [8].

3 Operational and technical features of waterjet propulsion

The principle of waterjet provides high maneuverability to the vessel, because it is a propulsion system with full steering capacity. Most waterjet units are equipped with steerable nozzles or deflectors, which provide directional jet control. The steering capacity in each of these cases is produced by the reaction to the momentum change of the jet [3], as can be seen in Fig. 3:

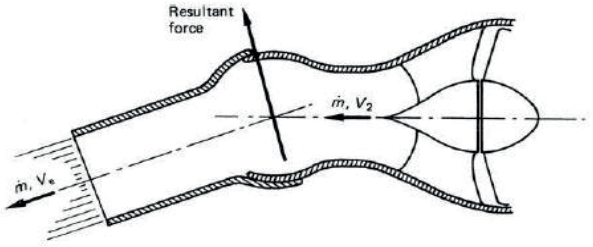

Fig. 3. Principle of waterjet maneuverability [3].

The angle at which the jet can be directed is variable, depending on the particular design of each manufacturer; however, it is generally expected to be of the order of ± 30°.

Concerning the capabilities of stopping, slowing, or reversing the flow of the water jet, these changes are usually achieved with the aid of a reverser, with the stopping force being produced by changing momentum principles. The design of the reversing device can be in a simple way, or it can be in a more sophisticated way, which allows a "shedding" of the jet to give good control to the braking forces, as shown in Fig. 4:

Fig. 4. Mechanism of waterjet thrust control [9].

With this latter type of system, the resulting thrust can also be continuously varied, from zero to maximum, in any power configuration for the engine. The latest technological advances in waterjets have put them ahead of conventional propeller systems for many types of high-speed marine applications, including military ships, ferries and pleasure craft. Modern waterjets offer several advantages, such as high efficiency, fast acceleration and excellent maneuverability [10].

In addition to operational advantages, submerged waterjets offer weight and space savings in the propulsion system and can be considered a key factor for propulsion on smaller platforms [11]. The benefits in terms of general layout and machinery arrangement could allow alternative uses of space to be considered, for example, the implementation of portable systems on board, or even for launch and collection stations. The advantages of the waterjet, when compared to the conventional outboard engine, will be analyzed in detail below.

3.1 Security

In contrast to the conventional outboard engine, waterjet propulsion is not threatened by floating solid fragments such as logs, ropes or fishing nets. Swimmers and divers are not at risk of suction by the propellant, which can occur with conventional outboard engines. This advantage is of great use to the military ships, which constantly operate with divers and researchers, and are often forced to stop machines because they operate with conventional outboard engines.

3.2 Maneuverability

Maneuverability is one of the most important characteristics of ships. In this context, the waterjet is very relevant because, even at a low speed, it provides excellent maneuverability due to the high versatility of the spatial position of the output nozzle, which provides modular thrust power and variable direction to the ship [12]. This is very useful for military ships, as it allows 360° spin maneuvers on the axis itself, as well as front and reverses maneuvers without strides and the need for full deceleration.

3.3 Efficiency

Fig. 5 shows the estimated efficiency of several types of propulsion systems in function of ship speed.

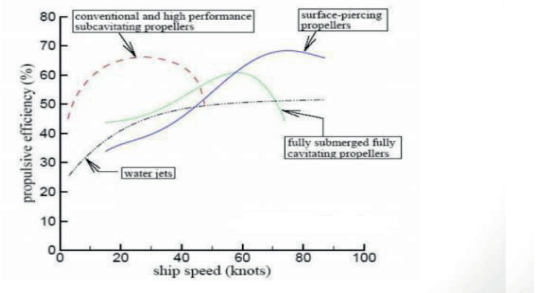

Fig. 5. Efficiency of propellers in relation to ship speed [1].

Analyzing fig. 5, it is observed that, for speeds of up to 45 knots, conventional propellers have higher efficiency than waterjet. However, it is verified that for speeds greater than 22 knots, conventional propellers show a efficiency drop, reaching their maximum speed at about 45 knots. From this point on, the use of other types of propulsion, such as surface and supercavitating propellers, is justified.

Note: 1 knot means one mile/h, approximately 1.852 m/h.

Supercavitating propellers have their highest efficiency at speeds of approximately 60 knots. From this point on, the use of surface propellers is justified, which present greater efficiency at speeds of about 80 knots.

Analyzing the waterjet, it is noted that its efficiency remains practically constant at speeds from 40 to almost 90 knots. Although supercavitating and surface propellers are more efficient than waterjet, they do not offer protection to propellers, which is essential for operation in low-depth regions. Therefore, analyzing the waterjets in relation to the conventional propulsion of subcavitating propellers, it is noted that, without taking into account the protection advantage of the propellant, waterjet propulsion is more efficient at speeds above 45 knots.

3.4 Noise and Cavitation

Compared to the conventional outboard, the waterjet ensures lower noise and vibration levels [13]. This factor is extremely important for military vessels because the less noise is emitted, the more they can omit their acoustic signature and, consequently, hinder detection by enemy sensors.

3.5 Grounding

Grounding maneuver is very common in river navigation, whether intentional or accidental. Waterjet propulsion offers the ability for the ship to land or even disengage only with the use of the propellant, as it provides high thrust power. This characteristic is very favorable to military ships, as it allows access to inhospitable and winding regions without endangering the integrity of the ship and propellant.

3.6 Use of waterjet in foreign Navies

Waterjet is increasingly being applied to military ships from developed countries such as the United States, South Korea, Finland and Norway. Waterjet propulsion offers significant advantages in many high-speed or special purpose ships, such as military ships [14].

As examples of waterjet applications in military ships it is possible to cite Littoral Combatant Ship (LCS) program of the U.S. Navy. They are the largest ships ever built that employ waterjet - the USS Freedom (LCS- 1) and USS Independence (LCS-2) -, which have a total length of respectively 115 and 127 meters.

In addition to the use in medium and large ships, the application of waterjet propulsion in amphibious assault vehicles and submarines of foreign navies stands out.

3.7 Use of Waterjet in MB

This section discusses the use of waterjet in MB small crafts, which are among the newest and most modern in the Brazilian fleet.

Pacific 24 speedboat. The PACIFIC 24 is a semi-rigid hull speedboat with the waterjet propulsion system, manufactured by VT Halmatic. Its main functions are rescue, visit inspection/approach actions, and can be used secondarily for transporting material and personnel.

DGS 888 Raptor. The DGS 888 Raptor is an armored multimission vessel designed to operate in harsh environments. It features the powerful FPT Industrial N67 EVO engine, which delivers 570 HP to an AlamarinJet AJ340 waterjet propulsion system, and enables the vessel to reach speeds of more than 42 knots, and has noise and vibration reduction.

Brazilian Corvette Project. The use of waterjets compensates in terms of efficiency and consequently in financial terms from the operation of the medium at speeds predominantly above 25 knots [15]. Fig. 7 illustrates efficiency in function of the ship speed in general. This occurs because, at high speeds, the water flow over the intake duct increases, reducing the work needed to be attended by the impelling ones.

Fig. 6. Efficiency of conventional and waterjets propellants [16].

In order to verify the possibility of obtaining more economically viable propulsion for the new Brazilian Corvettes at lower speeds, a study about mixed propulsive arrangements, using propellers and waterjets, was conducted [17]. Thus, it would be used the conventional propellers for lower speeds and waterjets for higher speeds. After the tests, it was concluded that two MTU 16V 1163 M94 engines (one per shaft) would provide power to the propellers. To meet the power required by the waterjets, the GE LM2500+G4 turbine would be selected [17].

4 Methodology

An appropriate comparison between waterjet and conventional propeller can only be made in terms of the quasi-propulsive coefficient [3]. Given the above, in this chapter, a comparative analysis will be made between the quasi-propulsive efficiencies of the waterjet and a conventional propellant to provide the same thrust to the ship.

To enable the proposed analysis, the Holtrop-Mennen method [18] was used to obtain the quasi-propulsive efficiency of the conventional propellant. The method consists of a series of mathematical formulations that were obtained through the use of regressions based on random models and real-scale data in the Netherlands Ship Model Basin [19].

4.1 Comparative analysis between waterjet and conventional propulsion systems

To obtain the parameters of the conventional propulsion to be compared, the Holtrop-Mennen method [18] was applied to the data of the propulsion system of the Patrol Ship (NPa) Grajaú. As its formulas are valid for typical forms of merchant ships, the results for other forms, such as a military ship, tend to be incoherent. For this reason, the ship was considered with only 1 propellant, parallel draught, and the coefficients of the waterline and master section were approximated to typical values of forms similar to NPa Grajaú (Fig. 7).

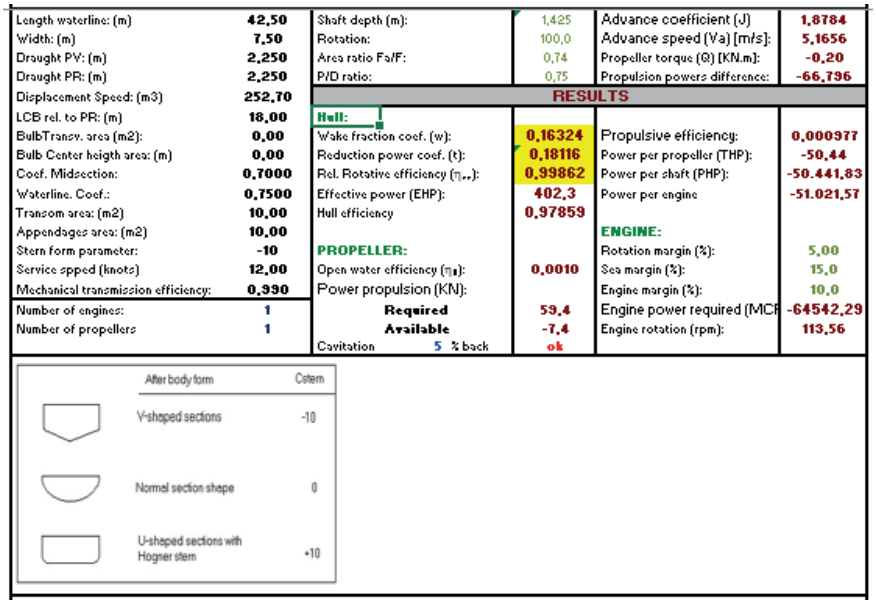

Fig.7. Holtrop-Mennen spreadsheet interface after entering the input data.

For the proposed analysis, we selected the propellers that provide the thrust necessary for the ship to demand three ranges of Ship Speed (VS) - 12, 21 and 35 knots - as efficiently as possible. The propellant considered the most efficient after the method application has 2 blades, diameter of 1.65 m, area ratio equal to 1.05 and the following features (Table 1):

Table 1. Operating parameters of the propellant operating at the three speeds analyzed.

V_s (knots)	V_a (m/s)	T (KN)	K_T	n (RPS)	RPM	J	P/D	η_0
12	5	60	0,493	4	240	0,7575	0,95	54
21	9	182,3	0,462	7,2	432	0,7575	0,95	49
35	15	262,6	0,345	10	600	0,9163	0,95	44

The conventional propellant and the waterjet operating in three-speed ranges will be compared: 12, 21 and 35 knots. Ressalta-

For the calculations related to the waterjet, the following premises will be established:

1. The vertical and horizontal inclination angle of the waterjet will be considered equal to zero;
2. "Vena contracta" occurs in the output plane of the nozzle (A_j=A_n); The advance speed (V_a) is uniform;
3. Pump losses are included in stator losses;
4. The wake fraction coefficient (w) and reduction of propulsive power (t) were obtained by Holtrop-Mennen method and considered equal for both propellers;
5. The pressure coefficient was considered equal to 0.07, and h_j was considered equal to 0.06584, based on previous studies [16];
6. The jet area A_j was considered equal to 2.7449 m^2, obtained for a waterjet operating to provide a thrust power required for the NPa Grajaú to demand the service speed (12 knots) (12) (13) (14).

$$\eta_D = \eta_H \cdot \eta_0 \cdot \eta_{rr} \tag{12}$$

$$\mu = (1 - w)\frac{V_s}{V_j} \tag{13}$$

$$\eta_D = \frac{\eta_P \cdot \eta_r \cdot \left(\frac{1-t}{1-w}\right) \cdot 2\mu(1-\mu)}{1+\psi-(1-\zeta)\mu^2+\frac{2gh_j}{V_j^2}-\frac{C_P \cdot \mu^2}{(1-w)^2}} \tag{14}$$

After applying the calculations, the quasi-propulsive efficiency for the conventional propeller and the waterjet is obtained, according to Table 2:

Table 2. Comparative analysis between hydrojet and conventional propulsion.

V_s (knots)	Conventional Propulsion		Waterjet	
12	η_0	0,54	$\eta_{jet}*\eta_{pump}$	0,44
	η_{rr}	0,99	η_{rr}	1
	η_H	0,9761	η_H	0,97
	η_d	0,521	η_d	0,43
21	η_0	0,49	$\eta_{jet}*\eta_{pump}$	0,48
	η_{rr}	0,99	η_{rr}	1
	η_H	0,97	η_H	0,97
	η_d	0,47	η_d	0,48
35	η_0	0,44	$\eta_{jet}*\eta_{pump}$	0,53
	η_{rr}	0,99	η_{rr}	1
	η_H	0,97	η_H	0,97
	η_d	0,43	η_d	0,52

Evaluating the results of table 2, it is concluded that:

1. For the speed of 12 knots, the conventional propellant presented higher efficiency than the waterjet; at the speed of 21 knots, the two thrusters presented very close efficiencies, with a slight advantage for the conventional (about 1%); at the speed of 35 knots, the waterjet proved to be much more efficient than the conventional one.

2. In short, waterjet propulsion is justified for ships that need to develop speeds greater than 25 knots (as shown in Fig. 7), such as warships and small vessels operating in the Amazon. Besides, after the study carried out in section 3, it remains clear that the maneuverability and safety provided by the waterjet in relation to conventional propulsion present significative advantages for vessels operating in areas with low depth and presenting obstacles, such as riverside regions.

3. In the case of vessels that need to develop speeds below the threshold of 25 knots, if the criterion evaluated is only energy efficiency, it is observed that conventional propulsion is more advantageous.

5 Conclusion

In view of the above findings, the waterjet propulsion system can be very useful for MB vessels, mainly for operation in regions with small depths, with floating solid fragments, such as trunks, ropes or fishing nets and winding terrain, such as the wetland and rivers of the Northern region of the country. The high maneuverability and speed provided by the waterjet would be very useful for the fulfillment of MB's mission in these areas.

In the comparative analysis between waterjet and conventional propeller, it was clear that the speed of the ship is a primary factor to evaluate which type of propellant is most

efficient. Therefore, before choosing the most suitable propellant, it is necessary to determine the speed of operation of the ship. The installation of waterjet is justified in vessels that spend high speeds (above 25 knots), mainly small boats, such as organic boats of larger ships.

Regarding to the construction project of the national corvette, it was possible to observe that MB envisions the implementation of the waterjet propulsion system also in large ships, being used mainly in hybrid arrangements, taking advantage of the fact that each propellant presents a certain range of greater efficiency, and that these features complement each other.

The use of waterjet propulsion systems is a very broad issue, given the wide range of vessels that can use it. In this paper, only the military uses of waterjet were addressed, and it was verified that this propellant is increasingly used for this scope, as it offers very important operational and functional advantages for this purpose.

One factor that offered some limitation to the analysis proposed in this paper was the use of the Holtrop-Mennen method, which is not indicated for unconventional forms, as is the case of military ships. However, since most of the parameters of these ships are confidential, there was no other alternative for performing the calculations. Even with this limitation, the results obtained with the estimates were satisfactory.

Future works could study the use of software such as CFD to determine the pressure and the thrust power, given that these parameters are extremely important for waterjet efficiency.

Abstract. Each year, in South America, flooding related disasters cause millions of dollars' worth in damage and hundreds of casualties. In this context, humanitarian logistics provide tools to improve the preparedness of vulnerable communities. In this paper, an approach based on system dynamics modeling is proposed to evaluate the expected short- and medium-term impacts and expected recovery time in two municipalities located in South America, characterized by flooding risk, especially during the April - June season when the augmentation of the average precipitation levels occurs. The real cases of Chia (Colombia) and Santa Ana del Yacuma (Bolivia) are analyzed and compared.

Keywords: System Dynamics, Floods, Humanitarian relief operations, risk management.

1 Introduction

In the last decade, humanitarian operations have gained great importance due to the high levels of uncertainty and elevated monetary costs which are to be found within a humanitarian relief context (Tomasini & Wassenhove, 2009). Considering the impact humanitarian crisis can cause, contributions to evaluate and mitigate its effect has gained significant attention. These include the study of medical goods distribution or transportation of injured population, inventory management problems, location, and management of physical resources such as food, clothing or raw materials, and the supply chain design of humanitarian systems characterized by the necessity for quick and efficient response.

In South America, according to recorded data, in the last 30 years, natural disasters have affected near 103.8 Million people and have caused at least 60 thousand deaths (Centre for Research on the Epidemiology of Disasters, 2019). Since 1990, the most frequent natural disasters registered in South America are flood events. Thus, floods are considered as a constant threat for populations located near water sources, such as

rivers, ravines, creeks, lakes, etc. Given the likelihood of flooding during months with high levels of rain precipitation, governments throughout South America, have employed a vast amount of resources for the prevention, mitigation, and response.

Humanitarian and relief operations in flooding events are characterized by an increasing need for quick and efficient response. In the last decade, researchers have developed several methods for dealing with humanitarian problems based on optimization techniques, such as linear and stochastic programming; however, as far as we know, there is a lack of research incorporating System Dynamics (SD) as a tool for risk assessment, damage mitigation and humanitarian logistics operations planning for dealing with flooding events (Haiyan et al., 2020).

In this paper, an approach based on SD modeling is proposed to evaluate the expected short- and medium-term impacts and expected recovery time in two municipalities located in South America, i.e., Santa Ana del Yacuma, Bolivia and Chía, Colombia, characterized by flooding risk due to their proximity to rivers, especially during the April - June season when the augmentation of the average precipitation levels occurs.

SD is chosen as a modelling approach since it provides advantages to understand behaviors of quantitative and qualitative variables within complex systems over significant time horizons (Sterman, 2000).

2 Risk Assessment Model

The proposed SD model is composed by three sub systems, defined as (SS#). The model aims to reflect the resulting behavior of the studied populations after a flooding event happens limiting the inflow of food to the municipalities.

The first subsystem **(SS1)** represents the state of the access roads for each one of the municipalities measured in the fraction of enabled or disabled roads. This sub-system considers the possible impact caused by flooding events and the government's reaction speed after the disaster, the expected reaction time, and the fluctuating need for higher or lower repairing rates for the roads. In this sub-system a flood-related disaster is bound to occur in a specific time**,** allowing the simulation to reach a stable state regarding the population's behavior before and after the flooding event happens.

SS2 aims to measure the impact of the edible goods that arrive to the population. This sub-system represents and measures the amount of food (kg) that is available for consumption. The amount of food depends on the total population, the expected delivery lead time, i.e., 1 to 15 days, and the amount of agronomic production in the municipalities that depend on the labor of adult and elderly population. Besides, SS2 considers the possibility for food to spoil at a predetermined and fixed rate, assuming that on average, food lasts 15 days before it becomes not suitable for human consumption.

SS3 represents the social structure and demographic behavior of the municipalities, in which three population types are considered: children, adults and elders. Children population is considered to range between the ages of 0 and 18 years old; the adult population ranges from 19 and 60, and elders are considered to have 61 or more years. The age groups were stated to integrate into the model the differences regarding death

rates and food consumption in the three groups. Additionally, this sub-system considers the child and adult migration using estimated rates based on historical data.

3 Experimental results and analysis

Scenario simulations were generated using the software VENSIM® in a Lenovo Y50-70 desktop computer with 12 GB Ram and an intel Core i7@ 2.6 GHz processor. To determine the impact caused by floods and government's reaction speed while facing disaster, three output criteria were considered, i.e., the portion of enabled roads that allow the inflow of goods, total population, and amount of available food (See Figures 1 and 2). Input parameters of Colombia were estimated from the existing data published by DANE (National Administrative Statistic department) (Departamento Administrativo Nacional de estadística DANE, 2020) and Gobernación de Cundinamarca (2016), and Bolivia data from the INE (National Institute of Statistics) and the Instituto Nacional de Estadística (2014). The simulation model considers a horizon of 30 months to allow the system to achieve a steady behavior before a flood related event occurs, allowing the comparison of the expected impact among both populations.

Results show that in both cases, equilibrium is achieved at the beginning of the second month, indicating that during the first ten months there is a stable behavior regarding available consumption and population growth. At the beginning of the 12th month, roads are rendered unavailable due to the impact caused by flooding, hence, there is a reduction in the flow of goods to the municipalities and the amount of available food in two months span, indicating that in both cases the municipalities cannot withstand a flood-related natural disaster without depleting their food supply.

Both populations experienced a measurable impact regarding the amount of available food, Requiring a minimum food stock during the following two months. Additionally, the food arrival rate depends on the fraction of enabled roads given the different estimated government's reaction speed. According to the generated data, Chía tends to recover the full capacity of its roads sooner than Santa Ana.

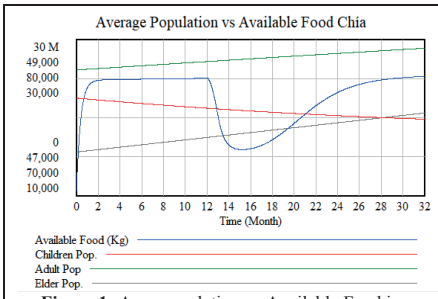

Figure 1: Avg. population vs Available Food in Chía

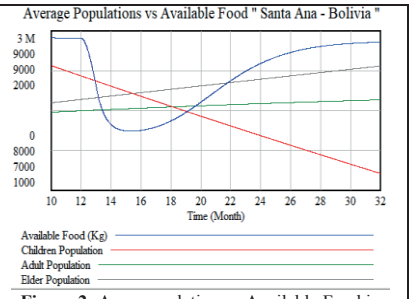

Figure 2: Avg. population vs Available Food in Santa Ana

Regarding the population behavior death rate of infants and elders increases in approx. 0.002% and 0.0023% in Santa Ana and Chía, as seen in Figures 1 and 2. This

phenomenon is explained by the limited resources encountered during the flooding aftermath, however, the increase in death rates does not disrupt the normal behavior of the population's growth and migration.

4 CONCLUSIONS

The proposed method provides a simulation tool for the expected impact assessment of flooding event among populations, allowing to evaluate the time required for populations to regain their normal dynamic. The method was tested in two municipalities located in South America, characterized by flooding risk, especially during the April - June season when the augmentation of the average precipitation levels occurs. According to data, governments' reaction speed supposes the main reason for a fast recovery, indicating the need for governmental entities to design, evaluate and execute different response plans in order to minimize the expected impact among population.

From the obtained results, some interesting new avenues for future research are presented, for example, consider other variables that are also important on this type of disasters, such as the availability and quantity of medical resources and populations' displacement in response to the disaster. Further, the impact of consecutive flooding events within a short period of time, or different preparedness strategies, could also be assessed. Also, we encourage researchers to keep exploring new methods and hybridizing methods for the decision-making process in a humanitarian context.

Resumen. El presente trabajo tiene como objetivo seleccionar el mejor Plan Agregado de producción para una empresa del rubro electromecánico que fabrica tres familias de productos. Para el desarrollo de las alternativas de planificación se adoptan estrategias de nivelación, seguimiento y mixtas. Se emplean como medidas de ajuste transitorio de capacidad la fabricación para inventario, uso de horas extras, subcontratación de parte de la producción y la contratación y despido de personal. La mano de obra es de uso compartido entre las tres familias. Para el análisis de las cuatro alternativas propuestas se analizan múltiples criterios tales como el costo total, la estabilidad de la mano de obra y el plan de producción, los niveles de subcontratación e inventario, considerando las restricciones que pueden existir respecto a los clientes, la fuerza de trabajo y el entorno. Mediante la aplicación del Proceso Analítico de Jerarquías se selecciona la alternativa con el mejor plan agregado de producción para la empresa en estudio. Este plan adopta una estrategia de nivelación de mano de obra, respondiendo al criterio más relevante de mantener la estabilidad de la fuerza de trabajo. La implementación de este método permite materializar el proceso de selección del plan de producción de forma sistemática y consistente con las prioridades estratégicas de la empresa y el área productiva.

Palabras clave: Plan Agregado de Producción, Proceso Analítico de Jerarquías, Toma de Decisiones Multicriterio.

Abstract. The objective of this work is to select the best Aggregate Production Plan for a company in the electromechanical field that manufactures three families of products. For the development of planning alternatives, leveling, monitoring and mixed strategies are adopted. Manufacturing for inventory, use of overtime, subcontracting of part of production, and the hiring and firing of personnel are used as temporary capacity adjustment measures. Labor is shared between the three families. For the analysis of the four proposed alternatives, multiple criteria are analyzed such as the total cost, the stability of the workforce and the production plan, the levels of subcontracting and inventory, considering the restrictions

that may exist with respect to the clients. The workforce and the environment. By applying the Hierarchies Analytical Process, Alternative 1 is selected as the best aggregate production plan for the company under study. This plan adopts a workforce leveling strategy, responding to the most relevant criterion of maintaining the stability of the workforce. The implementation of this method allows to materialize the selection process of the production plan in a systematic way and consistent with the strategic priorities of the company and the production area.

Keywords: Aggregate Production Plan, Analytical Hierarchy Process, Multi-criteria Decision Making.

1 Introducción

La principal función de toda organización es la generación, a partir de ciertos procesos, de algún tipo de producto. Para que estas organizaciones sean efectivas y eficientes los directivos del sistema de operaciones deben comprender y aplicar algunos principios fundamentales de la planificación para la generación del producto y también para controlar el proceso que lo origina.

Para lograr la integración de los procesos organizacionales la planificación y control de la producción debe desarrollarse siguiendo un enfoque jerárquico (Domínguez Machuca et al., 1995). Este enfoque, permite coordinar los objetivos, planes y actividades de los niveles estratégico, táctico y operativo. Significa que los planes de cada nivel persiguen sus propias metas, pero teniendo en cuenta los objetivos de nivel superior, de las cuales dependen y los del nivel inferior, en los que actúan como factor restrictivo. Sin este enfoque es muy difícil lograr la integración de procesos organizacionales.

El Plan Agregado, es un plan de producción a mediano plazo que busca traducir de forma más detallada el Plan Estratégico de la empresa. Su propósito es planificar y coordinar los recursos, incluyendo el tipo, la cantidad y la pertinencia de los mismos, de manera tal de cubrir las necesidades con la demanda prevista (Chapman., 2006).
De una forma más específica es una fuente importante para la planificación de los niveles de inventario, el flujo de efectivo, las necesidades de recurso humanos (número de personas, niveles de habilidad, tiempo requerido, programa de entrenamiento), necesidades de capital, niveles de producción, capacidad, actividades de ventas y marketing.

Para el desarrollo de este trabajo se utiliza el caso de estudio propuesto en el curso de Doctorado “Procesos y Planificación de la Producción Avanzada” de la Universidad Nacional de Cuyo dictado en agosto de 2020.

El objetivo consiste en analizar y seleccionar el mejor plan agregado de producción para la empresa en estudio bajo un enfoque mutlicriterio mediante la aplicación del Proceso Analítico de Jerarquías (PAJ). Este método permite sistematizar y reducir los niveles de riesgo e incertidumbre en el proceso de toma de decisión.

2 Marco Teórico

2.1 Plan Agregado

El plan agregado de producción busca determinar la cantidad y los tiempos de producción necesarios para satisfacer la demanda a mediano plazo. Los administradores de operaciones tratan de determinar la mejor forma de satisfacer la demanda pronosticada ajustando los índices de producción, los niveles de mano de obra, los niveles de inventario, el trabajo en tiempo extra, las tasas de subcontratación, y otras variables controlables.

Por lo general, el objetivo de la planeación agregada es minimizar los costos para el periodo de planeación (Heizer y Render., 2009). Existen, además, aspectos estratégicos como suavizar los niveles de empleo, reducir los niveles de inventario, o satisfacer un nivel de servicio alto a los que se les asigna en ciertas ocasiones, mayor importancia que a la reducción de costos.

El horizonte temporal varía entre 6 a 18 meses, esto depende del tiempo en que la empresa requiera determinar un estimado de la necesidad de recursos, con el objetivo de actuar apropiadamente para garantizar su disponibilidad (Chase y Jacobs, 2014). Con respecto a su diseño, los bloques de tiempo de planificación o periodos de planificación en general son: meses, bimestres o trimestres. Dependerá del nivel de detalle que es útil para la planificación y la cantidad de esfuerzo necesario para obtener la información (Domínguez Machuca et al., 1995).

En el Plan Agregado, como su nombre lo indica, los productos se acumulan o agregan en familias. La clave para efectuar la agrupación es el uso de recursos similares, por ejemplo, el personal, los equipos o las materias primas (Krajewsky et al., 2008). Un motivo fundamental para realizar la agregación es el uso de pronósticos, que son la principal fuente de demanda para efectuar el Plan Agregado y tienden a ser más precisos cuando se desarrollan de forma agregada. Si bien la agregación facilita el desarrollo del plan, no debe llevarse al extremo ya que puede provocar perdida de información útil. El grado de agregación apropiado dependerá del tipo de producto, tipo de clientes, y del proceso productivo.

Con respecto a la capacidad, para esta etapa de planificación se considera fija, es decir que no pueden tomar acciones estructurales de ajuste. Solamente pueden aplicarse medidas transitorias de ajuste de capacidad (Domínguez Machuca et al., 1995).

Las empresas tienen diversas opciones para efectuar un ajuste transitorio de la capacidad. En general, todas estas alternativas se engloban en dos categorías (Chapman, 2006). Una de ellas se enfoca en el lado de la oferta (operaciones) para intentar cambiar el suministro de producción y se las denomina estrategias internas. Estas incluyen las contrataciones y despidos del personal, la contratación de trabajadores temporales, el uso tiempo extra o tiempo inactivo, las subcontrataciones, la fabricación para inventario, entrega con retraso, la posibilidad de no atender la demanda y la modificación de la tasa de producción. La otra categoría se concentra en el lado de la demanda (comercialización) en un intento por alterar los patrones de demanda para ajustarlos al resultado de la producción. Estas son llamadas estrategias externas y consideran la fijación

de precios, la realización de promociones y publicidad y la oferta de paquetes de productos.

2.2 Estrategias del Plan Agregado

Para encontrar la mejor alternativa que organice los recursos y cumpla con la demanda, bajo ciertas condiciones de operación, se debe delinear una estrategia para la elaboración del Plan Agregado. Cuando se habla de mejor, en general, se refiere a la maximización de las utilidades de la organización, pero resulta indispensable que se establezcan otras condiciones u objetivos. Se puede considerar la posibilidad de satisfacer la totalidad de la demanda, minimizar la inversión en inventarios, minimizar el impacto adverso en las personas que puede generar la volatilidad en la fuerza de trabajo por despidos frecuentes, entre otras cuestiones.

Es importante comprender los criterios para delinear una estrategia adecuada que, en general, dependerá de las políticas de la empresa, sus prioridades competitivas, el tipo de sistema productivo, entre otros. Las tres estrategias que se emplean para realizar el Plan Agregado son la nivelación, la persecución o seguimiento y una combinación de ambas (Chapman, 2006).

La estrategia de nivelación busca nivelar determinado recurso (la producción o la mano de obra), es decir, que sus valores se mantendrán constantes en todos los periodos del horizonte de planificación. Esto implica que la demanda fluctúa alrededor de la disponibilidad de dicho recurso, y en su defecto, se harán esfuerzos por alterar los patrones de demanda para que se ajusten de manera efectiva a los recursos establecidos.

La estrategia de persecución o seguimiento altera los recursos periodo a periodo durante el horizonte de planificación. Esto significa que se aumentan y disminuyen sus valores de manera tal de ajustarse a la demanda establecida. Suele aplicarse en entornos donde es difícil alterar la demanda y hay disponibilidad para alterar la base de recursos.

Las estrategias combinadas o mixtas son las más comunes de aplicar. Aquí se mezclan y ajustan las dos estrategias anteriores, nivelando los recursos en algunos periodos y en otros ajustándolos a la demanda.

2.3 Proceso Analítico de Jerarquías

Cuando se requieren utilizar métodos de apoyo a la toma de decisiones en escenarios de múltiples dimensiones de evaluación suele utilizarse el PAJ ya que permite tomar decisiones en base a criterios múltiples. Es un método de trabajo sencillo, lógico y estructurado, basado en la descomposición del problema en una estructura jerárquica (Martínez Rodríguez, 2007).

El proceso requiere que quien toma las decisiones proporcione evaluaciones objetivas y/o subjetivas respecto a la importancia relativa de cada uno de los criterios que se seguirán para tomar la decisión y que especifique su preferencia con respecto a cada una de las alternativas de decisión referida a cada criterio. El resultado del PAJ muestra la prioridad total de las alternativas de decisión respecto a la meta (Toskano Hurtado, 2005)

Para tomar una decisión en forma organizada, es necesario seguir los siguientes pasos (Saaty, 2008):

1. Definir el problema, estableciendo sus componentes o elementos relevantes.
2. Estructurar la jerarquía del problema. Para ello, se elabora una representación gráfica del problema en función de la meta global, los criterios a ser usados y las alternativas de decisión. Se deben identificar los criterios más generales hasta los más particulares. Si se requiere, pueden desprenderse subcriterios. Estos últimos deben guardar una relación jerárquica con el criterio del que se desprenden.
3. Establecer las preferencias: El PAJ, requiere a quien toma las decisiones, señalar un juicio de valor con respecto a todos los elementos de un nivel, referido a cada uno de los elementos del nivel inmediato superior. Se utilizan matrices de comparaciones pareadas para establecer dichas preferencias. Las comparaciones pareadas son las bases fundamentales del PAJ. Se emplea la escala de Saaty con valores de 1 a 9, como se muestra en Tabla 1, para calificar las preferencias relativas de los elementos.

Tabla 1: Escala de Saaty (2008)

Planteamiento verbal de la preferencia	Calificación numérica
Importancia o preferencia absoluta	9
Importancia o preferencia muy fuerte o demostrada	7
Notablemente más importante o preferible	5
Moderadamente importante o preferible	3
Igualmente importante o preferible	1
Valores intermedios	2,4,6,8

4. Priorizar y sintetizar: En un problema jerarquizado, las prioridades pueden ser locales, globales o totales. Una consideración importante en términos de la calidad de decisión final se refiere a la consistencia de juicios que muestra el tomador de decisiones en el transcurso de la serie de comparaciones pareadas. La consistencia perfecta es difícil de lograr ya que los juicios son realizados por personas. Esta metodología calcula la relación o razón de consistencia de Saaty, considerando aceptable los valores menores a 0,1. Por último, se realiza la síntesis del problema para obtener la prioridad total de las alternativas mediante la agregación multiaditiva de las prioridades globales. Esto permite ordenar el conjunto de las alternativas consideradas y seleccionar la mejor alternativa para obtener la meta buscada.

3 Metodología

La metodología adoptada para este trabajo es un estudio de caso. El tipo de investigación es cualitativa y cuantitativa, inicialmente se analizan datos y luego mediante la aplicación de la herramienta propuesta se realizan cálculos matemáticos para selección.

Los pasos a seguir en este trabajo son los siguientes:
1- De manera conjunta entre analistas y expertos de consulta se determinan de las características y necesidades del sistema productivo.

2- Se acuerda también con los expertos, la información relevante para elaborar alternativas para el plan agregado de producción bajo el método de prueba y error con una planilla de cálculo electrónica. Este método es una técnica que funciona considerando todas variables de decisión a la vez para que los planeadores puedan comparar la demanda proyectada contra la capacidad existente. Suele ser muy usado por su facilidad de comprensión e implementación. Si bien no proporciona una solución óptima, es una metodología rápida y sencilla para encontrar una solución satisfactoria de las distintas combinaciones de las condiciones que se introducen al modelo.
Se comparan los resultados obtenidos en las distintas alternativas.
3- Se selecciona el mejor plan mediante la aplicación del PAJ, utilizando como entrada la información generada en los pasos anteriores. El procesamiento se efectúa con el software Expert Choice®.

4 Resultados

4.1 Características del sistema productivo

La empresa en estudio pertenece al rubro electromecánico y se fabrican tres tipos de familias de productos distintos A, B y C. Cada uno de estos productos demandará materiales e insumos en mayor o menor medida. Cada producto para ser fabricado según especificaciones de ingeniería de fabricación, debe pasar obligatoriamente por cuatro procesos agregados, donde en cada proceso hay un tipo de operario con sus herramientas y máquinas necesarias, en el siguiente orden: mecanizados de materiales que conformaran el producto; limpieza y pulidos; ensambles entre piezas y materiales, y ajustes; y pruebas y ensayos finales. En cada uno de esos procesos son necesarios insumos y materiales, los cuales cada uno de ellos se agrupan en familias.

Para cada producto existe un pronóstico de demanda (Figura 1), que es determinista por los pedidos de compras y encargos anticipados, y que hay que cumplir sin postergar entregas en cada mes.

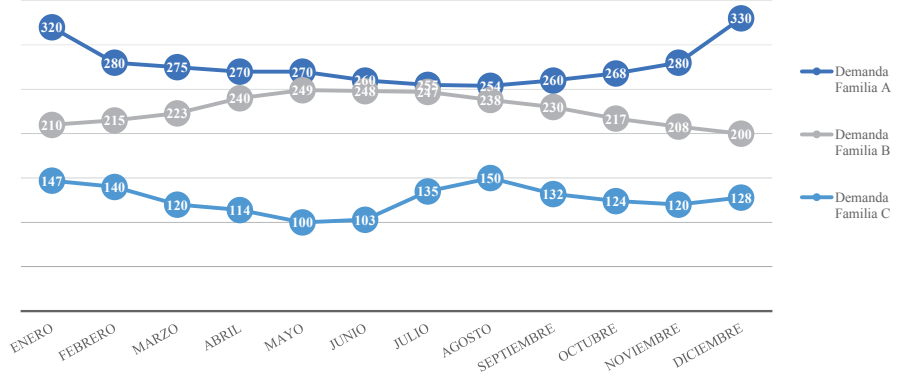

Fig. 1: Demanda determinística anual

Para fabricar cada producto, según los procesos indicados inicialmente, se requiere de los tiempos promedios por cada proceso por operario, estos tiempos se muestran en la Tabla 2. Cada operario trabaja 8 horas a diario, en caso de trabajar horas extras no debe superar las 2 horas extras por día, y al mes no debe superar 20 horas extras. La planta tiene una capacidad para 20 operarios del tipo A; 15 del tipo B; 30 del tipo C y 25 del tipo D, en caso que se requiera contratar más operarios para hacer frente al cumplimiento de la demanda, se debe abrir un nuevo turno de 8 horas regulares para los nuevos operarios que superen dichas cantidades de capacidad limite. Los costos de contratación, despido y hora extras se exhiben a continuación.

Tabla 2. Tiempos de fabricación por operario, costos y plantilla.

Familia de Operarios	Tiempo fab. A (hs)	Tiempo fab. B (hs)	Tiempo fab. C (hs)	Salario mensual	Plantilla fija inicial	Costo Contratación	Costo Despido	Costo Horas Extras
Operarios A	2	1	4	18000	20	40000	60000	150
Operarios B	4	3	7	22000	15	55000	85000	187
Operarios C	3	5	2	25000	26	62000	112000	213
Operarios D	2	1	3	20000	18	45000	95000	170

No hay stock inicial de ninguno de los tres tipos de productos para ayudar en el mes de enero, por lo tanto, se deben fabricar todos a partir de ese mes. En la Tabla 3, se establecen los costos de subcontratar una unidad de producto final terminada, y los costos de mantener una unidad de producto en stock por cada mes que se conserva almacenado.

Tabla 3. Costos de subcontratación y almacenamiento.

Costos	Familia A	Familia B	Familia C
Subcontratación de producto terminado	2300	2200	2450
Almacenamiento de producto terminado	100	85	120

En cada uno de los procesos son necesarios insumos y materiales que se agrupan en familias. Los tipos de insumos son A; B; C y D, y los tipos de materiales que también formarán parte de estos productos son A; B; C; D y E. Cada una de las familias de productos finales demanda una determinada cantidad de cada tipo de familia de insumo y materiales, que es detalla a continuación en las Tablas 4 y 5.

Tabla 4. Costos y requerimiento de insumos.

Familia de insumos	Familia de Producto A	Familia de Producto B	Familia de Producto C	Costo/ Unidad	Stock Inicial	Stock Final exigido	Costo Stock/ Mes
INSUMOS A	2	3	5	25	400	500	1,25
INSUMOS B	3	3	2	102	450	560	5,1
INSUMOS C	1	2	0	68	387	450	3,4
INSUMOS D	4	1	0	35	350	460	1,75

Tabla 5. Costos y requerimiento materiales.

Familia de materiales	Familia de Producto A	Familia de Producto B	Familia de Producto C	Costo/ Unidad	Stock inicial	Stock Final exigido	Costo Stock/ Mes
MATERIALES A	5	0	3	124	201	580	6,2
MATERIALES B	2	1	5	201	408	570	10,05
MATERIALES C	1	2	4	154	389	600	7,7
MATERIALES D	0	4	3	186	652	620	9,3
MATERIALES E	6	4	2	27	501	480	1,35

4.2 Alternativas del Plan Agregado de Producción

Con el objetivo de seleccionar el mejor Plan Agregado de producción se elaboran cuatro planes alternativos, siguiendo diversas estrategias y medidas de ajuste de la capacidad. A continuación, se describen los lineamientos adoptados en cada una.

- **Alternativa 1:** Esta alternativa propone la implementación de una estrategia de nivelación de mano de obra, tratando de abastecer la totalidad de la demanda durante cada período de planificación. Las alternativas de capacidad aplicadas para alcanzar los objetivos establecidos son el uso de horas extras, la generación de inventario, la subcontratación y la contratación y despido de la fuerza de trabajo. La mano de obra es de uso compartido entre las tres familias de producto y se establece un nivel de fuerza de trabajo constante por tipo de operario durante todo el periodo de planificación. De esta manera, existen meses con tiempos ociosos de trabajo que se utilizan para fabricar inventario y evitar los quiebres de stock y la reducción de necesidad de subcontratación.
- **Alternativa 2:** Este plan se realiza siguiendo una estrategia combinada de nivelación de las cantidades a producir en cada periodo del horizonte de planificación

con una nivelación de mano de obra. Se emplean como medidas de ajuste transitorio de capacidad la fabricación para inventario, uso de horas extras, subcontratación de parte de la producción y la contratación y despido de personal. Se considera que la mano de obra es compartida entre las tres familias, para cada etapa del proceso productivo. Las horas de trabajo ociosas se las utiliza para producir inventario para evitar el desabastecimiento de la demanda y la reducción de la cantidad de productos a subcontratar. La nivelación de la mano de obra se realiza en dos tramos. Durante el primer semestre, se establece un nivel mayor de mano de obra para generar inventario mediante la utilización del tiempo ocioso y durante el segundo semestre se establece un nivel de mano de obra menor.

- **Alternativa 3:** El plan se realiza adoptando una estrategia de persecución donde se produce la cantidad de unidades requeridas para abastecer la demanda. Esta estrategia no genera inventarios y la mano de obra es de uso compartido entre las tres familias de producto. Las alternativas de ajuste de capacidad aplicadas son la contratación y despido de la fuerza de trabajo, el uso de horas extras y subcontratación.
- **Alternativa 4:** El plan que propone se obtiene mediante una estrategia de persecución combinada con una estrategia de nivelación de mano de obra. Durante un periodo del horizonte de planificación se nivela la mano de obra, mientras que se ha hecho uso de una estrategia de ajuste al momento de absorber las necesidades de los periodos de demanda alta. La mano de obra es de uso compartido entre las tres familias de producto. Las alternativas de ajuste de capacidad aplicadas son la contratación y despido de la mano de obra, generación de inventario, uso de horas extras y subcontratación. Se busca minimizar la cantidad de horas ociosas mediante la producción para inventario con el fin de evitar el desabastecimiento de la demanda y la reducción de la cantidad de productos a subcontratar.

El motivo de tratar de minimizar la subcontratación se debe a que el costo variable unitario de las tres familias reporta un valor superior en relación a la fabricación en horas regulares (28%) y horas extras (31%).

4.3 Comparación de Alternativas

En la Tabla 6, se presentan los costos asociados a las alternativas de Plan Agregado de producción propuesto para las tres familias. Los cuatro planes alcanzan un nivel de servicio del 100% ya que no se producen quiebres de stock en ningún periodo y de esta manera se logra abastecer la totalidad de la demanda. La alternativa 2 es la que menores costos genera, sin embargo, se puede apreciar que en todos planes los costos más representativos son los de materia prima, mano de obra regular y contratación y despido. Los costos de horas extras, inventario y subcontratación obtienen valores menos significativos respecto a los anteriores.

Tabla 6. Costos asociados a las alternativas del Plan Agregado

Alternativa	1	2	3	4
Costo HR	$ 11.568.000	$ 10.890.000	$ 10.898.000	$ 10.922.000
Costo HE	$ 776.524	$ 877.158	$ 732.998	$ 762.835
Costo Subc.	$ 90.650	$ 95.550	$ 346.400	$ 314.600
Costo Cont./Desp.	$ 3.109.000	$ 3.488.000	$ 4.565.000	$ 3.836.000
Costo Inventario	$ 263.185	$ 122.610	$ 0	$ 94.275
Costo MP	$ 16.860.904	$ 16.007.883	$ 15.868.801	$ 16.046.154
Costo Total	$ 32.668.263	$ 31.481.201	$ 32.411.199	$ 31.975.864

En la Tabla 7 se presentan los indicadores de desempeño más significativos para el análisis de cada plan. El coeficiente de variación de la mano de obra y del plan de producción se considera con el objetivo de comparar la estabilidad que proporciona cada plan. La alternativa 1 presenta la menor variabilidad de la mano de obra y la alternativa 3 la menor variabilidad del nivel de producción. Asimismo, se presenta el porcentaje de inventario y subcontratación de cada plan respecto a la producción total para los diferentes planes presentados. La menor generación de inventario se obtiene en la alternativa 3 y la menor subcontratación se realiza en la alternativa 1.

Tabla 7. Indicadores de desempeño por alternativa

Alternativa	CV MO	CV Producción	% Inventario	% Subcontratación
1	0%	6,77%	33,75%	0,47%
2	3,80%	5,78%	15,84%	0,52%
3	4,99%	3,00%	0,00%	1,88%
4	3,81%	8,87%	13,15%	1,75%

4.4 Selección del mejor Plan Agregado

Para comenzar el PAJ se elabora la estructura jerárquica del problema planteado. Se determina como meta global "Seleccionar el mejor Plan Agregado de Producción" y se establecen como criterios más relevantes para tomar esta decisión los costos totales del plan, la estabilidad de la mano de obra, estabilidad del plan de producción, el nivel de inventario y el nivel de subcontratación. Estos se evalúan en forma cuantitativa, considerando los resultados presentados en las Tablas 6 y 7.

Se pretende encontrar la mejor alternativa que reporte menores costos a la empresa. Los criterios de estabilidad de la mano de obra y del plan de producción apuntan a reducir los porcentajes de variabilidad de ambos factores. Una menor variabilidad en la fuerza de trabajo genera un impacto positivo en su motivación y moral y en consecuencia en la eficiencia y efectividad de su trabajo. Por su parte, un plan estable proporciona facilidades en su gestión e implementación.

Respecto al criterio de nivel de inventario, se toma como mejor solución aquella alternativa en la que se reporte una menor generación de inventario debido a los requerimientos de espacio y recursos necesarios para su gestión y guarda.

El criterio de nivel de subcontratación proyecta medir el riesgo estratégico que supone la tercerización de la producción y se intenta minimizar su valor.

A partir del establecimiento de la meta global y la definición de los criterios de decisión, se presenta en la Figura 2 la estructura jerárquica del problema.

Fig. 2: Estructura Jerárquica

Mediante reuniones de trabajo con el grupo de analistas y expertos se determinan las preferencias respecto a la prioridad de los criterios y las alternativas de decisión en relación a cada criterio de selección. Estas valoraciones se ingresan al software Expert Choice® y se obtienen las prioridades locales y globales y la consistencia de los juicios.

En las Figuras 3 y 4 se presentan pesos de los criterios de selección y la priorización final de las alternativas, con el índice de inconsistencia, indicativo de la coherencia de los juicios.

Fig. 3: Pesos de los criterios

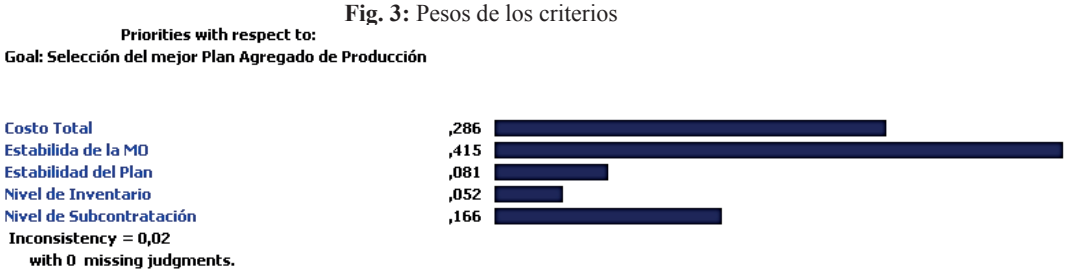

Fig. 4: Priorización de las alternativas

Se evidencia que los criterios más importantes son la estabilidad de la mano de obra (41,5%) y los costos totales (28,6%), seguidos por el nivel de subcontratación (16,6%), estabilidad del plan (8,1%) y el nivel de inventario (5,2%)

Como resultado final, se obtiene que la Alternativa 1 es la mejor con una prioridad total del 37%, seguida por la Alternativa 2 con un 31,4%, la Alternativa 4 con 17,3% y finalmente la Alternativa 3 con un 14,3% de prioridad.

Se corrobora que todas las matrices de comparación pareada son consistentes, obteniendo un valor de consistencia global de 0,02. De esta manera, se verifica la calidad de la decisión final ya que los juicios del tomador de decisiones son consistentes en todo el proceso de análisis jerárquico.

5 Conclusiones

La implementación del PAJ permite la estructuración del problema de selección de un Plan Agregado de Producción factible en forma sencilla, teniendo en cuenta criterios de selección acordes con las prioridades estratégicas del área productiva y de la empresa en estudio. Los criterios más relevantes para el proceso de selección son la estabilidad de la mano de obra y los costos totales que genera la implementación del plan.
Se plantean cuatro planes como alternativas viables a implementar. Todos logran abastecer la demanda prevista al presentar un nivel de servicio del 100% para las tres familias de producto. Se utilizan como opciones de ajuste de capacidad el uso de horas extras, la generación de inventario, la subcontratación y la contratación y despido de la fuerza de trabajo.

Respetando los criterios y restricciones establecidos se obtiene una jerarquización de los cuatro planes considerados y se selecciona uno de ellos, alternativa 1, como el mejor Plan Agregado de Producción. El plan correspondiente a esta alternativa aplica una estrategia de nivelación de mano de obra, reportando una ventaja significativa a la empresa, ya que proporciona una estabilidad total a la fuerza de trabajo al establecer un plantel constante durante el horizonte de planificación. Asimismo, la estabilidad de la fuerza de trabajo logra evitar el impacto negativo en la motivación y moral y en consecuencia en la eficiencia y efectividad de su trabajo. También permite reducir los problemas derivados de las restricciones o presiones que puedan proceder del entorno empresarial como pueden ser las regulaciones contractuales o actividad de los sindicatos no deben ser minimizadas a la hora de definir los niveles de mano de obra del plan.

La metodología propuesta permite a la Gerencia de producción efectuar el proceso de planificación de la producción de forma sistemática y consistente con las prioridades de la empresa. La utilización de Expert Choice resulta amigable y soluciona la selección de la alternativa de planificación más conveniente en función de los criterios utilizados y sus preferencias relativas. Si bien las hojas de cálculo electrónicas no proporcionan soluciones óptimas, resultan herramientas sencillas y de fácil comprensión para la elaboración de plan agregado ya que es posible incorporar y relacionar todas las variables de decisión que intervienen en el proceso.

Se concluye que la metodología multicriterio propuesta, en particular PAJ, es de factible y eficaz implementación para la empresa. Factible, en tanto utiliza datos de entrada que son derivados de la actividad habitual del proceso de gestión de la producción; y eficaz porque permite obtener el mejor Plan agregado que logra combinar los

recursos de manera tal de satisfacer la demanda prevista y considerar los criterios establecidos en función de las características y necesidades de la empresa.

Abstract. The level of attention of workers in their diary activities is an important factor to keep the quality of production and its own safety. Computer vision based tools can improve the human support by supervising handled operations by cameras and image analysis. In this context, the gaze following estimation is useful to detect if someone is looking in the right direction and keeping their focus of attention in the predictable time. Due pandemic COVID-19 times, we developed an adapted device and a computational tool based on deep-learning to detect if a person is looking to a temperature measurement device who enable or deny access to their workspace. We present the method architecture in context of Industrial Internet of Things (IIoT) to a real-life application as an automated solution to access control. It is also presented the quantitative data analysis from measurement tests performed at factory entrance and it is pointed future perspectives of improvement of proposed method.

Keywords: Gaze Following, Computer Vision, Deep Learning, COVID-19

1 Introduction

The recent event called Covid-19 pandemic worldwide, brings necessity to productive and service sectors rethink actions and to look for self-adjustment procedures to continue its operation in the new reality.

Gaze following based on computer vision is a useful tool to infer attention level from someone over its routine activities [1]. The non-contact measurement device, as cameras, leaves someone comfortable in its own workspace and capture reliable data according its movements and intentions. In retail, for example, they can infer consumer interest in different display items based on human-object eye contact in real time, seeking to understand consumer interest in different focuses of attention, such as price, packaging, average time look, or the items that attracted the most in the window. At the same way, into classroom activities the interaction among students and teacher can be measured to identify who is paying attention to some specific activity [2],[7-8]. Other important application to gaze-following is to protect operator's

healthy in shop-floor routinely tasks, by measuring the attention level of a specific assembly/disassembly task, or by handling dangerous equipment or materials, in order to identify concentration debility or stress issues.

In this work, the term gaze following (GF) refers to the "focus of attention" that means the direction in which the person is looking (object which someone is fixing in the look [1],[3]) in terms of its head position. We apply the GF concept to measure if a person is looking to a thermometer device in order to enable him to access a factory plant. In this way, the process to temperature measurement can be automatized replacing a people dedicated to proceeding the measurement in order to avoid contact a face-to-face. By this way, a vision-based system brings guaranties to identify a person by facial recognition and to give access permission to his local of work. Figure 1 shows the conceptual idea of proposed method.

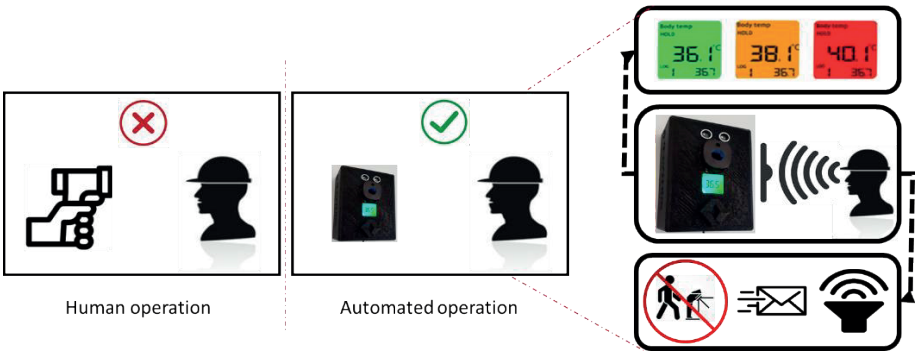

Fig. 1. Conceptual sketch of proposed method.

According fig.1, the infrared pistol type thermometer can be replaced by a wall fixed device with the same function of head temperature measurement without proximity with a human operator. The proposed approach is an AI supported software associated to a computer vision system to guaranty the data gathering veracity. The kernel of system are the computational algorithms based on convolutional neural networks (CNN) to explore facial recognition, head pose estimation and gaze direction. The literature supporting this approach is given in the next section.

2 Background

The literature used as basis of conceptual understanding about gaze following was conducted by the research development methodology who includes: (i) Systematic Literature Review (SLR) and content analysis, and (ii) experimental procedures. The purpose of the review is to identify which are the main requirements for the application of vision systems and which are the most efficient AI techniques for implementing a gaze-following tool applied for temperature measurement test to enable or deny access the working area in a factory.

It is proposed to carry out the systematic literature review as in [4] and modified as presented in [5]. The modified m-SLR merges content analysis and regression analysis tasks in a single step. The content analysis stage filters the results of the research, providing a more precise perspective of the researched topic, while the regression analysis increases the robustness of the selected articles, adding statistical evidence for the selection of the articles.

Trending topic keywords can result in many documents being evaluated by content analysis, and many of them may not be related to the desired topic. To minimize this effect, Latent Semantic Analyzes (LSA) is applied to the text mining procedure, as proposed by [6], which is the language processing technique (NLP), followed by a reduction in dimensionality based on the decomposition of singular values (SVD).

After applying this methodology with content analysis over many documents, we found the following articles currently considered the actual state of the art by the use of deep learning and computer vision techniques for gaze following and given support to this research. They are:

i. Recasens *et al.*[7-8], proposed a convolutional neural network (CNN) architecture whose pipeline is divided in two different paths, where one is dedicated to discovering salient points in the image (as target of view) and the second path determines the head pose. Thus, to determine a Gaze Pathway, the pipeline receives as input only the cut image of the head and its location. Then, first apply the convolution layers to the image of head, and after it concatenates the result of the convolution with the position of the head and use them as input to row fully connected layers. Finally, a sigmoid activation function is used to generate results between 0 and 1 producing a heat map (*gaze mask*) of a region that is the attention focus.

ii. Lian *et al*. [2] presented a new and more intuitive approach to gaze following estimation, composed by two steps. In first, the image of head and its position in image is used to an initial estimative of several field of gaze, and the gaze following is coded in different scales. In the second stage, those all fields of gaze are concatenated together original image, and thus serving as input to a regression model as in [9]. The gaze-following datasets are annotated by a third person and the proposed model is used in a real scenario the authors proposed an specific metric called *MAng*, minimum angular error that measures the minimum angle between the predicted point and the annotated truth (*ground truth*). Thus, it was created a new dataset called Daily Life Gaze dataset (DL Gaze) of videos annotated by the people who were on the scene in order to obtain a more accurate ground truth. In this way, it is possible to infer the accuracy of the proposed model in everyday scenes.

iii. Ruiz *et al*. [10] combined the neural ResNet50 [11] with a multi-loss architecture, where each loss contains a combined classification and regression, which correspond to the yaw, pitch and roll angles individually. Obtaining robust results, his proposal to classify the head position was named HopeNet.

iv. Yang *et al.* [12] proposes a method based on the TensorFlow [13] deep learning framework that improves the previous methods based or not on the marking of points on the face for estimating head positioning (*head pose estimation*). It stood out for its high capacity to determine the head angulation in a wide range of positions and even with partial occlusion of the face. It is due on the fact that the proposed architecture does not use the points of the face to determine the angle of the head.

v. Kellnhofer *et al.* [14] present a large-scale gaze-tracking dataset (the Gaze360) and a method for robust 3D gaze estimation. The dataset consists of subjects in indoor and outdoor environments with labelled 3D gaze across a wide range of head poses and distances. They introduce a discriminator which tries to identify the source domain of the image features as a binary classification task. The features are the output of the backbone network (ImageNet-pretrained ResNet-18 [11]). The discriminator loss is added to the original supervised loss for those images where ground truth is available. Thus, this approach is suitable for deep learning of 3D gaze from images and video.

Following SLR, we conduct an experimental procedure to evaluate the literature based models and proposed an application method to assess the gaze field from subjects looking at temperature measurement device in order to identify subjects with possible fever symptom related with COVID-19 as presented in next sections.

3 Proposed Method

An application structure is proposed according steps indicated in fig.2. It is shown four subsequent processes that deals about the subject detection, gaze direction measurement, temperature measurement and access permission.

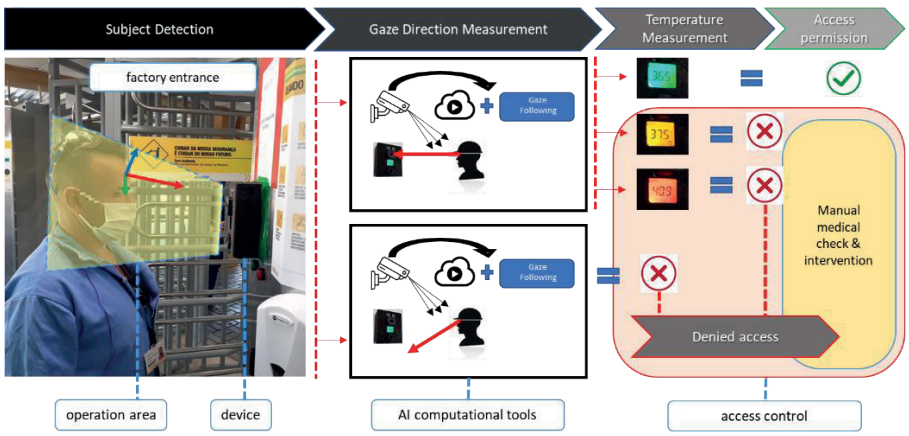

Fig. 2. Functional blocks of proposed method.

According fig.2, the functional blocks are:

Subject detection: the first step is to proceed the subject detection. Due safety protocols have been applied during COVID-19 pandemic restrictions; the factory entrance lines were organized so that it exists distance regulations between individuals. Immediately in front of each entrance, it was set up the sensing device. The individual must stand in front of device in a maximum range of 50 cm between device and user measured by an ultrasound sensor. The measure will be taking only if the correct gaze direction is detected.

Gaze Direction Measurement: This is a system feedback step and it remains active while the subject is not correctly positioned in front of sensor device. Once correct gaze direction is identified the temperature measurement is triggered.

Temperature Measurement: After correct head pose estimated and gaze direction detected, an infrared sensor measures the temperature from subject's head. According nominal value measured is less than threshold value (for instance, 37.5°C) an information is passed to access controller of gate who provide autonomous action to open or not the gate.

Access Permission: if the temperature measured is equal or above thresholding value, device sounds a beep, a message is sent to the medical staff and gate is blocked until next subject from line takes his temperature. The subject should go to specific place on entrance to manual verification and medical procedures.

3.1 Hardware specification

The hardware prototype is powered by a 9V DC switching source and can be analyzed in three distinct parts: the detection circuit, the temperature measurement circuit and the alarm and notification circuit, with all of them connected by a microcontrolled board.

For the control, an Arduino UNO development board kit is used, which has an ATMega328P programable microcontroller, with a digital and analog data input and output system, capable of interacting with components and devices connect-ed to it.
For the detection circuit, we embedded a low-cost ultrasonic sensor, model HC-SR04, consisting of two transducers, an emitter and a receiver operating at 40kHz that matches with our purpose of no long-range readings [16]. The distance evaluation is managed through the development board that evaluates the time from the exit until the return of the emitted ultrasonic signal, considering the speed of the sound signal in the air of approximately 340m/s.

To temperature measuring, we embedded an adapted commercial thermometer. The infrared sensor captures the waves, converting them through its own circuit into an analog signal that, after conversion to the Celsius scale, is shown on the equipment's display, which is distinguished by the colors green, yellow and red, in this sequence of temperature's scale.

To make an accurate reading of the temperature, the sensor was calibrated with a distance of 50cm. Measures below this value cause the Arduino to send a 5V signal to the base of the NPN TIP41C transistor, saturating it, causing it to activate the button

(trigger) of the temperature measurement circuit. The nominal value and the signal responsible for the changing colors were used as input to the Arduino, which generates alerts through its digital and analog pins for the third circuit of the device.

The alarm and notification circuit have an audible alarm and a lamp informing the security professional which device has high temperature signals. The user, likewise, receives these signals more discreetly on the device, in addition to being denied access to the factory. The analog signal is used in conjunction with an ESP8266 module, which is a microcontroller device with Wi-Fi communication capability with an integrated TCP/IP protocol [17]. This module is used integrated with Arduino, sending emails to a list of company supervisors.

Figure 3 presents a block diagram that describes the device and its circuits. It also shows the sequence of its operation.

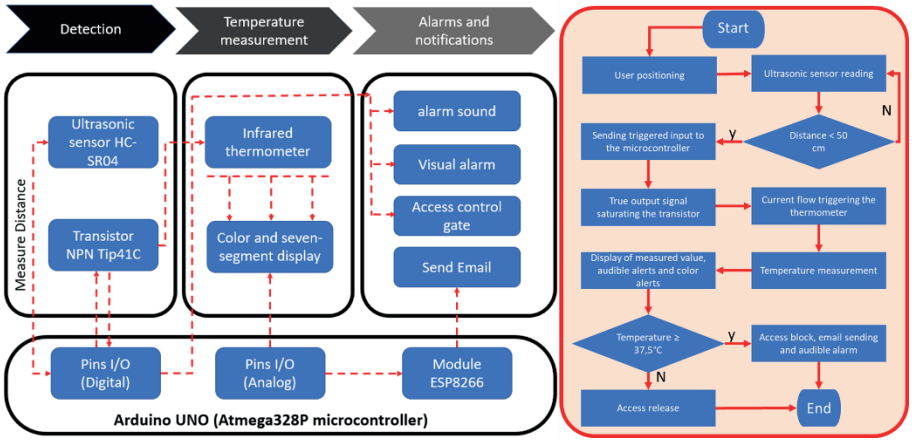

Fig. 3. Hardware components diagram.

In order to guaranty the correct head position to temperature measuring, we configurate the environment with a digital camera to capturing images from each one posed in front of device. From image it is possible to get the direction where people are looking, that is, if its gaze is on the device as target. Thus, a gaze following algorithm was implemented to work together with measuring device.

3.2 Gaze Following Pipeline

The task of determining the gaze direction necessarily requires face detection procedure. Automatic face detection is a prerequisite in several computer vision systems, which aims to detect and estimate bounding boxes at different scales of size and face positions. The algorithm to determine the gaze direction presupposes the existence of the starting point of interest in the field of vision. Thus, the flowchart presented in figure 4 present the sequential steps to a gaze following pipeline.

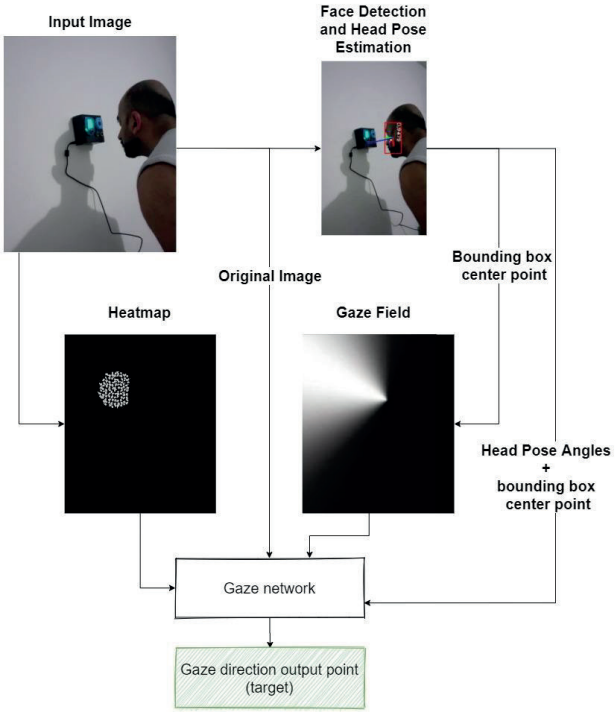

Fig. 4. Gaze following pipeline.

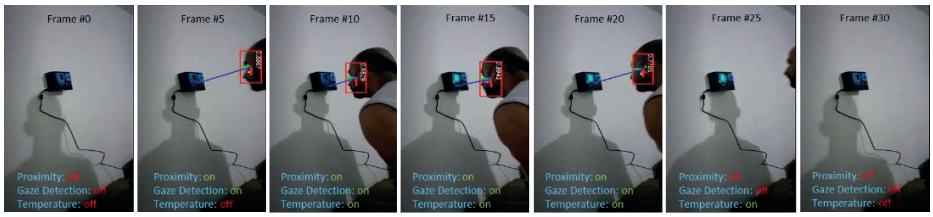


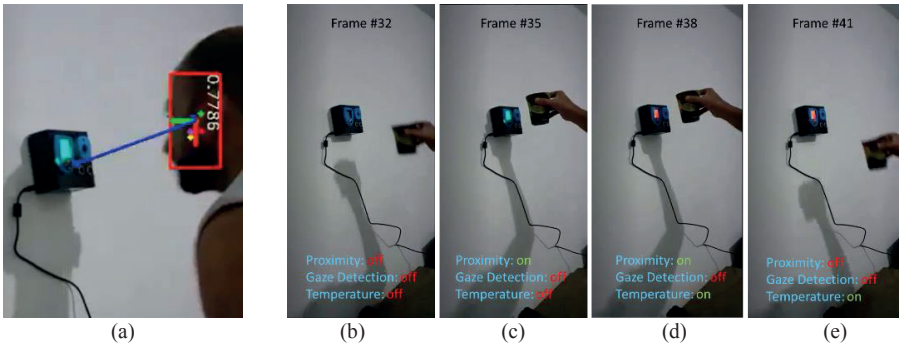
As the first stage of the pipeline, the image is processed by a neural network for facial detection. The model adopted for the first stage was the RetinaFace [15]. Then, as proposed by [1], with the result of the first stage of the pipeline, the position of the head is estimated from the cut of the face detected in the image. Then it determines the position of the head, as proposed by [10], which results in three axes (pitch, yaw and roll) whose values serve as input for the second step.

We consider as origin of coordinate center of gaze the center of the face's bounding box. The field of vision direction is generated with the point of origin of the look, called gaze field (in figure 4). Thus, the data to determine the direction of gaze, was performed by a neural network model that receives as input parameters: (i) the angles resulting from the estimation of the position of the head, (ii) the original image, (iii) the field of direction of the look (gaze field) and (iv) the gaze point origin.

The gaze target is determined by the neural network (Gaze Network) proposed in [1]. The output is activated by a sigmoid function that generates values in the scale of 0 to 1 in the same size as the input image. Thus, it is possible to present a heat map image of the possible targets of the subject eyes. The higher value among all of heat map resulting from the merging of data in the Gaze Network is considered the target point to build a line of view. In this way it is possible to determine the direction of the gaze and also its respective target. The heat map is an important output to results monitoring of the Gaze Net neural network [2].

4 System Evaluation

A test was performed to gaze following evaluation in a controlled indoor laboratory environment in order to measure the system accuracy and to find all associated possible errors. Fig.5 shows a frame sequence for an automated measuring experiment.



(a) (b) (c) (d) (e) (f) (g)

Fig. 5. Frame sequence for gaze following and temperature measurement testing.

In fig 5.(a) the sensor device is in idle state, waiting the detection of someone; in (b) and (c) the proximity of presence of an individual was detected and the gaze direction is also detected but temperature is not measured until the correct direction vector (yaw, pitch and roll) is out of expected angle range. In (d) and (e) the temperature is taken and displayed to user. In (f) the user moved away after the temperature value displayed, and the gaze vector does not appear after distance increased. In (g) the system come back to idle status. Thus, in this controlled environment, the detection and measurement work in correct way about 100% of all performed tests.

The detail of head position based detection is present in fig.6(a). The coordinate system orientation is determined by gaze following pipeline according method of [1]. The bounding box circumscribe the detected face.

The strength of method permits detection from partial face (or partial occlusion) in image.

(a) (b) (c) (d) (e)

Fig. 6. (a) Head identifying; (b)Simulation with no head detection and using a hot coffee cup. (c) proximity detected but still without temperature measurement. (d) temperature measured and displayed. (e) cup withdraw and temperature display remaining on with configurable time.

In Fig.6(b) to Fig.6(e) a test was performed using a hot coffee cup, and as expected there are not gaze detection because a human face does not exist in image. Also, the temperature was measured to check the different values displayed and to validate the threshold value.

5 Case study

As a case study was carried out in a real factory scenario. The equipment was placed in a testing phase in one of the access gates, as presented in fig.7.

(a) (b)

Fig. 7. Real environment configuration

The effectiveness of the response obtained during three testing sections at the time of entry of the workers rotation, where there is the major number of subjects circulation at same time, is presented in table 1.

Table 1. Results of testing during a sampling period.

	testing sections			**total**
	1	2	3	∑
Monitored volunteers	82	65	70	217
Fever symptom detected	1	3	0	4
Incorrect user pose (#)	7	5	6	18
Incorrect user pose (%)	8.5	7.7	8.6	8.3
Detection failure (#)	4	3	3	10
Detection failure (%)	4.9	4.6	4.3	4.6

From the experiment, 217 people were monitored in one single gate, where 4 showed signs of fever and were leaded to the health sector. The table 1 shows results where: (i) The number of incorrect user pose is when the algorithm detected the per-

son, however, the user was not looking at the equipment. This situation occurred in about ~8% of detections. (ii) the detection failure considered the situations in which the user had his face recognized, but the look has not been identified, or those all cases where neither the face has been identified. This situation occurred in about ~4,5% among all detections. Of course, in all cases when detection is incorrect (or uncertain) the gate remains closed. In this case the person should go to a manual screening to testing. Or of course, try again in another gate do get access.

Assuming that the factory plant has around 7,500 employees and with 4 main entrances with 8 gates, the projection of the gain is that around of 13% needs to be retested by a manual way. Thus, in this way, it is possible to reduce from 32 employees to just 1 operator by entrance with manual thermometer to retest operations.

6 Conclusion

This research presented a gaze following method applied to a real situation on COVID-19 scenario. A sensing device was built in order to automate the process of temperature gathering without human intervention on measures. The contribution given by automatization of process allow a useful reduction of workers exposure to direct contact to making the manual measures.

By complementary way, a software was developed to management and system operation based on computer vision and artificial intelligence algorithms. In this context, a gaze following pipeline was proposed to certify the correct gaze direction of head position; and if it is correctly detected a trigger enable the temperature measurement. After that, according value measured a threshold enable or denies the access to factory plant.

The tests carried out demonstrated the importance of an efficient face detector model in the pipeline. Given the current situation of COVID-19, people are always wearing masks and failure to detect the face will cause the pipeline to break. The model adopted from [15] did not present limitation in detecting faces in images form subjects wearing a mask in the tests performed, as shown in evaluation table 1.

Some improvements can be developed, as for instance, face recognition to automatization of identifying possible ill subjects, identification of users without wearing mask or without sanitize his hands, message dispatch to managers and medical staff among other facilities.

Abstract. This paper proposes a mixed-integer linear programming (MILP) model that is implemented based on a rolling horizon scheme to solve an aggregate production planning decision problem of a manufacturing company that produces snacks in Monterrey, Mexico. The demand of the company is characterized by trends and seasonality. The proposed solution is evaluated by means of computational experiments to determine the relation between demand uncertainty and flexibility of a production system. A 2^k factorial experimental design and a multivariate regression were performed. Results show forecast bias and length of frozen period in the rolling horizon have a strong effect on total profit. The safety stock level was also found to be a significant factor, depending on the level of bias.

Abstract.

Keywords: Production planning · Rolling horizon · Forecast error · Flexibility factors

1 Introduction

This study considers a production planning problem for a snack factory located in the metropolitan area of Monterrey, Mexico. The company has presented significant costs due to high inventories, overproduction, and stockouts. Executives consider that the company experiences a bullwhip effect due to the lack of a precise forecast and an assertive communication between departments in the company. This can be also a problem related to the flexibility of the production system of the company, as even in the cases in which forecasts have a good accuracy, the company does not achieve the desired results. The company operates like this. The production manager receives a demand forecast estimated by the sales department. Then, the production manager defines an aggregate production plan every month, and that plan is executed on a weekly basis by sales and production departments. The level of uncertainty and

variability of the demand of the company are important factors to be considered for their planning operations. This uncertainty can be related to sales, prices, technology development, etc.

One strategy that can be employed to modeling the decision-making process of the production manager is by means of a rolling horizon scheme [14]. Unlike a fixed-horizon production planning process, in a rolling horizon strategy demand forecasts are updated every iteration of the planning horizon [10]. Hence, under a rolling horizon planning scheme, several different optimization sub-problems are solved considering a forecast of demand. After the realization of the demand, the resulting plans are updated, and the iterations continue until the production plan for the entire planning horizon has been determined [1].

Based on the characteristics of the company considered as a case study, a mixed integer linear programming model is proposed, to support the production planning decisions of the company. The proposed model is implemented considering a rolling horizon scheme. A set of experiments is conducted to evaluate the mathematical relation between demand forecast errors and the flexibility of the production system.

The remainder of this paper is organized as follows. Section 2 presents a literature review regarding districting problems. Section 3 presents the proposed mathematical formulation and solution approach. Section 4 describes the experimental design and Section 5 discusses the analysis of results. Conclusions and recommendations for future research are given in Section 6.

2 Literature review

Production planning is an area of great interest for both practitioners and academics. Since the pioneering studies that proposed linear decision rules and suggested some basic applications methods, innovative models and solution methodologies to handle these problems have been proposed in the literature. Jalmania et al. [5] present a comprehensive literature survey and future research directions for aggregate production planning problems under uncertainty. They analyze and classify the literature and identify future research paths, highlighting that few studies on rolling horizon implementations for aggregate production planning can be found in the literature, in both the deterministic case and the case under uncertain conditions.

Among the contributions that consider a rolling horizon for Aggregate Production Planning (APP) models, we can mention the study conducted by Demirel et al. [1]. They proposed a mixed integer linear programming model under a rolling horizon scheme with flexibility requirements where demand is regarded as an uncertain variable. Jain and Palekar [3] and Hahn and Brandenburg [2] consider the APP in process industries. The former contribution develops a stochastic linear programming method to study APP with resource limitation considerations in a continuous food producing company. The latter contribution develops a sustainable APP decision model for a chemical process industry by applying stochastic queuing networks. Only Jain and Palekar [3] consider a rolling horizon implementation.

Lin and Uzsoy [7] use two different chance-constraint formulations to reduce planned release changes while maintaining a desired service level under stochastic demand in a rolling horizon environment and compare them with an LP formulation that does not consider uncertainty. Vogel et al., [11] develop a hierarchical and an integrated model considering two levels of hierarchical production planning, the APP and the Master Production Scheduling (MPS), in order to show that it is possible to integrate them into a single model and, at the same time, fulfill their requirements. The interaction of both levels was implemented on a rolling horizon approach. Li and Ierapetritou [6] propose a methodology to derive the production capacity constraints based on short-term scheduling model through parametric programming technique and use this capacity information in the rolling horizon framework to improve the final solution's quality.

Zhang et al., [14] develop a two-stage integer stochastic planning model for an international enclosure manufacturing company with seasonal demand and market growth uncertainty. The model was implemented considering different solution methodologies, including two rolling horizon algorithms, comparing their performance. Sitompul and Aghezzaf [8] propose a preventive maintenance model that considers a non-cyclical planning, which means that the preventive maintenance periods do not necessarily fall at equally distant times. They solve the problem at the detailed level using a rolling horizon approach and calculate the average of the total costs at the detailed level. Stephan et al., [9] propose a multi-stage stochastic dynamic programming method to support real world capacity provision and adjustment decisions in automotive manufacturing networks. They compared their proposed methodology with respect to a rolling horizon two-stage stochastic planning approach. Wu and Ierapetritou [12] present a hierarchical approach for production planning and scheduling under uncertainty, using a multi-stage formulation. The optimal schedule is determined using a rolling horizon strategy. Yao et al. [13] address a medium-term capacity and production planning model to plan and support production operations for meeting multiple product demands considering a multi-facility manufacturing system. The system has limited product flexibility, and, continuous and discrete capacity change options with varying implementation time and cost. For testing, the MILP problem approach was implemented with a rolling horizon schedule as solution method in practice.

Table 1 summarizes in chronological way the most related contributions to this work, including those previously described. The table classifies the contribution with respect to the type of model proposed, the solution methodology and the type of planning horizon (fixed or rolling one). The last row corresponds to the contribution presented by this manuscript.

3 Mathematical Formulation and solution approach.

In this section we present the mathematical formulation for the aggregate production planning problem (Section 3.1) and the solution approach based on a rolling horizon scheme (Section 3.2).

3.1 Mathematical Formulation

In this paper we consider a manufacturing company that produces set of I products, manufactured in a set of L product lines during a planning horizon of T periods. The aim of the company is to maximize the global net profit balancing the sales revenue and operational costs subject to the plant capacity over the planning horizon T. The indexes, sets, constants, and variables are listed below, followed by the model formulation.

Objective

z: total profit [$].

Sets

I: set of products i.

L: set of product lines l.

T: set of time periods t.

Variables

Inv_{it}: inventory units of product i in period t [units].

B_{it}: unfulfilled units of product i in period t [units].
Z_{ilt}: binary variable that takes value of 1 if a set-up is made for product i on production line l in period t [0,1].
Mp_{ilt}: manufactured units of product i on production line l in period t [units].
S_{it}: sold units of product i in period t [units].

Constants

M: A big number.
Cs_{il}: set-up cost of product i manufactured on production line l [$].
Cp_{il}: production cost of product i manufactured on production line l [$].
Ch_i: holding cost of product i on inventory [$].
Cb_i: cost of unfulfilled product i [$].
Ts_{il}: set-up time of product i manufactured on production line l [time units].
Tp_{il}: time required to produce product i on production line l [time units].
Q_l: maximum capacity of the production line l [time units].
β_{it}: availability of the production line l in period t [0-1].
d_{it}: demand forecast for product i in period t [units].
P_{it}: sale price of product i in period t [$].
$Inv0_i$: initial inventory units of product i [units].
SS_{it}: safety stock units of product i in period t [units].

Objective Function

$$Max\ z = \sum_{i=1}^{I}\sum_{t=1}^{T} P_{it}S_{it} - \sum_{i=1}^{I}\sum_{l=1}^{L}\sum_{t=1}^{T} Cs_{il}Z_{ilt} - \sum_{i=1}^{I}\sum_{l=1}^{L}\sum_{t=1}^{T} Cp_{il}Mp_{ilt} - \sum_{i=1}^{I}\sum_{t=1}^{T} Ch_i Inv_{it} - \sum_{i=1}^{I}\sum_{t=1}^{T} Cb_i B_{it} \quad (1)$$

Subject to

$$\sum_{i=1}^{I}(Ts_{il}Z_{ilt} + Tp_{il}Mp_{ilt}) \leq \beta_{lt}Q_l \qquad \forall l,t \qquad (2)$$

$$Mp_{ilt} \leq MZ_{ilt} \qquad \forall l,t \qquad (3)$$

$$Inv_{it} = Inv_{it-1} + \sum_{l=1}^{L} Mp_{ilt} - S_{it} \qquad \forall i, t = 2,\dots,T \qquad (4)$$

$$Inv_{i1} = Inv0_i + \sum_{l=1}^{L} Mp_{i1} - S_{i1} \qquad \forall i,t \qquad (5)$$

$$S_{it} = d_{it} - B_{it} \qquad \forall i,t \qquad (6)$$

$$Inv_{it} \geq SS_{it} \qquad \forall i,t \qquad (7)$$

$$S_{it}, Mp_{ilt}, Inv_{it}, B_{it} \geq 0; \qquad \forall i, l, t \qquad (8)$$

$$Z_{ilt} = \{0, 1\} \qquad \forall i, l, t \qquad (9)$$

In the objective function (1), the first expression represents the total net profit. The second and third term describe the setup and production costs. The last terms represents the inventory and stockout costs. Constraint (2) is the capacity constraint in time units for each production line. Constraint (3) guarantees that there can be production in a period and production line, only if there is a setup. Constraints (4) and (5) enforce inventory balance. Constraint (6) defines the amount of products *i* to be sold according to the demand forecast and the unfulfilled units for each period of time *t* and demand scenario k. Constraint (7) sets the minimum safety stock for each product *i*, each period *t*. Constraints (8) and (9) are non-negativity constraint for all variables, specifying Z_{ilt} as binary.

3.2 The Rolling Horizon method

For this study, we define *H* as the number of periods for which we wish to create production plans. The planning horizon each time the model is run is of *T* periods, $T < H$. Parameter *R* is introduced to help describe the general rolling horizon strategy. *R* is a horizon ($R<T<H$) in which production plan is fixed and the real demand can be observed and used to update forecast, adjusting the plan over a planning horizon of *T* periods. The steps of the algorithm are further described:

1. Make the forecast for the demand in $t=1...T$ with its respective measures of error and deviation. Run the model to get the production plan Mp_{ilt}. Set the current period as $c = 1$.
2. For $t=c...R$, fix the resulting production plan and take the values of actual demand in this horizon. Save these values as parameters Mp_{ilt} and d_{it} respectively in the MILP model. Run the model with this update and get the values of Inv_{it} and B_{it}.
3. For $t = R + 1, \dots, R + T$, update the forecast and run the model in the same way as step 1 recognizing the current period is updated by *R* periods to the current time, and considering the value of $Inv_{iR} = Inv0_i$ in this horizon.
4. If $c < H$, update $H=H-R$ and return to step 2; else, stop.

4 The experimental design

The experimental design was performed to test the impact of specific factors, both forecast error and production flexibility on total profits of the company. We propose a factorial design 2^k. For the statistical analysis, *Minitab 18* was used in all combinations generated of three factors that were varied in two levels, high and low. In total, we will consider 2^3 instances* 5 replicates = 40 aleatory experiments.

4.1 Instance Generation

The bias of the forecast demand error is considered in order to evaluate the inaccuracy of the method employed by the company to forecast the demand. With respect to the flexibility of the production system, we consider the level of safety stocks. The length of the frozen horizon is also included in the experiment. The value of Tp_{il} is equal to 1 second per piece and Ts_{il} is 25 minutes. Given that the company does not have capacity limitations, we assume that capacity is high enough to produce all the units required by the company. Table 2 presents the rest of the parameters and their values for the high and low level of the experiments. The values were defined according to the characteristics of the case study under consideration. The bias factor is interpreted as the percentage by which the real demand is underestimated. Thus, a value of 60% indicates that the forecast is on average only 40% of the real demand.

Table 2. Parameters to evaluate in the factorial experimental design.

Parameter	Nomenclature	High Level	Low Level
SS	Safety stock service level	95%	85%
bias	Absolute value of bias *(underestimated)*	60%	10%
R	Number of periods in the frozen horizon	6	1

To generate the instances, a data set of real demand faced by the company corresponding to the periods from year 2016 was used for experimental purpose. The forecasts were prepared with the specified bias and Root-Mean-Square Error (RMSE) as representative for the company's historical forecast error.

4.2 Numerical results and discussion

The proposed MILP was implemented in AMPL TeamEAT Version 20120911 (MS VC++ 6.0, 32-bit) with Gurobi 5.0.1 as the solver. The rolling horizon procedure was automated with Python 3.6, using the *amplpy* library for interacting with AMPL. Likewise, *pandas* and *xlrd* libraries were used to read instances files and write files with the results of the experiments. To solve the test instances, an Intel Core (TM) i3-6006U CPU @ 2.00 GHz 1.99 GHz computer, with 8gb RAM was used. The runtime for 40 instances was 3 hours, 1 minute and 20 seconds. The overall results of the experiments are summarized in Table 3. The minimum, mean and maximum values obtained for each of the variables is shown, as well as the minimum, mean and maximum computational times for the solved instances. Tables 4 through 9 present the results by parameter level.

Table 3. Global results after implementing the solution method with Python.

	Mean	966	900	539	66	$96923.00
	Max	1443	1236	865	207	$143683.00

As can be observed in previous tables, the parameter related to the bias has an important effect on profits. For the rest of the parameters, the profits do not present a significant variation in the results obtained by each level. However, the frozen horizon R has an impact on the values of inventory, with a higher mean and maximum value when we consider the low level of R=1.

In addition to the results shown in the above tables, to verify the significance of the factors studied on the variables of interest, a multivariate regression analysis was performed. For this, Minitab 18 version was used. The analysis considered the step-by-step method to eliminate non-significant terms. The only coefficient that resulted significant for total profit as an individual factor was the bias. The rest of the parameters only have an impact interacting directly with bias, that is, their behavior depends on the level of bias: the safety stock level *SS (1-α)* and the number of periods of frozen horizon R. Tp_{il} and Ts_{il} depend strictly on previous interaction to be significant. An R-square adjusted value of 84.8% was obtained. Table 7 summarizes these results.

Table 7. Significance of the coefficients.

Term	Coefficient	Standard Error Coefficient	T-value	P-value	Variance Inflation Factor (VIF)
Constant	126505	2098	60.31	0	
bias	-103504	5552	-18.64	0	2.19
SS*bias	-179520	74970	-2.39	0.018	1
R*bias	-21675	2374	-9.13	0	1.19

Considering the factors and interactions that resulted more significant, we present a comparative analysis of them with respect to profits: (i) bias; (ii) Interaction of bias and *R*; and (iii) Interaction of bias and safety stocks.

(i) Comparative analysis of bias with respect to profits

Fig.1 presents the behavior of high and low level of bias on profits during experimentation. We can observe a decrease on profits when bias is higher, so the lower the value of this, the higher the benefits, which lead us to conclude that profits are highly influenced by the bias.

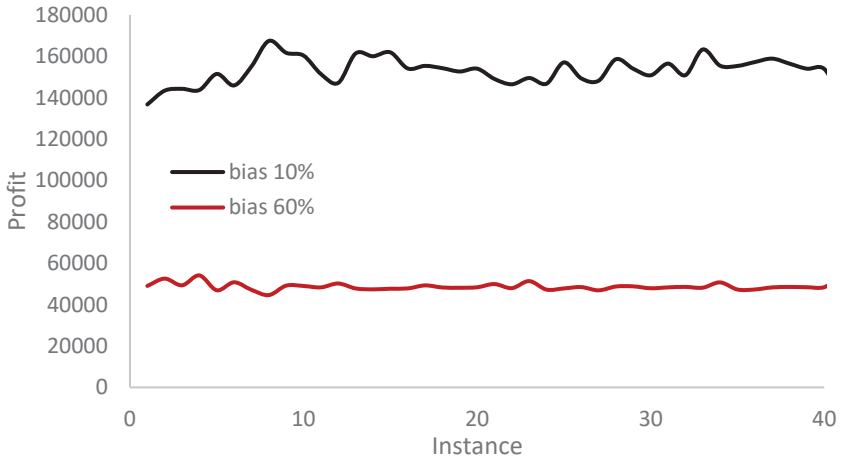

Fig.1. Comparative analysis of the levels of bias with respect to total profit

(ii) Comparative analysis of the interaction of bias and R with respect to profits

Fig. 2 illustrates the behavior of bias and *R* with respect profits. As we can observe, when the bias has the biggest value (60%), the profits are low, even for a shorter length of the frozen period *R* (*R=1*), but these short-frozen period tends to raise the profits a little by fast reaction. On the other hand, when the bias is small (10%), more stable and better profits are achieved when the length of the frozen period *R* is higher (*R=6*).

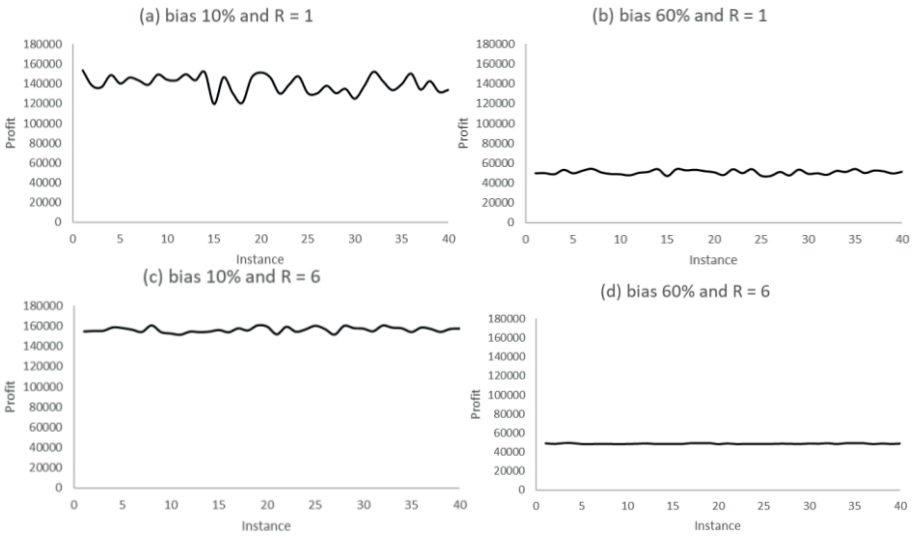

Fig.2. Analysis of the interaction of bias and the frozen period *R* with respect to total profits.

(iii) Interaction bias and Safety Stocks on profits comparative analysis

Fig. 3 presents the corresponding graphs to compare the bias and safety stock with respect to profits. As we can observe in the figure, for the same safety stock level, the level of bias has an important effect on total profits, being significantly higher when the bias is small (10%). The same conclusions can be derived when considering a higher safety stock level (95%), significant differences on the profits are achieved depending on the level of bias.

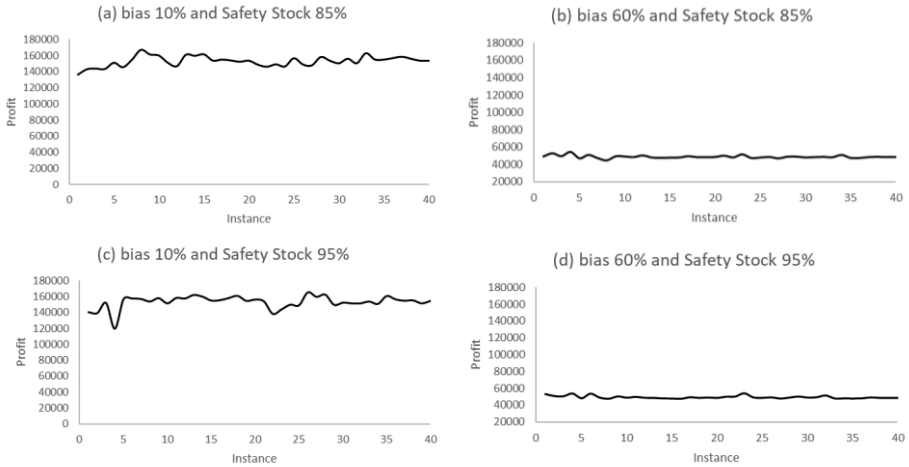

Fig.3. Analysis of the interaction of bias and safety stocks with respect to total profits

5 Conclusions and recommendations for future research

In this paper, we have proposed a Mixed-Integer Linear Programming (MILP) optimization planning model, motivated by a case study company that produces snacks in Monterrey, Mexico. To solve the model, a rolling horizon scheme is considered in order to resemble current practices of the production managers of the company, that determine their aggregated plans for a medium term planning horizon, and adjust them according to the demand faced. The proposed framework has been implemented in Python and AMPL.

Numerical experiments were performed, for which a set of instances were generated. Values of the parameters were defined to resemble the operations of the company. The experiments incorporated the forecast bias as a factor to be considered, to evaluate the impact that this has on profits and the other variables of the model (production amount, inventories, etc.). We also performed a statistical analysis to determine the factors that are most significant on the profits. Results show that the bias is the most significant factor affecting profits, and the other variables. The rest of the factors are not significant. Only the interaction of the bias and the frozen period R, and the interaction of bias and safety stock.

For future research we propose to extend this work in two ways. First, consider a stochastic version of the problem that can consider different demand scenarios. And the second aspect is to incorporate a recourse action during the frozen period R, considering the situation in which the company is more flexible and can adjust their production plans according to demand changes or changes in the customer´s orders.

Resumen.
Propósito- obtener una perspectiva acerca de los problemas de enrutamiento de un recolector y alistamiento de pedidos en un almacén.
Diseño / enfoque- se efectúa una revisión sistemática de la literatura para identificar modelos matemáticos que abordan las operaciones de preparación de pedidos; haciendo especial énfasis en la forma de almacenamiento y su impacto en dicha labor.
Hallazgos- la revisión de la literatura reveló que gran parte de las publicaciones en revistas científicas han desarrollado el problema de enrutamiento en un sistema de almacenamiento tradicional, han sido pocos los artículos que abordan este problema en un sistema de almacenamiento disperso, por lo que es un campo con muchas oportunidades de investigación.
Limitaciones / implicaciones de la investigación- se describe una agenda orientada de investigación, en la cual se analiza profundamente las estrategias propuestas para la optimización de las operaciones de preparación de pedidos.
Implicaciones prácticas: se muestra un tema de investigación bastante novedoso, por tanto, se presenta como una propuesta a considerar para futuras investigaciones.
Originalidad / valor- esta revisión presenta una línea de tiempo de los modelos que se han propuesto por diversos autores a lo largo de los años, haciendo un paralelo en el enfoque se le ha dado a la solución del problema de enrutamiento de un recolector en almacenes tradicionales y con almacenamiento disperso, una forma de almacenamiento que ha tomado fuerza y ha sido poco documentada.
Palabras clase: Logística, Revisión de literatura, Almacenamiento tradicional, Almacenamiento disperso, Comercio electrónico.
Tipo de papel: Revisión de literatura.

1 Introducción

La industria está atravesando un proceso de cambios vertiginosos por causa de los constantes avances en las tecnologías de la información y la comunicación, siendo el internet el medio de comunicación más utilizado actualmente y partiendo de la necesidad de las empresas por facilitar a los clientes los procesos de compra, surge con gran fuerza la era del comercio electrónico; una alternativa que permite a los usuarios acceder, seleccionar y pagar los productos en cualquier momento y lugar del mundo (Weidinger, 2018). El comercio electrónico (E-commerce) es un proceso de compra, venta, distribución, mercadeo y/o suministro de información de bienes o servicios a través de Internet (Alejandro López Ruiz, 2018) , este comercio utiliza las variadas formas que existen de relacionarse entre empresas y consumidores, una de las más frecuentes es la de tipo empresa-consumidor (B2C) utilizada por los minoristas de comercio electrónico que atienden la demanda del cliente final; el desarrollo de E-commerce tipo B2C ha presentado nuevos desafíos para las empresas, uno de ellos es el proceso logístico de preparación de pedidos en los almacenes, ya que es complejo por sus ajustados tiempos de entrega y por la gran variedad de pedidos en pequeñas cantidades (Roxana Silva, 2009).

Al presente, uno de los retos más grandes que enfrenta el comercio electrónico, es la preparación de pedidos, que consiste en extraer y organizar los productos demandados por los clientes. Se conoce como la actividad más importante en los almacenes, ya que, representa hasta el 60% de todas las actividades laborales en el mismo y, para un almacén típico, el costo de la preparación de pedidos se estima en hasta el 55% del gasto operativo total del almacén (Tompkins et al., 2003).

El almacenamiento disperso (también llamado estanterías mixtas) surge como una solución alternativa para este desafío logístico que afronta el E-commerce B2C, en donde las cargas unitarias se dividen en artículos individuales que se distribuyen por todo el almacén, lo que lleva a múltiples posiciones de almacenamiento por unidad de mantenimiento de existencia (Weidinger, 2018). Partiendo de esto, los productos son organizados de forma aleatoria en diferentes estantes, de modo que el selector tiene la oportunidad de encontrar los artículos demandados en un menor tiempo debido a que aumenta la probabilidad de encontrarlos en distancias menores (Weidinger, Boysen y Schneider, 2019).

Teniendo en cuenta que el almacenamiento disperso supone una alternativa viable para optimizar los tiempos de preparación de pedidos para E-commerce B2C, En esta revisión se abordaran dos aspectos: el primero, la transición y las ventajas que tiene el almacenamiento disperso en los almacenes de comercio electrónico , con el objetivo de establecer una nueva perspectiva respecto a los sistemas de almacenaje tradicional; segundo, enfoques de solución al problema de enrutamiento de un recolector (Single Picker Routing Problem , SPRP) en el que se busca optimizar la ruta que recorre el selector en el proceso de picking, también conocido como preparación de pedidos.

En la literatura se encuentran varias revisiones acerca del enrutamiento del recolector de pedidos en los almacenes tal como en Masae, M., Glock, C., & Grosse, E. (2019). Es por esto que el propósito de este estudio es sintetizar toda la información acerca del proceso de picking en almacenes de comercio electrónico partiendo de las diferencias existentes entre almacenamiento tradicional y almacenamiento disperso o también conocido como estanterías mixtas.

2 Almacenamiento tradicional y almacenamiento disperso.

Al caracterizar los almacenes de recolectores a partes, en la literatura actual se distingue entre almacenamiento dedicado y compartido, Para la estrategia de almacenamiento dedicada o tradicional, cada unidad de mantenimiento de existencias (SKU) tiene una posición de almacenamiento fija, mientras que en el almacenamiento compartido o disperso las SKU entrantes se asignan a cualquier posición de almacenamiento adecuada disponible (Weidinger, 2018).

La principal intención del almacenamiento disperso es que, con las unidades esparcidas por todo el almacén, las distancias promedio desde cualquier lugar del almacén hacia la unidad más cercana de cada SKU se reducen considerablemente, esto aumenta la probabilidad de que un SKU demandado esté cerca (Boysen, Koster, Weidinger, 2018). Además, los almacenes de estantes mixtos suelen tener varios puntos de acceso (depósitos) donde los pedidos completados se entregan al sistema de transporte central, de esta manera, la improductividad de los recolectores disminuye considerablemente y se pueden cumplir mejor los horarios de entrega ajustados (Boysen, Koster, Weidinger, 2018).

3 Estructura del trabajo

Este documento es una revisión de literatura sobre los problemas de enrutamiento de un recolector y alistamiento de pedidos en un almacén. Primero, se presenta la metodología utilizada para llevar a cabo la investigación. En la (sección 2) se encuentra la información obtenida en la revisión, mediante dos líneas de tiempo, la primera muestra los métodos de solución propuestos antes del almacenamiento disperso y la segunda presenta los métodos propuestos después del almacenamiento disperso. En la (sección 3) se muestra cómo se le ha dado solución al problema de Enrutamiento de un recolector. Finalmente, las conclusiones son presentadas en la (sección 4).

4 Metodología

Para el desarrollo de la revisión de literatura acerca del problema de enrutamiento de un recolector (Single Picker Routing Problem, SPRP) en los almacenes de comercio electrónico, se realizaron los siguientes pasos:

Primero, se identificó el objetivo de la investigación, para este tipo de revisión se hizo uso de las bases de datos conocidas como Scopus, Web of Science, ScienceDirect. En primera instancia se buscaron artículos relacionados con los sistemas de almacenamiento y los problemas que se encontraban dentro de estos, se identificó que el problema principal del que se quería realizar la revisión era el conocido como SPRP, también llamado single picker routing problema enfocado en almacenes de comercio electrónico.

En segundo lugar, se identificaron las dos bases de datos principales de las que se iba a extraer la información, estas bases de datos son Scopus y Web of Science; seguido de esto se establecieron dos ecuaciones de búsqueda con las que se iban a refinar los resultados de la revisión de literatura.

Tercero, se encontraron los resultados dados por las bases de datos, además se realizó un análisis tipo bola de nieve de citas en los artículos más relevantes y se analizaron mediante el software libre VOSviewer, una herramienta que permite construir y visualizar redes bibliométricas, realiza también redes de co-ocurrencia, co-autoria, acoplamiento bibliométrico; a partir de técnicas de minería, mapeo y análisis de clusters.

Para Scopus la búsqueda incluyó las palabras clave “mixed shelves”, “picker”, “routing”, “tabu search”, “e commerce”, obteniendo 36 documentos. Para el análisis bibliométrico realizado en la base de datos Web of Science, se obtuvieron 60 artículos en idioma inglés, que fueron alcanzados con la ecuación de búsqueda: mixed shelves *and* routing *and* e commerce *or* tabu search *and* warehouse.

En cuarto lugar, se llevó a cabo una síntesis de la información y un análisis detallado acerca del tema seleccionado para la revisión de literatura; mediante este paso se desarrolló un análisis preliminar de literatura en donde se destacan los trabajos de diferentes autores relacionados con el problema SPRP para almacenes de comercio electrónico y esta revisión se divide en dos partes, la primera hace referencia a las publicaciones que trataron el tema teniendo en cuenta el almacenamiento tradicional y la segunda parte, hace referencia a las publicaciones que contemplaron el almacenamiento disperso, también conocido como estanterías mixtas.

Finalmente teniendo toda la información sintetizada se realiza un segundo análisis de publicaciones relacionados única y exclusivamente con el problema SPRP para almacenes de comercio electrónico con almacenamiento disperso, esto con el fin de tener un conocimiento más amplio acerca del tema.

5 Análisis

Todas las empresas que se encuentran relacionadas con el comercio electrónico, presentan grandes ventajas tales como, la facilidad de promocionar sus productos mediante plataformas virtuales, ofrecer a los clientes diferentes medios en los que se pueden efectuar las compras, entre otras. Por otro lado, se encuentran con actividades laboriosas, como lo es la preparación de pedidos dentro de los procesos de almacenamiento, ya que esta requiere más tiempo y por lo tanto más trabajo. Algunos autores estimaron que representa hasta el 55% de los costos operativos totales del almacén y que se vuelve más complejo en almacenes de comercio electrónico debido a las grandes cantidades de pedidos (Tompkins, White, Bozer & Tanchoco, 2010).

A lo largo del tiempo, se han propuesto diferentes modelos matemáticos con los que se pretende ayudar a optimizar las operaciones de preparación de pedidos. Tres de los problemas que se tienen en cuenta en este tema son, la asignación de artículos a las diferentes ubicaciones de

almacenamiento (Grosee, Glock & Neumann, 2017), el procesamiento por lotes de pedidos y el enrutamiento del preparador de pedidos a través del almacén (Van Gils, Ramaekers, Caris & Koster, 2018). Para la solución de estos problemas se han propuesto tres métodos diferentes de solución.

1. Los algoritmos exactos, por medio de estos se llega a una solución óptima. Algunos ejemplos en donde se ha utilizado este método como solución son, De Koster y Van der Poort (1998), y Roodbergen y De Koster (2001a, b).
2. Las heurísticas, se definen como algoritmos dependientes de problemas creados con sus especificaciones (Sörensen, 2015). Algunos ejemplos son, heurística del punto medio, forma de S, retorno, combinada; se encuentran explicados en Roodbergen y De Koster (2001).
3. Las metaheurísticas, se definen como algoritmos independientes de problemas de alto nivel. Algunos ejemplos son optimización de colonias de hormigas (OCH), algoritmo genético (AG), búsqueda Tabú (BT) en Daniels, Rummel & Schantz, (1998).

El problema del enrutador de pedidos en un almacén se relaciona al problema clásico del vendedor ambulante (TSP) así como lo exponen Ratliff y Rosenthal, 1983. En esta investigación, los autores abordan el problema en un almacén rectangular que contiene cruces solo en los extremos de los pasillos. Años más tarde, Kashi y Dirk, 1997; consideran una generalización del problema del vendedor ambulante (TSP) llamado problema del comprador viajero (TPP), en el que se busca comprar los productos visitando subconjuntos de mercados en un recorrido de manera que los costos totales de viaje y compra sean minimizados (Ravi and Salman,1999).Y como método de solución para resolver el problema en relación con la ubicación de la planta, los autores proponen un algoritmo de ramificación y acotamiento, también conocido como Branch & Bound. Mediante esta investigación se llega a la conclusión que los problemas de tamaño de hasta 25 ciudades y 100 productos se puede resolver mediante el algoritmo, obteniendo resultados en un tiempo de cálculo razonable; también se demuestra que el problema del comprador viajero tiene aplicaciones en las áreas de programación, almacenamiento y enrutamiento (Kashi, Dirk,1997) siendo de gran importancia para futuras investigaciones.

Rubrico, Ota, Higashi y Tamura, 2008; Resuelven el problema de programación mediante la metaheurística Búsqueda Tabú, se busca que la demanda sea transferida entre los agentes para equilibrar la carga y de

esta forma sea más eficiente el proceso de picking dentro de la gestión del almacén. Posterior a esto, Henn y Wascher, 2012. Lo que se pretende es combinar un conjunto de pedidos para luego agruparlos y de esta manera se minimice la duración total de todos los recorridos de recolección para los artículos solicitados; convirtiéndose en un problema de procesamiento por lotes de pedidos, los autores lo resuelven mediante dos enfoques basados en el principio de búsqueda tabú, demostrando que los métodos propuestos proporcionan soluciones que permiten la eficiencia de la operación en los almacenes de distribución.

Tiempo después, Liu, Li y Liu, 2017; añaden al problema de enrutamiento de vehículos la variante de la capacidad y con tiempo de pedido disponible (CVRPOAT), se analiza dicho problema ya que se encuentra inmerso en las operaciones de la industria de comercio electrónico. Se busca minimizar la suma de los tiempos de finalización del vehículo; se presenta un algoritmo de búsqueda tabú para abordar el tema y se compara con un algoritmo genético, los resultados indican que el algoritmo de búsqueda tabú es superior al algoritmo genético para tratar el problema mencionado.

Otro aspecto importante a tener en cuenta en la industria de comercio electrónico es la preparación de pedidos, proceso mediante el cual se recuperan artículos de sus ubicaciones de almacenamiento para satisfacer los pedidos de los clientes. Zulj, Glock, Grosse y Schneider, 2018; parten de la necesidad de generar un ahorro considerable de tiempo y costos en el proceso considerado como el más laborioso en el almacenamiento, y buscan una solución para un almacén en el que la asignación de almacenamiento está determinada por el peso de los artículos. Los autores utilizan el algoritmo basado en graficos propuesto por Ratlif y Rosenthal (1983) y proponen una estrategia de que busca brindar estrategias para el proceso de asignación mencionado.

Para el problema de asignación de pedidos, el procesamiento por lotes de pedido y los problemas de enrutamiento de recolectores en los almacenes de recolección de olas, Ardjmand, Shaker i, Singh y Bajgiran, 2018; presentan un modelo matemático que se resuelve mediante un algoritmo exacto de descomposición lagrangiana combinado con un algoritmo de optimización de enjambre de partículas. En los problemas a gran escala se utiliza recocido simulado paralelo hibrido y optimización de colonias de hormigas. Los autores en su investigación, mediante experimentos numéricos muestran que el aumento de la cantidad de recolecto-

res y la capacidad de recolección presenta un mayor impacto en la reducción de la producción improvisada cuando existe proporcionalidad entre los pedidos y la cantidad de recolectores.

En el año siguiente, se realiza una investigación teniendo en cuenta los avances tecnológicos en la robótica móvil, Lee, H.-Y., Murray y C.C, 2019; exploran un enfoque diferente al habitual para la preparación de pedidos de un almacén. En dicha investigación se consideran dos tipos de robots que realizan los procesos de recolección de artículos y de entrega a la estación de empaque. Los autores desarrollan una formulación de programación lineal entera mixta, mediante la cual llegan a las conclusiones, aumentar el número de pasillos transversales disminuye el rendimiento del sistema; las estaciones de empaque ubicadas en el centro mejoran el rendimiento del sistema; y la distancia promedio desde cada ubicación de recolección hasta la estación de empaque y la distancia promedio entre ubicaciones de recolección son métricas efectivas para identificar cambios específicos en la flota (Lee, H.-Y., Murray, C.C.,2019).

En todas las investigaciones se ha determinado que el diseño del almacén es fundamental para la optimización de las operaciones de preparación de pedidos. Yener y Yazgan, 2019; investigan la efectividad del diseño de almacenes para determinar el tiempo promedio del proceso de preparación de pedidos y la distancia recorrida mediante una técnica de minería de datos. En el mismo año, Boysen, Koster y Weidinger, 2019; presentan un ensayo en el que se exponen todos los tipos de sistemas de almacenamiento que han optado los minoristas de comercio electrónico, desde los tradicionales hasta la adaptación de las estanterías mixtas, también conocido como almacenamiento disperso.

Al abordar la temática de almacenamiento disperso, es necesario mencionar que han sido pocos los documentos publicados sobre el tema; según la revisión sistemática de la literatura publicada en Masae, Glock, & Grosse, (2019) en una muestra central de 54 documentos tan solo 4 han desarrollado el problema de enrutamiento en un sistema de almacenamiento disperso, lo cual permite evidenciar un campo de oportunidades para desarrollar algoritmos de enrutamiento para esta área.

En Singh & Oudheusden, (1997) por primera vez se estudia un almacén con almacenamiento disperso. En este artículo no se tuvo en cuenta el diseño particular del almacén, sino que se planteó el objetivo de encontrar un recorrido que minimizara la suma de los gastos de la ruta de viaje y la compra para el problema del comprador viajero (TPP). El tema

de almacenamiento disperso es introducido en el artículo cuando se proponen aplicaciones potenciales de la estructura del problema del agente viajero y se enuncia que para una situación en la que un artículo se almacena en un área de ubicación única del almacén, el problema ha sido reconocido como una variante del problema TPS, pero cuando un artículo se almacena en más de un área, el problema tiene la estructura de un TPP siendo ésta bastante compleja de resolver, por lo que para dar una solución se consideró un algoritmo de ramificación y acotamiento que funciona para cualquier tipo de matriz que considere las distancias de viaje de una ubicación de almacenamiento a otra (Masae, Glock, & Grosse, 2019)

Con el seguimiento computacional de los inventarios, las piezas ahora se pueden almacenar en múltiples ubicaciones. En Daniels, Rummel, & Schantz, (1998) se estudia la preparación de pedidos para una secuencia en la que se visita una sola vez cada ubicación del almacén donde las piezas se almacenan en múltiples ubicaciones, simplificando la reposición de inventario y eliminando la necesidad de reservar espacio para cada artículo. Se contempla el conjunto de ubicaciones en las que se almacena cada pieza y la cantidad de stock en cada una de ellas, siendo un problema combinatorio de asignación y secuenciación. Para su solución se muestra un procedimiento basado en la búsqueda tabú y una prueba de dureza NP para matrices de distancia .

El auge de la venta de minoristas en línea de empresa a consumidor, ha hecho que surja la necesidad de adaptar las estrategias de almacenamiento a las necesidades particulares que se derivan de este mercado. Las nuevas estrategias deben hacer frente a múltiples desafíos tales como pedidos pequeños y tiempos de entrega críticos. Bajo esta circunstancia, emplear una estrategia de almacenamiento tradicional, con solo una o unas pocas posiciones de almacenamiento por SKU, daría como resultado largos recorridos de recolección. Por el contrario, una nueva estrategia emergente adaptada a las necesidades de los minoristas en línea, esta estrategia es conocida como almacenamiento disperso (Weidinger, 2018).

En Weidinger 2018, se investiga el problema de enrutamiento del recolector en un almacén de almacenamiento disperso rectangular, donde se pueden encontrar artículos del mismo SKU en diferentes posiciones de almacenamiento; lo que se busca es el recorrido más corto que permita satisfacer la demanda. El problema consiste en una selección y enrutamiento interrelacionados entre sí. Se proporciona una prueba de dureza

NP y se presentan tres heurísticas de enrutamiento utilizando reglas de selección de ubicación de almacenamiento que calculan los valores de prioridad para los artículos solicitados, que influyen en la secuencia de selección de los artículos solicitados en un pedido.

En Weidinger, Boysen & Schneider, (2019) se extendió el problema ya que se contaba con los depósitos ubicados en los extremos trasero y delantero de cada pasillo, de esta forma los puntos de inicio y finalización de los recorridos podían ser cualquiera de estos dos. Para dar solución a esto se adaptó el enfoque del vecino más cercano con el que se buscaba encontrar una primera solución factible para el ruteo del selector con estanterías mixtas (MSPR), cabe destacar que en este documento se resalta que el almacenamiento disperso es adecuado cuando se tienen pedidos de pequeño tamaño que requieren pocos artículos por línea de pedido, cuando se produce un pedido ocasional más grande con múltiples artículos, el stock en un solo estante puede no ser suficiente, y el recolector tiene que visitar múltiples posiciones de almacenamiento para reunir suficientes artículos. Por lo tanto, los pedidos de gran tamaño aumentan el esfuerzo de recolección bajo el almacenamiento de estanterías mixtas (Weidinger, Boysen, & Schneider, 2019).

En Yang, Chao & Guo (2020) se abordó la investigación desde la formulación de problemas de optimización de selección de lotes de pedidos para tres sistemas de almacenamiento típicos, la principal contribución de este documento es explorar exhaustivamente los problemas de optimización de preparación de lotes de pedidos mediante la formulación de modelos y desarrollos de algoritmos desde la perspectiva de diferentes escenarios de almacenamiento (Yang, Chao, & Guo, 2020). Los autores usaron cuatro tipos de algoritmos para resolver el problema de procesamiento por lotes de pedidos para los diferentes sistemas de almacenamiento, dichos algoritmos fueron: El algoritmo de distancia de intervalo de ubicación en donde se calcula la distancia entre ubicaciones de almacenamiento, el algoritmo de selección de ubicación con el que se elige la ubicación de selección de varias ubicaciones que almacenan la SKU idéntica, el algoritmo de enrutamiento decide la ruta de un recolector para visitar los lugares seleccionados en un viaje, el algoritmo de procesamiento por lotes de pedidos agrupa los pedidos en lotes.

Cabe destacar que en los resultados de esta investigación se evidencia que el rendimiento de las combinaciones de algoritmos propuestos es satisfactorio para resolver problemas con diferentes tamaños, tanto en calidad de la solución como en eficiencia del cálculo.

6 Enfoque a SPRP

El problema de enrutamiento de un solo recolector trata con la determinación de la secuencia de acuerdo con las ubicaciones de los artículos que se deben visitar en un almacén de distribución y la identificación de las rutas correspondientes que deben recorrer los operadores humanos (recolectores de pedidos) para recolectar conjunto de artículos solicitados por clientes internos o externos (Scholz, Henn, Stuhlmann, & Wäscher, 2016). El problema de enrutamiento de un solo selector (SPRP) representa un caso especial del clásico problema del vendedor ambulante (TSP) y, por lo tanto, también se puede modelar como un TSP (Scholz, Henn, Stuhlmann, & Wäscher, 2016).

En Ratliff y Rosenthal (1983) se define al problema de preparación de pedidos como uno de los más importantes a tener en cuenta en el proceso de almacenamiento, dicho problema se reconoce como una variante del conocido y complejo problema del vendedor ambulante.

En Daniels, Rummel , & Schantz (1998) se define que la preparación de pedidos en entornos de almacén convencionales implica determinar una secuencia en la que hay que visitar las ubicaciones únicas donde se almacena cada parte del pedido, y por lo tanto a menudo se modela como un problema de vendedor ambulante. En esta investigación se formuló un modelo para determinar simultáneamente la asignación y las decisiones de secuencia, y se comparó con modelos anteriores para la preparación de pedidos. Se discute la complejidad del problema de preparación de pedidos y se establece un límite superior en el número de asignaciones factibles, se presentan y prueban experimentalmente varias extensiones de la heurística de TSP a la nueva configuración del problema y un algoritmo de búsqueda tabú.

En Scholz, Henn, Stuhlmann, & Wäscher (2016) tratan una aplicación del TSP que surge en la gestión del almacén de distribución en cuanto a su función principal, la preparación de pedidos. En este documento se presenta la primera formulación matemática para el SPRP que tiene en cuenta las propiedades específicas de las soluciones óptimas de este problema. En particular, se demuestra que el tamaño de la formulación es independiente del número de ubicaciones donde se deben elegir los artículos, mediante extensos experimentos numéricos se demuestra que la formulación propuesta para el SPRP es superior a las formulaciones estándar de TSP y Steiner TSP. Se considera el problema de enrutamiento de un solo selector en un diseño de bloque único que representa un caso

especial del problema del vendedor ambulante, centrándose en el SPRP en diseños de bloque único, pero también se demostró cómo varias situaciones relevantes como el diseño de bloques múltiples, depósito descentralizado se integran a la formulación propuesta (Scholz, Henn, Stuhlmann, & Wäscher, 2016).

En Schneider & Goeke (2018) se establece que el problema estándar de enrutamiento de un solo recolector (SPRP) busca el recorrido de costo mínimo para recolectar un conjunto de artículos dados en un almacén rectangular de un solo bloque con pasillos de picking paralelos y una política de almacenamiento dedicada, es decir, cada SKU solo está disponible desde una ubicación de almacenamiento en el almacén (Schneider & Goeke, 2018). Se presenta una formulación compacta que renuncia a las restricciones clásicas de eliminación de subtour explotando directamente dos de las propiedades de un recorrido de picking óptimo utilizado en el algoritmo de programación dinámica de Ratliff y Rosenthal (1983) y se extiende la formulación de tres entornos importantes que prevalecen en los modernos almacenes de comercio electrónico: almacenamiento disperso, desacoplamiento del recogedor y el carro, y múltiples depósitos finales.

En Weidinger (2018) se investiga el problema de enrutamiento del selector en un almacén con un sistema de almacenamiento disperso rectangular, se identifica como un problema combinado de selección y enrutamiento. En esta investigación se opta por analizar este tipo de almacenamiento ya que es considerada una nueva estrategia emergente adaptada a las necesidades de los minoristas en línea. Para dar solución al problema propone tres enfoques con el fin de calcular los valores de prioridad P para una determinada posición, dichos enfoques son, Single position, MinMax y MinMin. El objetivo es encontrar el recorrido de selección más corto, el problema se conforma en dos partes, una primera de selección y otra de enrutamiento. Las heurísticas que se presentan están basadas en el trabajo de Ratliff y Rosenthal (1983) expuesto anteriormente, y se determina que la heurística que se presentó, menos compleja que el algoritmo de Búsqueda Tabú en Daniels et al (1998), resuelve instancias de tamaño real en tiempos computacionales razonables.

En Weidinger, Boysen, & Schneider (2019) se considera un almacén de estanterías mixtas. Los autores aplican una construcción de una heurística con la cual se extiende soluciones parciales de forma gradual, con el fin de obtener valores de solución asertivos se generan muchas soluciones parciales en paralelo y solo tienen presentes las más prometedoras

dentro de un conjunto central de soluciones, también se aplica el algoritmo de Ratliff y Rosenthal (1983) explicado previamente, como un subprocedimiento para determinar el recorrido optimo del recolector circular en un almacén rectangular en donde se busca realizar el proceso de recolección de pedidos pasando por las diferentes posiciones de almacenamiento. Para resolver el problema se formula un programa de enteros mixtos que permite resolverlo con un solucionador estándar Gurobi. Luego, se presentan procedimientos de solución heurística mediante una adaptación al enfoque del vecino más cercano y un procedimiento basado en agrupaciones y dos últimas heurísticas ejecutadas con el procedimiento de mejora adicional mediante búsqueda local (NN+, piscina+).

En Masae, Glock y Vichitkunakorn (2020) se investiga acerca del proceso de preparación manual de pedidos, el cual se caracteriza por los trabajadores que deben viajar a través del almacén para realizar el proceso de picking. Se considera un almacén convencional con dos bloques, superior e inferior, donde cada bloque tiene r pasillos paralelos con igual longitud y ancho, se encuentran tres pasillos transversales; se tiene en cuenta que los puntos de inicio y finalización del recorrido de preparación de pedidos deseado puede ser cualquier ubicación en el almacén. Este tipo de modelo surge a partir de Löffler et al (2018) en donde se propone un algoritmo óptimo de enrutamiento de selector de pedidos para puntos de inicio y finalización arbitrarios en un almacén convencional con un solo bloque, es por esto que se extiende el trabajo al tener dos bloques y se soluciona mediante procedimientos propuestos en los trabajos de Ratliff y Rosenthal (1983) y Roodbergen y de Koster (2001a). Para solucionarlo, los autores proponen una heurística de enrutamiento en forma de S, enumeran los dos pasillos secundarios de selección de 1 a 2r, comienzan enumerando en el bloque superior, los pasillos secundarios de izquierda a derecha, luego en el bloque inferior de derecha a izquierda.

7 Conclusiones

El almacenamiento disperso es una estrategia que ha tomado fuerza en los últimos años, esta ha sido implementada especialmente en el segmento B2C, relacionada con el comercio electrónico, ya que éste presenta tiempos de entrega ajustados, demandas volátiles y pequeños pedidos; esta forma de almacenamiento es adecuada para este segmento, debido a que los pedidos pequeños requieren pocos artículos y el Stock de

los estantes mixtos es suficiente, pero cuando se requiere muchos artículos para cumplir con un pedido resulta contraproducente tener estantes mixtos, ya que, si el stock se agota en un estante, el selector va a tener que ir a más visitar más estantes para cumplir la orden, aumentando las distancias y el esfuerzo de la labor de recolección.

Se ha encontrado que el tema de almacenamiento es muy amplio y que en él se encuentran diversos tipos de problemas de investigación, tal como lo es el relacionado con el proceso de picking, SPRP también conocido como single picker routing problem; es importante tener claro la importancia de este tema ya que representa un gran porcentaje de las actividades laboriosas que se llevan a cabo dentro de un almacén y que repercuten significativamente en los gastos operativos. A su vez se invita a estudiar más este tipo de problema, ya que por medio de estas investigaciones se llega a analizar los diferentes tipos de almacenamiento que existen y la importancia que tiene en la era que vivimos del comercio electrónico.

Resumo. Apesar de todos os esforços para contenção viral, a COVID-19 é declarada como pandemia pela Organização Mundial da Saúde (OMS). Várias medidas de contenção vêm sendo aplicadas em vários países, que de certa forma vem retardando, o número de pessoas infectadas e contribuindo para o achatamento da curva de infecção, de modo a possibilitar a priorização do tratamento de pacientes com evolução mais grave da doença. No estado do Paraná foram aplicadas medidas de contenção por meio de decretos sancionados pelo governo estadual e prefeitos municipais, onde foram suspensas as atividades econômicas não essenciais à saúde, as aulas da rede público-privada entre outras medidas, que também afetaram a população da Região Metropolitana de Curitiba (RMC), onde, no Brasil, um conglomerado composto por vários municípios é chamado de região metropolitana. As ações aplicadas para a contenção da pandemia revelaram uma problemática, que trouxeram como consequências a desaceleração da economia de várias regiões. Diante destes fatos, a pesquisa foca em analisar o impacto causado pelas medidas de contenção da pandemia COVID-19, nas operações econômicas das operadoras de refeições coletivas em 2020. Os dados da pesquisa foram coletados por meio do método de pesquisa documental baseada nas previsões do crescimento econômico para 2020 e boletins epidemiológicos. A pesquisa apresentou como resultado, os possíveis impactos, que poderá ser causados pelas medidas de contenção da pandemia COVID-19 nas operações das operadoras de refeições coletivas.

Palavras-chaves: Medidas de contenção COVID, Impacto na Economia, Prestadoras de Serviços, Refeições Coletivas.

1 Introdução

Atualmente, o vírus SARS-CoV-2 denominado como o novo *Coronavírus Disease* 2019 (COVID-19) é uma doença infecciosa causada pelo coronavírus da síndrome respiratória aguda grave (SARS) [1, 2]. Os primeiros casos de infecções surgiram no continente Asiático, no final do ano de 2019. Em 11 de Março de 2020, a Organização Mundial da Saúde (OMS) declarou o COVID-19, como pandemia e recomendou aos países ativar os mais altos níveis de protocolos nacionais de biossegurança, para garantir a contenção da disseminação viral na sociedade [3, 4, 5, 6]. A resposta global, para a contenção da pandemia COVID-19 [7, 8] e recentemente mencionada por [9] são que, as medidas de contenção aplicadas pelos países "foram muito poucas e muito tarde". Considerando o período do início dos casos até 04 Abril de 2020, as situações com a propagação da pandemia somam mais de 1.000.000 de casos confirmados e 57.206 mortes em 208 países em todos os continentes [7].

O modo rápido de transmissão da propagação do COVID-19 e a suscetibilidade da população fizeram com que esforços nacionais e internacionais para contenção da pandemia fossem ganhando ritmo [7]. Neste contexto, foram adotadas medidas de saúde pública, como reforço nas operações da vigilância sanitária, rastreamento exaustivo de contatos, distanciamento/isolamento social, restrições de viagens, fechamento de escolas, instruções sobre a higienização básica, antecipação de vacinas contra a gripe para o grupo de risco e suspensões de serviços não essenciais à saúde, de forma a contribuir para um achatamento da curva de contágio evitando a superlotação dos hospitais [4, 10]. Para conter o avanço da pandemia no Estado do Paraná, foram sancionadas determinações por meio dos decretos estaduais, (4.317/2020), que propõe medidas restritivas mais severas sobre as atividades econômicas não essenciais a saúde [10]. E o (4258/2020), que determina a suspensão das aulas de escolas e universidades públicas e privadas por tempo indeterminado [11]. As medidas estão alinhadas aos esforços, que vêm sendo aplicados em várias partes do mundo, desta forma, reforçar o enfrentamento contra a pandemia COVI-19. Neste contexto, desencadeou questionamentos propícios por meio de uma pesquisa documental baseada nas previsões do crescimento econômico para 2020 e boletins epidemiológicos, qual será o impacto das ações tomadas em terreno desconhecido para contenção da pandemia?

Sendo assim, a pesquisa foca em analisar o impacto causado pelas medidas de contenção da pandemia da COVID-19, nas operações econômicas das operadoras de refeições coletivas em 2020, baseada em uma pesquisa documental sobre o cenário econômico e a evolução epidemiológica por meio do modelo SIR epidemiológico de pandemia.

2 Procedimentos metodológicos

2.1 Objeto da pesquisa

As operadoras de refeições coletivas atuam em diversos segmentos, industriais, educacionais, hospitalares entre outros. O foco está na administração dos restaurantes internos oferecendo uma alimentação aos colaboradores.

2.2 Abordagem metodológica

2.2.1 Pesquisa documental

A pesquisa documental assemelha-se a pesquisa bibliográfica sendo a natureza, a diferença das fontes. Enquanto a pesquisa bibliográfica fundamenta-se em contribuições de diversos autores, sobre determinados temas embasados cientificamente, a pesquisa documental vale-se de materiais com fontes diversificadas, dispersas e em muitos casos não recebem o tratamento analítico de forma científica [14]. A pesquisa documental classifica-se como exploratória, pois foca em abordar um tema pouco conhecido e explorado [14] e apresenta como objetivos produzir novos conhecimentos, criar novas formas de compreender os fenômenos e apresentar, como este método desenvolve-se, para que o pesquisador possa "mergulhar" no campo da pesquisa, para obter e captar os fenômenos a partir de perspectivas contidas em documentos, para "colher" resultados e compartilhá-los no meio científico [15]. A pesquisa documental está restrita a documentos contidos em três variáveis: fontes escritas ou não, fontes primárias ou secundárias sendo classificados em contemporâneas ou retrospectivas [16].

Assim, como qualquer outro método, a pesquisa documental apresenta vantagens e desvantagens. Dentre as vantagens [14] citam-se os fatos, que estes documentos se constituem, de uma fonte rica e dados estáveis, na qual, para [15] o pesquisador poderá retirar as evidências, que fundamentam suas afirmações. Entretanto, para [14, 17] a pesquisa documental também apresenta limitações como desvantagens, as quais afirmam que os documentos são amostras não-representativas dos problemas [14]**,** mas para [18] a pesquisa documental é necessária para entender o passado para construir o futuro.

2.2.2 Modelo SIR de pandemia

O Modelo SIR (Suscetível, Infectado e Recuperado) é um arquétipo matemático utilizado para descrever epidemia proposta por Kermack e McKendrick em 1927. O modelo classifica a população em três classes: **(S)** suscetíveis: os que pode ser infectados; **(I)** Infectados: as pessoas que estão infectadas e podem transmitir a doença; **(R)** Recuperados: são aqueles curados da infecção e tornan-se imune ou morrem. Pode ser descrito da seguinte forma [19, 20, 21].

$$\frac{ds}{dt} = \text{Variação Temporal Suscetível} \qquad \frac{ds}{dt} = -\beta\ SI \tag{1}$$

$$\frac{ds}{dt} = \text{Variação Temporal Infectado} \qquad \frac{ds}{dt} = \beta SI - \mu I \tag{2}$$

$$\frac{ds}{dt} = \text{Variação Temporal Recuperado} \qquad \frac{ds}{dt} = \mu I \tag{3}$$

A manipulação algébrica, possíbilita de forma estimada verificar através de indicadores do modelo, o atingimento da taxa de produtibilidade (R_0), o qual determina a média de infecções causadas por um indivíduo contaminado. Por meio desta simplificação, as constantes BS (taxa de transmissão de infecção) e μ (taxa de recuperação) podem ser ajustadas exponencialmente, sendo assim, a taxa de reprodutibilidade (R_0) é expresso da seguinte forma [20, 21].

$$R_0 = \frac{\beta s}{\mu} \tag{4}$$

Para entender a dinâmica da pandemia considera-se R0 > 1, no qual a doença é transmitida mais rapidamente que o tempo de recuperação do infectado, tornando a população infectada. Se R0 < 1, os infectados se recuperam mais rapidamente e a vírus não tem força para se propagar e desaparece naturalmente [21, 22].

2.3 Delineamento da pesquisa

Para análise do crescimento econômico foram pesquisados relatórios sobre a previsão de crescimento do *Gross domestic product* (GDP) para 2020, publicadas entre 2º Semestre de 2019 e 1º Semestre de 2020 por instituições financeiras e de apoio a empresas, tais como: O Banco Mundial, O Fundo Monetário Internacional (FMI), O Banco Central do Brasil (BACEN), O Serviço Brasileiro de Apoio às Micro e Pequenas Empresas (SEBRAE), O Instituto Brasileiro de Geografia e Estatística (IBGE), A Associação Brasileira das Empresas de Refeições Coletivas ABERC e outras cunho regional como: Agência Estadual de Notícias do Paraná (AEN. PR), O Instituto Paranaense de Desenvolvimento (IPARDES), a Secretaria da Fazenda do Paraná entre outras. Para a simplificação do modelo SIR na pesquisa, utilizou-se dos relatórios dos informes epidemiolôgicos da COVID-19" publicados pela Secretaria Estadual de Saúde do Estado do Paraná (SESA-PR) no 1º Semestre, entre as datas de 14 de Março a 12 de Julho de 2020. Os dados coletados estão relacionados a RMC, com aproximadamente 3.615.027 habitantes [23,

24]. Para todos os cálculos e simulação matemática foi utilizado o *software Microsoft Excel®* por meio do Modelo SIR de epidemias adaptado de [25, 26, 45].

3 Análise do passado, presente e futuro

3.1 Projeção de crescimento da economia para 2020 (Passado)

A projeção de crescimento do (**GDP**) mundial prevista para 2020 é de (3,3%), um crescimento de 14% comparado ao GDP (2,9%) de 2019. Considerando a expectativa de arrefecimento entre o embate comercial sino-americano para um maior crescimento econômico mundial [27, 28]**.** No Brasil, o cenário econômico apresenta melhoras, após a recessão de 2014-2016 a economia vem obtendo crescimento. O relatório Focus apresentado pelo BACEN apresentou o crescimento de 1,2 % para o PIB brasileiro em 2019. Para [27], o crescimento para 2020 é de 2,5% com as expectativas associadas às reformas (Trabalhista e Previdenciária), já aprovadas e as discussões no Congresso Nacional sobre as novas reformas (Tributária e Administrativa), bem como à recuperação da confiança de consumidores e empresários. Segue ilustrado pela (Fig.1) o histórico e a previsão de crescimento do GDP da economia para 2020 [27, 29, 30].

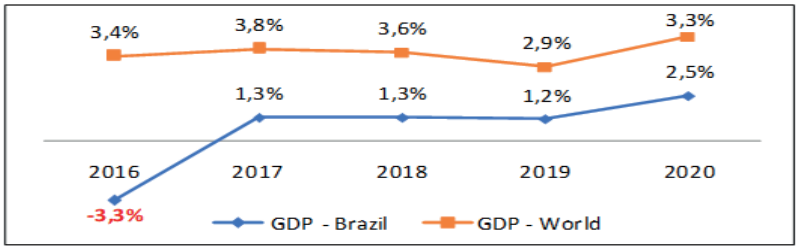

Fig.1. Taxas de crescimento (GDP) para economia em 2020, adaptado de [27, 29, 31, 30]

No Estado do Paraná, a projeção de crescimento econômico publicados recentemente (Fig.2), aponta o estado entre os cinco primeiros, com a maior participação GDP nacional com 6,4%, entre todos os estados, o Paraná, foi o que mais cresceu em 2019, aproximando-se da quarta colocação [28].

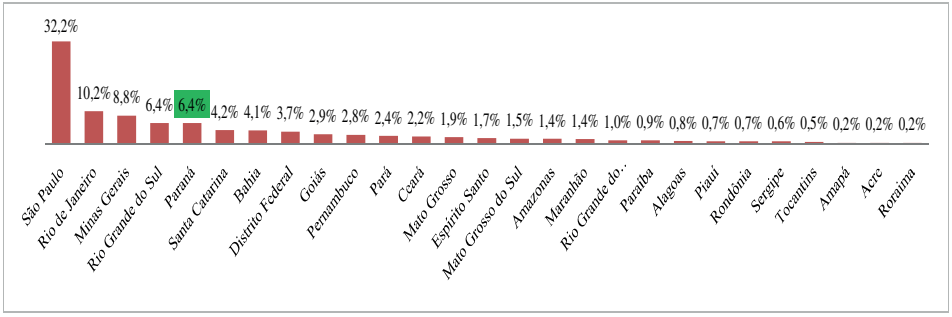

Fig.2. Taxas de crescimento GDP estados Brasileiros, adaptado de [28]

As indústrias do Paraná acumulam o segundo melhor desempenho do país, com avanços principalmente nos setores de fabricação automotivo e alimentos [32]. Apontada pela (Fig.3), o Paraná, também segue otimista, com a previsão de crescimento do GDP em 2,6% para 2020, com base na super safra de grãos do verão, com a conquista do novo status sanitário, novos investimentos em infraestrutura e o potencial para atrair novos investidores com a previsão de crescimento do GDP nacional projetado para 2,5% para 2020 [27, 33, 34, 29, 31].

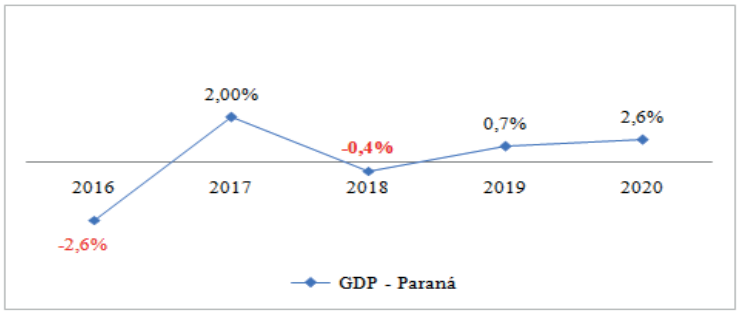

Fig.3. GPD 2020, adaptado de [34]

De acordo com a (Fig.4), o setor de refeições coletivas forneceu em 2019 um total de 426 milhões de refeições/mês movimentando cerca de R$ 20,6 bilhões/ano. O setor gerou 210 mil empregos diretos para produzir um volume de 7,5 mil toneladas de alimentos/dia e representou para os governos, uma receita de R$ 2,6 bilhões/ano entre impostos e contribuições. Para 2020, estima-se um aumento em 3,5%, elevando o número de atendimento para 441 milhões de refeições/mês, considerando um crescimento de 12% no faturamento para R$ 23,1 bilhões/ano [35].

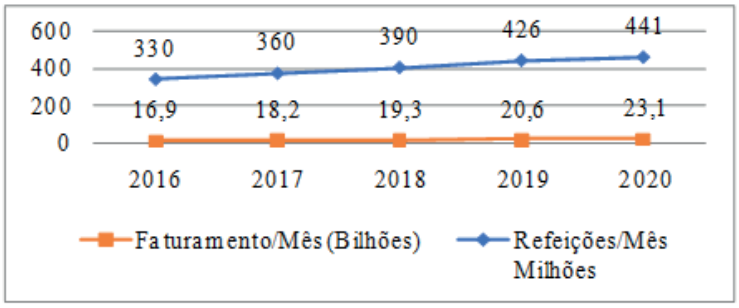

Fig.4. Dados de mercado de refeições coletivas, adaptado de [36]

3.2 Cenário econômico atual (Presente)

O primeiro caso de COVID-19 no Brasil, de acordo com a (Fig.5), foi em 26 de Fevereiro de 2020. Em (26 Março de 2020), após 20 dias do primeiro caso, o Brasil, testava positivo para 234 casos. Em 12 de março, o Estado do Paraná, registrava cinco (5) casos, todos confirmados na RMC. Como mais de 1.604 casos confirmados e 25 mortes entre os dias 17 e 22 de Março de 2020, no Brasil. No Paraná, apenas 54 infectados e sem óbitos, deste, 31 foram infectados na RMC.

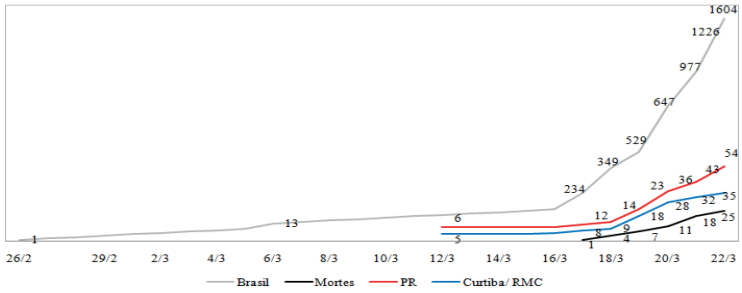

Fig.5. Evolução COVID-19, adaptado de [24, 37]

Neste cenário, o governo estadual e municipal sancionaram medidas, (tais como: isolamento social, fechamento do comércio e suspensões de aulas para rede pública e privada) para prevenção e contenção da pandemia. Neste período de quarentena, estima-se que, as operadoras de refeições coletivas tenham perdas significantes, entre 18% e 35% para o mês de Março, sendo que para o mês de Abril, as perdas poderiam chegar a 55% devido às paralisações parciais e até mesmo totais das atividades públicas e privadas. As perdas ocorrem diretamente no faturamento das operadoras, já que a cobrança é com base no número de refeições servidas aos funcionários dos clientes contratantes [37].

Observa-se (*Fig.6), ao passo que a pandemia evolui no Brasil e na RMC, medidas de contenção são tomadas precocemente, instantaneamente causa a desaceleração da economia em várias regiões, inclusive na RMC, impactando diretamente as operações das operadoras de refeições coletivas mediante a suspensão das aulas da rede pública e privada e das atividades não essenciais a saúde, também são afetados.

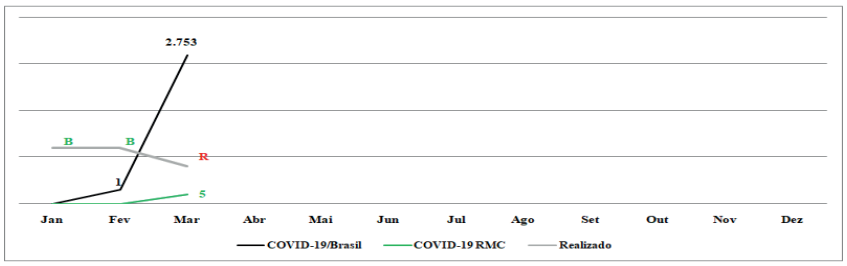

***Fig.6.** Impacto das medidas de contenção da COVID-19 nas operadoras de refeições coletivas (2020). Segue para a escala de leitura: (E) excelente (B) bom e (R) ruim.

Neste cenário, as operadoras de refeições coletivas fazem a adesão aos programas de incentivos do governo federal, estadual e municipal. São ações para mitigar os impactos econômicos gerados pelas medidas de contenção da pandemia, na busca de preservar a saúde financeira, muitas delas seguindo o movimento desemprego zero "ação de responsabilidade social" adotado por partes das empresas.

Outras notícias publicadas, relacionadas aos impactos gerados pela pandemia na economia, já trazem dados de retração de (-6,3%) no crescimento GDP mundial, o cenário de crescimento segue na contramão da previsão para 2020 de 3,3%, ou seja, uma revisão de crescimento mundial de (-3,0%), o que atinge a economia de vários países. No Brasil o impacto no crescimento é ainda maior, onde a retração está próxima dos (-7,8%). Com base, na taxa de crescimento prevista para 2,5%, que havia sido projetado em 2020, estima-se, que a retração do GDP oscilará próximo dos (-5,3%), os dados podem ser visualizados através da (Fig.7) [27, 31, 40].

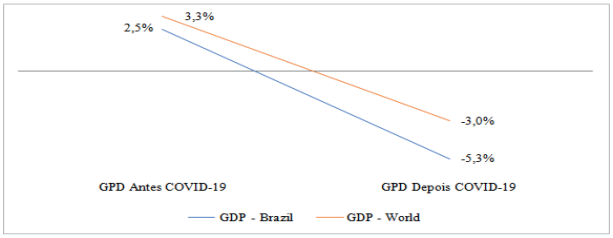

Fig.7. Taxas de crescimento (GDP) para economia, adaptado de [27, 31, 40]

A retração do GDP do Brasil reflete em todos os estados e segmentos. O estado do Paraná [34] prevê três cenários de retração: um otimista, uma base e outro pessimista. De acordo com a Tabela 1, os números são negativos e mostram que será um ano desafiador em função do desgaste econômico que estaria por vir.

Tabela 1. Previsões de crescimento do GDP para 2020, adaptado de [34]

Paraná	(GDP) 2020 antes COVID-19	(GDP) 2020 after COVID-19		
	Real	*Optimistic*	*Base*	*Pessimistc*
	2,6	-0,1	-2,9	-6,1

3.3 Contextualização para simulação de um cenário (Futuro)

A abordagem matemática elaborada por meio do Modelo SIR, para analisar hipoteticamente a evolução da pandemia, na população da (RMC), simula a evolução de contaminação de pessoas infectadas para os próximos 360 dias, com base nos casos registrados entre os dias 14 de Março de 2020 e 13 de Maio de 2020, de acordo com a Tabela 2, [24] considerando o fator de isolamento social no Estado do Paraná medido por [41] e exibido pela (Fig.8), assemelham-se com taxa de isolamento no Brasil.

Tabela 2. Números de casos confirmados RMC, adaptado de [24]

Data		Casos Confirmados	
		Infectados Acumulados	Variação Mês
0	14/mar	5	5
30	13/abr	387	382
60	13/mai	833	446
90	12/jun	2.831	1.998
120	12/jul	16.376	13.545

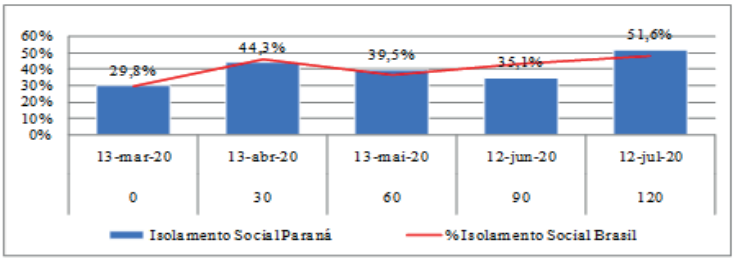

Fig.8. Taxa de Isolamento Social Paraná, adaptado de [41]

Embora o Modelo SIR possua finalidades acadêmicas e de pesquisas para descrever como a pandemia propaga-se em uma população, não se recomenda utilizá-lo como ferramenta

de tomada de descisão, já que é um modelo básico e há incertezas sobre a patologia do vírus da COVID-19, como infecções, modo de transmissão entre outros. No que tange a simulação foram considerados os parâmetros clínicos tais como a constante de recuperação $\mu = 0{,}14$ (14 dias) e o período de incubação do vírus DT = 0,5 (cinco dias) com base nos dados da *Cappra Institute for Data Science,* baseada no modelo criado pela Alison Hill, já as constantes de infecção $\beta = 0{,}23$ e os números de caso de infecção transmitida por uma pessoa infectada com $R_0 = 1{,}65$ foram geradas a partir do número de casos confirmados para região na RMC. Ilustrada pela (Fig.9), os números esperados de indivíduos infectados, recuperados, suscetíveis ao longo do tempo, já com intervenção aplicada por uma taxa média de isolamento social de 43,8% no Estado do Paraná, na qual a RMC está inserida, apontou, com base nos casos já confirmados dos primeiros 60 dias, após o primeiro caso confirmado, que aproximadamente 2.189.766 de pessoas serão infectadas no período de 360 dias, após o primeiro caso registrado, ou seja, um potencial de 60,54% da população poderá ser contaminada, com pico sendo previsto para meados de Setembro de 2020.

Obviamente, com as medidas aplicadas para a contenção da pandemia, o pico poderá ser estendido, em função de uma disseminação lenta e com o contágio sob-controle, estima-se, que o afrouxamento as medidas de contenção na RMC, possa acontecer de forma parcial, com a retomada gradual, com segurança, primeiramente na reabertura do comércio em Julho e em seguida o retorno das atividades educacionais a partir de Setembro interrompendo, segundo [42] uma sequência de quatro meses sem aulas presenciais, já que ações de ensino a distância foram aplicadas para continuidade do ensino. Dentre os planos de contenção da pandemia, outras ações para o combate a fome foram aplicadas por órgãos públicos (municipal, estadual e federal), como a contratação de empresas por meio de licitações, para o fornecimento de cestas básicas, a famílias dos alunos da rede pública de ensino e famílias cadastradas nos programas sociais de baixa renda. Estas ações contribuíram para famílias de produtores rurais e algumas operadoras de refeições coletivas, a mitigarem os impactos econômicos em suas operações [43, 44].

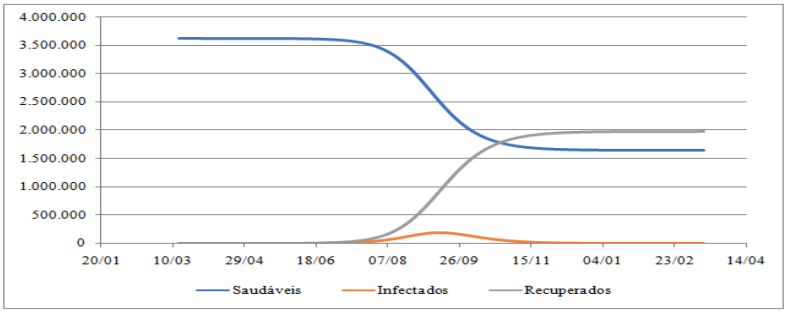

Fig.9. Simulação I - Evolução COVID-19 na população da RMC 2020

4 Análise e Discussão de Resultados

Com base nas previsões de crescimento do cenário econômico para 2020, as operadoras de refeições coletivas, projetaram um faturamento positivo para 2020, visto um cenário promissor de crescimento econômico em relação ao ano anterior (2019), não somente para Brasil, como também mundial. Como a RMC aderiu às medidas de contenção, logo no início de casos registrados, o pico da pandemia possivelmente foi achatado e provavelmente pode acontecer em meados de Setembro (Fig.9), uma segunda análise de simulação foi realizada por meio do modelo SIR, com base nos números de casos de pessoas testadas positivo entre o dia 0 (zero) 14 de Março de 2020, até o dia 120 na data de 12 de Julho 2020, o resultado apresentou similaridade ao da primeira simulação (Fig.9). Este cenário pode afetar as operações econômicas das operadoras de refeições coletivas, de Março até meados de Setembro (Fig.10) com perda parcial da receita. No entanto, considerando um retorno parcial das atividades, com o afrouxamento da quarentena aplicada, conforme observados em outros países, os resultados "Ruim", podem estender-se até Dezembro, quando agrupado ao período sazonal, ou seja, em 2020 serão apenas dois meses com resultado em escala "Bom" para os meses de Janeiro e fevereiro, antes do início da quarentena e dez meses seguidos de resultados em escala "Ruim" de queda no faturamento. Obviamente, neste período foram e estão sendo criados e executados planos de contingências e estratégias de negócios, para mitigar as perdas. Cabe lembrar que o retorno as normalidades, o aumento no faturamento também ocorrem instantaneamente de acordo com o plano público de retorno das atividades, lembrando que as receitas das operadoras são dadas em função da quantidade de clientes atendidos.

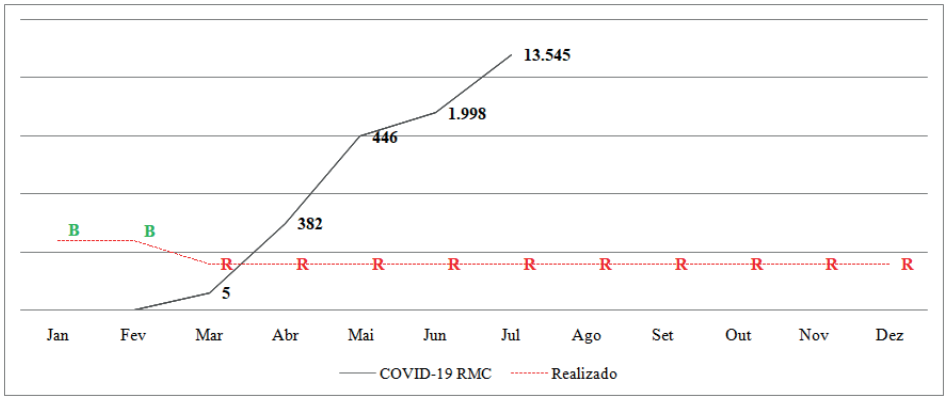

Fig.10. Impacto das medidas de contenção da COVID-19 nas operadoras de refeições coletivas (2020). Segue para a escala de leitura: (E) excelente (B) bom e (R) ruim.

5 Conclusões

O estudo retratou-se por meio de uma pesquisa documental e desenvolveu a construção do conhecimento sobre a previsão de crescimento econômico, para analisar os impactos causados pelas medidas de contenção da pandemia COVI-19 nas operações econômicas das operadoras de refeições coletivas em 2020, diante da desaceleração econômica generalizadas na região metropolitana de Curitiba (RMC).

Com o avanço da pandemia, a previsão de crescimento GDP mundial previsto para 3,0% desacelerou para -3,0. No Brasil com crescimento projetado para 2,5%, a queda prevista é -5,3%. A economia do estado Paraná prevista para crescer 2,6%, a queda estimada será de -6,1%. Duas simulações realizadas por meio do modelo SIR de pandemias, com base em dados de pessoas que contraíram o vírus a partir do primeiro caso confirmado (14 de Março de 2020) uma até o dia nº60 (13 de Maio de 2020) e a outra até dia nº120 (12 de Julho de 2020), apontam o pico de infecção para meados de Setembro de 2020, considerando todas as medidas públicas de contenção da pandemia aplicada na região com uma taxa média de isolamento social de aproximadamente 40%, bem como os parâmetros clínicos considerados na metodologia de aplicação. Cabe mencionar, que as medidas de contenção sendo mantidas sempre empurram o pico da curva para frente, com um menor número de pessoas sendo infectadas no período.

As operadoras foram impactadas diretamente e a partir do início da quarentena vem apresentando resultados ruins por meses seguidos. Neste período, já somam 120 dias, até 12 de Julho de 2020. As operadoras de refeições coletivas vêm buscando alternativas para mitigar as perdas, como, adesão aos programas sancionados pelos governos (Municipal, Estadual e Federal), para preservar os caixas das empresas, à medida do possível, desenvolvendo estratégias para a manutenção dos negócios entre outros. Conforme observado em outros países, como a Itália, China, Espanha entre outros, o retorno as atividades vêm acontecendo de forma gradativa. Estima-se que as operadoras de refeições coletivas apresentem resultados em escala de (R) ruim, de Março á Dezembro de 2020, ou seja, dez meses consecutivos de resultados abaixo do esperado.

O segmento de alimentação é forte, mas assim como todos os outros, o ciclo de vida está ligado à cadeia de valores, onde um alimenta o outro, em questões econômicas. Num futuro próximo, com as pessoas adaptando-se a uma nova forma de viver e a vacina para combater o vírus da COVID-19, já em fase de teste, seja disponibilizada a população, tão logo, a vida volta ao “novo normal” e as empresas vão recuperando suas economias adaptando-se a um novo conceito de vida, deixado pelo legado da pandemia.

An operational planning model to support first mile logistics for small fresh-produce growers

Abstract. In this work, we propose a hierarchical optimization model to support har-vest and local routing decisions of fresh agricultural products. The proposed model has been motivated by the fact that small growers of fresh produce very often face difficulties in terms of availability of local (or first-mile) logistics at reasonable prices which results in lower profit margins and more food waste. So, in order to reduce the cost of first-mile logistics they can co-ordinate the consolidation of the harvests from different growers to send their products to the packing facility. Hence, we integrate harvesting and routing operations for a set of small growers with the aim to reduce their operational costs. The proposed framework has been implemented and preliminary evaluated with some instances considering as case study farmers of fresh produce in the central region of Chile.

Keywords: First mile logistics · Small fresh-produce growers · Harvesting and distribution planning

1 Introduction

Fresh fruit and vegetables consumption have been growing in recent years worldwide. The combination of the growth of global population, nutrition concerns and more open borders will sustain, if not accelerate, the current growth of international trade of fresh fruits and vegetables. As an example, Figure 1 presents the imports of fresh fruits and vegetables into the US for consumption, from 2015 until 2019 expressed in thousands of US dollars. We can observe that in both cases, the graph shows a remarkable increasing trend.

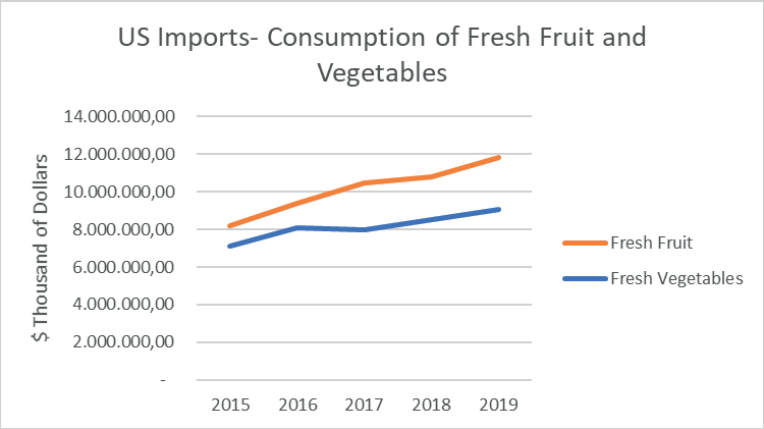

Fig. 1. US Imports for consumption of fresh fruit and vegetables (Thousand of Dollars). Source: Source: FAS- USDA database, accessed on August 13th, 2020.

This expanded demand of fresh fruits and vegetables represents a challenge since it requires the development of efficient supply chains that can meet this increasing demand considering all the complexities derived from the perishability of the product. Hence, the transportation, storage and distribution of these products need to be carefully planned to minimize food waste due to inefficient logistics practices. This opens the question of how to reengineer traditional supply chains for fresh produce into flexible and rapid response supply chains to best serve the rapidly changing market.

The covid-19 pandemic has caused serious problems in the supply chains of agricultural products. For instance, the media has reported cases of lack of food at the supermarket shelves and crops being wasted at the farms because of lack of traditional markets, such as food service outlets, for the farmers[12]. Furthermore, there has been shift of consumption to supermarket chains and direct-to-consumer channels. This highlights the need to develop tools to make rapid logistics connections between farmers and the evolving markets. This is even more relevant in the case of small growers who very often face additional challenges. For instance, even prior to the pandemic, small growers were experiencing difficulties accessing some markets, due among other factors to poor logistical channels, lack of negotiation power and lack of access to financial resources. Furthermore, due to some food safety regulations and first-mile logistics challenges, usually supermarket chains do not procure directly from small growers. Some of the changes caused by covid-19will be permanent and hence, we need to prepare for the new conditions.

Currently, very often two or more intermediaries take possession of the product between the farm's gate and the final consumer, resulting in multiple locations holding

[11] https://www.magazine.bayer.com/en/feeding-the-world-in-a-pandemic-can-food-supply-chains-cope-with-covid-19-.aspx
[2] https://onlinelibrary.wiley.com/doi/epdf/10.1111/cjag.12237

inventory throughout the supply chain. In this case, customers and growers are not directly connected to the final market, and are limited to operate under the market signals transmitted by those intermediates which results in distorted market information and, capturing a lower margin of the value chain than if they would sell directly to the final consumer. The long distribution chain also contributes to the high levels of waste observed in the fresh produce industry. Accordingly, improvements in the fresh food supply chains, may provide social benefits that range from higher income for small and regional farmers, to more abundant healthy food for the consumer [1].

Figure 2 presents a schematic view of the main processes of a fresh produce SC. The main echelons of a prototypical fresh produce supply chain are indicated, as well as the physical flow of products through it [2].

	Agricultural practices and Harvesting	Consolidation & Cold-Chain Entry	Processing / Packing	Transportation and logistics	Final Distribution Logistics
Strategic Decisions	• Selection of farming technology & equipment • Financial planning • Design of supply networks, • Evaluation of perennial crops, Crop rotation strategies	• Selection of storage equipment & technology • Financial planning • Design of supply networks • Selection of cold technology • Location of cold chain facilities	• Selection of storage equipment & technology • Financial planning • Design of supply networks	• Design of the global supply chain network • Design of the domestic supply chain network	• Design of supply network • Market selection and contracts with customers (incoterms and other conditions) • Pricing analysis
Tactical and Operational Decisions	• Cropping planning • Harvesting planning • Planting policies • Equipment scheduling • Water allocation • Land preparation • Labor planning	• Storage planning • Cold chain scheduling and planning • Transportation planning and scheduling • Plan opening chambers	• Storage planning • Cold chain scheduling and planning • Transportation planning and scheduling • Batch production planning • Load assignments • Packing	• Domestic transportation planning and scheduling • International transportation planning and scheduling • Packing and unpacking • Inventory decisions and cargo handling • Empty container logistics • Clearance and other procedures management	• Transportation planning and scheduling • Packing and unpacking • Inventory decisions and cargo handling

Fig. 2. Schematic view of the main processes of a fresh produce supply chain. Source: Villalobos et al. [2].

In this paper, we aim to provide planning tools for small growers based on an integrated planning and coordination environment for supply chains of fresh fruits and vegetables that includes information acquisition and coordination supply-demand tools to close the logistics and information gap between small growers and existing and emerging markets, especially those created by direct sales to consumers through ecommerce. The aim is to increase the benefits obtained by the small growers by means of a coordination

scheme in their first mile operations. We focus on the operational planning decisions related to the harvesting and transportation of produce to the packing facilities. In particular, we propose a hierarchical planning decision model to determine joint harvest and truck scheduling for a group growers. We apply the proposed model to a case study that consists of small growers that produce fruits and vegetables in the central region of Chile. The underlying problem is to coordinate harvest and truck routing to achieve cost savings in first mile logistics, which it is usually one of the main hurdles for the integration of small farmers have to solve to insert themselves into the main marketing channels.

The remainder of this paper is organized as follows. Section 2 presents a literature review regarding operational harvesting and transportation decisions of a fresh produce supply chain. Section 3 presents the proposed mathematical formulation. Section 4 presents the experimental design and numerical results. Conclusions and recommendations for future research are given in Section 5.

2 Literature review

Research on agricultural supply chains have gained the attention of academics in several aspects. There are many planning decisions in a fresh-produce agricultural supply chain at the strategic, tactical, and operational level. We can find multiple contributions addressing different planning aspects [3-17]. Comprehensive reviews of operational research tools to support planning decisions can be found in [18,19] and Villalobos et al., [1] present a review of technologies to support real-time decisions for fresh produce logistics.

Among strategic level decisions, we can refer to Flores and Villalobos [8] who focused on the development of market intelligence tools. They developed an opportunistic shipment policy that increases a farmer´s commercialization reach within a secondary market with minimal or no capital investment once a base market has been established. From the perspective of the first mile decisions, we can refer to Ahumada et al. [4] that present an integrated tactical planning model for the production and distribution of fresh agricultural problems under uncertainty. The proposed model aims to maximize the revenues of a single and large producer that has some control over the logistics decisions associated with the distribution of the crop.

Ahumada and Villalobos [3] on the other hand, propose an operational model for planning the harvest and distribution of perishable agricultural products considering a single large grower. The aim of the work is to optimize the savings provided by the trade-off between the freshness with which the products are delivered and the transportation costs. The model generates short-term decisions related to harvesting, packing and transportation. They consider time constraints, available labor, and the effects of harvesting decisions on product quality; their modeling strategy is based on harvest

patterns and one of the decisions considered is which pattern should be used for harvesting each plot of the planted area. The model takes the perspective of a single grower who produces tomato and bell peppers.

Ferrer et al. [7] propose an optimization approach for scheduling wine-grapes harvest operations. They propose a mathematical model that schedule the harvesting operations considering the quality loss due to harvesting before or after the optimal date. They consider penalizations for harvesting before or after the optimal date. This is an important difference with respect to the work to be presented in this paper. Rather than modeling the initial and final harvesting times, in this paper we consider patterns that determine the frequency of the harvesting along the days of the planning horizon. For instance, one harvesting pattern corresponds to harvesting every single day, another corresponds to harvesting every other day, and so on.. . Ferrer et al. [7] consider routing aspects into their model, as they assume that equipment and personnel should be moved from one block of the planted area to another. They model the routing problem as a TSP (Traveling Salesman Problem). This is another difference with respect to our work in which we consider more than one vehicle to transport the fresh produce from the small farms to a packing center.

In terms of previous works in the literature that specifically consider small growers, we can refer to Flores et al. [9]. They propose a framework for the strategic design of local agricultural systems for small growers. In terms of contributions focused on the transportation of harvested products, we can refer to Alarcon-Gerbier et al., [11]. They address the combined problem of fresh produce harvest-decisions and the scheduling of truck arrivals to processing plants of tomato. González-Araya et al. [12] consider the same problem and propose a GRASP methodology for solving the model. Although it has certain similitudes to our work, they consider a problem with different objectives than those considered in the models to be presented in this paper. For instance, their objective function is based on the minimization of waiting times of trucks, while we aim to reduce total costs.

Another related contribution is presented by Yantong et al. [13] who propose an inventory routing planning model for perishable food with quality considerations. They consider the case of sending products to different retailers from a single depot, focused on the last mile logistics, that differs from our case that focuses on first mile activities. Furthermore, they do not consider labor restrictions which is an important aspect include in our model.

Lamsal et al. [14] address the integrated harvest and delivery scheduling problem for planning the movement of the crop from the farm to a processing plant. They consider the case of multiple and independent producers and assume that no on-farm storage is allowed. They consider a time-frame of 24 hours. In contrast, in our case we assume a longer planning horizon (for instance, 2 weeks) to coincide with the planning of harvesting operations observed in practice. Furthermore, while in our case, we are

maximizing profits, their model penalizes positive and negative deviations from the mill´s unloading capacity.

Gvozdenovic and Brcanov [15] address the problem of transporting agricultural goods from the fields to the factory using a fleet of vehicles. They consider the transportation of sugar beets used in sugar production. The transport between the fields and the factory is modeled by a time-span network. They do not consider harvesting decisions, which is an important difference with respect to our work.

Another related work is presented by Plessen [16] that addresses a tactical decision problem for harvest-planning based on the coupling of crop assignment with vehicle routing. They determine which crop to assign to each field, the sequence to serve the fields during the harvest and the dispatching of multiple harvesters located at multiple depots to the multiple fields. One important difference is that in our case we consider an operational planning decision model and assume that crops have been already planted. Furthermore, we are not considering the dispatching of harvesters but consider a limited labor available.

Jiang et al. [17] propose an integrated harvest and distribution scheduling model considering time windows for perishable products. The distribution of products is done directly from the farms to the consumers. They consider a single farm and several consumers located in different places, which is the main difference with respect to our work. In our case we assume that products are transported to a packing facility from which they will be transported to a distant location. They consider a single type of product while in our case we allow multiple products. Another important difference is that they model the scheduling problem based on the initial and final time of harvesting at the farm, while in our case, the timing is determined by the harvesting patterns selected which simplifies the modeling structure.

In this paper, we aim to extend the operational planning model proposed by [3] to consider small growers that are organized by a supply chain coordinating agent who uses planned routes for consolidating cargo instead of using direct shipments. In contrast to the most of the existing related literature, we consider a planning horizon of several days, and harvesting patterns as the planning cornerstone as it is done by [3].

3 Mathematical formulation and proposed solution approach

We consider the problem of planning the harvesting and distribution of fresh products from several small farmers to a packing facility. We propose a hierarchical approach based on two stages that are iteratively solved, as it is illustrated in figure 3. The first step consists of solving the harvest planning model, estimating the distribution costs as a direct shipment. Once the harvesting decisions have been made, a routing model is solved to consolidate shipments from several growers. The solution of the routing

problem provides the transportation costs to the harvesting model. The procedure is repeated until both models converge.

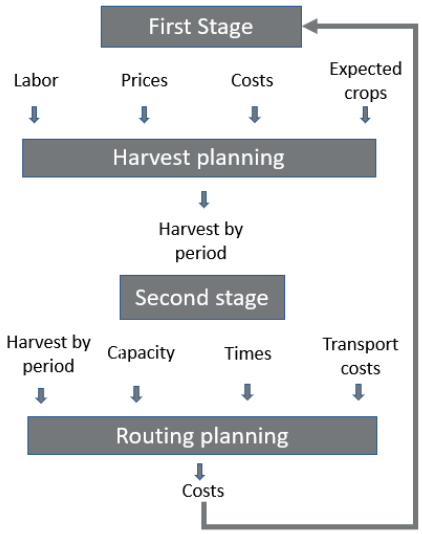

Fig. 3. Hierarchical solution implementation.

Sections 3.1 and 3.2 present the harvesting and routing mathematical formulations are respectively.

3.1 Harvesting planning model

We consider the planning problem of harvesting and distributing products by means of consolidated routes serving *I* farms and delivering the consolidated cargo to a single packing facility. Each farm produce K products. As in Ahumada and Villalobos [3], in order to simplify the model, we define harvesting patterns as the basic planning unit. Each harvesting pattern has different labor requirements and results in different amounts harvested. Then the harvesting decision problem consists of determining the timing and the harvesting pattern to be used to by each grower so that profits are maximized. Thus the problem becomes what harvesting pattern (if any) to use every day to harvest all the fruit that is ripe that day. We assume that only one pattern can be used in a single day for each planted plot. According to the products planted, it is expected certain volume of products to be harvested in each farm. The available labor for each farm is restricted, and for each box of product harvested is necessary certain hours of labor, which is also equivalent to cover a hectare of product in each farm. Each product has a minimum demand to be covered. We aim to maximize profits for the farmers, assuming a certain price for the products to be sent to their market as well as certain price of the product savage. Harvested products are transported to a packing facility, so

we also consider the corresponding transportation costs. The notation employed is further described.

Sets and Parameters
$t \in T$: planification periods (days).
$k \in K$: products.
$i \in I$: farms.
$v \in V$: harvest patterns.
EH_{tikv}: expected harvest in period t from farm i of product k by pattern v (in boxes of product).
SH_{tv}: if the pattern v is required to harvest in period t.
VS_{tk}: percentage of product k which is discarded in period t.
LAH_{it}: available labor for the farm i in period t.
LRH_{ik}: hours needed to harvest a box of product k in farm i.
LBH_{ik}: hours of labor necessary to cover one hectare of product k in farm i .
MOP_i: maximum working hours per farm i.
D_{kt}: minimum quantity to send of product k in period t.
P_{kt}: price of the product k in period t.
PS_{kt}: price of the product k salvaged in period t.
CH_k: cost of harvesting a box of product k.
$Clabor$: cost of one hour of work.
CT_i: estimated cost of transporting a box to the consolidation center from farm i .
Cap: truck capacity.

Variables
X_{tikv}: harvested area of product k in the farm i with harvest pattern v in the period t.
QH_{tik}: harvested boxes of product k from farm i in the period t.
SP_{tikr}: shipped boxes of product k from farm i in the period to the consolidation point, using truck r.
QS_{tik}: discarded boxes of product k from farm i in the period t.
Opl_{it}: hours of labor contracted in the farm i in the period t.

The proposed model is formulated as a mixed integer programming (MIP) model as follows:

$$Max(\sum_t \sum_i \sum_k \sum_r SP_{tikr}\, P_{kt}) + (\sum_t \sum_i \sum_k QS_{tik}\, PS_{kt} - (\sum_t \sum_i (LAH_{it} + OPL_{it}) Clabor) - (\sum_t \sum_i \sum_k QH_{tik} CH_k) - (\sum_t \sum_i \sum_k \sum_r SP_{tikr} CT_l) \quad (1)$$

Subject to:

$$QH_{tik} = \sum_v X_{tikv} EH_{tikv} \quad \forall\, t, i, k. \quad (2)$$
$$QH_{tik} \leq Cap \quad \forall\, t, i, k. \quad (3)$$
$$QS_{tik} = \sum_v X_{tikv} EH_{tikv} VS_{tk} \;\forall\, t, i, k. \quad (4)$$
$$\sum_k (LRH_{ik} QH_{tik}) + \sum_k \sum_v X_{tikv} SH_{tv} LBH_{ik} \leq LAH_{it} + OPl_{it} \quad \forall\, t, i. \quad (5)$$

$$\sum_r SP_{tikr} = QH_{tik} \quad \forall\, t,i,k. \tag{6}$$
$$\sum_i \sum_r SP_{tikr} \geq D_{kt} \quad \forall\, t,k. \tag{7}$$
$$\sum_v \sum_t X_{tikv} \leq AP_{ik} \;\forall\, i,k. \tag{8}$$
$$Opl_{it} \leq MOP_i \quad \forall\, t.i. \tag{9}$$
$$\sum_i \sum_k SP_{tikr} = Cap \;\forall\, t,r. \tag{10}$$
$$X_{tikv}\,, QH_{tik}, SP_{tikr}, QS_{tik}, Opl_{it} \geq 0 \;\forall t,i,k,v,r. \tag{11}$$

The objective function (1) maximizes the benefits of selling the normal and the salvage products minus the cost of labor, harvest and transport. Constraint (2) indicates that the amount harvested depends on the area harvested according to the pattern and the expected harvest. Constraint (3) limits the harvest to the truck capacity. Constraint (4) indicates that the quantity of the product discarded depends on the area harvested according to the pattern, the expected harvest and the estimate of the quantity discarded. Constraint (5) limits the quantity harvest to the labor available. Constraint (6) define that all the quantity harvested must be send. Constraint (7) indicates that the quantity sent to destination must be at least the minimum quantity. Constraint (8) limits the area harvested per pattern to the total area planted. Constraint (9) indicates that the extra labor is limited to a maximum working hours per day. Constraint (10) limits the quantity sent to the truck capacity. Constraint (11) indicates the nature of the variables.

3.2 Routing problem

The second phase of the hierarchical approach consists of a planning problem for the recollection of the harvests from a set of farms located in different locations. Each one of these farms harvests a given quantity of products in a determined period of time according to a preestablished plan. The aim is to send all the products harvested by the farmers to a packing center, minimizing the costs of transportation. A fleet of trucks with limited load capacity is available to do the transportation of products. Time windows are defined for the collection of these products, as well as the operating times of the packing facility.

Parameters

$r \in R$: trucks.
$I_0 = I \cup \{0\}$, where the node 0 corresponds to the packing facility.
HS_{ti}: amount of harvest to send from the farm i in the period t.
Cap: trucks capacity.
TBF_{ij}: Travel time between farms (i,j).
C_{ij}: Travel cost between farms (i,j).
S_i: Charging time in the farm i or discharge at the consolidation point.
E_i: Earliest time to get to the farm i.
U_i: Later time to get to the farm i.
M: Scale very large.

Variables

X_{tijr}: if the arc (i,j) is visited by the truck r the period t.
Y_{tir}: if the farm i is visited by the truck r the period t.
VT_{tir}: time to visit the farm i by the truck r the period t.
$VTCE_{tr}$: departure time from the consolidation point by the truck r the period t.
$VTCA_{tr}$: time of arrival at consolidation point by the truck r the period t.

Objective function

$$Min \sum_t \sum_i \sum_j \sum_r C_{ij} X_{tijr} \quad (12)$$

Constraints

$$\sum_i X_{tizr} - \sum_j X_{tzjr} = 0 \ \forall z,r,t. \quad (13)$$
$$\sum_i Y_{tir} \leq \sum_i X_{t0ir} M \ \ \forall \ r,t. \quad (14)$$
$$\sum_i Y_{tir} \leq \sum_j X_{tj0r} M \ \ \forall \ r,t. \quad (15)$$
$$\sum_i HS_{ti} Y_{tir} \leq Cap \ \ \forall r,t. \quad (16)$$
$$\sum_{j!=i} X_{tijr} = Y_{tir} \ \ \forall i,r,t. \quad (17)$$
$$\sum_{i!=j} X_{tijr} = Y_{tjr} \ \ \forall j,r,t. \quad (18)$$
$$\sum_r y_{tir} M \geq HS_{ti} \ \ \forall i,t \ where \ i \in I: HS_{ti} \geq 0. \quad (19)$$
$$\sum_r y_{tir} = 1 \ \ \forall i,t \ where \ i \in I: HS_{ti} \geq 0.$$
$$VT_{tir} + S_i + TBF_{ij} - \left(1 - X_{tijr}\right)M \leq VT_{tjr} \ \ \forall \ i,j,r,t. \quad (21)$$
$$VTCE_{tr} + TBT_{0j} - \left(1 - X_{t0jr}\right)M \leq VT_{tjr} \ \ \forall j,r,t. \quad (22)$$
$$VT_{tir} + S_i + TBT_{ij} - (1 - X_{ti0r}) \leq VTCA_{tr} \ \ \forall \ i,r,t. \quad (23)$$
$$E_i \, y_{tir} \leq VT_{tir} \leq U_i \, y_{tir} \ \ \forall \ i,r,t. \quad (24)$$
$$E_o \leq VTCE_{tr} \ \ \forall \ r,t. \quad (25)$$
$$VTCA_{tr} \leq U_o \ \ \forall \ r,t. \quad (26)$$
$$VT_{tir}, VTCA_{tr}, VTCE_{tr} \geq 0 \ \ \forall \ i,r,t. \quad (27)$$
$$X_{tijr}, \ Y_{tir} \in \{0,1\} \ \forall \ i,j,r,t. \quad (28)$$

The objective function (12) minimize the transportation cost from all farms to the consolidation center. The constraint (13) defines the correct flow of the trucks. The constraint (14) and (15) indicates that each route must start and finish in the consolidation center. The constraint (16) limits the amount sent to the truck capacity. The constraints (17) and (18) defines the relation between variables X_{tijr} and Y_{tir}. The constraint (19) indicates that if there is a harvest to be removed, the truck must visit the farm. The constraint (20) restrict to visit once each farm that has harvest. The constraints (21), (22) and (23) defines times of arrival between farms, to a farm from the consolidation center and to the consolidation center. The constraint (24) restrict the time of arrival to each farm. The constraints (25) and (26) restrict the time of departure and arrival to the consolidation center. The constraints (27) and (28) define the nature of the variables.

4 Experimental design

To evaluate the performance of the proposed framework numerical experiments were carried out. The instances were generated considering six factors that were varied using two levels (low and high): the number of farms (I), the cost of harvesting a box (CH_k), the available extra working hours (MOP_i), the harvest yield (EH_{tikv}), the capacity of the trucks (Cap) and the labor cost ($Clabor$). This resulted in an experimental design of 2^6, that is, 64 different instances. The values of the parameters were estimated according to information provided by INDAP (Chilean Agricultural Development Institute) website and interviews with technical personnel of this Institute.

Table 1. Parameters used in the experiment

Parameter	Low Level (-1)	High Level (1)
I (Farms)	4	6
CH_1 (USD)	\$1.55	\$1.705
CH_2 (USD)	\$0.43	\$0.473
CH_3 (USD)	\$1.5	\$1.65
MOP (hours)	120	150
EH_{ti1v} (boxes)	9,000	11,000
EH_{ti2v} (boxes)	5,400	6,600
EH_{ti3v} (boxes)	540	600
CAP (boxes)	1,000	1,800
I (Farms)	\$3.28125	\$3.9375

For each of the instances, 6 replicates were created, in which the yield of the harvest varies 10% of the expected yield for each level and product. The location of the farms was set considering the central region of Chile. The location of the farms was defined by using google maps and the areas were the products grow in the central region of Chile (the Metropolitan Region of Santiago and the Region of Valparaiso).

The proposed optimization framework was implemented in Phyton version 3.7.6 with the AMPL 2.0 API. Gurobi 5.0.1 solver is used to solve the mathematical models. To solve the experiments, an MSI computer with an Intel Core i7-7700HQ CPU 2.80 GHz, with 8 GB of installed memory and Windows 10 with a 64-bit system is used.

Due to the computationally difficulty of solving the routing model, the number of farms was limited to 4 and 6 farms (in the low and high-level values). The computational results are presented. Table 1 which shows the minimum, maximum and average times to solve the instances.

Table 2. Computational times (seconds).

	Minimum	**Maximum**	**Average**
Harvesting time (s)	0.15	0.80	0.18
Routing time (s)	0.17	22.80	0.95
Total time (s)	1.70	25.39	3.10

Table 3 presents the benefits obtained when consolidating products for the transportation from the farms to the packing facility, considering the values (low and high) of each parameter, as well as the general results. The table presents the increase (%) of profits with respect to the direct shipment strategy where each farm transports their products without any coordination with other growers.

Table 3. Numerical results in terms of profits increase.

	Profit Increase (%)		
	Minimum	**Maximum**	**Average**
Overall results	9.20%	26.02%	16.81%
Profit Increase by Factor			
Farms			
-1 (low level)	9.20%	11.22%	10.00%
1 (high level)	21.63%	26.02%	23.63%
Box Cost			
-1	9.21%	25.81%	16.81%
1	9.20%	26.02%	16.82%
Labor Hours			
-1	9.20%	26.02%	16.92%
1	9.24%	25.62%	16.71%
Yield			
-1	9.47%	26.02%	17.52%
1	9.20%	23.79%	16.11%
Capacity Truck			
-1	9.20%	16.28%	16.28%
1	9.87%	17.35%	17.35%
Labor Cost			
-1	9.23%	26.02%	16.82%
1	9.20%	25.74%	16.81%

We performed an analysis to determine the factors that are more relevant in increasing the profits of the small growers. We found that the most relevant factors were the number of farms, the harvest yield, and the truck capacity (see Fig. 4). As the number of farms increases, the profits of the farmers increase due to the reduction of logistics costs.

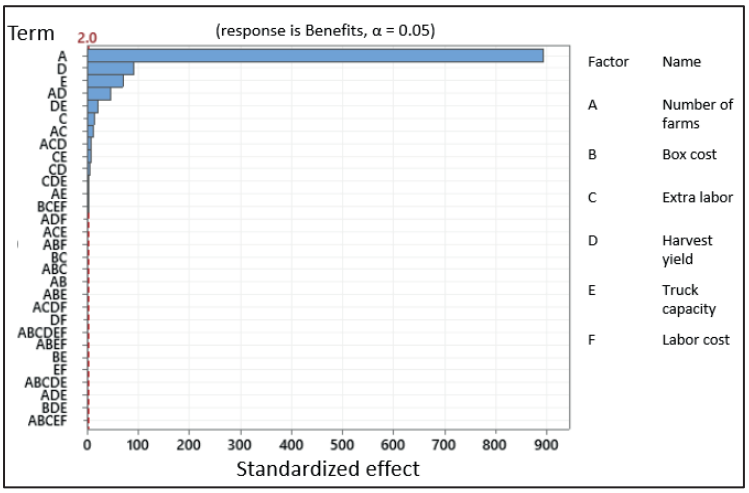

Fig. 4. Pareto chart of the Standardized Effects on the experimental design 2^6.

As an example, we present the routes found in one of the instances solved by the proposed optimization framework. This instance corresponds to 4 farms that produces strawberries and cauliflower. The percentage of profit increase in the final solution with respect to a direct shipment strategy is 10%. Figure 5 presents the routes found in the optimal solution. Figure 5a presents the route of truck 1 which starts in the packing center (blue point D), then goes to farm 2 (red dot B), continue to farm 1 (red dot C) and finally return to the packing center. Figure 5b presents the route of truck 2 that initiates the route with the farm 4 (yellow dot B), departing from the packing center (blue dot D). Then it visits the farm 3 (yellow dot C), to finally return to the packing center.

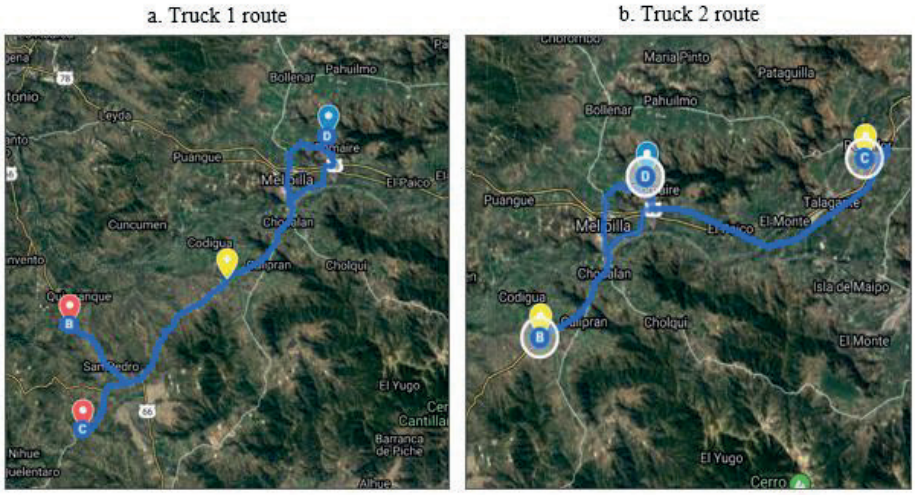

Fig. 5. Illustration of the routes found in one of the instances solved.

5 Conclusions

In this work, we presented an optimization framework to support first mile operations considering the case in which small growers coordinate the transportation of fresh products to a packing facility. We hierarchically integrated the harvesting and routing decisions. A reduced version of the harvesting planning model proposed by Ahumada and Villalobos [1] was used, considering harvesting patterns and labor availability restrictions. The routing model is a classical VRP with time windows. The proposed solution framework was implemented in Phyton and Gurobi. An iterative scheme was used to integrate the harvesting and routing models. Preliminary testing was performed considering small instance sizes only, given the complexity to optimally solve the large routing models. Results provide insights in terms of the profit increase obtained by coordinating the transportation of products from the farms to the packing center, in comparison to direct shipments of the farmers. This illustrates the benefits that small farmers can achieve if they can be organized in a cooperative scheme that may support the logistics operations. Results also show that the most significant factors that impact the profits increase are the number of farms, and then, the capacity of the trucks.

As ongoing research, we are considering several aspects to improve the routing model to apply to more realistic aspects. For instance, we plan to allow cargo splitting to better use the capacity of the trucks. We are also evaluating alternatives that can reduce the computational time of the routing model, such that providing an initial solution to the solver based on a heuristic algorithm. In terms of the harvesting model, as we have simplified the model proposed by Ahumada and Villalobos[3], we are evaluating some extensions that include the incorporation of perishability and quality aspects in the model, as well as compatibility of the products.

Further research should consider the integration of a tactical planning model as the one proposed by Ahumada and Villalobos[4] with the operational planning model so that the planting and harvesting decisions can be related to the coordination with first mile logistics. Cooperative schemes and negotiations among the small farmers to incorporate into the models should also be explored.

Resumo. A manufatura inteligente associada ao advento da indústria 4.0 marcam uma nova era associada a soluções tecnológicas, onde sistemas físicos e virtuais (CPS) são empregados para aperfeiçoar processos e operações em um ambiente altamente competitivo. Nesse contexto, digital twin (DT) e prognóstico e gestão de saúde de ativos (PHM) desempenham um papel fundamental na manufatura permitindo através de monitoramento e análise por meios físicos e virtuais, maximizar o uso de ativos com estimativa de vida útil restante (RUL) e minimizar interrupções não programadas. Esse artigo propõe uma extensão a esse contexto abordando a otimização do inventário de materiais e peças de reposição, que representa um valor significativo que por muitas vezes fica imobilizado sem previsão de uso, causando um impacto financeiro nas organizações. É avaliado na literatura o uso de DT e PHM relacionado ao controle de peças de reposição, bem como lacunas encontradas e oportunidades a serem abordadas.

Palavras-chave: Digital twin, PHM, RUL, Peças de reposição

1 Introdução

Atividades de MRO (Manutenção, Reparos e Operações) são consideradas essenciais para uma operação adequada de ativos industriais, e consequentemente um desempenho superior na manufatura de produtos. Embora amplamente reconhecida como uma atividade essencial, seu custo operacional tem um impacto financeiro relevante nos processos de manufatura criando um trade-off entre a necessidade e o custo resultante. Além dos valores resultantes das atividades de planejamento, execução e reparo, ainda há o acréscimo do custo de inventário dos itens utilizados que nem sempre é transparente nas organizações.

Contudo, com o advento das novas tecnologias de informação que possibilitaram o surgimento da internet das coisas (IoT) e a 4ª revolução industrial (indústria 4.0), corroboram para o desenvolvimento de soluções para maximizar o resultado das atividades de MRO com um custo adequado à manufatura.

Uma das soluções em potencial que tem recebido uma expressiva atenção de pesquisadores, além dos players e indústria, é o Digital Twin (DT) que teve o conceito

desenvolvido inicialmente no campo aeroespacial [1] e com um número de publicações crescentes em aplicações complexas como manutenção de aeronaves e usinas geradoras de energia [2]. Embora em um menor número de publicações, recentes esforços na pesquisa têm sido encontrados utilizando a abordagem de DT para manufatura e manutenção industrial [1, 3, 4] e alinhados com o conceito de manufatura inteligente (smart manufacturing).

Enquanto DT desempenha um papel importante no desenvolvimento da manufatura inteligente, PHM (Prognostics and Health Management) representa um avanço nas técnicas de manutenção baseada na condição (CBM), indo além do monitoramento do estado de um componente ou sistema de um equipamento. A combinação de dados históricos, monitoramento on-line e uso de algoritmos, permitem que PHM possa estimar a vida útil restante (RUL) de um componente, além da predição de falhas futuras [5, 6, 7, 8].

Há um número crescente de pesquisas sobre esses temas com diferentes objetivos como o aumento de performance e confiabilidade dos ativos utilizados na manufatura, bem como a redução dos custos relacionados às atividades decorrentes de manutenção. Embora exista a preocupação sobre os custos incidentes para manter a operacionalidade dos equipamentos, poucos esforços são empregados para estender esse benefício ao inventário de peças de reposição, que impactam no custo operacional da manufatura nem sempre de forma transparente.

Esse artigo propõe uma revisão dos estudos feitos com a abordagem de DT e PHM para otimização de custos de inventário, bem como avalia as lacunas existentes e oportunidades que podem ser exploradas. O restante do artigo é organizado na seguinte ordem: a seção 2 apresenta a metodologia de pesquisa utilizada para esse estudo, na seção 3 é feito uma revisão dos conceitos de DT e PHM encontrado na literatura, na seção 4 é discutido os trabalhos encontrados com aderência ao tema pesquisado e na seção 5 é concluído o estudo e apresentado propostas para trabalhos futuros.

2 Metodologia

Para conduzir o estudo, duas buscas diferentes foram feitas para encontrar o referencial teórico para o tema proposto, utilizando a base da ScienceDirect e da CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior), que foi adicionada na segunda etapa. Na primeira etapa foram utilizados os seguintes termos combinados: (“digital twin” AND MRO) OR (PHM AND MRO) OR (“smart manufacturing” OR MRO) considerando a busca dos termos em todo o artigo e com data superior a 2010. Foram encontrados 45 artigos na base da ScienceDirect com termos pesquisados.

Em função do número de publicações encontradas foi feito uma busca adicional combinando todos os termos e utilizando taxonomia entre os termos principais de pesquisa, a busca foi restrita ao título, resumo e palavras-chave na base da ScienceDirect, e ao assunto na base da CAPES. Os termos utilizados na busca foram os seguintes: (“digital twin” OR “smart manufacturing” OR “industry 4.0”) AND (PHM OR prognostics OR “predictive maintenance”) AND (MRO OR “spare parts” OR maintenance). Foram encontrados 57 artigos na base da ScienceDirect e 22 na base da CAPES. Em

ambas as etapas foram considerados artigos publicados em inglês e com data de publicação superior a 2010.

Após a remoção de artigos duplicados e fora do contexto de manufatura e indústria, restaram 115, dos quais foram avaliados o conteúdo para averiguar a aderência ao tema proposto. Para considerar que o artigo possuía aderência ao tema, foi levado em consideração a abordagem de DT e ou PH com conexão direta ou indireta com o inventário de peças de reposição. Dessa forma, a citação do inventário ou custo de peças foi considerado uma aderência direta ao tema, e a predição de vida útil de componentes com foco em custo foi considerada uma forma indireta, já que essa informação pode ser usada com um dos indicadores para uma otimização de níveis de estoque. Como resultado, 34 artigos foram selecionados para a pesquisa, conforme representado (Fig. 1).

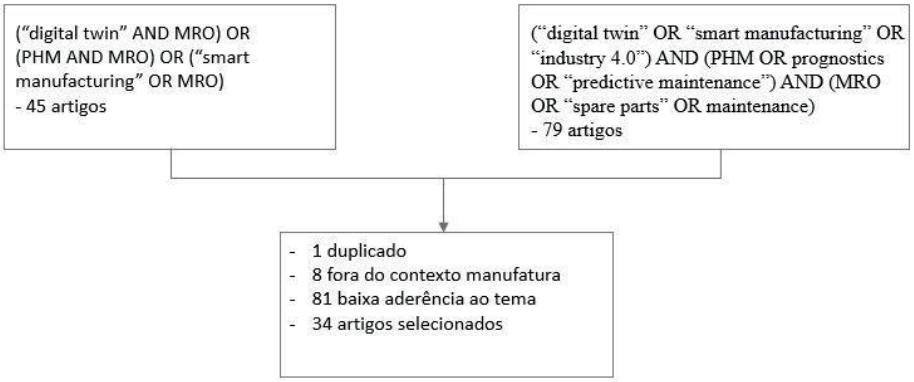

Fig. 1. – Metodologia aplicada na pesquisa

3 Tecnologias Relacionadas

3.1 Digital Twin

Apesar de serem altamente relacionados, os conceitos da tecnologia de DT surgiram antes da Indústria 4.0 em uma apresentação na faculdade de Michigan em 2002 [9] como uma proposta do conceito de PLM (Product Life Cycle), e desde então tem recebido uma expressiva atenção por pesquisadores. De uma forma geral, DT é a representação virtual de sistema ou objeto físico capaz de simular as características e comportamentos de sua contraparte física, além de ambos estarem mutualmente conectados [3]. Entre as várias definições sobre DT, [3] afirma que a mais comumente usada foi proposta em 2012 por Glaessegen e Stargel, no qual DT é composto por três partes: produtos físicos, produtos virtuais e as conexões entre eles. Contudo, uma das primeiras definições foi dado pela NASA [1], onde DT é uma simulação probabilística integrada multi-física, multi-escalável de um produto ou sistema que utiliza os melhores modelos físicos disponíveis para refletir a vida do seu correspondente gêmeo.

Apesar de DT ter uma expressiva abordagem em aplicações complexas relacionado a aeronaves, usinas geradoras de energia, aerogeradores [2] e engenharia aeroespacial [10], a atenção tem se voltado para novas aplicações na manufatura industrial como modelagem de produtos, processos e operações bem como a interoperabilidade entre eles [11]. Também é ampla a abordagem de DT em equipamentos e sistemas industriais de alta performance, tanto para processos de manufatura [1, 3, 12, 13, 14] como para manutenção preditiva [15, 16, 17, 18], mas não limitado a essas áreas de aplicação incluindo todo o ciclo de vida do produto [4].

DT utiliza dos recursos do CPS (cyber-physical systems) para implementar soluções dentro do contexto da manufatura inteligente, integrando os sistemas físicos como ativos e processos de produção, com os elementos do ambiente virtual [19] de processamento e simulação. [20] define como CPS como um ambiente onde sistemas naturais e elaborados pelo homem são fortemente integrados aos sistemas de computação, comunicação e controle. CPS é uma parte fundamental no contexto da indústria 4.0, promovendo uma conectividade avançada de dados em tempo real e uma gestão inteligente com alta capacidade analítica [21].

3.2 PHM

A manutenção preventiva tem sido uma grande aliada dos processos de manufatura, garantindo uma maior disponibilidade dos ativos produtivos com um mínimo de interrupções não programadas [22]. Embora tenha seus pontos positivos, tem um custo relativamente elevado não evita todas as falhas decorrentes de manutenção, isso porque com sua característica de inspeções ou trocas de componentes programadas por tempo (TBM) nem sempre tem sua eficácia comprovada [23]. As inspeções cobrem apenas uma parte das características necessárias para garantir o funcionamento adequado de sistemas e componentes, e a troca programada nem sempre consegue usufruir todo o potencial de uso de um componente, que por muitas vezes pode ser trocado antecipadamente gerando um custo adicional ao processo [24].

Com o avanço em tecnologias de inspeção muitas atividades de manutenção preventiva têm sido gradativamente substituídas pela manutenção preditiva ou baseada na condição (CBM), onde inspeções com auxílio de equipamentos conseguem medir a saúde do conjunto ou componente monitorado, evidenciando potenciais pontos de falhas antecipadamente [24]. Técnicas como análise de vibração, termografia e ferrografia permitem analisar o estado de um equipamento planejando intervenções programadas reduzindo o risco de interrupções durante sua operação. Contudo, muitas dessas atividades também são programadas em intervalos de tempo, além da necessidade serem analisadas por um especialista, não faz uma estimativa adequada da vida útil restante (RUL) [19].

Considerado uma evolução do CBM, o PHM (Prognostics and Health Management) faz o uso de ferramentas e algoritmos com características preditivas para previsão da vida útil restante e identificar possíveis pontos de falhas [25]. A vantagem da manutenção preditiva baseada nos fatores de saúde do equipamento, é poder trabalhar com um prognóstico precoce com indicação do que e quando ser tratado, auxiliando nas tomadas de decisões estratégicas do planejamento de manutenção [26]. Dentro do contexto de

manufatura inteligente e indústria 4.0, PHM desempenha um papel importante na manutenção preditiva, buscando manter a confiabilidade dos ativos com a correta estimativa de RUL ao longo do seu ciclo de vida [27], através da avaliação da degradação dos sistemas e componentes monitorados.

Segundo [19] o termo prognóstico e gestão de saúde, tem origem na área de medicina, mas foi adotado pela manutenção e gestão de ativos em função de sua semelhança em sua semântica, já que PHM é baseado na monitoração de sinais importantes através de sensores em pontos estratégicos e seus dados armazenado para análise. Embora PHM seja considerado um modelo de manutenção preditiva, aborda um conjunto de técnicas e métodos empregados para gerar prognósticos e suportar a gestão de manutenção [27], como monitoramento da condição em tempo real e previsão futura baseada em dados históricos e atualizados, além da estimativa de vida útil restante [8].

4 DT e PHM para Gestão de MRO e Inventário

Na literatura é possível encontrar uma ampla abordagem da aplicação de DT e PHM no contexto de manufatura e manutenção, visando o aumento de performance dos ativos e sua confiabilidade, além de propiciar uma melhor previsibilidade das ações tomadas pela gestão da manutenção. A aplicação proveniente dessas tecnologias na era da indústria 4.0, consequentemente conduz a uma redução de custos para as organizações, entretanto, nem todos os benefícios ainda estão sendo explorados. Além do suporte no planejamento das atividades de manutenção e da redução de paradas não programadas, a estimativa do RUL obtida por meio de DT e PHM, também pode beneficiar o planejamento e otimização do inventário de peças de reposição. O alto custo de muitos itens de reposição que muitas vezes são armazenados sem previsão de uso, impactam financeiramente as organizações, já que o valor do item fica imobilizado e não pode ser convertido em capital para uso, além dos custos da gestão do inventário.

Dentro da literatura utilizada nesse estudo, [28] Kumar et al. é o único a considerar diretamente o uso da manutenção preditiva e a estimativa de RUL como fator para redução do custo de inventário de materiais e peças de reposição. Mesmo quando não citado diretamente, RUL pode ser considerado um fator importante para a gestão de níveis de inventário, [29] propõe uma prova de conceito do uso de DT em máquinas com baixa disponibilidade de aquisição de dados através de aplicação de monitoramento em paralelo dos principais componentes para estimativa de RUL.

Quando a área de aplicação é a indústria, é possível observar o uso de DT e PHM em equipamentos complexos como centros de usinagem e fresadoras com comando numérico (CNC), [15] propõe um sistema de manutenção preditiva hibrida com DT baseado em modelo e orientado a dados para estimar e acompanhar a RUL dos principais componentes, [12] também apresenta um estudo com modelagem similar para previsão da condição de máquinas-ferramenta com objetivo na análise e previsão da degradação de ferramentas de corte. [23] Einabadi et al. propõe um método de manutenção preditiva dinâmica para indústria 4.0, baseado em dados em tempo real e redes neurais artificiais (ANN) para prognóstico de falhas, reduzindo intervenções desnecessárias de manutenção, explorando a vida útil de componentes o máximo possível e

reduzindo ou prevenindo paradas não programadas. Ainda no contexto de ativos complexos, Tao et al. [30] propõe uma aplicação em DT baseado em PHM para controle de ciclo de vida de turbinas aerogeradores. O estudo de caso aplicado apresentado por [30] aborda não somente as questões de eficiência, mas indiretamente os custos envolvidos em função da complexidade das atividades em função das características do equipamento. No quadro 1 é apresentado de forma resumida uma visão geral dos principais estudos relacionados ao tema.

Quadro 1 - Visão geral dos principais estudos relacionados ao tema pesquisado

Autores	Dimensão	Framework	Principais abordagens
Roy et. al (2016)	Manutenção		Análise e monitoramento de degradação de componentes elétricos e mecânicos de forma geral sob o contexto de MRO e PHM. Aborda obsolescência, manutenção autonoma e planejamento integrado.
Li et. al (2020)	Manutenção Aeronaves	x	Aborda design de projetos PHM, baseado na definição de expectativas de stakeholders
Lamoureux et. al (2014)	Manutenção Aeronaves		Validação de indicadores de PHM antes da implementação
Werner et. al (2019), Booyse et. al (2020), Nuñez et. al (2017), Susto et. al (2018), Cattaneo et. al (2019)	Manutenção		Estratégia para a implementação de manutenção preditiva em indústria com uso de DT e PHM com foco em RUL
Raman et. al (2018)	Engenharia aeroespacial		Aborda a importância de DT em MRO nos métodos de manufatura modernos
Luo et. al (2020)	Manutenção	x	Aplicação de DT orientado a dados hibridos para manutenção preditiva e estimativa de RUL
Short et. al (2019), Aivaliotis et. al (2019)	Manutenção		Aplicação de DT com modelagem para manutenção preditiva
Sénéchal et. al (2019)	Manutenção	x	Aborda CPS, prognósticos para atividades de manutenação com foco em sustentabilidade
Einabadi et. al (2019)	Manutenção		Apresenta o uso de sensoremento e redes neurais no contexto de industria 4.0 para estimativa de RUL
Traini et. al (2019), Ruiz-Sarmiento et. al (2020)	Manutenção	x	Machine learning aplicado à manutenção preditiva para redução de custos e com foco em RUL
Ardila et. al (2020)	Manutenção		Propõe um sistema de informação para PHM baseado em três pilares: Heterogeneidade, integração e usabilidade de busca
Kumar et. al (2017)	Manutenção	x	Big data aplicado à CBM para maior precisão na estimativa de RUL e redução de custo de peças de reposição
Tao et. al. (2018)	Geração de energia		Aplicação de DT orientado a PHM para ativos de alta complexidade de manutenção
Kraft et. al (2017), Liu et. al (2018)	Manutenção aeronaves		DT voltado à aplicações de MRO

Muitas pesquisas com abordagem na estimativa de RUL também são encontradas na área de manutenção de aeronaves, que além da complexidade é extremamente crítico em função segurança envolvida, sendo inclusive monitorada por autoridades reguladoras [31]. Contudo, além das expectativas diferenciadas desse tipo de atividade, é possível encontrar aplicações visando um maior controle dos itens de reposição [31, 32, 33], bem como a vida útil dos componentes em uso [32, 33, 34].

5 Conclusão

Com o advento da indústria 4.0 e as tecnologias relacionadas que impulsionam o desenvolvimento de novas técnicas e métodos para um desempenho superior e sustentável na manufatura, é possível perceber a necessidade de mudança de paradigmas e comportamentos nessa nova era industrial, onde IoT está cada vez mais presente. Muitas abordagens na literatura e na indústria já demonstram os primeiros movimentos para mudança com propostas e resultados promissores, embora, muito ainda precisa ser explorado no contexto da manufatura inteligente.

DT e PHM desempenham um papel importante quando o assunto é desempenho e previsibilidade de ativos, e esse trabalho procurou relacionar os estudos que possuem conexões com o inventário de materiais e peças de reposição para ativos utilizados na manufatura. Dentro dos resultados encontrados não foi identificado uma grande relação direta com o tema, entretanto, como a estimativa de RUL é uma preocupação em boa parte dos temas pesquisados, é correto afirmar que de forma indireta a otimização de níveis de inventário pode ser tratada.

Como trabalhos futuros é sugerido uma maior conexão entre abordagens de DT e PHM com inventário de materiais e itens de reposição, aumentando o potencial de resultados na organização estendendo a conexão na cadeia de valor do ativo. A fase de maturação das novas tecnologias ainda está no início, e há um grande potencial a ser explorado em breve.

Abstract. There is a need for the Brazilian Navy to make investments in combat vessels for application regarding the defense operations in the Amazon region, carried out by the Marine Corps. For the decision-making analysis, the hybrid method named PROMETHEE-SAPEVO-M1 is worked, allowing an evaluation with qualitative and quantitative data, generating weights for the criteria in a structured way, and providing a robust analysis from the results by three different models of evaluation along with an intra-criterion analysis. In search to enable the implementation of the methodology to the case, a web platform based on the method is used, presenting a friendly interface, requiring only numeric entries and preference indications. The method implemented shows to be effective to the study from the moment that it makes possible a robust analysis, providing the Brazilian Navy and its Marine Corps to identify the most favorable vessel for acquisition in search of safeguarding the Amazon.

Keywords: Decision-making, Multiple Criteria Decision Analysis, PROMETHEE, Brazilian Navy.

1 Introduction

Based on the Brazilian Federal Constitution [1], the Brazilian Navy (BN) aims to prepare and employ naval power contributing to the defense of the country, guaranteeing constitutional powers and ensuring law and order, fulfilling the duties provided by the law, with emphasis on those related to the Maritime Authority, aiming to contribute to safeguarding national interests [2]. In this context, it is possible to deduce that the efficient use of its resources is essential to the BN, ensuring the protection of the national territory and, in this scenario, the Amazon region.

The Amazon region has strategic and geopolitical importance for Brazil, where its area presents 60% of the surface of Latin America, with 67.8% belonging to the country [3]. According to Andrade [4], the territory has 13,190 km of borders with other countries, and around 25,000 km of navigable areas within nine Brazilian states, which considering the connection to the Atlantic Ocean, enable the Amazon to become commercially relate to the United States, Europe, and Asia.

Not Considering only political aspects, in the Amazon region, it is necessary to focus attention on the recurrent threats related to terrorism, drug trafficking, guerrilla, and paramilitary groups [5]. According to the Brazilian Defense Strategy, in search to counter threats to the Amazon, it is crucial to carry out a series of strategic actions related to the military presence to defend natural wealth. Regarding the BN, it is necessary to provide naval, aircraft, and Marine Corps (MC) assets in a permanent condition of employment, especially on the waterways of the main rivers in the Amazon region [6].

Currently, the BN has military organizations from the MC located in the Amazon region, sustaining a relatively small number of troops when compared to the challenge of safeguarding the Amazon, and has been presenting low investments regarding vehicles of river fighting [4]. The current vessels used are practically destined for the transport of troops but presenting a set of limitations, such as low firepower, low autonomy, absence of armored protection, and other aspects.

Considering the hypothesis of possible investment in modern river fighting vessels, in search of the increase of effectiveness in strategic actions and contemplating limited resources, a decision-making analysis process is necessary, enabling to identify which alternative, among those available for employment, is favorable for acquisition. In search to make possible an adequate realization of this procedure, a set of criteria and variables must be analyzed [5].

Contemplating an analysis composed by the set of criteria and the trade-off presented between them, the implementation of Multiple Criteria Decision Analysis (MCDA) methods would provide to BN and its MC a robust analysis regarding the decision-making process, by the moment that these methods enable the structuring and a better understanding of preferences regarding the problematic [7].

The MCDA methods can be understood as techniques that support and enable the decision-maker, being an individual agent, group, or organization, to structure and evaluate complex problems transparently, introducing quantitative and qualitative criteria [8], where the criteria preference is defined in an interactive process with other technical-political actors [9]. As presented by Greco et al. [10], the MCDA methods allow the analysis of a decision-making process, considering various aspects of evaluation,

such as technical, environmental, and socioeconomic, at operational and strategic scenarios for decision-making.

Considering a real decision-making problem, the method to be implemented should enable an integrated algorithm, providing to perform qualitative and quantitative data, facilitating to structure and analyze variables where it is not possible to define a precise numerical input along with variables in a quantitative format [11]. Consider aspects of subjectivity in the MCDA modeling is an important role [12], transcribing the preferences of the decision-maker by the implemented method, being clear concerning the manipulations and attributions regarding the problem in evaluation.

1.1 Questions and Objectives

The paper aims to present a case study based on the MCDA methodology through the hybrid method PROMETHEE-SAPEVO-M1 [13] by the moment that its axiomatic structure enables the evaluation of both qualitative and quantitative data, in an integrated way, correlated to the problematic. Considering the hypothetical situation of acquiring new combat vessels the study aims to provide to the BN a procedure for decision-making analysis in search to obtain a ranking of the vehicles and identify the most favorable between them.

Enabling an effective application of the method to the case study, a web platform [14] based on the modeling will be worked, supporting the data evaluation in the given case, providing an assertive analysis by its friendly interface and complete format of results presentation by numerical and graphical models.

After the paper introduction, section 2 presents the concepts of the PROMETHEE-SAPEVO-M1 method and its axiomatic structure. Section 3 exposes the implementation process of the modeling in the case study intended for the multicriteria evaluation based on the analysis of combat vessels for use Amazon operations. Section 4 concludes the work, presenting the gains of the new method and proposal for future studies.

2 PROMETHEE-SAPEVO-M1 method

The method is a new variant of the PROMETHEE method (Preference Ranking Organization Method for Enrichment Evaluations), proposed by Brans, Vincke, and Mareschal [15], where a structure based in cardinal inputs, were added technics of ordinal evaluation based on the concepts of SAPEVO-M method, an extension of SAPEVO method [16], representing the integration of two MCDA methods.

The PROMETHEE-SAPEVO-M1 method enables the evaluation of data in different natures, where the qualitative and quantitative procedures are performed by ordinal and cardinal entries, respectively. Another main point of the modeling is its weights set for criteria, provided by a pairwise comparison to transparently obtaining of the importance as the subjective view of the decision-maker.

The modeling provides three models of analysis as partial outranking, complete outranking, and a ranking by intervals. Also, it is provided an intra-criterion analysis by veto threshold, enabling the evaluation of the alternative performance in a specific criterion. This format of results analysis enables decision-makers to make a sensitivity

analysis of the case by the comparison between the results suggestions in each preference model.

2.1 Evaluation procedure

The evaluation process is structured into a matrix (Criterion x Alternative) (1), composed of a set of alternatives A, where $a_i \in A$, $i = 1, \ldots, n$, evaluated under a set of qualitative criteria h, $h = 1, \ldots L$, and a set of quantitative criteria j, $j = 1, \ldots k$.

	a_1	a_2	a_3	...	a_n
h_1	a_{11}	a_{21}	a_{31}	...	a_{n1}
h_L	a_{1L}	a_{2L}	a_{3L}	...	a_{nL}
j_1	a_{11}	a_{21}	a_{31}	...	a_{n1}
j_k	a_{1k}	a_{2k}	a_{3k}	...	a_{nK}

(1)

Considering the presence of qualitative and quantitative criteria, first, the set A is performed concerning qualitative criteria h, $h = 1, \ldots L$. Considering a pairwise comparison between the alternatives regarding each criterion from set h, the analysis is based on the preference evaluation present on an importance scale, table 1.

Table 1. Importance scale.

Absolutely worse	**-3**
Much worse	**-2**
Worst	**-1**
Equivalent	**0**
Best	**1**
Much better	**2**
Absolutely better	**3**

For each qualitative criterion evaluated, it is obtained a matrix of preference relation between the elements belonging to the set A. By the equation (2), the punctuation is normalized, obtaining an importance degree of each alternative in a specific criterion. Then the values are submitted toa maximization procedure $P_h(a_1, a_2) = P(d) = f(a_1) - f(a_2)$, enabling to obtain the difference between the alternatives, as works the PROMETHEE method. The qualitative evaluation finishes making the normalization of difference by the equation (3).

$$v = \frac{\sum a_{ih} - \min a_{ih}}{max\ a_{ih} - \min a_{ih}} \tag{2}$$

$$P(d) = \begin{cases} d/1 & d \leq 1 \\ 1 & d > 1 \end{cases} \tag{3}$$

The evaluation process regarding the quantitative criteria j, $j = 1, \ldots k$, it is sustained the cardinal format based on the PROMETHEE procedure.

Comparing the alternatives a_1 and a_2 from set A, $P_j(a_1, a_2) = P(d)$ represents the preference degree of a_1 over a_2 according to the criterion j. When the criterion needs to be maximized, uses $P(d) = f(a_1) - f(a_2)$ to define a preference function. If it is necessary to minimize the criterion, $P(d) = f(a_2) - f(a_1)$ is used as preference function.

Six types of preference function have been proposed to normalize the differences between the alternatives [17], where based in parameters of indifference and preference, it is possible to obtain linear and strict preference, for more detail of application, please consult [18].

After the evaluation of alternatives, it is necessary to obtain the criteria weights. Considering both qualitative and quantitative criteria only in one set j, $j = 1, ..., L + k$, the ordinal scale presented in the table 1 is used, where the preference relation between the criteria is performed.

In this evaluation, two variables called *maximum sum* and *minimum sum* is considered, enable the normalization of punctuation (4). The *maximum sum* is obtained by $x = (n-1).\ 3$, representing the highest possible preference punctuating sum of each criterion, as closer a criterion is to *maximum sum*, greater will be its dominance in the set. In other hands, *minimum sum* is obtained by $x = (n-1).\ -3$, representing the minimum value possible within that assessment, as lower be the value and its closer to the *minimum sum*, the criterion will represent a little importance in the set.

$$\upsilon = \frac{\sum c_{ij} - (max\ sum)}{(max\ sum) - (min\ sum)} \tag{4}$$

After the normalization, each degree will be submitted to equation (5), providing the weights according to their respective criteria, and enabling to generate the global index preference $\pi\ (a_1, a_2)$, indicating the preference degree of alternative a_1 over a_2, where (6):

$$w(c_j) = \frac{\upsilon(c_j)}{\sum \upsilon(c_j)} \tag{5}$$

$$\pi(a_1, a_2) = \sum_{j=1}^{k+l} P_j(a_1, a_2) w_j \tag{6}$$

2.2 Results analysis model

Finished the aggregation procedure, the results are analyzed in different formats of manipulation, by a partial and complete outranking, and an outranking by intervals.

The Partial outranking is handles with by the positive outranking flow (7) and negative outranking flow (8), representing how a_1 outranks the other alternatives and how a_1 is outranked by the other options. How higher be the positive flow and lower be the negative flow, more favorable will be the alternative, where (9) (10) (11):

$$\phi^+(a_1) = \frac{1}{n-1}\sum_{x \in A} \pi(a_1, x) \tag{7}$$

$$\phi^-(a_1) = \frac{1}{n-1}\sum_{x \in A} \pi(x, a_1) \tag{8}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\begin{cases} \phi^+(a_1) > \phi^+(a_2)\ and\ \phi^-(a_1) < \phi^-(a_2), or \\ \phi^+(a_1) = \phi^+(a_2)\ and\ \phi^-(a_1) < \phi^-(a_2), or \\ \phi^+(a_1) > \phi^+(a_2)\ and\ \phi^-(a_1) = \phi^-(a_2); \end{cases}$ (9)

- a_1 is indifferent to a_2 ($a_1 I a_2$) *if* $\phi^+(a_1) = \phi^+(a_2)\ and\ \phi^-(a_1) = \phi^-(a_2);$ (10)

- a_1 is incompatible to a_2 ($a_1 R a_2$) *if* $\begin{cases} \phi^+(a_1) > \phi^+(a_2)\ and\ \phi^-(a_1) > \phi^-(a_2), or \\ \phi^+(a_1) < \phi^+(a_2)\ and\ \phi^-(a_1) < \phi^-(a_2); \end{cases}$ (11)

The Complete outranking is based in the net outranking flow (12), in this case, how higher be the net flow, more favorable is the alternative, where (13) (14):

$$\phi(a_1) = \phi^+ a_1 - \phi^- a_1 \tag{12}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\phi(a_1) > \phi(a_2)$ (13)

- a_1 is indifferent to a_2 ($a_1 I a_2$) *if* $\phi(a_1) = \phi(a_2)$ (14)

The third model of evaluation, consisting in an interval procedure [$x(a_1)$, $y(a_1)$] (15), based in a standard error value, defining a complete outranking by intervals, where (16) (17):

$$\begin{cases} x_{a_1} = \phi(a_1) - \alpha\sigma_{a_1} \\ y_{a_1} = \phi(a_1) + \alpha\sigma_{a_1} \end{cases} \tag{15}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\phi(a_1) > \phi(a_2)$ (16)

- a_1 is indifferent to a_2 ($a_1 I a_2$) *if* $\phi(a_1) = \phi(a_2)$ (17)

In search to obtain a robust analysis of the decision-making problem, the intra-criterion analysis by veto threshold suggests an equivalence between alternatives with low performance (a_x) and high performance (a_y) in global analysis, from the moment that a_x presents a strict preference over a_y in a specific criterion cj.

The veto v_j does not influence the outranking flows, but the analysis works as additional information to the decision-making process, where $v_j \geq p_j \geq q_j$. For qualitative criteria $v_h = 1$, and for quantitative criteria $v_j = max(a_{ij})$. If a preference threshold (p_j) be set and it is greater than v_j, the veto becomes equivalent to preference $v_j = p_j$.

3 Case study

In search to obtain an effective proposal to assist the defense of the Amazon region, the case study will address the allocation of resources assertively for the acquisition of River Combat Vessels. The analysis is evaluated concerning four vessels, as exposed in figure 1, to rank them according to their respective criteria. The decision-making process will be worked by the PROMETHEE-SAPEVO-M1 method, along with its web platform.

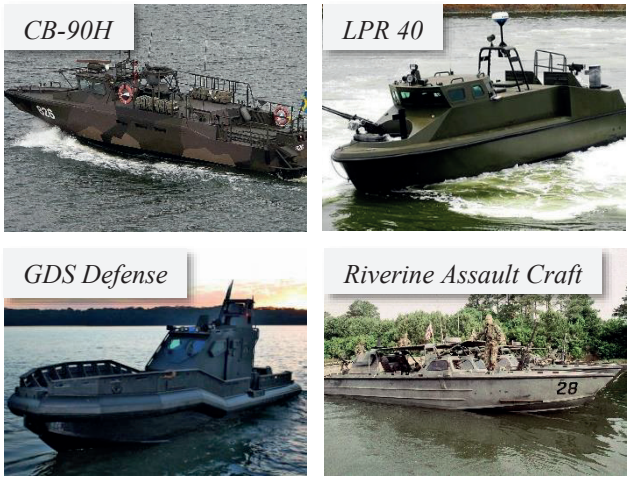

Fig. 1. River Combat Vessels to analysis.

Based on information acquired through specialists of MC, being them officers with experience in real operations in riverside environments, a set of ten criteria was defined, being five for a qualitative and five for quantitative assessment. The criteria were classified as the variables with the greatest operational importance, performing several operations in the Amazon region. The criteria are detailed below:

- *Fighting Power:* Important requirement for operations, when considering the occupation of points on the rivers and carry out river blocks, the criterion will be evaluated qualitatively, considering the set of armament that composes each vessel;
- *Navigation System*: Criterion characterized by the set of equipment as radar, GPS, and echo sounder, evaluated qualitatively;
- *Protection System*: Characterized by the shielding system that makes up the vessel, performed qualitatively;
- *Cost*: Criterion of great importance, however, evaluated qualitatively, due to the need for secrecy regarding the respective values of each vessel;

- *Maintenance*: Qualitative criterion regarding maintenance difficulties in isolated regions and the need for specific training, along with their costs;
- *Maximum Speed*: Criterion that considers the need for fast occupation at critical points in the rivers, measured in nautical knots;
- *Cruising Speed*: The criterion is related to the maximum time of working regarding the best performance of the vessel, measured by nautical knots.
- *Autonomy*: Considering long hours operations and the difficulty of supply points in the rivers of the Amazon, the autonomy indicates the ability to operate without the need for refueling, evaluated by nautical miles;
- *Displacement Weight*: Criterion characterized by the maximum capacity for loading troops and equipment destined for operations, measured by tons;
- *Troop Capacity*: Required when the number of troops is related to the combat power, measured by the number of combatants per vessel.

With the data for analysis, table 2 exposes the evaluation matrix, composed of qualitative, presenting a subjective indication of preference, and quantitative criteria, related to the numerical performance of each alternative.

Table 2. Evaluation matrix of case study.

Criteria	*CB-90H*	*LPR 40*	*Riverine Assault Craft*	*GDS Defense*
Fighting Power	Very good	Good	Good	Good
Navigation System	Very good	Very good	Fair	Good
Protection System	Very good	Very good	Good	Fair
Cost	High	Medium	Medium	Low
Maintenance	High	High	Fair	Good
Maximum Speed (knots)	45	35	50	35
Cruising Speed (knots)	37	28	38	28
Autonomy (Nautical miles)	300	270	280	270
Displacement Weight (T)	18	12.5	7.5	1.7
Troop Capacity (Qty)	20	16	10	10

3.1 Method application and result analysis

By the web platform, it is necessary to register the data related to the structure problem regarding the number of alternatives and criteria and their names. The software process follows the same axiomatic structure of the method, first evaluating the alternatives regarding the qualitative criteria. Indicating the preference between the pairs based on the ordinal scale (table 1), as exemplified in figure 2, it is possible to obtain the matrices

of relation, exposing the preference degree between each pair of alternatives in each criterion.

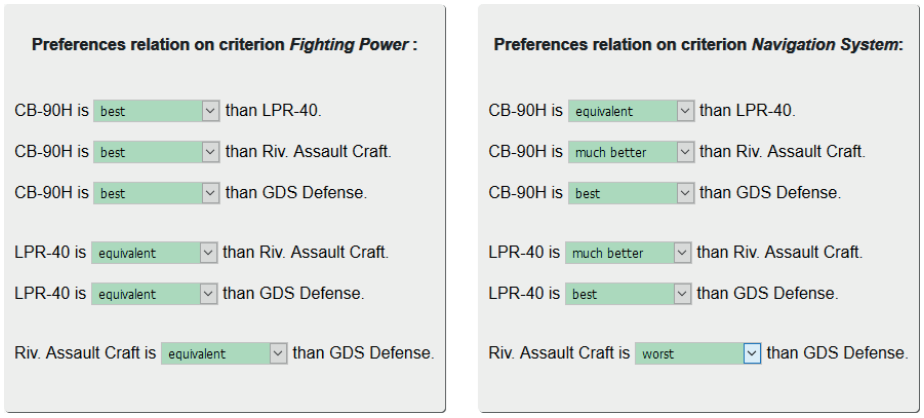

Fig. 2. Evaluation of vessels under qualitative criteria, PROMETHEE-SAPEVO-M1 Software web.

Regarding the quantitative evaluation set (figure 3), it is necessary to indicate the numerical performance of each alternative in each criterion, defining if it is a process of maximization or minimization. The type of preference function to the normalization process is the main topic of the analysis procedure, where is considered two models for evaluation.

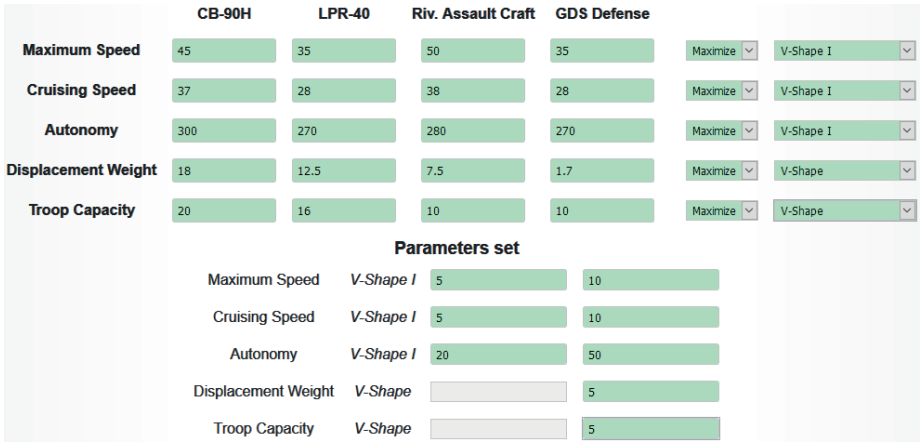

Fig. 3. Evaluation of vessels under quantitative criteria, PROMETHEE-SAPEVO-M1 Software web.

To evaluate the Maximum Speed, Cruising Speed, and Autonomy, it was considered the V-shape I function, by the moment that the function considers a limit of indifference q, where all differences under this limit will not indicate any preference, and the limit of strict preference p, where all value upper than this threshold will present the maximum preference degree, remembering that all differences between the limits p and q

presents a linear preference. For normalization of the differences in *Displacement Weight* and *Troop Capacity*, is set the preference function *V-shape*, defining only a strict preference threshold, by the moment that these criteria are sensible and a minimum variation between two alternatives need to take into account. Figure 3 exposes the threshold values in detail.

After the evaluation of alternatives, the procedure follows comparing the criteria in search to obtain the preference relation and the weight respective to each one, as presented in table 3. In the software, the process is similar to qualitative evaluation, just indicating the preference relation between each criterion. In table 3 is presented the punctuation of each criterion along with the final weights obtained based on the variables of *maximum sum* and *minimum sum*.

Table 3. Matrix of importance relation and weights obtained.

maximum sum = 27

minimum sum = -27

	Fighting Power	*Navigation System*	*Protection System*	*Cost*	*Maintenance*	*Maximum Speed*	*Cruising Speed*	*Autonomy*	*Displac. Weight*	*Troop Capacity*		Punctuation		Final Weights
Fighting Power	0	3	1	1	2	3	3	2	3	2	=	20	=	0,174
Navigation System	-3	0	-2	-1	1	1	1	1	3	2	=	3	=	0,111
Protection System	-1	2	0	1	2	2	2	1	3	2	=	14	=	0,152
Cost	-1	1	-1	0	1	2	2	1	2	1	=	8	=	0,130
Maintenance	-2	-1	-2	-1	0	1	1	0	1	0	=	-3	=	0,089
Maximum Speed	-3	-1	-2	-2	-1	0	-1	-3	1	-2	=	-14	=	0,048
Cruising Speed	-3	-1	-2	-2	-1	1	0	-2	2	-1	=	-9	=	0,067
Autonomy	-2	-1	-1	-1	0	3	2	0	1	3	=	4	=	0,115
Displacement Weight	-3	-3	-3	-2	-1	-1	-2	-1	0	-3	=	-19	=	0,030
Troop Capacity	-2	-2	-2	-1	0	2	1	-3	3	0	=	-4	=	0,085

Once established the weights of each criterion, the preference degree obtained from qualitative and quantitative evaluations are weighted. Then, for each pair of alternatives is generated the global preference index, representing the degree of dominance of each vessel over the others in the set, as presented in figure 4. Through these indexes, it is possible to define the positive and negative flows, indicating how the alternative outranks and how it was outranked regarding the other, respectively, and the net flows, representing the difference between the previous flows and as higher be this punctuation, more favorable becomes the alternative.

	CB-90H	LPR-40	Riv. Assault Craft	GDS Defense	Positive Flows	Net Flows	Intervals (standard error = 0.041)	
CB-90H	0	0.041	0.048	0.064	0.153	0.118	x = 0.077	y = 0.159
LPR-40	0.004	0	0.03	0.032	0.066	-0.009	x = -0.05	y = 0.032
Riv. Assault Craft	0.009	0.016	0	0.022	0.047	-0.05	x = -0.091	y = -0.009
GDS Defense	0.022	0.018	0.019	0	0.059	-0.059	x = -0.1	y = -0.018
Negative Flows	0.035	0.075	0.097	0.118				

Fig. 4. Global index of preference between each pair of alternatives, along with the positive, negative and net outranking, PROMETHEE-SAPEVO-M1 Software web.

The PROMETHEE-SAPEVO-M1 method enables three models of results analysis, based on a partial, complete, and intervals outranking. A graphical representation of each model of preference analysis provides the evaluation of all alternatives performance.

In figure 5, the preference relationships between the vessels assessed are detailed by a chart regarding the partial outranking. It observed that the alternative of better performance was the vessel *CB-90H*, presenting the highest positive and the lowest negative flow, indicating a total preference within the evaluation. The *LPR-40* vessel registered a partial preference regarding the alternatives *Riverine Assault Craft* and *GDS Defense*, where these alternatives presented an incompatible relation between each other, by the parallel indication in the chart.

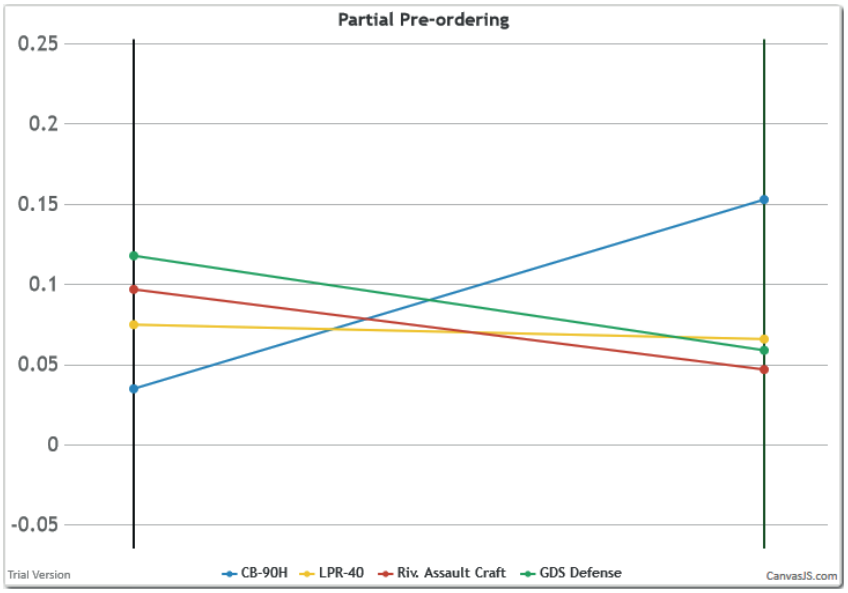

Fig. 5. Partial outranking chart, PROMETHEE-SAPEVO-M1 Software web.

In the second analysis, is obtained the complete outranking by the net outranking flows, related to the difference between the positive and negative flow of each alternative. In this evaluation model, how greater be the net flow obtained, most favorable becomes the alternative. In the given case, the vessel with the best performance was the *CB-90H*,

preceded by the *LPR-40*, *Riverine Assault Craft*, and *GDS Defense*, respectively, as exposed in figure 6.

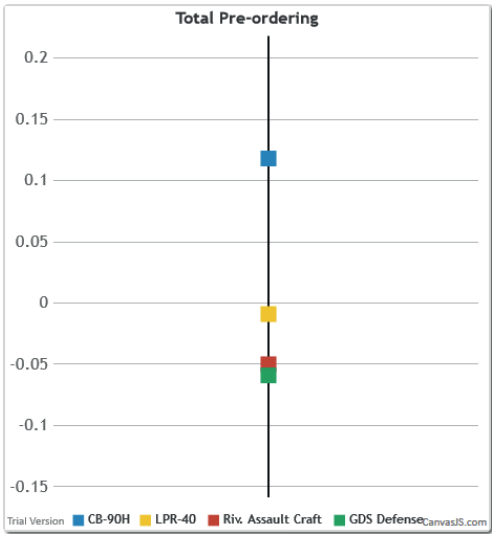

Fig. 6. Complete outranking chart, PROMETHEE-SAPEVO-M1 Software web.

The last model of analysis, outranking by intervals, enabled by the standard error, indicates if a given alternative is relatively superior concerning another or if the difference between the preferences is so small that both can become equivalent.

In the case study, the standard error value obtained was 0.041 (figure 4), so it was possible to generate the lower and upper limits for each alternative. In this assessment, both *Riverine Assault Craft* and *GDS Defense* vessels continued to present no preference regarding the others in the set, and the *CB-90H* vessel keeps presenting strict preference in the context, as detailed in figure 7.

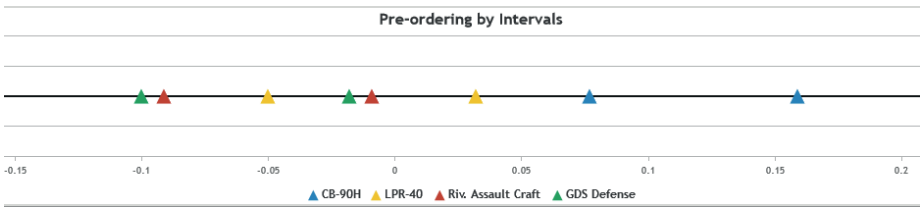

Fig. 7. Outranking by intervals chart, PROMETHEE-SAPEVO-M1 Software web.

Even already identified the best alternative, a distillation process was carried out in search to provide a second favorable alternative, by the moment that the exclusion of some alternative can present influence in the final ranking. In this context, was excluded the alternative *CB-90H*, and obtained new outranking flows. As exposed in figure 8, the alternative *LPR 40* continued to indicate the best performance concerning its positive, negative, and net flows. An important observed point is related to the outranking by intervals, where, unlike the previous analysis, the alternative presented total preference regarding the other from the set.

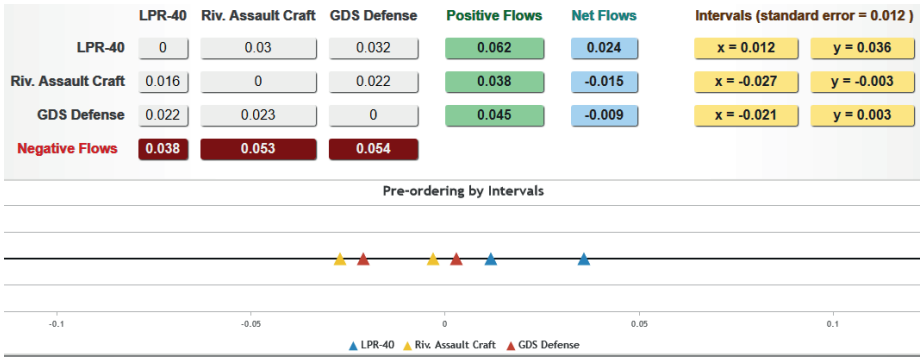

Fig. 8. New outranking flows, after distillation process along with the interval analysis charts, PROMETHEE-SAPEVO-M1 Software web.

Concerning the intra-criterion analysis, was not observed any relative relation that could present some influence or change in the choice of the most favorable alternative.

4 Conclusion

The proposed study aimed to present a decision-making process, through the application of MCDA concepts, considering the hypothesis regarding the acquisition of River Fighting Vessels by the BN for application in the riverside operations by MC in the regions of the Amazon.

The PROMETHEE-SAPEVO-M1 method proved to be efficient and effective, from the moment that it made possible a decision analysis composed of multiple criteria, being these of both quantitative and qualitative nature, and presenting an integrated format of results analysis based in three different models. The modeling also showed its robustness in terms of obtaining the weights, presenting a structured and transparent manner, making it possible to identify the criteria of most influence regarding the evaluation of the vessels.

The computational platform applied was of great help for the implementation of the algorithm in the given case, being necessary for the decision-maker to only make the inputs regarding the quantitative data and indicate the importance among the alternatives in the specific criteria. The tool also showed its potential by delivering both the results through numerical and graphical representation, bringing a better visual analysis and identifying the alternative of higher performance in the evaluation.

This work supports the military organizations within the hypothesis of identifying the acquisition of vessels as an effective way of assistance in defense operations in the Amazon region. In future studies, the BN and MC can perform a new evaluation, adding more criteria in search to obtain a more robust assessment and identifying among the possible vessels, which alternative will be more favorable for the acquisition and obtaining the intended efficiency in the Amazon operations.

Abstract. Manufacturing companies seek to achieve product quality combined with waste reduction in the various activities they perform. Thus, the objective of this work was to detect through Quality Tools causes that result in defects in cocoa butter fill activity. The sequence of the steps performed in this research occurred through data collection that covered a period of three months and then information was extracted and analyzed with the aid of tools such as: Check sheet, Cause and Effect Diagram, Pareto Diagram, Control Letters (Letter P), 5 whys and 5W2H. Finally, an action plan was proposed to eliminate the root cause of the identified problems, and for the actions that were implemented, the impact of the same was verified. The results of the actions focused on reducing the occurrences of defects in packaging, and the decrease in the waste of this material is evident. Thus, it was possible to observe the importance of a system for product quality is within expected standards avoiding process losses.

Keywords: Process Improvement, Quality Tools, Cocoa Butter.

1 Introduction

According to the National Association of Cocoa Processing Industries (AIPC, 2020), the average Brazilian cocoa grind for the past three years was 219,498 tons. However, this does not yet reach the installed capacity, which is 275,000 tons. In Brazil, this segment is composed of three large companies, responsible for 97% of the cocoa milling (AIPC, 2020). As it is a commodity, these companies need to guarantee the quality of products, processes and services, in addition to seeking to reduce costs to increase profit margins.

In this context, one of the alternatives for companies in the cocoa milling business to improve their production performance, is the use of managerial techniques, which enable an improvement in the operational performance of their processes.

Thus, this work aims to study the impact of using quality tools, such as Verification Sheet, Cause and Effect Diagram, Pareto Diagram, Control Letters (Letter P), 5 whys and 5W1H, for reduction of waste in a cocoa milling company, resulting from the cocoa butter filling process.

Quality tools are extremely important in the analysis of the conditions of the processes that can influence product quality, employee productivity and financial performance, as found in the survey carried out in more than 100 industrial companies by Brkic et al (2012).
The elimination of losses related to butter packaging results in the economy of resources destined to the process, which can promote reinvestments in the company (new equipment, increased efficiency, artificial intelligence, among others) to improve the speed and volume of the production.

2 Literature review

The term quality is often associated with the level of perfection or the ability to realize a project exactly according to the plan, in this perspective, Paladini (2007) declares that this concept involves several elements with perspectives of innumerable levels of importance and that it is not recommended to strategically focus efforts in just one or disregard any, thus weakening the company in question.
From the point of view of Toledo et al (2014), companies that benefit from the use of statistical tools obtain higher quality and productivity by minimizing the cause of the problems faced. Whether basic or of higher levels, such techniques enable the identification and prioritization of problems, achieving better results than unstructured analytical processes.
Montgomery (2004) points out that there is a need to teach tools to companies in general, so that they can achieve the resolution of statistical problems in the process and thereby achieve the minimization or elimination of losses and, consequently, identifying opportunities and improvements to the process.
For Daychoum (2012), the verification sheets are defined as tables or spreadsheets that aim to facilitate the collection and analysis of data, allowing a visualization mainly of their behavior patterns. Toledo et al (2014) states that from the Pareto Diagram or Analysis it is possible to verify the most relevant aspects to be prioritized over a certain unwanted event that needs to be resolved. And in this way, it allows to dedicate greater efforts and act initially, in the factors that will bring better and more noticeable results.
The control charts allow you to display the statistical control of a given process and the monitoring of its control items according to the location and its dispersion (Werkema 2013). From the point of view of Montgomery (2004), control charts have two general classifications, which are: control charts by variables and control charts by attributes. Still according to the author, this second classification is usual in situations where the quality characteristics do not allow to be quantified or measured on a continuous scale, in this way, conforming or non-conforming products, the existence or absence of attributes or quantify defects in products.
Attribute control charts can be classified into two main types, portrayed by Costa, Epprecht and Carpinetti (2013) as follows:
1. Graphics for the non-conforming fraction (p): they are used to monitor processes that manufacture a certain number of defective items even in cases where special

causes do not occur. From the data collected, according to Montgomery (2004), the control limits calculated are determined considering the standard deviation of the variables as shown in equations (1), (2) and (3). They behave according to the variation of the results due to uncontrolled causes in the process.

$$LSC = \underline{p} + 3\sqrt{\frac{\underline{p}(1-\underline{p})}{n}} \quad (1)$$

$$LC = \underline{p} \quad (2)$$

$$LIC = \underline{p} - 3\sqrt{\frac{\underline{p}(1-\underline{p})}{n}} \quad (3)$$

LSC = upper control limit;
$\overline{p}$ = general mean of the variable;
and LIC = lower control limit.

2. Graphics for number of non-conformities (c): for this model, the graphs are constructed in such a way that the occurrence of non-conformities in samples of constant size follows the Poisson distribution and for that, a large number is required potential opportunities or locations for non-conformities and that the likelihood of a non-compliance occurring in any of these locations is reduced.
The cause and effect diagram, also known as the Ishikawa diagram or "fishbone diagram", according to Simanová (2015), allows the survey and exposure of factors that directly or indirectly influence the investigated process, and can be used in almost all areas of human activity. Mahto and Kumar (2008) complement that the causes must be distributed among six categories entitled as man, machine, environment, materials, management and measures.
The 5 whys tool, for Slack, Chambers and Johnston (2002), is a technique that performs, through the simple questioning "why", the analysis of a given problem considering how it occurred. In Chaves' perspective (2000), this tool contributes to more in-depth analyzes, and for any problem there are numerous questions that determine the 5 whys.
Finally, the 5W2H is a checklist that, according to Oliveira and Tsan Hu (2018), ensures that all perspectives of a problem under study can be addressed. The acronym comes from English words that are: what, who, where, when, why, how and how much.

3 Methodology

To achieve the proposed objective, an action research was carried out in a cocoa processing industry, located in the south of Bahia. Through the chosen method, it was possible to analyze a problem situation, and from the researcher's intervention, verify the change in the behavior of the process, after the interventions performed. The study started with a bibliographic search, with the purpose of forming the theoretical framework that guided the data collection. Data collection covered a period of three months. Observations were carried out from June to August 2019 in which defects in

the cocoa butter filling process were identified. For this purpose, check sheets of the Defect Location Checklist were used to quantify the frequency of occurrences.
The collections were made at the company's inspection area, where the products were destined for storage, at the end of the manufacturing steps. These data were collected twice to scale the problem studied and to visualize the behavior of each sample during this period. From the data collected, a Pareto chart was constructed, which helped in separating special causes from common causes. The collected data were tabulated, and then the Defective Fraction Control Chart (Chart P) was drawn up, which shows the behavior of the 35 samples collected. In which each of these represents 1 pallet with 40 products, that is, there were 35 samples of n = 40. After carrying out the analysis of the causes and carrying out the actions established to solve the main problems, Letter P, of the same structure, was applied again, with the intention of verifying if the variability of the process was reduced, and if the special causes had been eliminated. After prioritizing the defects, using the Pareto diagram, it was possible to use the cause and effect diagram tool to identify the root cause of the problems. This stage counted on the participation of the team responsible for the production of cocoa butter, in an open meeting, it was possible to list the contributing causes for the defects selected as a priority. Subsequently, the 5 (five) whys tool was used in order to determine the symptoms of the problems, showing in more depth what is really causing the irregularity and establishing a countermeasure to reduce the chances of recurrence. For this stage, a meeting was held again with the team of engineers responsible for the process and the gathered information were confirmed by the operation responsible for the sector. Finally, the countermeasures defined with the aid of the previous tool were mapped and activities were carried out to achieve them. For this, the 5W1H tool was used to outline what would be done, who would do what, in what time interval, where it would be applied and all the reasons why the activities should be done.

4 Results

The research was carried out in a multinational cocoa processing factory located in the southern region of Bahia. With an average of 250 direct employees, the company serves the chocolate and cosmetics market in the sale of products such as liquor, powder and cocoa butter. The study kept the focus on the final stages of the butter manufacturing process, illustrated in figure 4, being more specific between the filling sector and the cold chambers, the stage studied does not have automated machinery.

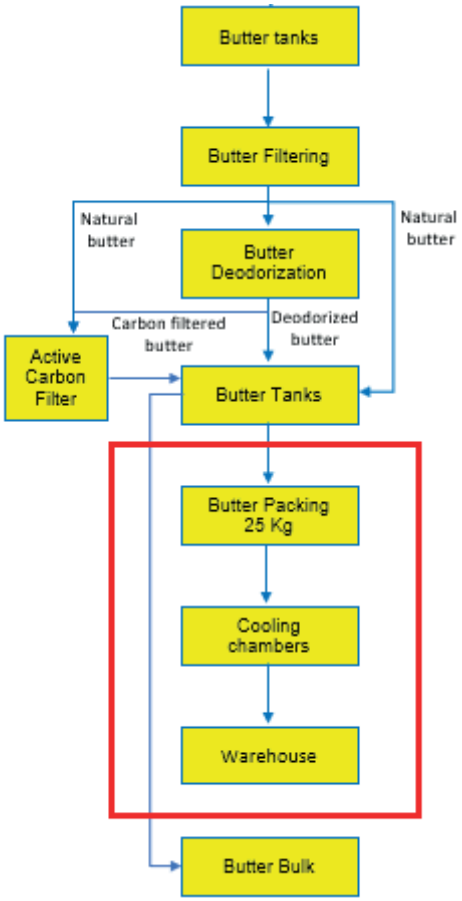

Figure 4. Cocoa butter process after extraction.

From the data collected from the process, a non-conforming fraction graph (p) was constructed, as can be seen in figure 5, and when analyzing the process data, it was found the presence of special causes and high variability in the process -button of butter, which reflects among other things in the cost of this process, since according to Montgomery (2004), the variability of the process directly influences the manufacturing cost.

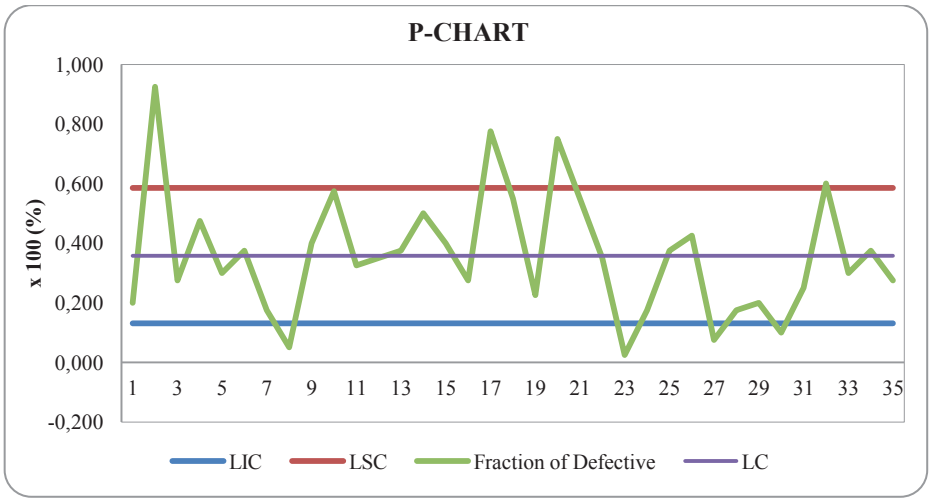

Figure 5. Control chart p of the first collection of defects in packaging (survey data).

The control chart p considered the presence of a defect in a box, that is, it has a defect or not, and only by analyzing this graph it was not possible to identify what the defect was. Thus, in order to verify the main types of defects in the boxes, a pareto chart - figure 6 was elaborated, in which it is possible to observe that the defects "dirty box" and "bulged box represented 90% of the problems, for this reason were chosen to be the object of this study.

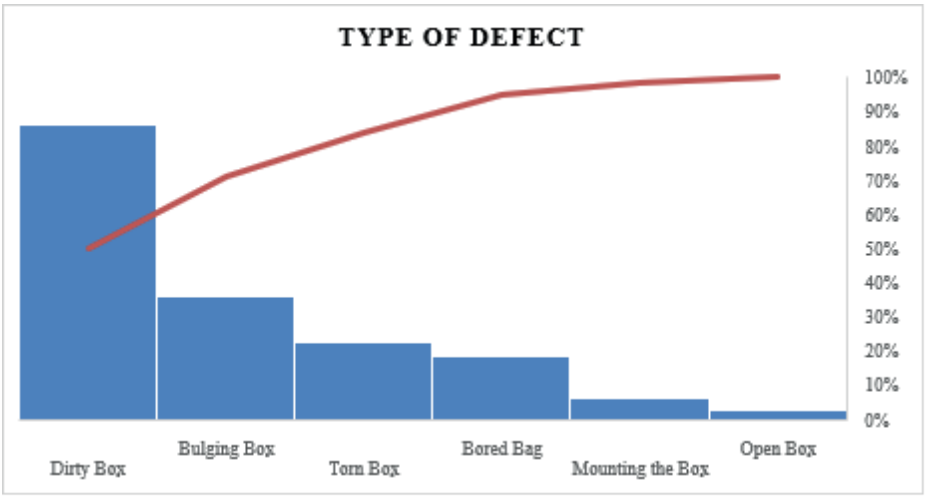

Figure 6. Pareto diagram on types of defects in butter packaging (survey data).

To identify the factors that cause the defects: dirty box and curved box, the Ishikawa Diagram, figures 7 and 8 were used. From the analysis of the result of these diagrams,

it was observed that there were causes that resulted in both defects, as for example the inefficiency of butter tempering. For this reason, these were prioritized since, at first, their resolution should result in the reduction of both problems with the same actions.

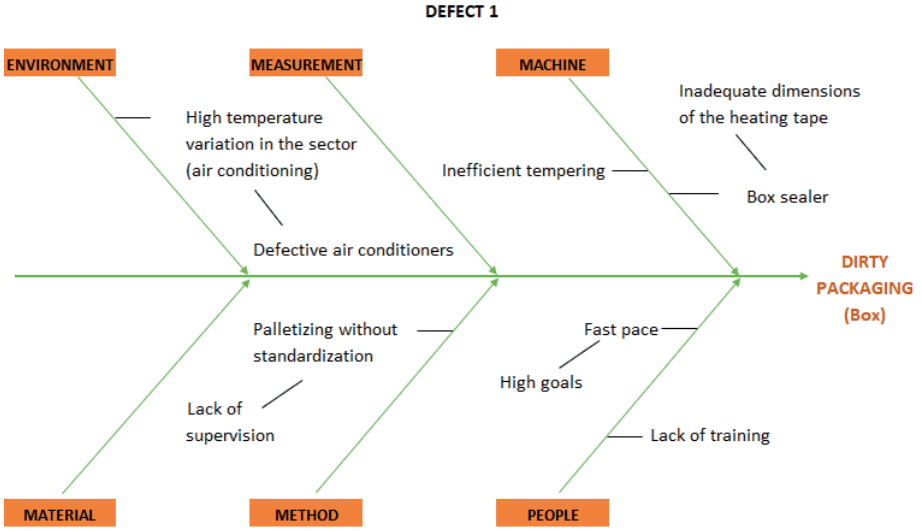

Figure 7. Ishikawa diagram for the defect "Dirty Packaging (Box)" (survey data).

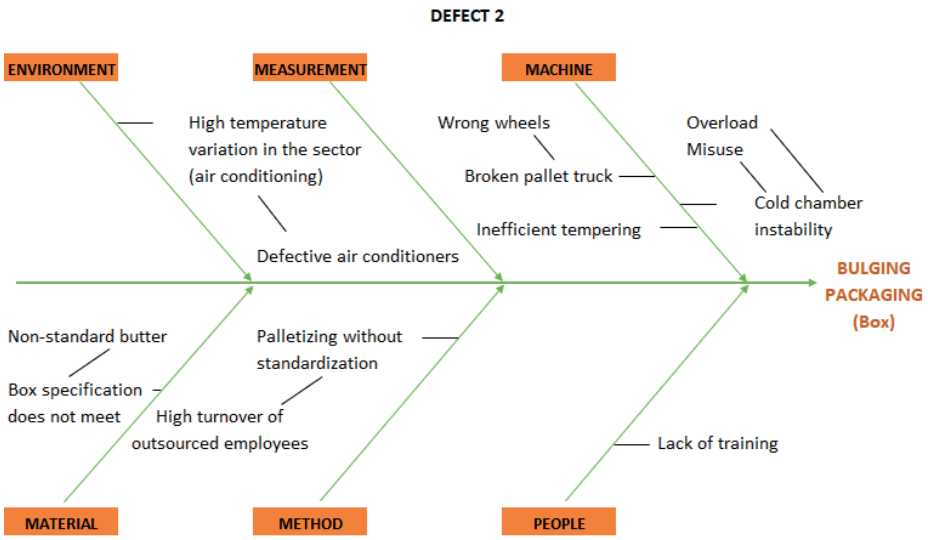

Figure 8. Ishikawa diagram for the defect "Bulk Packing (Box)" (survey data).

After defining the potential causes for the two problems, a structured action plan was drawn up based on the 5W1 H quality tool. For this, all the actions carried out and those that were not carried out were raised, as can be seen in Annex 1. After the im-

plementation of the actions, a new data collection was carried out, in August 2019, to verify their efficiency. A new attribute control chart was built, shown in figure 9.

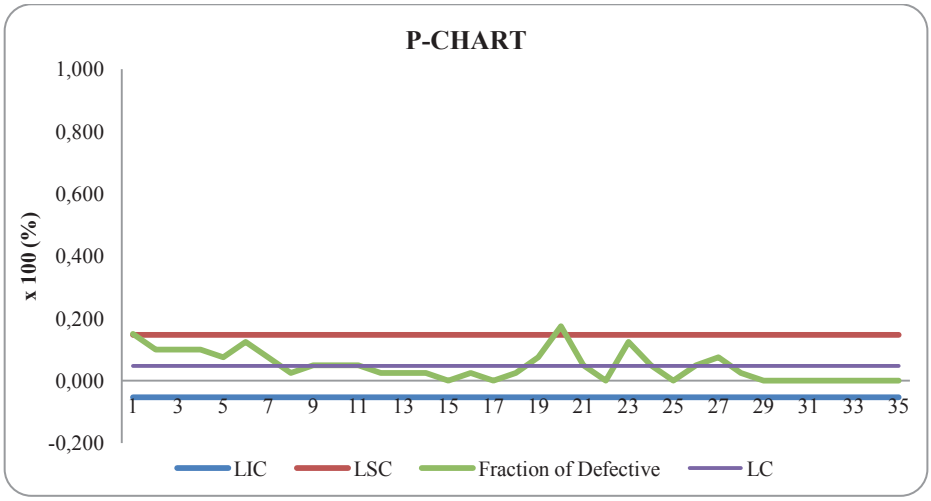

Figure 9. Control chart p for the second collection of defects in packaging (survey data).

As can be seen, there was a reduction in the variability of the process after the application of the actions and with that, the narrowing between the control limits becomes noticeable once the standard deviation has decreased. Although the process showed an improvement, there were still the appearance of special causes due to the defects that were not treated in this research.

The effect of the actions was reflected in the decrease of the number of defects and, consequently, in the reduction of the number of packages that were used in excess in the process of reworking the final product, becoming evident the impact on the waste of this material. An improvement can be seen by differentiating the number of boxes used in the production of the product from those that were stored in the physical packaging condition. In Figure 10, it is possible to check the quantity of boxes wasted in each period for an average of approximately 700 tons produced/month.

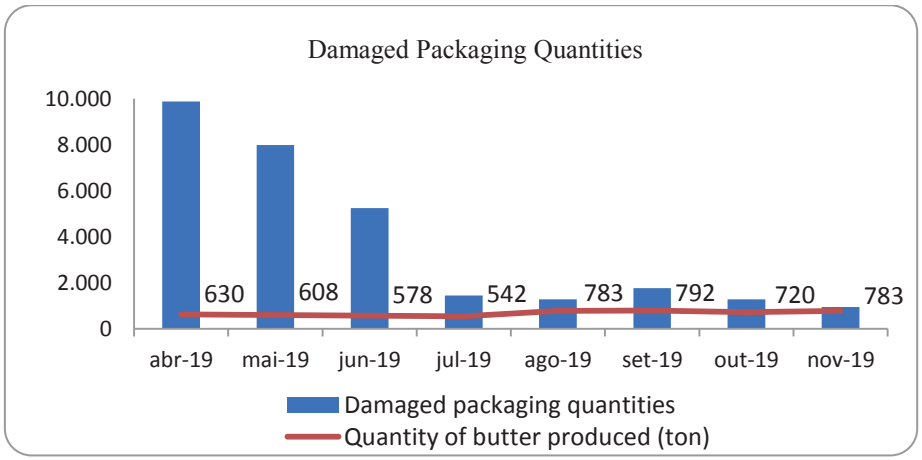

Figure 10. Number of boxes wasted in the company per month (survey data).

The number of damaged boxes was 9875 units before the study was carried out. After the application of certain actions discussed, there was a drop to an average of 1443 wasted boxes, which demonstrates how significant the measures taken were, reflecting directly on the cost of the product, since each box costs $ 0.41.

5 Discussions and conclusions

The purpose of this work was to identify which factors interfere in the filling stage and cause defects in cocoa butter packaging in the filling and inspection sector of a company in southern Bahia. This objective was achieved through the use of Statistical Process Control (CEP) and Quality Tools in the construction of the study.

In this study, it was possible to notice that the filling operation was out of control when detecting special causes in the letter P, referring to the first collection. After carrying out some of the established actions, such as changing the seasoning and the refrigeration system, repairing pallet trucks and others, there were still special causes, showing that this process still has some deficiencies, reflecting the non-elimination of all the root causes of the process, since not all the proposed actions have been carried out.

It is noted that there was a reduction in the causes that led to the occurrence of defects in the filling process, this can be seen in the decrease of this event by approximately 90% when comparing the results from the months of April to November of the year 2019, as shown previously. As a result, the company benefited both in reducing its own costs and also in reducing reprocessing, avoiding excess costs and inconveniences during the manufacturing process.

The use of statistical techniques requires continuous learning combined with knowledge of the process and the effort to implement them, enabling the obtainment of results that contribute to the success of the business. The recurrence of the causes

of quality variability is due to differences or inconsistency in several factors and the control of these causes can be achieved through training, raw material control, preventive maintenance, standard operating procedures and among others.
According to the work developed by Erginel et. al (2011), control charts were used to evaluate data and verify the stability of the cookie packaging process in a food industry in Turkey, which could conclude the existence of a stable process.
The Charter of Control was a fundamental tool, which effectively made it possible to understand and substantiate the decision making that was reflected in course adjustment actions. Such a tool associated with others, seen previously, have shown good results proving the applicability of this type of study to the work of the cocoa processing industry.

Abstract. A transformação digital é um requisito chave para o futuro das organizações, porém, promovê-la é uma tarefa complexa. Neste contexto temos IIoT (*industrial internet of things*) como habilitador para criação de CPS (*cyber physical systems*) e DT (*digital twin*). Este artigo busca na literatura exemplos de arquiteturas, frameworks e estudos de caso referentes a IIoT e compara estas referências a uma pesquisa de campo de implementação de CBM (*condition based maintenance*) em uma máquina CNC. Visto que o número de artigos referente a implementação de IIoT em cenários *brownfield* ainda é pequeno tanto na academia como no meio profissional, este artigo propõe fornecer um mapa orientativo para auxiliar na condução de projetos piloto de IIoT neste cenário. Observa-se uma forte demanda na manufatura para aplicação dos conceitos e tecnologias de IIoT de forma modular e incremental, sendo estes determinantes para o desenvolvimento de maturidade em relação aos requisitos da indústria 4.0.

Keywords: CBM, IIoT, CPS, DT, Brownfield.

Abstract. Digital transformation is a key requirement for the future of organizations, however, promoting it is a complex task. In this context, we have IIoT (industrial internet of things) as the enabler for creating CPS (cyber-physical systems) and DT (digital twin). This paper searches the literature for examples of architectures, frameworks, and IIoT case studies and compares these references with field research regarding CBM implementation (condition-based maintenance) on a CNC machine. Since the number of articles referring to the implementation of IIoT in brownfield scenarios is still small, both in academia and in the professional environment, this paper proposes to provide a guide map to assist in the conduct of IIoT pilot projects in the brownfield scenario. There is a strong demand for manufacturing for the application of IIoT concepts and technologies in a modular and incremental way, and it could be determinants for the development of maturity concerning the requirements of industry 4.0.

Keywords: CBM, IIoT, CPS, DT, Brownfield.

1 Introdução

Originalmente utilizado na Alemanha no ano de 2011 o termo 4ª revolução industrial ou Indústria 4.0 (I4.0) teve como premissa aumentar a produtividade, flexibilidade, interconexão e segurança na cadeia produtiva alemã [1]. No artigo [2] relata-se que em 2013 foi organizado o primeiro grupo de pesquisa para I4.0 onde elaborou-se recomendações iniciais para implementação, sendo elencado três componentes chaves: IoT, CPS e *Smart factory*. Boyes et. al [1] ainda afirma que a *Industrial Internet of Things* (IIoT) é meio pelo qual os objetos no chão de fábrica estabeleçam uma interconexão em uma rede até plataformas computacionais, permitindo habilitar acesso, coleta, análise de dados para tomada de decisões e controle em tempo real.

Em termos de cenários para implementação de IIoT este artigo caracteriza-se pela aplicação em ambiente *brownfield* [3], este termo faz referência a aplicações em instalações já existentes. Este artigo foca no cenário *brownfield*, visto que esta é uma característica de grande parte da manufatura no Brasil. Tem-se como válido, nesta situação, tentar equacionar as mudanças demandadas pela transformação digital às características já existentes na manufatura, como estruturas de *hardware* e *software*, modelos de gestão, cultura organizacional e viabilidade em termos de custo.

No que tange ao contexto de implementações de IIoT, observam-se dificuldades desde a definição de requisitos para infraestrutura de hardware e software escaláveis e adaptáveis ao legado de máquinas, como a falta de convergência da Tecnologia da Automação (TA) e a Tecnologia da Informação (TI), além dos custo para implementação e a justificativa técnica dos projetos [4]. Neste contexto, o artigo tem como objetivo utilizar as referências acadêmicas e iniciativas industriais relacionadas à IIoT, somadas às observações de uma pesquisa de campo como fundamentação para elencar pontos que norteiem projetos pilotos de IIoT. Diante destas considerações apresenta-se a questão problema: Como as organizações poderiam se preparar para implementação de projetos pilotos de IIoT? Para tratar desta problemática o artigo está organizado em 5 seções. Na seção 2 é descrita a metodologia de pesquisa utilizada. Na seção 3 apresenta a revisão da literatura em relação a frameworks e trabalhos de implementação de IIoT na manufatura. Já na seção 4, apresenta-se um mapa orientativo resultante das informações da literatura e observações da pesquisa de campo com foco na implementação de IIoT para CBM em uma máquina CNC. Encerrando o artigo, na seção 5, apresentam-se as considerações finais.

2 Metodologia de Pesquisa

Uma pesquisa bibliográfica foi executada nas plataformas Science Direct, IEEE e Springer, a seleção dos artigos foi executada em duas etapas, pesquisando-se, na primeira etapa, por títulos através da composição dos termos conforme Figura 2. Em segunda etapa foi avaliado o tópico resumo, priorizando artigos com aderência a orientação para aplicação ou estudo de implementação de IIoT em chão de fábrica.

Em acréscimo à revisão da literatura, uma pesquisa de campo foi conduzida de forma a amparar o desenvolvimento de um mapa orientativo, caracterizando assim como uma

pesquisa aplicada, descritiva e de campo. Ilustra-se na Figura 1 a delimitação da pesquisa de campo (linha pontilhada), onde avalia-se a implementação de um sistema IIoT para aquisição de dados de componentes de máquinas, habilitando-se desta forma o primeiro nível da arquitetura 5C de CPS denominado CBM. Ainda na Figura 1 representando o conteúdo de pesquisa deste artigo, somam-se a IIoT e CBM os níveis PHM, CPS da arquitetura 5C e o DT, todos estes tendo como habilitador da interconexão entre camada física e virtual a IIoT.

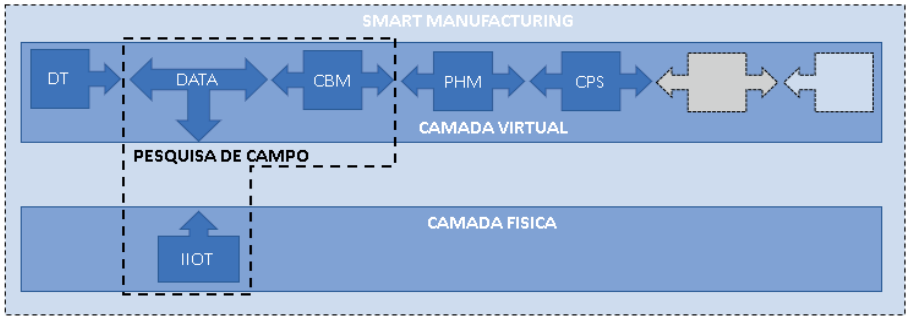

Fig. 1. Principais elementos da pesquisa bibliográfica e de campo (Fonte: Autor)

Destaca-se que o referencial teórico a ser utilizado na construção do mapa orientativo da seção 4 será formado de elementos identificados nos artigos obtidos da pesquisa relativos aos grupos 1, 2 e 3 conforme ilustra Figura 2. Já os elementos identificados nos artigos do grupo 4 serão utilizados para contextualização em relação as técnicas associadas às camadas 1 e 2 da arquitetura 5C de CPS, orientação esta, devido a correlação ao projeto da pesquisa de campo realizado.

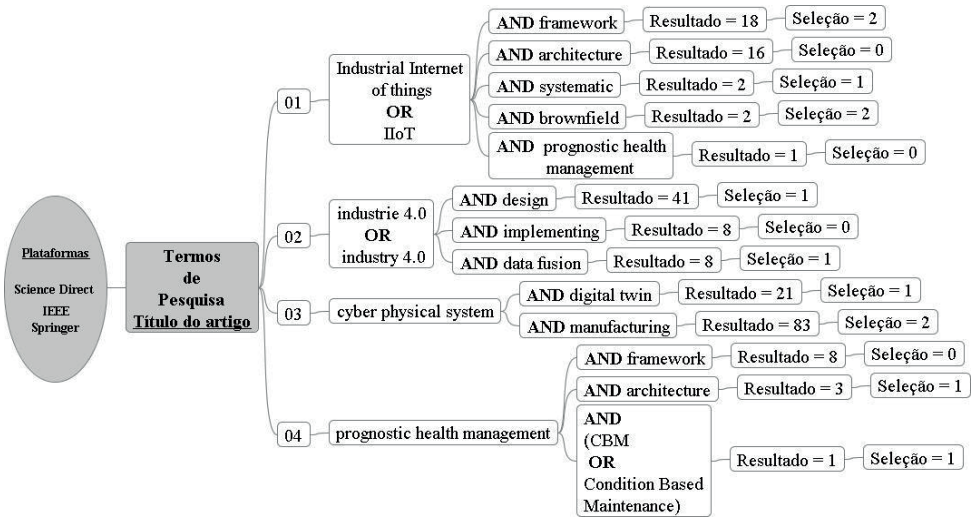

Fig. 2. Composição de termos da pesquisa bibliográfica (Fonte: Autor)

Levantam-se três hipóteses em relação aos aspectos internos do cenário observado que podem dificultar a implementação de projetos de IIoT: (H1) falta de conhecimento estruturado no tocante ao nível de implementação de IIoT; (H2) falta de priorização de projetos de IIoT devido a não comprovação da relação custo e benefício; (H3) falta sinergia entre indústria e academia para pesquisa, desenvolvimento, aplicação e validação de conceitos.

3 Revisão da Literatura

Relacionado ao escopo da IIoT, conforme artigo [2] caracterizam-se alguns princípios da I4.0 como: interconexão, transparência da informação, decisões descentralizadas e assistência técnica. Observando os princípios listados e o cenário Brasil em termos técnicos, ou seja, introdução de novas tecnologias em infraestruturas já existentes, qualificação profissional, matriz de ensino, modelos de gestão, metodologias de trabalho e fatores sócio econômicos, observa-se potenciais oportunidades bem como desafios [4]. Estes se apresentam sob conceitos associados como *Cyber Physical System* (CPS), *Digital Twin* (DT) e *Prognostics and Health Management* (PHM) que definem conceitualmente escopos de iniciativas e aplicações IIoT.

3.1 Iniciativas e Trabalhos Relacionados a IIoT – Pontos Chaves da Bibliografia Selecionada

Os autores [1] apresentam uma revisão da literatura sobre hierarquias para sistemas IIoT e elaboração de um framework. O framework visa orientar a implementação de IIoT, propondo uma infraestrutura dividida em seis categorias principais e suas respectivas subcategorias. Para exemplificar listam-se as seis principais: (i) Setores da indústria, (ii) localização do dispositivo, (iii) Conectividade, (iv) Características funcionais do dispositivo, (v) tecnologia do dispositivo e (vi) usuário.

Já em [4] , os autores apresentam como resultado da revisão da literatura e entrevista com especialistas da área de IIoT, uma proposta de framework, dividido em três categorias principais e sub categorias, conforme segue: (i) Arquitetura de IIoT - subdivide-se em hardware, software, segurança e comunicação, (ii) Implementação - subdivide-se em pré implementação, implementação e pós implementação, (iii) Conhecimento - subdivide-se vantagens, desafios, treinamento e reconhecimento.

No artigo [3] é investigado aplicações de baixo custo de IIoT em cenário brownfield. As principais contribuições identificadas foram a abordagem de custo para projetos, um comparativo entre sete modelos de arquiteturas de IIoT em relação a seis requisitos: (i) ciclo vida do produto, (ii) segurança de dados, (iii) neutralidade, (iv) detalhamento a nível teórico, (v) implementação orientada a nível de detalhe e (vi) recomendações para implementação. Um fato interessante é que apenas a arquitetura *Azure IoT* recebe classificação satisfatória em relação aos requisitos (v) e (vi).

Ainda no artigo [3] apresenta-se um estudo de caso utilizando o framework da metodologia CRISP-DM (*Cross Industry Standard Process for Data Mining*), processo

este divido nas fases de compreensão do negócio, compreensão dos dados, preparação dos dados, modelamento, avaliação e desdobramento.

Sob a ótica de dados e informação, no artigo [5], é apresentado um mapeamento de conceitos, modelos, arquiteturas e frameworks referente a aplicação de *data fusion* na I4.0, e este é definido como uma questão estratégica para processamento dos dados coletados de várias fontes no chão de fábrica. Em termos de definição o autor cita *data fusion* como um processo automático ou semiautomáticos de autodetecção, associação, correlação, estimação de dados e informação de múltiplos canais incluindo as bases do IIoT.

Os autores [6] apresentam uma revisão sistemática da literatura delimitada por quatro questões envolvendo: (i) atores, áreas e local de aplicação, (ii) padrões e tecnologias de comunicação para IIoT, (iii) áreas de IIoT com mais esforços de pesquisas e (iv) principais implementações de IIoT. Do resultado das quatro questões destacam-se: (i) 79,6% dos artigos tem origem em universidades e em maioria concentrados na Europa, Ásia e América do Norte.

Sobre a questão (ii) apresenta-se um estudo comparativo entre o número de artigos que elencam padrões de comunicação versus as camadas de comunicação de rede (*Modelo OSI - Open System Interconnection*) que estes padrões pertencem, (iii) sumariza os esforços de pesquisa em relação as três perspectivas do modelo RAMI 4.0, ressaltando-se a falta de pesquisa sobre as camadas produto, ativo e integração, e finalizando, (iv) é apresentado percentual de artigos de IIoT e I4.0 versus objetivos de desenvolvimento, destaca-se os 3 menores percentuais referente IIoT – pois estes seriam elementares para a aplicação prática de IIoT, estes são organização do trabalho e projeto, treinamento e contínuo desenvolvimento profissional e padrões regulatórios, conforme Figura 3.

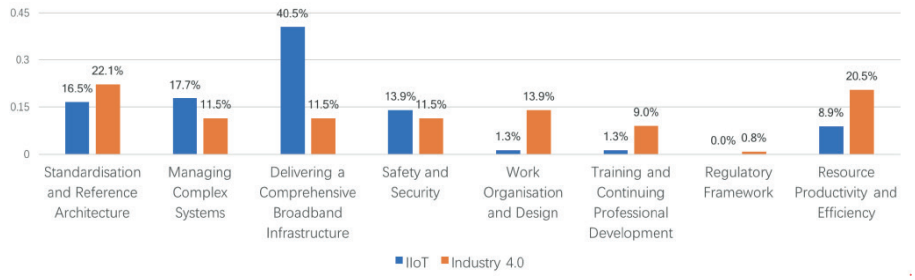

Fig. 3. Comparação entre IIoT e I4.0 e oito áreas de ações prioritárias (Fonte: [6])

3.2 Áreas Correlatas a IIoT – Cyber Physical System (CPS) e Digital Twin (DT), Prognostics and Health Management (PHM)

A contextualização do tema IIoT se ampara em três conceitos com bastante evidência atual – CPS, DT e PHM. Inicia-se com uma breve descrição dos mesmos e na sequência destacam-se as principais contribuições com base em artigos selecionados.

Os CPS's são caracterizados pela integração de sistemas físicos com redes de comunicação e sistemas computacionais onde operações são monitoradas, controladas e

coordenadas. Como exemplo de aplicação tem-se carros autônomos, robôs cirurgiões, fábricas inteligentes entre outros. A arquitetura de CPS é dividida em 5 camadas (5C): conexão inteligente, conversão de dados, cyber, cognição e configuração, [7].

O Digital Twin (DT) também é resultado da integração preconizada pelo CPS, entretanto, tem como objetivo produzir uma versão virtual idêntica ao mundo físico, replicando características físicas, comportamentais e geométricas. O DT tem foco em usar as informações coletadas em tempo real e dados históricos para, por exemplo, desenvolver produtos, modelar e simular cenários, gestão de ciclo de vida de produtos, entre outros. Apesar da similaridade entre o CPS e DT, o CPS tem uma abordagem mais no poder de computação e comunicação com o mundo físico com foco no controle e tomadas de decisão autônomas no processo; já o DT possui uma abordagem relacionada ao uso de modelos matemáticos para simulação e virtualização [8].

Os autores do artigo [7] apresentam o CPS para manufatura no conceito de *Cyber Physical Production System* (CPPS), destacando-se no trabalho uma pesquisa bibliográfica abrangente, uma tabela de convergência entre tecnologias do mundo virtual e físico (tecnologia da informação e automação) e a apresentação da arquitetura 5C demonstrando sequência de implementação de um sistema CPPS. Um compilado de dez estudos de caso de implementação do nível de sensor a rede de produção e cadeia de suprimento é ainda apresentado.

Em [9] apresenta-se as definições e técnicas associadas da arquitetura 5C para CPS em seus cinco níveis na sequência hierárquica de implementação, (i) *smart connection*, (ii) *data information convertion*, (iii) *Cyber*, (iv) *cognition*, (v) *configuration*. Os autores também apresentam um guia de implementação de CPS. Destaca-se que com esta infraestrutura implementada, este sistema permite registro, troca, rastreabilidade, comparação e a adição de conhecimento baseados nos dados monitorados dos elementos conectados à rede via interfaces e algoritmos utilizados no CPS. Outra questão relevante é a abordagem para análise de dados para CPS nomeada "*time machine*".

Sobre "*time machine*" apresenta-s em três seções paralelas, (i) *snapshot machine* para gerenciar a ocupação de espaço e o poder de processamento o armazenamento é executado somente quando ocorre mudanças significativas da máquina ou componente monitorados, (ii) *similarity identification* com o volume de dados das diversas máquina gera-se a probabilidade de identificar padrões de falha em menor intervalo de tempo com a comparação de comportamento de máquinas similares, segundo autores é possível empregar algoritmos de modo a aumentar precisão da predição do estado futuro do sistema monitorado.

E em (iii), apresenta-se *synthesis optimized future steps*, a predição de vida útil remanescente auxilia a estratégia de manutenção além de garantir uso ótimo do ativo. Padrões históricos de máquinas similares em seus estágios de utilização são também úteis para simulações de possíveis cenários de uso futuro. Concluindo [9] elenca-se vantagens de CPS categorizada em três níveis, (i) nível componentes críticos, estes monitorados via sensores provendo dados e convertidos em informação em tempo real, habilitando-se um gêmeo digital do componente que em etapas subsequentes podem favorecer a predição e auto cognição.

Em segundo (ii) a nível máquina como um conjunto de componentes monitorados tornando-se possível criar o gêmeo digital de cada máquina e por fim (iii) a nível de

sistemas de produção com conhecimento agregado de máquinas e componentes monitorados e interconectados, atribui-se características de auto comparação, autoconfiguração e auto manutenção.

Alinhado com a pesquisa de campo sobre IIoT para aplicação em CBM há o conceito da técnica de *Prognostics and Health Management* (PHM), visto que a primeira camada do CPS está relacionada a conexão e ações para monitoramento da condição (CBM) e a camada posterior de conversão com aplicação de PHM para auto reconhecimento. O conceito PHM refere-se ao monitoramento do estado de saúde de componentes de máquina, sendo o processo divido em duas funções - uma de diagnóstico onde a falha é identificada e isolada, e outra de prognóstico onde o modelo é atualizado, determinando-se a vida útil remanescente e ações de correção [10].

Em termos práticos a diferença principal entre CBM e PHM está no processamento e resultados obtidos ao aplicar os métodos; em relação ao consumo de dados as fontes são similares, com coleta dados em tempo real e históricos de componentes, máquinas, processos. No CBM grandezas são monitorados e quando estes atingem os limites pré-estabelecidos é feito diagnóstico e a especificação de ações corretivas,[11]. Já o PHM utiliza-se de modelos matemáticos para, além de identificar e isolar a falha, prever vida útil remanescente do componente e ainda faz uso dos dados para atualizar o modelo matemático [10]

Em [10] o PHM é apresentado em termos de desafios, necessidades, métodos e melhores práticas. Os desafios e necessidades foram agrupados em relação aos tópicos: etapas do PHM (diagnóstico e prognóstico), arquitetura e componentes, negócio e fatores humanos. Sobre os métodos de PHM, cita-se a análise baseada na experiência humana, modelos estatísticos e os híbridos. Em relação as melhores práticas são avaliadas PHM com base nas categorias: avaliação do custo benefício e confiabilidade, requisitos e gestão de dados, técnicas de medição, etapas diagnóstica e prognóstica, teste e o treinamento.

No artigo [12], os autores citam que não há uma definição consistente em termos de arquitetura para PHM, apresentando uma sistemática metodológica para definição de arquitetura de forma a abranger todo ciclo de vida do produto. Como resultado, propõe uma arquitetura genérica que representa o processo macro de PHM na seguinte ordem: aquisição de dados, processamento de dados, avaliação diagnóstica de falha, avaliação prognóstica e gerenciamento da saúde. Adicionalmente esta arquitetura é aplicada em um estudo de caso com o propósito de validação.

4 Iniciativa de Implementação de CBM – Mapa Orientativo

O objeto de estudo é um centro de usinagem CNC, ano de fabricação 1999 que integra uma linha de usinagem em uma indústria do setor automotivo. A arquitetura base da unidade de comando é composta de um CNC da família Siemens 840D com CLP incorporado da série S7 300 da Siemens, tendo-se a troca de sinais nível máquina via ligação ponto a ponto (sem rede). O projeto teve como escopo a implementação de CBM em treze pontos críticos da máquina, distribuídos para o monitoramento das grandezas de vibração, nível e temperatura de óleo hidráulico, consumo do sistema

pneumático, consumo de energia elétrica, temperatura de mancal de rolamento e temperatura do painel elétrico principal. Sumarizando as informações do projeto, apresenta-se o mapa da Figura 4 dividindo as informações levantadas em grupos: contexto, problemas e dificuldades, lições aprendidas e oportunidades.

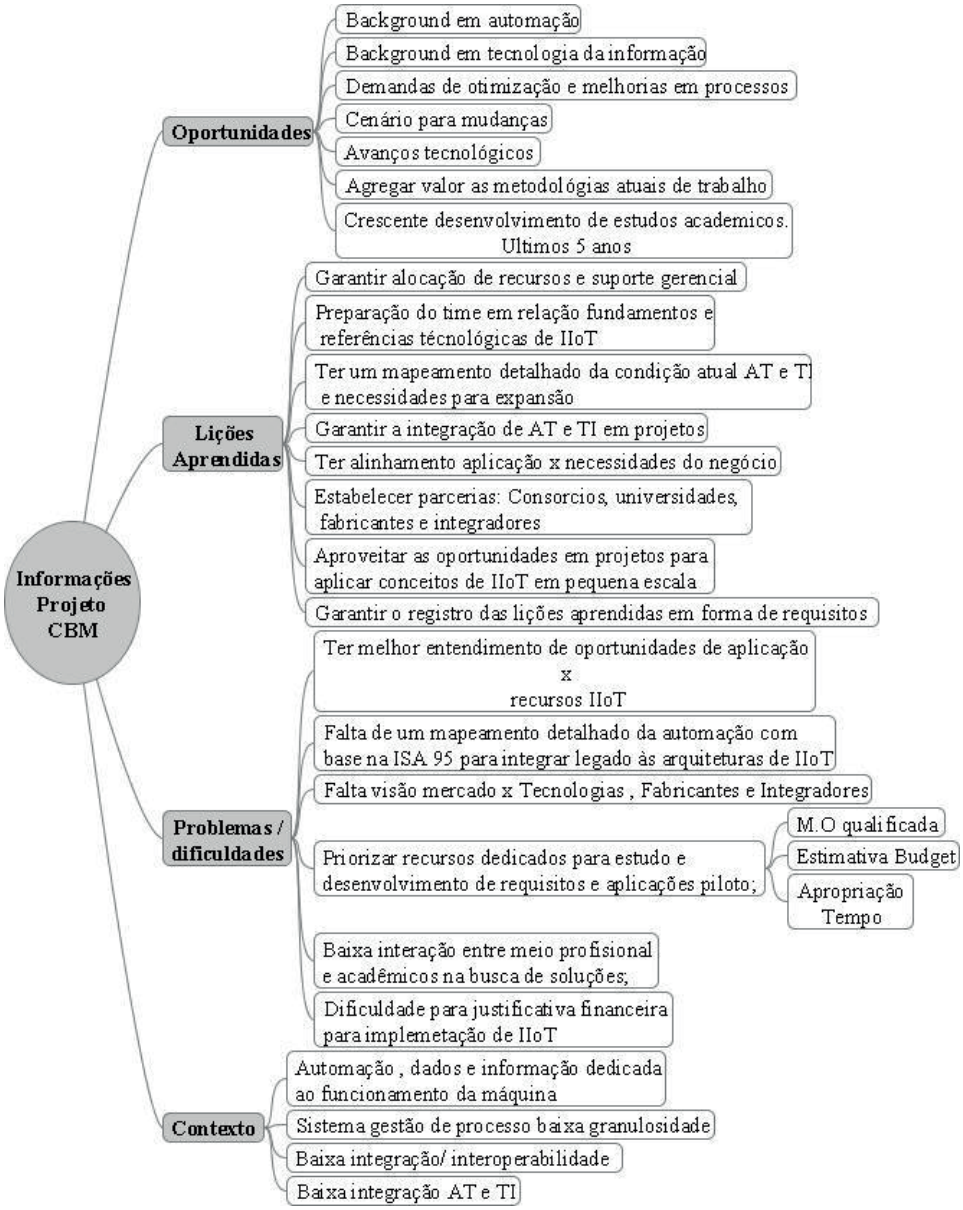

Fig. 4. Informações elencadas das observações do projeto (Fonte: Autor)

Tais informações da pesquisa de campo foram elencadas pelas observações de um dos autores que fez parte do time de implementação do projeto. Com base no compilado de informações do projeto e na revisão da literatura dos grupos 1,2 e 3 da Figura 2, foi elaborado o mapa orientativo da Figura 5 e 6 relacionando os pontos relevantes dos frameworks de IIoT e a arquitetura 5C de CPS. O mapa da figura 5 utiliza-se de insights e parte do framework [4] relacionando as etapas de pré implementação, implementação e pós implementação, bem como a arquitetura 5C de CPS apresentada em [9] e cinco categorias principais do framework de IIoT do artigo [1].

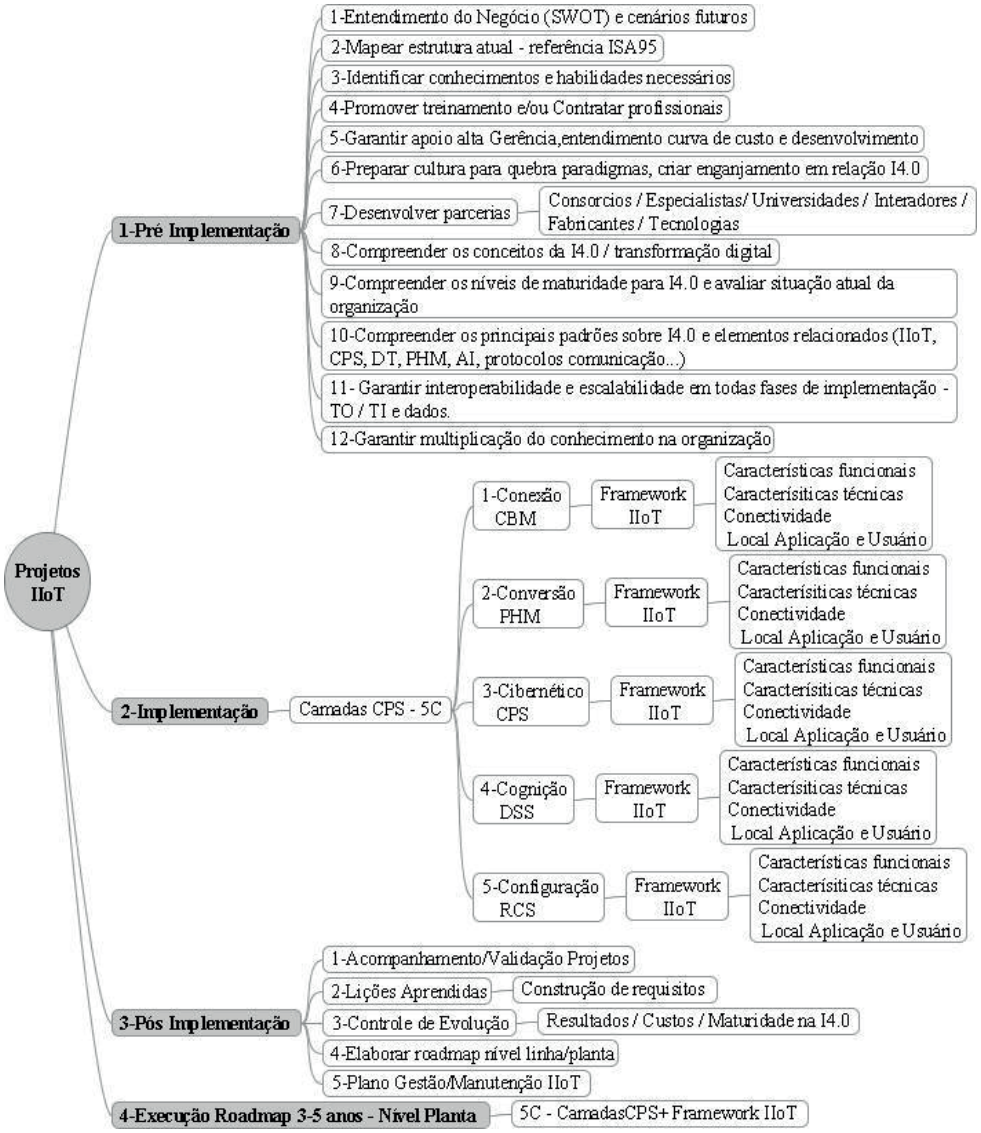

Fig. 5. Mapa orientativo para implementação projetos IIoT (Fonte: Adaptado de [1], [4], [9])

Na figura 6, apresenta-se o mapa unificando as seis categorias principais e o primeiro nível de subcategorias do framework proposto em [1] para detalhamento do componente framework de IIoT na etapa de implementação da Figura 5. Estas Figuras (5 e 6) visam dar suporte à condução de projetos piloto de IIoT em cenários brownfield de forma modular (por camadas CPS) e incremental (pequenos projetos).

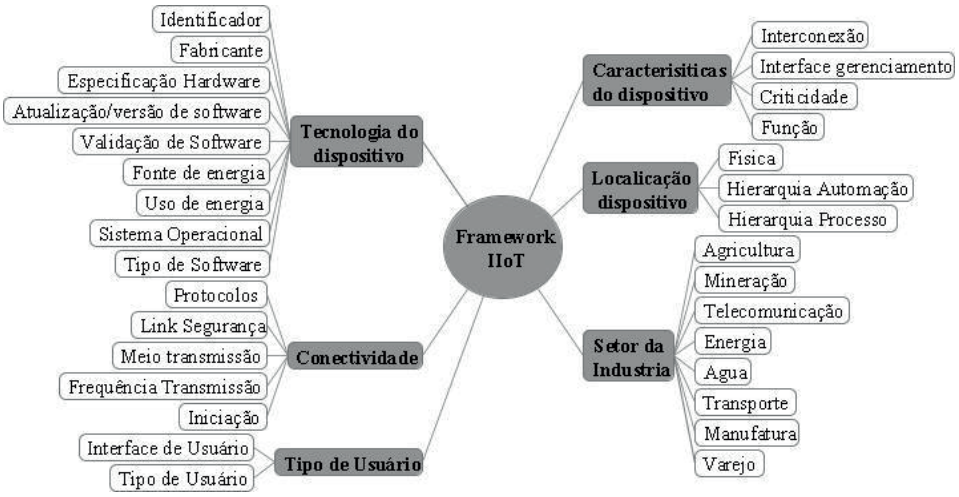

Fig. 6. Detalhamento framework IIoT Figura 5 (Fonte: Adaptado [1])

Conforme a Figura 5, inicia-se com a etapa de pré-implementação ou preparação, destacando-se como um passo essencial para efetiva implementação de projetos IIoT. O foco é preparar a organização em termos de entendimento da situação atual, oportunidades, recursos necessários, mudança cultural e demandas de reestruturação interna, além do desenvolvimento de parcerias.

Na fase de implementação, sugere-se o uso da junção das camadas 5C do sistema CPS e o framework de IIoT como referências para orientar projetos. De acordo com a abrangência do projeto é possível implementar a infraestrutura de IIoT em uma ou mais camadas da arquitetura 5C de CPS. Na arquitetura 5C, na 1ª camada (conexão), o foco é aquisição de dados, do processo, da produção e máquina monitorando, por exemplo, a condição. Na 2ª camada (conversão) o objetivo é aplicar recursos de análise de dados coletados na camada anterior, para identificar padrões, correlações e predição de vida útil remanescente [9].

A 3ª camada (ciber-física) atua como concentrador de todas as informações da rede de máquinas conectadas. A grande massa de dados coletados é processada para extrair informações de valor. Nesta camada, os dados entre máquinas são comparados através de ferramentas de análise e similaridades entre dados em tempo real são processados conduzindo a ações como previsão de comportamento futuro das máquinas [9]. A

correta implementação até a 3ª camada (ciber-física) é de extrema importância para se alcançar resultados efetivos nas 4ª e 5ª camadas.

A 4ª camada (cognição) é onde se aplicam sistemas de suporte a decisão. A partir desta camada a informação é transformada em conhecimento e é apresentado através de infográficos aos especialistas para tomadas de decisão e priorização por exemplo. Na 5ª e última camada (configuração), com base nas decisões da camada anterior, é estabelecido o feedback de ações corretivas e preventivas do mundo virtual para o físico, sendo que tais ações têm foco em autoconfiguração e auto adaptação das máquinas monitoradas [9].

Na Figura 7 apresenta-se uma correlação entre princípios e índice de maturidade da I4.0 e a arquitetura 5C de CPS [13]. Através da figura tem-se uma visão dos princípios para a manufatura atingir o nível de I4.0 (interconexão, transparência, decisão descentralizada e assistência). Atingindo tais princípios alcança-se as capacidades conforme índice de maturidade (computação, conectividade, visibilidade, transparência, predição e adaptação). Com a arquitetura 5C apresenta-se em termos macro os cinco níveis a serem implementados para atender os princípios I4.0 e alcançar as referidas capacidades (Índice de Maturidade 4.0).

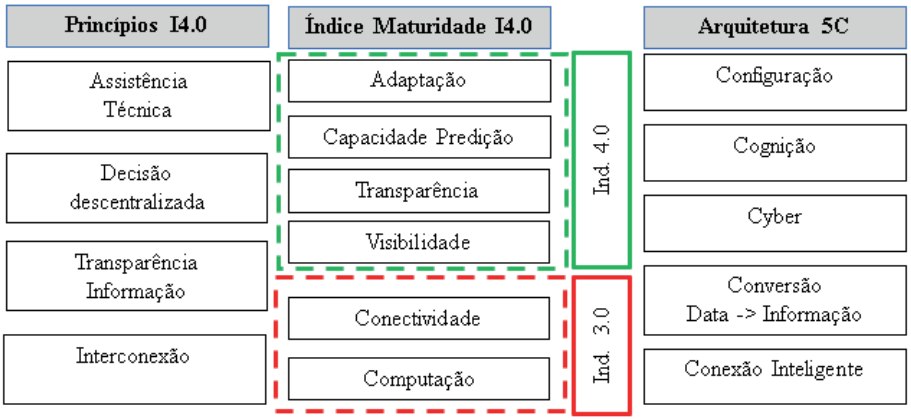

Fig. 7. Comparativo dos Princípios e Índice Maturidade I4.0 e Arquitetura 5C (Fonte: Adaptado [13])

Um fato relevante, conforme observa-se na Figura 7 é que no atual cenário (Industria 3.0) muitas indústrias já possuem parte da jornada iniciada. Outro ponto é que mesmo que não houvesse as necessárias adequações demandadas pela I4.0, ainda assim existiriam projetos relacionados a TA e TI devido a outros fatores, como exemplo, mudança de produto, melhorias para aumento produtividade, segurança e confiabilidade. Somando-se a estes fatos, a possibilidade de parcerias entre academia e profissionais com foco em melhoria e/ou validação de conceitos, frameworks e arquiteturas, caracteriza-se um excelente meio para desenvolver boas práticas na condução de projetos de IIoT e outros relacionados à I4.0 para vantagem competitiva na manufatura.

Concluindo a análise do mapa orientativo (Figuras 5 e 6), a etapa de pós implementação tem o papel de validar, acompanhar resultados e consolidar os conhecimentos

adquiridos através dos projetos pilotos. As informações levantadas atuam como base para definição de requisitos para elaboração de um *roadmap* para projetos de maior escala ou até mesmo de digitalização de toda planta, além de contribuir para aumento de maturidade e mudança cultural dentro das organizações.

5 Considerações Finais

Diante do questionamento em como as organizações poderiam se preparar para implementação de projetos pilotos de IIoT, conclui-se que seria possível alavancar bons desenvolvimentos nos aspectos técnicos, metodológicos e culturais relativos a IIoT. Para tal, sugere-se como base o mapa orientativo proposto nas demandas atuais de projetos dentro da manufatura. Quanto as hipóteses referentes às dificuldades de implementação de IIoT, conclui-se que as três são verdadeiras ao contexto avaliado.

A falta de conhecimento estruturado relativo ao nível de implementação de IIoT dentro das empresas (H1), se confirma devido o atual estágio de amadurecimento no campo de pesquisa e aplicação. No tocante a falta de priorização de projetos de IIoT, devido à dificuldade da avaliação da relação custo e benefício (H2), esta questão se correlaciona a anterior - a falta de entendimento dificulta descrever elementos que justifiquem o retorno sobre investimento e consequentemente uma tomada de decisão gerencial.

Já a falta de sinergia entre indústria e academia para pesquisa, desenvolvimento e aplicações de IIoT (H3), representa uma oportunidade de solução para as duas anteriores, porém envolvem ações nas esferas política, econômica e estratégica tanto do setor público como privado. Ressalta-se que já existem iniciativas em relação a parceiras entre instituições públicas e privadas, mas pode-se acelerar este processo de amadurecimento rumo a transformação digital através de ações mais abrangentes em termos de números participantes, estudos e iniciativas de aplicação.

Abstract. The purpose of this paper is to present a review, along the time, of the concept of supply chain and some elements specifically related to agrifood supply chain, collaboration along them, and how their different configurations can or not, affect the environment. The methodology used was article searching through key words in online journals' databases. Based on the review of 65 articles, a taxonomy is proposed that allows to identify 41 concepts; articles dated between 1985 and 2020. For each decade is possible to identify what are the main themes of discussion. Thus, it is shown that in the beginning of the analysis, supply chain was centered on logistic aspects and movement of materials from a supplier to final customers. In contrast, in the last period analyzed, the concerns are related to collaboration, environment protection and new emerging chains.

Keywords: Cadenas de suministro, Cadenas agroalimentarias, Revisión de literatura.

1 Introducción

El presente artículo muestra la evolución del concepto de cadena de suministro [CdS] y algunas de sus particularidades, como lo son las cadenas de suministro agroalimentarias [CdSA], las redes de cadenas de suministro [RCdS] y la colaboración para finalizar con una revisión de las nuevas tendencias incorporando elementos de sostenibilidad, capacidades dinámicas, CdS emergentes y CdS verdes. Al hablar de CdS, en la literatura es posible encontrar variadas definiciones de CdS, desde aquellas que se refieren a un proceso de carácter funcional a las que se enmarcan en una perspectiva de filosofía empresarial. Algunos autores la vinculan a los procesos que involucran a los proveedores y sus clientes y conectan empresas desde la fuente inicial de materia prima hasta el punto de consumo del producto acabado, así como con las funciones dentro y fuera de una empresa que garantizan el proveer de productos y servicios a sus clientes.

Esta revisión contempla 65 artículos desde el año 1985 al 2020, seleccionados a través de criterios de búsqueda específicos en bases de datos de revistas electrónicas y en buscadores de revistas especializadas. Respecto a los criterios de búsqueda se utilizaron aquellos relacionados a cadena de suministro, cadena de suministro agrícola o agroalimentaria, colaboración en la cadena de suministro, redes de cadenas de suministro, cadenas de suministro y sustentabilidad. El artículo se organiza en cinco apartados, este primer apartado introductorio que entrega la idea de lo que trata el artículo y cómo este se organiza. El segundo apartado entrega el enfoque metodológico bajo el cual se desarrolló el artículo. El apartado tres, desarrolla en extenso la revisión conceptual realizada y es el insumo principal para presentar la taxonomía en el apartado cuatro. Finalmente, el quinto apartado presenta las conclusiones.

2 Metodología

La búsqueda se realizó durante el periodo comprendido entre 2015 y 2020, en bases de datos de revistas electrónicas y en buscadores de revistas especializadas, lo que incluye publicaciones en portales como: Elsevier [www.sciencedirect.com], Emerald [www.emeraldinsight.com], Springer [www.springerlink.com], Academic Journals [http://www.academicjournals.org] , Ebsco [http://www.ebscohost.com], AgEcon [http://ageconsearch.umn.edu], Scielo Brasil [http://www.scielo.br]. Respecto a los criterios de búsqueda se utilizaron aquellos relacionados a industria agroalimentaria, cadena de suministro agrícola, gestión de la cadena de suministro, redes de suministro, colaboración en la CdS y sustentabilidad a lo largo de la misma. Como resultado de la búsqueda, finalmente, se seleccionaron aquellos que cumplen con el requisito de describir comportamiento y configuraciones de CdS, haber sido publicados desde el 1985 en adelante y hasta 2020, generando una base de análisis de 65 artículos. En tanto el alcance y perspectiva de la revisión es de 65 artículos que se distribuyen en un periodo de 35 años y fueron obtenidas en su mayoría de revistas científicas, libros, informes y documentos de trabajo.

3 Revisión de la Literatura

3.1 Cadena de Suministro – CdS

Tal como señala Valenzo, Martínez, y Pedraza [1] el concepto de cadena de suministro se origina en la literatura de la logística [2, 3], donde inicialmente, el énfasis estaba en la facilitación del movimiento del producto y la coordinación de la oferta y la demanda entre un proveedor y un comprador. Al revisar la literatura existente, es posible encontrar variadas definiciones de CdS, desde aquellas que se refieren a un proceso de carácter funcional, aquellas que podrían enmarcarse en la perspectiva de la filosofía empresarial y las últimas tendencias que hablan de cadenas de suministro sustentables o cadenas verdes. En primer lugar, la Asociación para la Gestión de Operaciones (APICS) define en su diccionario el término CdS como: El conjunto de todos los procesos que involucran a los proveedores y sus clientes y conectan empresas desde la fuente inicial

de materia prima hasta el punto de consumo del producto acabado y las funciones dentro y fuera de una empresa que garantizan que la cadena de valor pueda elaborar y proveer de productos y servicios a sus clientes [4].

Lee y Billington [5] señalan que una CdS se comporta como una red de trabajo para las funciones de búsqueda de material, Lummus [6] asume la CdS como una red de entidades por donde el material fluye, teniendo en cuenta que estas entidades pueden ser proveedores, transportistas, fábricas, centros de distribución, comerciantes y clientes finales. Algo parecido es lo que Christopher [7] define como una red de organizaciones relacionadas a través de conexiones en dirección a los proveedores o en dirección contraria hacia la creación de un producto o servicio y lo denomina upstream/aguas arriba y downstream/aguas abajo respectivamente.

Carter, Rogers y Choi [8] desarrollan una teoría sobre la cadena de suministro, aportando con una conceptualización inicial, base para próximos estudios. Ellos plantean que los investigadores de la cadena de suministro han comenzado a moverse más allá del día a día comprador-proveedor y comienzan a observar la red de suministro más que los pequeños nodos de la Red [9, 10]. Por otro lado Janvier-James [11] plantea que existen dos grupos de definiciones: El primero de ellos centrado en conseguir una cadena de suministro eficaz, resaltando la necesidad de tener claridad sobre la procedencia y destino de las mercancías que transitan a lo largo de la cadena de suministro, comenzando desde las materias primas, combinando una serie de actividades de valor añadido y terminando con la transferencia de un bien acabado a los consumidores [12, 13, 14]. El segundo grupo son consideradas por Mentzer et al. [17] como definiciones más complicadas ya que entregan una vista amplia de la CdS y esperan integrar a ella actividades adicionales a la función natural de una CdS [15, 16, 17].

Hace unos años y como resultado de las cadenas de suministro extendidas modernas, ha surgido un nuevo concepto: cadenas de suministro sostenibles o SSCM [del inglés sustainable supply chain management], obligando a cambiar el enfoque de la sostenibilidad corporativa a un enfoque integrado en todas las dimensiones de la cadena de suministro [18] teniendo en cuenta las dimensiones de empresa, medio ambiente y sociedad [19].

El concepto de SSCM se puede definir como la gestión de material, información y los flujos de capital, así como la cooperación entre empresas a lo largo de la cadena de suministro, teniendo como objetivo las tres dimensiones del desarrollo sostenible, que se derivan de los requisitos de los clientes y las partes interesadas [20]. Ahi y Searcy [21] plantean que la sostenibilidad se define comúnmente como la utilización de recursos para satisfacer las necesidades del presente sin comprometer la capacidad de las generaciones futuras para satisfacer sus propias necesidades. Según [22] las primeras iniciativas de sostenibilidad tendieron a centrarse en cuestiones ambientales, pero, con el paso del tiempo, adoptan cada vez más un triple enfoque de fondo: medioambiental, económico y social. Como este enfoque implica un mayor número de factores que interactúan, se puede esperar un mayor grado de complejidad.

3.2 Cadena de Suministro Agroalimentaria - CdSA

Tal como señala Chen [23] en [24] en los últimos años la industria agroalimentaria ha reconocido y abrazado la gestión de la cadena de suministro como concepto clave para su competitividad. La rápida industrialización de la producción agrícola, el oligopolio en el sector de distribución de alimentos, el rápido avance de la tecnología y las comunicaciones aplicadas a la logística, las preocupaciones de los clientes, las normas de seguridad alimentaria del gobierno, las exigencias de calidad, la aparición de alimentos modernos, la creciente importancia de la integración vertical y alianzas horizontales, así como la aparición de una gran cantidad de empresas multinacionales son sólo algunos de los desafíos del mundo real que han llevado a la adopción de la gestión de la cadena de suministro en el sector agroalimentario.

En general, una CdS agroalimentaria se compone de un conjunto de actividades en secuencia, desde "la granja al tenedor", incluyendo la agricultura [es decir, el cultivo de la tierra y la producción de cultivos], procesamiento / producción, los ensayos, envasado, almacenamiento, transporte, distribución y comercialización [25]. Estos escalones operativos son apoyados por actividades logísticas, servicios financieros y técnicos, mientras que sobre ellos mismos circulan cinco tipos de flujo: el material físico y los flujos de productos; los flujos financieros; los flujos de información; flujos de proceso y la energía y los flujos de recursos naturales.

Al revisar la literatura, algunas definiciones presentan la cadena agroalimentaria como aquella referida a toda cadena vertical de actividades, desde la producción en el establecimiento agropecuario, pasando por la etapa de procesamiento y por la distribución mayorista y minorista en otras palabras el espectro completo del cultivo a la mesa, sin importar cómo se organiza o cómo funciona la cadena [26]. En otros casos se utiliza para abarcar el continuum de procesos económicos vinculados a los alimentos, que se inician en la explotación agropecuaria y culminan en el consumo [27]. Para Fischer et al. [28] los consumidores cada día son más exigentes y esperan que la comida sea de alta calidad en términos de atributos físicos, las características del proceso de elaboración y aspectos sociales como el bienestar de los animales, el comercio justo y la gestión ambiental. Por tanto abordar estas necesidades de los consumidores exige una mayor coordinación de acciones de las empresas de toda la cadena [29, 30].

Las CdS agroalimentarias están evolucionando rápidamente en el tiempo con el fin de seguir los cambios agroalimentarios, siendo los mayores desafíos: la rápida urbanización, el crecimiento de los mercados, la financiación del sector, las preocupaciones por obtener alimentos de alta calidad y seguridad alimentaria, las poblaciones rurales regionales que no cumplen con los requisitos planteados por las empresas dominantes del sector, los efectos del cambio climático en la agricultura y el establecimiento de responsabilidad social empresarial (RSE). Por lo tanto, el reconocimiento de los problemas críticos que deben ser abordados por los interesados en las CdS Agroalimentaria surge como un requisito previo para la gestión de tales cadenas, a todo nivel, y así garantizar su eficiencia y sostenibilidad en general [24].

Handayati, Simatupang y Perdana [31], señalan que los productos agrícolas tienen un papel importante en la economía mundial, además la cadena de suministro de productos agrícolas se ha convertido en un tema candente porque los consumidores cada vez son más conscientes y preocupados por la disponibilidad y la inocuidad de los alimentos que se consumen [32]. Ellos exigen disponer de más información no sólo sobre la disponibilidad de un producto en los supermercados, sino también sobre sus actividades de producción, comercialización, distribución, transporte y transformación [33] y desarrollan un comportamiento cambiante porque ya saben lo que necesitan y qué valor esperan del producto que compran, por lo tanto es importante para una empresa facilitar este tipo de creación de valor.

3.3 Red Cadena de Suministro – RCdS

Es posible observar que la evolución del concepto de CdS ha sido tal que es posible hablar de Red/CdS, haciendo la siguiente distinción: se considera como CdS aquélla que sea lineal y unidireccional, sin embargo una red de suministro no es más que una CdS con bucles, relaciones laterales, intercambios, de material e información, en ambos sentidos, teniendo a la empresa focal como punto de referencia [34]. Algunos autores postulan, que es posible denominar como red de suministro a la gigantesca cantidad de interconexiones que se desarrollan como resultado de las interacciones entre los nodos de la CdS, tal como lo presentó García [35] o lo que se le denomina red de suministro en el enfoque de sistemas de medición del rendimiento que se presentó Alfaro, Ortíz y Rodríguez [36].

Sin embargo son Lamming et al. [34] quienes platean una primera clasificación de las redes de suministro y para ello establecieron que una Red de Suministro [RdS] es una extensión de las CdS, que buscan proporcionar y explicar la complejidad comercial asociada con la creación y despacho de productos y servicios de la fuente de materiales hasta el destino final o mercado cliente, alrededor de las actividades aguas arriba y aguas debajo de una empresa focal como punto de referencia [37]. Por tanto, al considerar según la definición de [34] la RdS como una extensión de la CdS surge un nuevo concepto a revisar, el enfoque de colaboración. En definitiva, se requiere un alto nivel de integración en la cadena de suministro; sin embargo no es suficiente para alcanzar el máximo nivel de competitividad y crecimiento de la industria: se necesitan nuevos modelos inter-empresariales que hagan a las empresas todavía más competitivas, ágiles y eficientes [38]. Barratt [39] plantea que para comprender el significado de la colaboración a lo largo de la CdS es necesario responder tres preguntas: ¿Por qué necesitamos colaborar?; ¿Dónde podemos colaborar?; ¿Con quién debemos colaborar? y a la vez ser capaces de reconocer los elementos presentes en la colaboración.

Actualmente, no se pone en duda que la CdS es clave y vital para el éxito de las empresas. En muchos casos, su capacidad de competir se ha vinculado directamente con su capacidad de colaborar con otras empresas. Muchos escritores [40, 41, 42, 43, 44, 45] han reconocido un aumento en la necesidad de colaboración, haciendo hincapié

en el establecimiento de relaciones de trabajo más estrechas y a largo plazo, incluso en varios niveles de la cadena como una forma de construir cadenas cada vez más eficientes para ofrecer un valor excepcional a los clientes [46] convirtiéndose para muchas empresas en una necesidad, más que una opción.

Sin embargo, la colaboración en la cadena de suministro no siempre es fácil de lograr, incluso cuando las restricciones de comunicación del pasado, con respecto al intercambios de datos y de información eficiente entre los miembros de la cadena, han sido superados con el uso de tecnología y el desarrollo de aplicaciones e-business [46]. Es claro que existe una gran cantidad de beneficios asociados a la colaboración en la CdS. Una primera aproximación, para visualizar estos beneficios, es a nivel macro pensando en la reducción de costos totales o el aumento de los ingresos [47], pero de igual forma existen riesgos, tal como lo señalan Dwyer, Schurr, y Oh [48], el más obvio es el fracaso en el intento de colaboración, lo que lleva consigo la pérdida de importantes inversiones en dinero, tiempo y retraso o abandono de los planes de negocio, además un riesgo inherente al fracaso es la exposición a la competencia.

Para Saleh y Roslin [49] la aparición de esta competencia ha aumentado la necesidad de que las empresas a lo largo de toda la cadena de suministro cooperen, coordinen, colaboren e integren esfuerzos, para generar un alto valor de retorno a todos los participantes de la cadena de suministro. Aun cuando lo anterior es un escenario ideal, la realidad muestra que los resultados de la integración de la CdS [SCI] no han sido exitosos en la mayoría de los casos, debido a la incapacidad de las empresas de colaborar con los socios de la cadena de suministro de manera eficaz y eficiente.

3.4 Nuevas Tendencias en la CdS

Pérdidas y desperdicios. Las pérdidas o desperdicios de alimentos son las cantidades de material comestible que se pierden a lo largo de la CdS de alimentos en diversas etapas, incluida la recolección, el almacenamiento postcosecha y la manipulación, procesamiento, distribución y consumo [50]. Teniendo en cuenta lo anterior, Balaji y Arshinder [51] señalan que el desperdicio a lo largo de las cadenas de frutas y hortalizas es muy alto en mercados emergentes, por tanto identifican 16 grandes causas de este desperdicio lo que permite a los diseñadores de CdS, gerentes y diseñadores de política pública tener mayores implicaciones en la seguridad alimentaria y la conservación de los recursos ambientales. Algunas de estas causas son: Falta de instalaciones frigoríficas, falta de métodos científicos de aprovechamiento, infraestructura logística deficiente, diseño pobre de la red logística, falta de métodos modernos de procesamiento y falta de diseño y métodos modernos de embalaje.

Cadenas de Suministro Emergentes. Anastasiadis y Poole [52] plantean que en gran medida, el concepto de desarrollo de North [53] coincide con la mejora creciente en la estructura y el comportamiento del mercado, produciendo nuevos cambios. Estos cambios, como lo que plantean Lorentz, Kittipanya-ngam y Srai [54] señalan el caso de

empresas en "mercados avanzados" que expandían sus operaciones hacia "mercados emergentes" para entender cómo las características de los mercados emergentes afectan las redes de suministro de cadenas de alimentos de empresas internacionales. Entre los hallazgos de [54] destacan la importancia, en primer lugar, de las instituciones y estructuras y, en segundo lugar, de las estrategias de los actores del mercado primario y secundario, para posibilitar la formación de nuevas CdS y redes de suministro. Detectando cuatro factores que afectan la aparición de CdS: La estructura propia de las cadenas y la capacidad de sus actores; Control de la calidad de los bienes y servicios; Infraestructura y procesos para administrar nuevos productos; Y la importancia de la configuración geográfica de las redes de suministro, pensando en la internacionalización de estas cadenas.

Por lo general, la estrategia de una empresa se formula a nivel de la alta dirección y luego se aplica en toda la organización. Sin embargo, las pequeñas y medianas empresas o empresas familiares, como el caso de la industria alimentaria en las economías emergentes, dependen en gran medida de un único decisor [55]. Incluso en el sector agrícola donde están surgiendo nuevas estrategias empresariales colectivas, la naturaleza de estas organizaciones genera problemas de toma de decisiones debido a las diversas preocupaciones de su base social [56]. Aspectos como la confianza del propietario con respecto a los miembros de la red de suministro [57] y la calidad de las relaciones entre los participantes de la CdS [58] son de vital importancia.

Cadenas de Suministro y Capacidades Dinámicas. Junto al estudio de la SSCM, Beske, Land y Seuring [59] ponen atención a un nuevo concepto denominado capacidades dinámicas [DC] examinando ambientes e industrias dinámicamente muy cambiantes como el caso de la industria alimentaria, en la cual los clientes tienen altas expectativas de seguridad alimentaria y una creciente demanda de alimentos producidos de manera sostenible. Las capacidades dinámicas fueron estudiadas primero por Teece, Pisano y Shuen [60] para explicar la ventaja competitiva y el rendimiento a alta velocidad frente al cambio dinámico de los mercados. Helfat et al. [61] definen las capacidades dinámicas como la capacidad de una organización para crear, extender o modificar deliberadamente su base de recursos y como tal mejorar la evaluación económica otorgada por sus competidores. Siguiendo las definiciones de [61], Beske et al. [59] plantean que las prácticas propuestas en la SSCM forman la base para desarrollar capacidades dinámicas, debido los distintos cambios que enfrentan las CdS [por ejemplo: manejo de los proveedores cuando cambian las condiciones en el entorno, incorporar todos los objetivos corporativos de responsabilidad social].

Mejora del Medio Ambiente a Través de la Colaboración de la Cadena de Suministro. La selección de proveedores adecuados de acuerdo con los criterios para la gestión de cadenas de suministro verdes, es crucial para las empresas en la lucha contra la contaminación y el cuidado del medioambiente [62]. Esta idea es validada, años más tarde, por Chavez et al. [63] quienes hacen hincapié en la necesidad de cooperar y colaborar a lo largo de toda la cadena, buscando la mejora del impacto sobre el

medioambiente y junto con ello un mejor desempeño económico. Por otro lado, en el 2010 Bai y Sarkis [64], sostenían que la selección de proveedores adecuados juega un papel crucial en GSCM ya que se transforma en una herramienta de apoyo al momento de seleccionar los mejores proveedores de acuerdo con criterios ambientales. Por lo tanto, se puede decir que, según muchos investigadores, la colaboración con los proveedores juega un papel crucial en la implementación exitosa de GSCM. Finalmente, los proveedores desempeñan un papel fundamental, en la gestión de la CdS verde, ya sea en las fases iniciales como en las finales, logrando a través de la logística crear el vínculo entre proveedores, clientes y empresas focales, quienes bajo un mismo enfoque de gestión de cadenas de suministro verdes, aportan a la mejora del medioambiente [65].

4 Taxonomía

La siguiente taxonomía muestra cómo a lo largo del tiempo el concepto de cadena de suministro ha ido cambiando y se le han ido integrando elementos propios de un mundo globalizado. En este caso en particular se hace una exploración a las cadenas de suministro agroalimentarias, como un tipo particular de cadenas de suministro que cumplen con abastecer a todo el mundo de alimentos frescos desde la granja a la mesa.

El análisis realizado, permite observar en la última mitad de los 80's, conceptos que hacen referencia a vincular la CdS a la logística y el movimiento de productos, apareciendo incipientemente los conceptos de sustentabilidad, medio ambiente y la colaboración a lo largo de la cadena. Conceptos como la necesidad de colaborar, establecer relaciones a largo plazo y estables entre las entidades presentes se observan en los 90´s, al mismo tiempo se reconoce que colaborar también tiene dificultades, incipientemente aparecen los conceptos de capacidades dinámicas de adaptación. En los 00's se refuerza lo que venía ocurriendo en los 90´s respecto a la colaboración, pero se comienza a visualizar la CdS como una red de cadenas, que son capaces de competir de forma conjunta, colaborando y gestionando de forma sostenible. Finalmente en la década del 2010, se incorporan los conceptos de cuidar la pérdida de productos, los mercados emergentes y quién toma las decisiones a lo largo de la CdS.

Id	Año	Autor	Logística	Movimiento de productos	Procesos que conectan productos y clientes	Red de trabajo	Red de entidades	Red de organizaciones	Conexión con proveedores	Cadena como una Red	CdS eficaz	CdS realiza otras actividades	CdS Sostenible	Gestión de material información Y los flujos de capital	Cooperación entre empresas	Satisfacer necesidades presentes sin comprometer el futuro	Medioambiental económico y social	Gestión de la CdS para la competitividad	Reconocer problemas típicos en la CdS	Actividades en secuencia	Producción hasta el consumo	Necesidad de coordinación	Consumidores exigentes	Red de suministro	Complejidad comercial a lo largo de la CdS	Necesidad de colaboración	Relaciones de trabajo más estrechas	Relaciones de largo plazo	Dificultades de la colaboración	Reducción de costos	Aumento de ingresos	Riesgos de la colaboración	Fracaso en el intento de colaborar	La competitividad requiere cooperar, coordinar y colaborar	Cuidar las pérdidas de alimentos en las CdSA	Nuevos mercados afectan las redes de suministro	Dificultad por un único decidor	Se requiere confianza del decidor hacia la CdS	Calidad de las relaciones entre los participantes de la CdS	Capacidades dinámicas de la CdS	Ventaja competitiva y rendimiento	Capacidad para crear, extender o modificar sus recursos	Proveedores responsables con el medio ambiente	Crear el vínculo entre proveedores, clientes y empresas locales

Fig. 1. Taxonomía de conceptos cadena de suministro a lo largo del tiempo, elaboración propia.

5 Conclusiones

El estudio de las cadenas de suministro, a lo largo del tiempo, ha ido tomando fuerza porque permite describir la forma en que todos los productos o servicios llegan a los consumidores. Inicialmente se vinculaba mucho con la logística y el flujo de materiales desde un proveedor al consumidor, pasando por el distribuidor, actualmente esa visión ha cambiado y el estudio de CdS se amplía a estudiar cómo estas cadenas se configuran, quiénes forman parte de ella y que entidades la componen, cómo se relacionan y quién toma las decisiones. El estudio de cadenas perecederas y en especial las agroalimentarias, en los últimos años sitúa al consumidor como actor principal, muy informado y exigente, preocupado de la pérdida de alimentos y la producción sustentable sin dañar el medio ambiente.

El presente review, permite conocer cómo este concepto ha ido cambiando en el tiempo y se le han ido incorporando distintas variables que hacen más complejo su estudio. En primer lugar, entender que las CdS no son empresas individuales, sino una red de colaboración que en conjunto debe competir contra otra red de suministro y para ganar esa competencia y lograr situarse como líder del mercado es importante configurar una cadena flexible, eficaz y moderna, que esté atenta a los cambios del entorno, a la incorporación de tecnología y a la constante mejora de sus procesos que fluyen a lo largo de ella.

Abstract. Organizations all over the world are going through the process of digital transformation. Enterprise Architecture (EA) is a method and an organizing principle that aligns functional business objectives and strategies with an IT strategy and execution plan. The Enterprise Architecture provides a guide to direct the evolution and transformation of enterprises with technology. Principles are a key concept in the definition of EA, they assist in recognizing the organization vision and validating the outcomes. The aim of this paper is to develop a decision model to evaluate the influence Digital Transformation (DT) technologies have on the architecture principles proposed by TOGAF. A literature review was conducted, and five main DT Technologies applied in the EA scope were identified. With that, a decisional model was created based on a decision-making method called PROMETHEE. The twenty-one architecture principles proposed by TOGAF were evaluated and the influence the technologies exercised on the principles were identified. As a result, Big Data and Cloud Computing technologies were indicated as having the greatest effect over the analyzed principles.

Keywords: Enterprise Architecture; Architecture Principles; TOGAF; Digital Transformation; Technologies.

1 Introdução

As organizações no mundo todo estão passando pelo processo de transformação digital. De acordo com Nightingale e Rhodes [22], empresas são sistemas complexos e altamente integrados, compostos por processos, organizações, informações e tecnologias de suporte, com interdependências multifacetadas e inter-relações além de suas fronteiras. A compreensão, a engenharia e a gestão dessas complexas dimensões sociais, técnicas e de infraestrutura são fundamentais para alcançar e sustentar o desempenho das empresas [22]. A fim de fornecer esse suporte e atacar o problema de alinhamento de negócios/TI, a Arquitetura Empresarial (AE) surgiu. Adotando uma abordagem holística, a AE foca não apenas nos aspectos técnicos, mas também nos

vários aspectos da empresa sobre os quais os sistemas de tecnologia da informação (TI) operam [3].

A arquitetura empresarial (AE) é um método e um princípio organizador que alinha objetivos e estratégias funcionais de negócios a uma estratégia de TI e plano de execução. A arquitetura corporativa fornece um guia para direcionar a evolução e transformação das empresas com tecnologia. Isso, por sua vez, torna a TI um ativo mais estratégico para implementar com sucesso uma estratégia de negócios moderna [13].

De acordo com Proença e Borbinha [24], a literatura atual da AE mostra foco no refinamento dos métodos existentes. Um ponto fraco é a atenção para os desafios decorrentes da aplicação de conceitos de AE em ambientes organizacionais específicos. Ainda não existem instrumentos adequados para avaliar o estado atual e identificar oportunidades de melhoria. Com isso, organizações tem enfrentado dificuldades em iniciar melhorias nos procedimentos de gestão da AE.

Kempegowda e Chaczko [15] afirmam que os princípios de arquitetura ajudam na obtenção da visão da organização e na validação dos resultados. Dá à equipe a capacidade de decidir durante a execução da estrutura do AE. Ele também fornece Governança para verificar e auditar a implementação do AE. Os princípios são um conceito-chave na definição de AE [11] e auxiliam na realização da visão da organização e na validação dos resultados. Eles dão a equipe a capacidade de decisão durante a execução da estrutura da AE. Além disso, fornece governança para verificar e auditar a implementação da AE. É fundamental que as empresas definam princípios que serão utilizados pelos Arquitetos para a tomada de decisões diárias [15].

O objetivo deste artigo é apresentar um modelo de decisão para avaliar os impactos das tecnologias de transformação digital sob os princípios de arquitetura propostos pelo TOGAF. A primeira seção contempla a introdução e os objetivos de pesquisa. Na segunda seção os conceitos teóricos que fundamentam o desenvolvimento deste trabalho são apresentados. A terceira seção contempla a estratégia de pesquisa abordada e em seguida, na quarta seção os resultados obtidos são apresentados. Por fim, a quinta seção traz as conclusões e discussões dos resultados obtidos.

2 Revisão de Literatura

2.1 Arquitetura Empresarial (AE)

A arquitetura empresarial (AE) representa a estrutura de uma empresa e consiste nos principais componentes de uma organização, tais como seus objetivos, estruturas organizacionais, infraestrutura de informações e processos de negócio. Essa arquitetura ajuda a organização ao determinar como a mesma pode atingir, de maneira efetiva, seus objetivos atuais e futuros. A performance de uma empresa, como as inovações geradas dentro da companhia, a reengenharia dos processos de negócio, e a qualidade e prontidão do fluxo de informações, podem ser melhoradas se o sistema de AE representar fielmente as características e natureza da organização [36]. De acordo com Korhonen e Halén [16], AE vem sendo sugerida como uma disciplina para assegurar uma estrutura coerente, tornar visível o sistema organizacional subjacente e para facilitar possíveis mudanças.

Atualmente, existem vários frameworks de arquitetura empresarial que podem ser usadas por organizações ou empresas de acordo com suas necessidades. Dentre os padrões existentes, quatro deles se destacam: Zachman Framework, Gartner Framework, Federal Enterprise Architecture Framework (FEAF) e The Open Group Architecture Framework (TOGAF) [26].

TOGAF é um padrão de arquitetura empresarial aberto e abrangente que contém diversos componentes, dentre os quais, o Architecture Development Method (ADM) se destaca, sendo o núcleo do TOGAF. O ADM descreve um processo iterativo para o desenvolvimento da AE, com a ajuda de diversas fases (Fase Preliminar, Visão de Arquitetura, Negócios, Sistemas de Informação, Tecnologia, Oportunidades e Soluções, Planejamento de Migração, Governança de Implementação, Gerenciamento de Mudanças na Arquitetura, Gerenciamento de Requisitos).

Quatro domínios de arquitetura são cobertos pelo TOGAF: a) Arquitetura de Negócios, b) Arquitetura de Dados, c) Arquitetura de Aplicativos e d) Arquitetura de Tecnologia. Estes domínios são frequentemente aceitos como subconjuntos do todo da arquitetura empresarial [31]. O framework TOGAF, um padrão do The Open Group, é uma metodologia e estrutura comercialmente consolidada de arquitetura empresarial usada pelas principais organizações mundiais visando o aumento da eficácia dos negócios [30].

O Zachman framework para Arquitetura Empresarial publicado por John Zachman em 1987 e é considerado um dos pioneiros nesse domínio [12]. O Framework é baseado nos princípios da arquitetura clássica que estabelecem um vocabulário comum e um conjunto de perspectivas para descrever sistemas empresariais complexos [32]. O Zachman Framework possui seis perspectivas: Planejador, Proprietário, Designer, Construtor, Subcontratado e Usuário. A segunda dimensão do framework lida com as seis perguntas básicas: o que, como, onde, quem, quando e por que. A estrutura não fornece orientação sobre sequência, processo ou implementação, mas se concentra em garantir que todas as visualizações sejam bem estabelecidas, garantindo um sistema completo, independentemente da ordem em que foram estabelecidas [37].

O Gartner define a AE como um processo contínuo que envolve avaliar o estado atual da arquitetura, definir objetivos para construir um estado futuro e gerenciar todo o portfólio continuamente durante o processo [5]. De acordo com o Gartner, a AE está mais voltada a uma estratégia do que uma disciplina de engenharia que é usada para construir uma visão consolidada da empresa alinhada com as necessidades de negócios de uma organização [8].

Princípios de Arquitetura Empresarial. The Open Group [30] define princípios de arquitetura como "regras e diretrizes gerais subjacentes para o uso e implantação de todos os recursos e ativos de TI na empresa. Eles refletem um nível de consenso entre os vários elementos da empresa e formam a base para a tomada de decisões de TI futuras".

De acordo com Kempegowda e Chaczko [15], os princípios assistem na obtenção da visão da organização e na validação dos resultados e dão à equipe o poder de decisão durante a execução do framework de AE. Com o aumento significativo de tecnologias como Cloud, Big Data, Social Media, Internet of Things, Robotic Process Automation

(RPA), Analytics, dentre outras, é crítico definir princípios que são de fácil entendimento, amplos e práticos de se usar [15]. Princípios de arquitetura são amplamente produzidos, aceitos e valorizados, no entanto, não são largamente aprovados e efetivamente usados por arquitetos empresariais, designers, desenvolvedores, CIOs e gerentes [23].

O The Open Group Architecrure Framework (TOGAF) vem mostrando grande aceitação nas organizações [15], sendo que, neste presente trabalho, os 21 princípios definidos pelo TOGAF foram usados para desenvolver um modelo de decisão para avaliar os impactos das tecnologias de transformação digital (Indústria 4.0) sob os princípios de arquitetura propostos pelo TOGAF. A versão atual 9.2, lançada em 2018, contém os mesmos princípios da versão 9.0, lançada em 2009.

2.2 Transformação Digital

Transformação digital é definida como "o uso de tecnologia para melhorar radicalmente a performance ou alcance das empresas" [34]. Outra definição conhecida do termo é a que "é atingida quando os usos digitais que vem sendo desenvolvidos possibilitam inovação e criatividade e estimulam mudanças dentro do domínio profissional ou do conhecimento" [20].

O termo Indústria 4.0 (I4.0), foi mencionado pela primeira vez na feira de Hannover em 2001. Lu [18] sumariza indústria 4.0 como um processo de produção integrado, adaptado, otimizado, orientado ao serviço e interoperável, que está correlacionado com algoritmos, big data, e grandes tecnologias. A I4.0 facilita a interconexão e a informatização da indústria tradicional. De acordo com Liao et al. [17] as tecnologias de modelagem e virtualização/visualização vem sendo as duas tecnologias de habilitação mais frequentes aplicadas na implementação da Industria 4.0. Os objetivos da Indústria 4.0 são os de promover uma customização habilitada para TI dos produtos produzidos; de realizar uma adaptação automática e flexível da cadeia de produção; de rastrear partes e produtos; de facilitar a comunicação entre partes, produtos e maquinas; de aplicar paradigmas de interação homem-máquina (HMI); de alcançar a otimização de produção habilitada para IoT em *smart factories*; e o de promover novos tipos de serviços e modelos de negócios de interação na cadeia de valor.

2.3 Métodos Multi-Critérios De Tomada De Decisão

De acordo com a Sociedade Internacional de Métodos Multicritério de tomada de Decisão, "Métodos Multicritério de tomada de Decisão (MCDM) é o estudo de métodos e procedimentos pelos quais as preocupações sobre múltiplos critérios conflitantes podem ser formalmente incorporadas no processo de planejamento de gestão" [14]. De acordo com Cestari et al. [9], um MCDM ajuda os decisores a entender suas preferencias, utilizando critérios para escolher a alternativa adequada ou priorizar e ranquear um conjunto de alternativas. Ao estruturar o processo de decisão é essencial entender o tipo de problema no qual a decisão está inserida. O tipo de problema guiará a escolha do método multicritério a ser utilizado. Dito isso, o método que mais se adapta aos requisitos de avaliação desta pesquisa é o PROMETHEE.

O PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluation) é um método multicritério desenvolvido por Brans et al. [6,7]. É um método de ranqueamento com concepção e aplicação simples se comparado com outros métodos multicritério. Este método se adapta bem a problemas onde um número finito de alternativas deve ser ranqueado de acordo com múltiplos critérios, que podem vir a ser conflitantes [2]. A tabela de avaliação é o ponto de partida do PROMETHEE, nesta tabela as alternativas são avaliadas sob diferentes critérios. A implementação do PROMETHEE necessita de dois tipos adicionais de informação, sendo eles: (1) Informação sob a relativa importância, ou seja, os pesos dos critérios considerados. (2) Informação sobre a função de preferência do decisor, que ele/ela usa ao comparar a contribuição das alternativas em termos de cada critério.

3 ESTRATÉGIA DE PESQUISA

3.1 Levantamento das principais tecnologias no contexto de AE

A fim de identificar as principais tecnologias da I4.0, uma revisão de literatura foi realizada. De acordo com Xiao e Watson [35], a revisão de literatura é uma característica essencial da pesquisa acadêmica. O avanço do conhecimento deve se basear em trabalhos existentes. Ao revisar a literatura relevante, entendemos a amplitude e a profundidade do corpo de trabalho existente e identificamos lacunas a serem exploradas.

Com o intuito de identificar as principais tecnologias de transformação digital aplicadas ao âmbito da arquitetura empresarial, uma revisão da literatura foi realizada. Primeiramente foram identificadas as palavras-chave que seriam aplicadas na pesquisa. O “eixo 1” contempla as palavras referentes ao universo de avaliação do espaço problema enquanto o “eixo 2” abrange palavras pertinentes ao segundo espaço de avaliação. As palavras-chave utilizadas na pesquisa estão presentes no Tabela 1.

Tabela 1. Palavras-Chave

Eixos / Operador Booleano	**Palavras-Chave**
Eixo 1	"Enterprise Architecture" OR "TOGAF"
Operador Booleano entre os eixos	AND
Eixo 2	"Technologies" OR "Digital Transformation Technologies"

Uma vez que as palavras-chaves foram reconhecidas, os critérios de pesquisa foram definidos: (i) pesquisa avançada, de 2016 a 2020; (ii) seleção de textos disponíveis em inglês e (iii) exclusão de textos que não contemplam o nome do autor. Uma busca com as palavras-chave foi realizada na base SCOPUS, gerando um resultado de 1531 artigos. Após a aplicação dos critérios de pesquisa citados acima 505 artigos permaneceram. Em seguida uma série de análises foram realizadas e como resultado,

32 artigos restaram. A Tabela 2 contempla os critérios de pesquisa aplicados na seleção dos artigos.

Tabela 2. Critérios de Pesquisa

Critérios de Pesquisa	**Resultados**
Limitados aos últimos 5 anos, ou seja, 2020,2019,2018,2017 e 2016.	557
Limitados à língua inglesa.	540
Exclusão de artigos que não possuem nome do autor	505
Análise de títulos	89
Análise de abstracts	34
Artigos disponíveis	32

Com os 32 artigos restantes, foi utilizado o software NVivo [25] no qual foi aplicada a ferramenta "word-count" para determinar as tecnologias mais mencionadas. Uma análise de cluster (Fig. 1) das palavras encontradas, foi gerada.

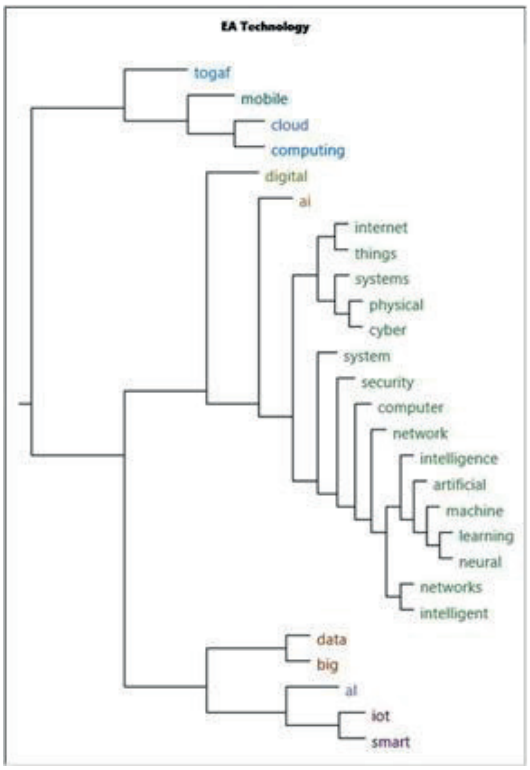

Fig. 1. – Análise de Cluster

Ao analisar os resultados gerados, cinco principais tecnologias no âmbito de I4.0 e AE foram identificadas: Cloud Computing, Internet of Things (IoT), Artificial Intelligence (AI), Big Data e Cyber-Physical Systems. O Tabela 3 contempla as tecnologias e suas respectivas descrições.

Tabela 3. Principais Tecnologias (Alternativas)

Tecnologias	Definição
Artificial Intelligence (AI)	Artificial Intelligence (AI) é o domínio da ciência e engenharia relacionado as teorias e práticas de desenvolvimento de sistemas que exibem características comumente associadas à inteligência de comportamento humano, como percepção, processamento de linguagem nativa, resolução de problemas e planejamento, aprendizado e adaptação e, atuação no meio ambiente. Seu principal objetivo científico é o entendimento dos princípios que possibilitam o comportamento inteligente em humanos, animais e agentes artificiais [29].
Big Data	Big Data é o desenvolvimento tecnológico na área de armazenamento e processamento de dados que oferecem a possibilidade de lidar com os aumentos exponenciais nos volumes de dados apresentados em qualquer formato em períodos cada vez menores [27].
Cloud Computing	A computação em nuvem é uma tecnologia em evolução que está constantemente gerando impacto no setor de TI. Ele executa todas as tarefas computacionais pela Internet usando técnicas de virtualização e permanece isolado de intrincadas vastas infraestruturas de hardware e software [1].
Cyber-Physical Systems	Sistemas ciberfísicos (CPS) São sistemas de entidades computacionais colaborativos que apresentam uma conexão intensa com o mundo físico circundante e seus processos em andamento, fornecendo e utilizando, ao mesmo tempo, serviços de acesso a dados e processamento de dados disponíveis na Internet [21].
	A IoT integra diversas tecnologias para transmitir informações de fontes que não são apenas pessoas (através de seus dispositivos tradicionais: laptop, desktop, celulares e similares), mas também objetos reais e virtualizados que fazem parte do

Internet of Things (IoT)	ambiente em que o serviço é entregue aos usuários. Outro aspecto é que esses dados não devem apenas estar disponíveis para um determinado aplicativo, mas devem se tornar uma espécie de base informativa comum, para que diferentes aplicativos possam compartilhar livremente e em escala global as fontes dessas informações devidamente organizadas na forma de uma rede genérica [4].

4 Resultados

Através da utilização do método PROMETHEE foi possível realizar uma avaliação das tecnologias, de maneira a determinar as que possuem maior influência sobre cada um dos critérios. Esta comparação entre as tecnologias foi realizada através da utilização de uma função de preferência e de um peso escolhido para cada critério. Neste artigo, os pesos dos critérios foram iguais para todos, sendo ele igual a 1. A função de preferência adotada foi a função Usual.

Os critérios escolhidos para a avaliação foram os 21 princípios de arquitetura do TOGAF (Tabela 4), já as alternativas utilizadas foram as tecnologias obtidas através da revisão de literatura realizada nesta pesquisa (Tabela 3). Tais critérios e alternativas foram escolhidos a fim de elaborar um modelo de decisão para avaliar as tecnologias de transformação digital(Indústria 4.0) mais impactantes sobre os princípios de arquitetura propostos pelo TOGAF.

Tabela 4. Princípios de Arquitetura TOGAF (Critérios)

Número	Princípios de Arquitetura TOGAF
1	Primazia dos Princípios
2	Maximizar os Benefícios para a Empresa
3	Gestão de Informação é Negócio de Todos
4	Continuidade de Negócios
5	Aplicativos de Uso Comum
6	Orientação de Serviço
7	Conformidade com a Lei
8	Responsabilidade de TI
9	Proteção da Propriedade Intelectual
10	Informações tratadas como Ativo
11	Informações Compartilhadas

12	Informações Acessíveis
13	Administrador de Dados
14	Terminologia Comum e Definição de Dados
15	Segurança da Informação
16	Independência Tecnológica
17	Facilidade de Uso
18	Mudanças com Base em Requisitos
19	Gerenciamento Sensível a Mudança
20	Controle de Diversidade Técnica
21	Interoperabilidade

Com estas informações em mãos, iniciou-se a criação do modelo de avaliação no software VISUAL PROMETHEE [33]. Além dos atributos já mencionados foi necessário escolher como as alternativas seriam avaliadas para cada critério. No campo "Min/Max" optou-se pelo Máximo, ou seja, quanto maior o desempenho da alternativa naquele critério maior a influência daquela tecnologia para o mesmo. Já a escala utilizada na avaliação foi a escala qualitativa 5-point, variando nos seguintes níveis de influência: 0 (sem influência), 1 (influência baixa), 2 (influência média), 3 (influência alta) e 4 (influência muito alta), respectivamente. O modelo devidamente estruturado no software está presente na Fig. 2.

Fig. 2. Estrutura do Método PROMETHEE

Para cada alternativa, dois índices são calculados: o fluxo positivo (Φ+) que representa o quanto uma certa alternativa é melhor que as outras e o fluxo negativo (Φ-), que

expressa o quanto uma alternativa é superada pelas demais [28]. Com a aplicação dos dados foram gerados os valores de "Phi" para cada uma das tecnologias através do software, ou seja, foram gerados os índices de fluxo positivo, negativo e o fluxo total de cada alternativa (Fig. 3).

Rank	action	Phi	Phi+	Phi-
1	Big Data	0,3095	0,3929	0,0833
2	Cloud Computing	0,2738	0,3810	0,1071
3	IoT	0,0833	0,3095	0,2262
4	AI	-0,1905	0,2262	0,4167
5	Cyber-Physical Systems	-0,4762	0,0357	0,5119

Fig. 3. Valores de "Phi" gerados pelo PROMETHEE

Percebe-se que o fluxo total de Big Data, Cloud Computing e IoT é positivo, já os fluxos de AI e Cyber-Physical Systems são negativos. A Fig. 4 apresenta o fluxo resultante, baseado no PROMETHEE, promovendo assim uma representação gráfica do resultado obtido.

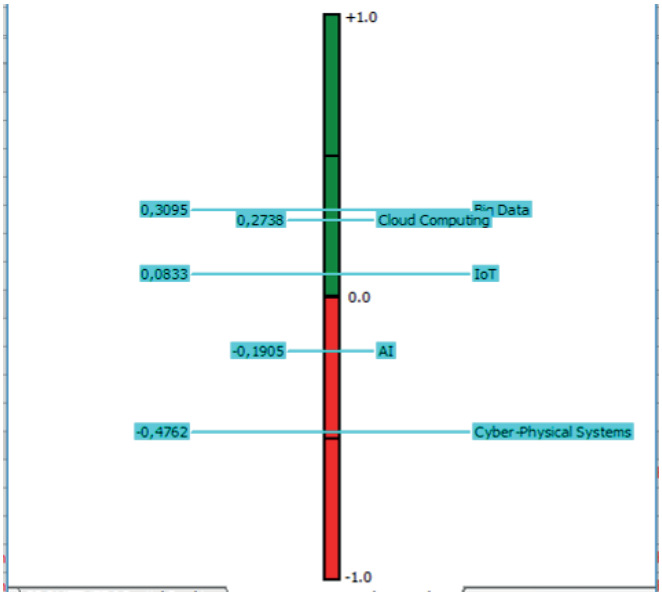

Fig. 4. Resultado gerado pelo PROMETHEE

Por meio da aplicação do modelo decisional foi possível determinar que a tecnologia com maior impacto nos princípios de arquitetura do TOGAF é a Big Data, seguida pelo Cloud Computing, com fluxos de 0,31 e 0,27 respectivamente.

5 Conclusão

O presente trabalho teve como objetivo aplicar um modelo de decisão para avaliar os impactos das tecnologias de transformação digital sob os princípios de arquitetura propostos pelo TOGAF. Para tal, primeiramente uma revisão de literatura for realizada a fim de identificar as principais tecnologias de transformação digital utilizadas no âmbito da arquitetura empresarial. Em seguida, o modelo decisional foi desenvolvido baseado no método multicritério de tomada de decisão PROMETHEE, auxiliando decisores a tomarem decisões mais assertivas, reduzindo riscos e impactos negativos que podem afetar a organização como um todo. Os 21 princípios de arquitetura apresentados pelo TOGAF foram definidos como critérios a serem utilizados na avaliação. Por fim, o modelo foi aplicado e como resultado apontou as tecnologias Big Data e Cloud Computing como as que geram maior efeito sob os princípios analisados.

Ambas as tecnologias têm sido altamente abordadas no âmbito acadêmico e aplicadas em organizações. Segundo Malik, Rashid e Wani [19], Cloud Computing elimina a necessidade de ter uma infraestrutura completa de software e hardware para atender aos requisitos e aplicativos dos clientes. Com isso princípios como: Aplicativos de Uso Comum; Independência Tecnológica; Facilidade de Uso; Controle de Diversidade Técnica, são diretamente impactados pelo uso dessa tecnologia.

De acordo com um estudo realizado por Chen e Zhang [10], os autores afirmam que 51% das empresas avaliadas acreditam que Big Data pode impactar no aumento da eficiência operacional e que 36% das organizações presumem que essa tecnologia pode auxiliar no direcionamento estratégico das empresas. Dito isso, dois princípios propostos pelo TOGAF são impactados: Maximizar os Benefícios para a Empresa; e Gerenciamento Sensível a Mudança. Big Data também trata os princípios que envolvem o gerenciamento de dados como: Gestão de Informação é Negócio de Todos; Informações tratadas como Ativo; Informações Compartilhadas; Informações Acessíveis; Terminologia Comum e Definição de Dados; e Segurança da Informação.

A fim de aprimorar o estudo realizado, propõe-se como trabalho futuro, detalhar as tecnologias encontradas. Isso acarretará uma avaliação mais assertiva e auxiliará no direcionamento de oportunidades de evolução e transformação das organizações com tecnologia.

Resumen. Las políticas de eficiencia energética (EE) son sumamente relevantes para alcanzar los compromisos de mitigación del cambio climático asumidos por Argentina. Para lograr un buen diseño e implementación de estas políticas es necesario analizar el gasto energético de los hogares, ya que la mejora de la EE podría aliviar los presupuestos familiares. En este contexto, el objetivo del presente trabajo es analizar de manera exploratoria cómo se distribuye el gasto energético de los hogares de Argentina en 2017-2018 por regiones y según clima educativo, y discutir la importancia de estudiar el comportamiento de esta distribución para diseñar e implementar políticas de EE. Para ello se utilizan los microdatos provenientes de ENGHo 2017-2018. Los resultados parecen evidenciar una relación inversa entre el nivel educativo del hogar y la participación del gasto energético sobre el gasto total. Esto podría indicar que es necesario formular políticas de EE especialmente dirigidas a los hogares más vulnerables.

Palabras clave: Gasto energético, Hogares, Eficiencia Energética.

1 Introducción

En un contexto de aumento de las emisiones antropogénicas de Gases de Efecto Invernadero (GEI), la Eficiencia Energética (EE) adquiere un rol preponderante. Mejorar la EE implica promover un aumento de los usos energéticos para un nivel dado de energía o bien la disminución de la cantidad de energía para satisfacer un nivel dado de usos (IEA, 2014).

A nivel mundial, en el año 2015, se firma el Acuerdo de París en la 21ª Conferencia de las Partes (COP) de la Convención Marco de Naciones Unidas sobre Cambio Climático (CMNUCC) con el objetivo de mantener el aumento de la temperatura media mundial muy por debajo de 2ºC con respecto a los niveles preindustriales. En el caso de Argentina, en el año 2016 se ratifica la firma del Acuerdo mediante la Ley 27.270 y en su Contribución Nacional Determinada (NDC por sus siglas en inglés) en la que se compromete a no exceder la emisión neta de 483 millones de toneladas de

dióxido de carbono equivalente (tCO2eq) en el año 2030. En el año 2017, se lanzó el Plan de Acción Nacional de Energía y Cambio Climático, contemplando como uno de los ejes centrales a la EE en distintos sectores de consumo final, incluyendo al sector residencial (MADS y MEM, 2017).

En Argentina, para evaluar la EE y mejorar su implementación en los hogares lo ideal es contar con un análisis microeconómico. Este análisis permite conocer cómo toman los hogares (y personas) las decisiones de consumo de energía e inversión en EE. Si se estudian dichos determinantes se pueden conocer los impulsores y las barreras a la EE y, de esta manera, se facilita el diseño de instrumentos de política.

En este contexto, el objetivo del presente trabajo es analizar de manera exploratoria cómo se distribuye el gasto energético de los hogares de Argentina para el periodo 2017-2018 por regiones y según clima educativo, y discutir la importancia de estudiar el comportamiento de esta distribución para diseñar e implementar políticas de EE. Para cumplimentar el objetivo, se realizará un análisis estadístico descriptivo a partir de los microdatos provenientes de la Encuesta Nacional de Gastos de los Hogares (ENGHo) y una revisión bibliográfica de la literatura existente.

2 Revisión de antecedentes en el estudio del gasto energético

En Argentina no existen antecedentes que estudien los determinantes del gasto energético de los hogares. Sin embargo, se encuentran diversos estudios que estiman la demanda de energía en el sector residencial, aunque sólo unos pocos utilizan microdatos en su análisis. Entre estos últimos se puede mencionar un grupo de trabajos que sin ser específicos del gasto energético, lo incluyen en su análisis. Marchionni et al. (2008) analizan la incidencia distributiva del gasto y consumo de servicios públicos, incluyendo electricidad y gas natural. Lakner et al. (2016) analizan la incidencia distributiva de los subsidios a los servicios públicos, incluyendo la energía.

Luego, otro grupo de trabajos estudia específicamente temáticas de energía. Margulis (2014) analiza la demanda residencial de electricidad en función de variables, tales como el ingreso y la cantidad de miembros del hogar, acceso a la red de gas natural y el precio en cada jurisdicción. Hancevic y Navajas (2015) evalúan el consumo de electricidad de los hogares según sus características socioeconómicas, de equipamiento y localización y lo vinculan con cuestiones de EE. Los autores encuentran que la falta de acceso al gas natural deriva en ineficiencias en el consumo de electricidad. Chévez et al. (2018) presentan un análisis del consumo eléctrico residencial a nivel territorial, encontrando que las mayores demandas eléctricas se presentan en regiones cálidas y que la mayor demanda de electricidad está asociada a un mayor nivel de equipamiento en los hogares.

3 Explorando el gasto energético en Argentina: ENGHo 2017-2018

El relevamiento de la ENGHo 2017-2018 se llevó a cabo entre noviembre de 2017 y noviembre de 2018, con el objetivo de obtener información acerca de los gastos y los ingresos de los hogares y sus características sociodemográficas (INDEC, 2019). Para ello, los bienes y servicios se agrupan en 12 divisiones según las necesidades que satisfacen. En este trabajo, el foco del análisis estará en la división denominada "Vivienda, agua, electricidad, gas y otros combustibles". En concreto, esta división representó el 14,5% del gasto de consumo para el total del país y la subdivisión específica de "Electricidad, gas y otros combustibles" representó un 5,9%.

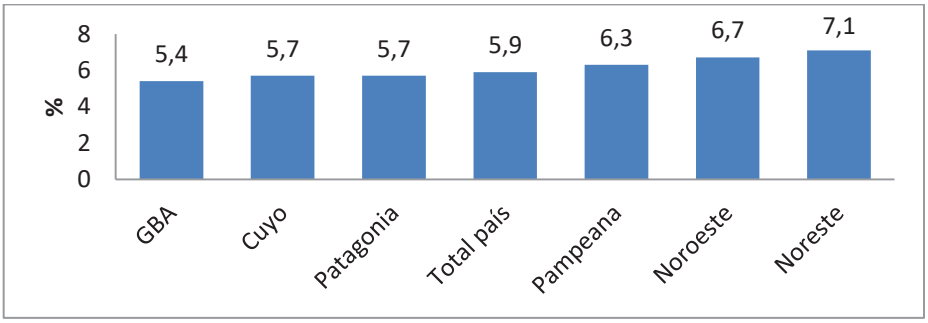

Fig. 1. Porcentaje del gasto en Electricidad, gas y otros combustibles según regiones 2017-2018. Fuente: elaboración propia en base a datos de INDEC

En la Fig. 1 se puede observar que las regiones de GBA, Cuyo y Patagonia poseen una menor participación del gasto energético en el gasto total de los hogares con respecto al total del país. Esto podría estar vinculado a los esquemas tarifarios regionales y a la existencia de subsidios.

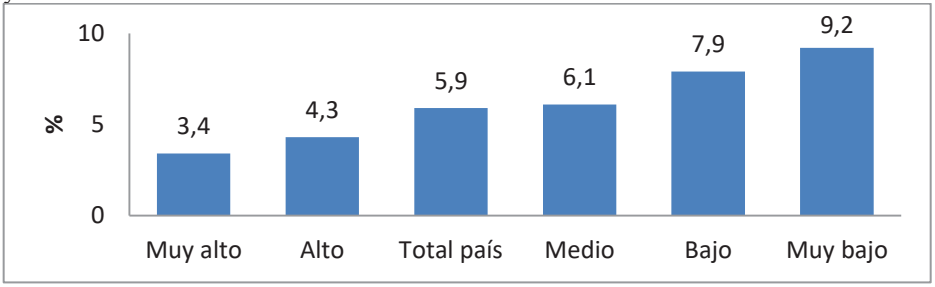

Fig. 2. Porcentaje del gasto en Electricidad, gas y otros combustibles según clima educativo del hogar 2017-2018. Fuente: elaboración propia en base a datos de INDEC

En la Fig. 2 se muestra la participación del gasto energético sobre el total por clima educativo del hogar[1]. Esto parece evidenciar una relación inversa entre las variables.

[1] El clima educativo en años de escolaridad: menor a 7 es muy bajo, desde 7 y menor a 11 es bajo, desde 11 y menor a 14 es medio, desde 14 y menor a 16 es alto, y mayor a 16 es muy alto (INDEC, 2019).

Aunque la significatividad de dicha relación debe ser evaluada con un abordaje econométrico.

4 Discusión y Conclusiones

Los resultados preliminares del análisis estadístico exploratorio indican que existen diferencias a nivel regional que podrían estar vinculadas con los distintos esquemas tarifarios de energía, aunque también puede relacionarse con el hecho de que algunas regiones poseen un mayor nivel de desarrollo económico y por lo tanto la población cuenta con mejores condiciones de vida. Asimismo, parece existir una relación inversa entre el nivel educativo del hogar y la participación del gasto energético sobre el gasto total. Esto podría indicar que es necesario formular políticas de EE especialmente dirigidas a los hogares más vulnerables, para mejorar no solo la EE sino la asequibilidad de la energía. Por último, se destaca la importancia de analizar el gasto en energía cuando se desea mejorar EE. Comprender los factores que determinan el gasto energético y sus interrelaciones puede contribuir a equilibrar el dilema entre satisfacer las necesidades básicas de los hogares y reducir el impacto ambiental (Jiménez y García, 2017). Además, las políticas de EE para el sector residencial pueden tener impactos significativos no solo para el consumo energético sino también en gastos relacionados, aliviando los presupuestos familiares (Op.Cit.).

Abstract. This paper presents an improvement of the branch-and-bound algorithm for the blocking-in-process and setup times permutation flow shop problem with total flow time criterion, which is known to be NP-Hard for m≥2. For that, a new machine-based lower bound which exploits the machine idleness and the occurrence of blocking is proposed. Computational experiments were performed using a database that contains 27 classes of problems, varying the number of jobs (n) and the number of machines (m). Results show that the algorithm can handle most of the n<20 problems in less than one hour. Therefore, this work can support the scheduling of many applications in manufacturing systems with limited buffers and setup times.

Keywords: Scheduling, Permutation flow shop, Blocking, Setup, Total flow time, Branch-and-bound.

1 Introduction

In the permutation flow shop scheduling problem, *n* jobs must be processed on each of the machines in the same order. It is also assumed that every job has the same processing sequence on every machine, each machine can process at most a single job and no interruptions are allowed. The processing time of each job on each machine is given. The total flow time objective measures the time the jobs stay inside the system, and its minimization results in cost reductions related to initial inventory and in-process maintenance costs. For $m \geq 2$, the flow shop with total flow time criterion problem is NP-hard [1].

Many papers considered the problem with unlimited buffers [2] or considering the setup time embedded in the processing time of the job [3], [4] and [5]. In this paper, the setup time is separated from the processing time, allowing a machine to be prepared to initiate the processing of a job before the previous machine has finished processing this job. This ensures better flexibility for scheduling, allowing for a better use of time, hence a possible reduction in the makespan. Furthermore, the setup time depends on the sequence of jobs, as well as the machine. In other words, there is a different setup time for each pair of jobs in each machine.

In an environment with blocking, there are limited buffers in between the machines. In this paper, a zero buffer constraint is considered, i.e., if machine k finishes the processing of job j and machine k+1 is not able to receive the job (because it is still processing job j-1 or is still being set up), the job remains on machine k, blocking it. In this case machine k is unable to receive the next job of the sequence. The absence of buffers can cause the occurrence of blocking, which is when a job completed on a specific machine blocks it until the following one is ready for processing. Another reason for the occurrence of blocking lies in the production technology itself [6]. For instance, in robotic cells, a machine may be blocked while waiting for the robot arm to pick up the finished job and move it to the next stage [7].The flow shop problem with zero buffer can be used to model any flow shop problem with limited buffer because a unit capacity buffer can be represented by a machine with zero processing time for all jobs [3]. Fig. 1 shows an example of the problem in a Gantt chart.

In Fig. 1 is shown the moment when job i just finished being processed by both Machine 1 and 2. Thus, both machines begin by being setup to start processing job j (S_{ij1} and S_{ij2}). It can be noted that Machine 2 must wait for Machine 1 to finish processing job j before it can start processing it, so it stays idle for a while. Right after finishing processing job j each machine can start setting up for the next job ($S_{j,j+1,1}$ and $S_{j,j+1,2}$). In this case, notice that Machine 1 finished processing job j+1 before Machine 2 had finished the setup process. Therefore, a *block* occurs, preventing Machine 1 from starting to setup for the next job.

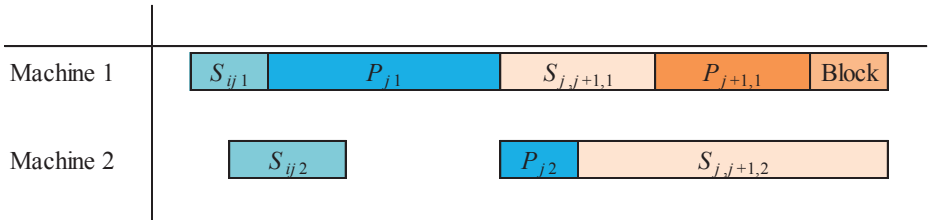

Fig. 1. Example of a blocking flow shop scheduling problem with setup times

Because of its complexity, large-size blocking flow shop problems are usually solved by heuristics. [8] are among the first authors that explored the blocking environment. Their work consisted of reducing the 2-machine flow shop with zero buffer and makespan minimization to a special case of the Traveling Salesman Problem, which can be solved in polynomial time using the Gilmore-Gomory algorithm [9]. [3]

developed the Profile Fitting constructive heuristic, which fits an unscheduled job that provides the least blocking and machine idle time in front of a partial sequence.
[10] developed a two-machine case branch-and-bound to minimize the mean completion time and a three-machine case for makespan on a flow shop environment. [11] extended this machine based lower bound to m machines when the objective is minimizing the sum of completion times, or total flow time when all release dates are zero. [12] developed a machine based lower bound with the preemptive relaxation, which dominated the formulation of [11] in terms of value. [13] proposed a new total flow time lower bound for flow shop that dominated both previous formulations. The results point out that the algorithm can easily handle $n \leq 15$ and can solve most of $15 < n \leq 20$ problems.
A reduced number of papers explores the blocking flow shop solved by a branch-and-bound algorithm. [14] presented a branch-and-bound algorithm for flow shops with zero buffer. The authors developed a departure time based lower bound that was used for the total tardiness and makespan objectives. [15] outperformed the lower bound for flow shop with blocking in order to minimize makespan proposed by [14] in 85.2% of the cases. Their lower bound calculated an underestimate departure time of the last job in non-partial sequence. [16] developed a lower bound for flow shop with zero buffer constraint with the total flow time criterion. The algorithm solved $n \leq 18$ and $m \leq 10$ problems and 17 instances of Taillards benchmark [17] in less than 20 minutes. [18] proposed an initial upper bound (UB) to reduce the computational time of the branch-and-bound algorithm. The initial UB was provided by a constructive heuristic, and a significant reduction of the computational time was noticed.
Just a few papers addressed the blocking with setup times in flow shop. [19] were one of the first to explore this problem. They adapted the lower bound presented by [10]. [20] was the first paper to address the use of a branch-and-bound algorithm for the problem. A lower bound was developed for the makespan in a flow shop with blocking and sequence dependent setup times, addressing two structural properties of the problem: an upper bound for the machine idle and a lower bound for the machine blocking time.
In this article a lower bound for the branch-and-bound algorithm for blocking with setup time permutation flow shop problems with total flow time criterion is presented, in order to optimally solve small and medium size problems. In Section 2 the problem is defined, and some basic calculations are shown. The branch-and-bound algorithm and the lower bound development are presented in Section 3. The computational tests are showed in Section 4 and the conclusions are presented in Section 5.

2 Problem Definition

The flow shop problem with blocking and setup can be defined by the following set of equations. Let σ={1, 2, …, i, j, …, n} be an arbitrary sequence of jobs, k={1, 2, …, m} be the sequence of available machines, *i* be the job that directly precedes job *j* in the sequence, P_{jk} be the processing time of the *j*-th job in the sequence on machine *k*, S_{ijk} be the setup time of machine *k* between the *i*-th and the *j*-th job in the sequence, S_{01k}

be the setup time of machine k before processing the first job in the sequence, R_{jk} be the completion time of the setup of machine k to the j-th job in the sequence and D_{jk} be the departure time of the j-th job in the sequence on machine k. Equations 1 to 5 show how the departure times are calculated for a given sequence:

$$R_{1k} = S_{01k} \; \forall 1 \leq k \leq m \tag{1}$$

$$D_{j1} = \max\left(R_{j2}, R_{j1} + P_{j1}\right) \; \forall 1 \leq j \leq n \tag{2}$$

$$D_{jk} = \max\left(R_{j,k+1}, D_{j,k-1} + P_{jk}\right) \; \forall 1 \leq j \leq n; 2 \leq k \leq m-1 \tag{3}$$

$$D_{jm} = D_{j,m-1} + P_{jm} \; \forall 1 \leq j \leq n \tag{4}$$

$$R_{jk} = D_{ik} + S_{ijk} \; \forall 2 \leq j \leq n; 1 \leq k \leq m \tag{5}$$

Initially, the setup completion times of the machines for the first job in the sequence are calculated by Equation 1. Then, the departure times of the first job in all machines are calculated by Equations 2, 3, and 4. Then, Equation 5 is used to calculate the setup completion time of all machines for the following job. Equations 2, 3, and 4 are used again to calculate the departure times of the following job in all machines. The total flow time is the sum of all departure times of all jobs on the last machine. Therefore, Equation 6 is used to calculate the total flow time.

$$TFT = \sum_{j=1}^{n} D_{jm} \tag{6}$$

3 The Branch-and-Bound Algorithm

The branch-and-bound algorithm branches an original high complexity problem in two or more sub-problems, called nodes, that are easier to solve. This process can be done recursively until a feasible solution is obtained. The nodes are defined by an exclusive sub-sequence which is called Partial Sequence (PS). The set of jobs not included in PS is called Non-Partial Sequence (NPS).

When a node is branched, one or more partial sequences (nodes) are created by adding up a new job from |NPS| to the partial sequence associated with the branched node. The search tree is created using the depth first rule, in which the node with more jobs in the PS is branched. The ties are broken by the minimum lower bound. For each node, a lower bound of the total flow time is computed and this node is fathomed if the incumbent solution is smaller than its lower bound. As the focus of this article is to evaluate the tightness of the proposed lower bound, the initial incumbent solution is set to a very high value and is updated every time a better feasible solution is reached.

3.1 Proposed Lower Bound

The effectiveness of a branch-and-bound algorithm is heavily related to the lower bounds used. Such bounds are more useful if their computational complexities are small and if they are tight. The proposed lower bound assumes a relaxation in which one

machine can process one job at a time and the others can handle the whole set of n jobs at a time. Since the SPT rule is optimal for total flow time criterion on a single machine [21], it is possible to obtain a lower bound for the flow shop problem. The lower bound considering a partial sequence σ of size s is computed as follows:

$$LB = TFT(\sigma) + \max_{1 \le k \le m} LB_k \tag{7}$$

$$LB_k = \sum_{t=s+1}^{n} (ED_{tk} + \sum_{r=k+1}^{m} p_{tr}) \tag{8}$$

In which ED_{tk} is the underestimate of the departure time of a job in position $t > s$ on machine k, as shown in Equation 9. Where *s* is the last job in σ and $p_{[j],k}$ is the (s-j)-th smaller processing time on machine k.

$$ED_{tk} = max\left(max\left(D_{sk} + \sum_{j=s+1}^{t-1} p_{[j]k}\,; D_{s,k+1} + \sum_{j=s+1}^{t-2} p_{[j],k+1} + Setup_{k+1}(t-1)\right) + Setup_k(t); D_{s,k-1} + \sum_{j=s+1}^{t} p_{[j],k-1}\right) + p_{[t]k} \tag{9}$$

For $k = 1$ and $k = m$, the formulation excludes the $k - 1$ and $k + 1$ terms, respectively.

4 Computational Results

This section describes the computational tests done in order to evaluate the effectiveness of the proposed lower bound (LB) when applied to a branch-and-bound algorithm. The experimentation used the problem instances database from [14], in which the processing times were randomly generated in a uniform distribution ranging from 1 to 99. The database consists of 27 different problem sizes, with 20 unique problems each, totaling 540 instances.
The database provided by [15] does not include setup times. Therefore, in order to analyze the influence of the setup times in the algorithm, four different setup time databases were generated for these tests. To create these databases, the values were uniformly distributed between:

- Database 1: 01 and 09;
- Database 2: 01 and 49;
- Database 3: 01 and 99;
- Database 4: 01 and 124;

The setup data ranges were defined to approximately: 10%; 50%; 100%; and 150% of the processing time. By doing so, it is possible to evaluate the influence of the setup time on the methods. If the results in problems where the setup time is 10% of the processing time and where the setup time is 150% of the processing time are similar, then it can be stated that the value of the setup time does not influence in which is the best method.
The processing time database was combined with each of the setup time database. Thus, a total of 2160 problems were analyzed.

The experimentation codes were written in C and ran on an Intel Core i7-8700K 3.7GHz, 16GB RAM DDR4 3000MHz using Microsoft Visual Studio Community 2017. The computational times were obtained through the function clock(). A time limit of 3600 seconds was set for the execution of the algorithm.
As no other lower bound for the $F_m|block, S_{ijk}|\sum C_{jm}$ was found in the literature, the tests were performed by comparing three variations of the proposed lower bound (LB). The purpose of the tests is to evaluate which variations of the LB solve the problems in a viable computational time. The three variations are:

- LB_1: $S_{i[1]k}$ and $S_{[1]jk}$ were defined as zero and were not included in the searches;
- LB_2: $Setup_k(j)$ was defined as zero and was not included in the searches;
- LB_3: LB was fully calculated.

To compare the performance of the lower bounds, the relative percentage deviation was calculated for the average number of created nodes and computational times, using the following equation:

$$RPD_{Variation} = \frac{\sigma_{Variation} - \sigma^*}{\sigma^*} * 100 \quad (10)$$

In Equation 10, $\sigma_{Variation}$ is the mean value of either the computational time or the number of created nodes obtained with the LB variation analyzed and σ^* is the best value obtained among all the LB variations.
Each problem was solved using all variations of the LB, and all algorithms were run in the same conditions. Tables 1, 2, 3, and 4 show the average CPU time spent, the average number of created nodes, and the number of unsolved problems considering database 1, 2, 3, and 4, respectively, for the setup times.

The RPD was calculated for all databases separately, and the results are shown in Table 5.

Table 5. RPD of the variations of the LB for all databases

Database	Ave. Node Count			Ave. CPU Time (ms)			Number of Unsolved		
	LB_1	LB_2	LB_3	LB_1	LB_2	LB_3	LB_1	LB_2	LB_3
Database 1	**0.00**	0.06	**0.00**	0.07	**0.00**	0.06	0.04	**0.00**	0.04
Database 2	0.12	0.14	**0.00**	0.11	**0.00**	0.04	0.14	**0.00**	0.07
Database 3	0.10	0.13	**0.00**	0.12	**0.00**	0.06	0.12	**0.00**	0.02
Database 4	0.08	0.17	**0.00**	0.10	**0.00**	0.05	0.14	**0.00**	0.08
Average	0.08	0.13	**0.00**	0.10	**0.00**	0.05	0.11	**0.00**	0.05

From Tables 1, 2, 3, and 4 it was possible to notice that the bigger the setup times, the smallest is the number of nodes for all variations of the LB. Thus, it can be noted that this factor is not significant for the comparisons. From Table 5 it was possible to observe that for all different databases the lower bound LB_3 was the one that most reduced the number of nodes. On the other hand, LB_2 solved more problems in less computational time. The results of LB_1 proved to be inefficient for all databases. As the most important measure for the B&B algorithm is computational time, it can be considered that the search of $Setup_k(j)$ is impracticable for the problem studied in this paper.

5 Conclusion

This paper considers a blocking permutation flow shop scheduling problem with the total flow time criterion, which is known to be NP-hard for $m \geq 2$. A machine based lower bound that exploits the occurrence of blocking and idle time (LB) is proposed and applied to the branch-and-bound algorithm. Four setup time databases were generated, each with different values range. The tests show that this range value did not affect the LB performance.

As no other lower bound was found in the literature, three different ways of applying the proposed LB were studied and compared. LB_1 got the worst computational time and was the variation that solved less problems within 3600 seconds, also got the second

worst number of nodes. So, it can be concluded that including both $S_{i[1]k}$ and $S_{[1]jk}$ in the search is important for the LB.
Overall LB_3 got the smallest number of nodes and LB_2 got the smallest computational time and number of unsolved problems. This can mean that including $Setup_k(j)$ in the search is not interesting for the LB.
For future works, the development of a dominance rule for pruning a higher number of nodes and the use of efficient heuristics as initial upper bounds are suggested. These suggestions aim at improving the algorithm, while applied along with LB_2. Furthermore, other exploration rules may be tested, such as the best bound rule, or a hybrid technique. Considering the efficiency of the proposed LB, another suggestion is to apply the rules used for incorporating the blocking constraints in this LB into a general case with a limited buffer greater than or equal to zero.

Resumo. A tomada de decisão na área da saúde é uma atividade complexa. Assim, diversas ferramentas têm sido desenvolvidas a fim de dar suporte ao usuário durante este processo. Uma destas ferramentas é a abordagem de questionário, utilizada em modelos de processo desenvolvidos em BPMN (*Business Process Model and Notation*). Além disso, a modelagem de processos focada nas decisões, como o DMN (*Decision Model and Notation*), está ganhando destaque, tanto na literatura quanto nos ambientes de negócios. Neste contexto, esta pesquisa tem como objetivo analisar o suporte à tomada de decisão fornecido pela abordagem de questionário em modelos de processo desenvolvidos em BPMN e DMN. Assim, essas linguagens foram utilizadas para a modelagem de um dos tratamentos disponíveis para pacientes diagnosticados com acidente vascular cerebral (AVC). Foi realizado um estudo da literatura a fim de investigar como o BPMN e o DMN vêm sendo empregados no apoio à decisão para processos na área da saúde. Também é apresentada a aplicação do BPMN e DMN junto à técnica de modelo de questionário no processo para tratamento do AVC. Para finalizar, a análise comparativa das duas técnicas é apresentada, mostrando que, em DMN, o processo apresenta um ganho considerável na simplificação visual do processo quando o foco é a observação das decisões. Também, quando aplicado junto ao modelo de questionário, é evidente que tal técnica torna muito mais fácil o processo de implementação de ferramentas para apoio a decisão durante o caminho clínico.

Palavras-chave: Configuração de Processo; Decisão; BPMN; DMN.

1 Introdução

A tomada de decisão na área da saúde é uma tarefa complexa, pois envolve diversos fatores, tais como diretrizes clínicas, sintomas dos pacientes, sistema de saúde, recursos disponíveis, entre outros [1]. Além disso, decisões nesta área envolvem múltiplos objetivos que muitas vezes são conflitantes [2]. Desta forma, processos na área da saúde devem ser flexíveis, ou seja, devem ser capazes de lidar tanto com mudanças esperadas como não esperadas, que afetam apenas algumas partes do modelo [3], [4]. Portanto, a tomada de decisão é representada nos modelos de processo de negócios. Porém, está

representação pode mudar conforme a linguagem utilizada. Diversas linguagens e métodos foram desenvolvidos para a modelagem de processos de negócios, tais como o BPMN (*Business Process Modelling Notation*) e o DMN (*Domain and Model Notation*). O BPMN têm sido amplamente utilizados para modelagem de processos. Porém, estes modelos podem ser complexos e de difícil compreensão. Além disso, o BPMN não considera as decisões lógicas do modelo de processo. Assim, o DMN surgiu a fim de preencher esta lacuna, possuindo, em seu escopo, uma notação mais simples. O DMN é visualmente um modelo simplificado do seu equivalente em BPMN, contendo as atividades agrupadas por decisões. E, internamente, dentro das fases que geram decisões, tabelas que possuem os critérios a serem avaliados. Sendo assim, capaz de apresentar, de forma resumida, a estrutura lógica do processo e cada critério avaliado em seu respectivo momento [5]–[8]

Nestas linguagens, partes do processo são caracterizadas por pontos em que são apresentadas duas (ou mais) opções ao usuário e, em que ele deve selecionar uma delas de acordo com os requisitos estabelecidos. Estes pontos são chamados de pontos de decisão ou pontos de variação [9]–[11]. Assim, fornecer suporte ao usuário durante este processo é fundamental para alcançar os resultados esperados. Ao levar isso em consideração, algumas abordagens foram desenvolvidas a fim de auxiliar o usuário durante esta tarefa. Uma destas abordagens, chamada abordagem do modelo de questionário, foi desenvolvida por [12] e, nela, cada ponto de decisão se refere à uma questão e as alternativas existentes para cada questão se referem a um caminho a ser selecionado no modelo do processo.

Neste contexto, esta pesquisa tem como objetivo aplicar o modelo de questionário tanto com o BPMN como o DMN a fim de analisar como a decisão é abordada em ambas as linguagens, bem como compreender os benefícios resultantes e os gaps existentes. Assim, este artigo é organizado da seguinte forma: na Seção 2 são apresentados os trabalhos correlatos, a Seção 3 apresenta a linguagem BPMN em conjunto com a abordagem de questionário aplicada ao tratamento de AVC. Na Seção seguinte é apresentada a modelagem do processo referente ao tratamento de AVC em DMN aplicando a abordagem de questionário. A Seção 5 apresenta a discussão.

2 Trabalho correlatos

Devido à complexidade existente na área da saúde, diferentes métodos foram utilizados a fim de dar suporte ao usuário durante a tomada de decisão. [13] aplicaram a análise de decisão por multicritérios (MCDA) a fim de priorizar os critérios relevantes na tomada de decisão. Já [14] desenvolve a automatização de um caminho clínico, e o integra aos controladores hospitalares do paciente, explicitando a importância do desenvolvimento de processos de decisão e auxílio à decisão para o processo hospitalar.

Em relação ao BPMN, [15] modela um processo hospitalar com o intuito de auxiliar a gestão e proporcionar uma melhor visualização dos processos a fim de promover melhorias. [16] propõem um framework de suporte à decisão na área da saúde. Em seu framework o processo referente ao tratamento de AVC isquêmico é modelado em

BPMN. Os autores utilizam em conjunto a abordagem de modelo de questionário e ontologias a fim de dar suporte ao usuário durante a tomada de decisão.

Por sua vez, apesar de sua ampla aplicação, o uso do DMN na área da saúde é escasso. De forma que, sua aplicação, tem focado na transformação de processos configurados em BPMN para DMN, extraindo seu modelo lógico e apontando boas práticas para tal transformação. Como o DMN é uma abordagem mais recente, e apresenta uma abordagem mais focada ao processo decisório é fundamental compreender as melhores formas de realizar essa conversão [17]–[19]. [20] desenvolvem uma ferramenta de visualização para gestão de infecções baseada tanto em BPMN quanto DMN. [21] também aborda o uso de DMN, junto a um software, como base para tomadas de decisões flexíveis, tornando os processos baseados em dados e customizáveis. Assim, esta pesquisa visa analisar a aplicação da abordagem de questionário tanto com o BPMN como o DMN, a fim de compreender os benefícios resultantes e os gaps existentes. A próxima seção apresenta abordagem de questionário aplicado a um processo desenvolvido em BPMN e DMN.

3 Decisão com Business Process Model Notation (BPMN)

É notável o uso do BPMN para processos, sendo, inclusive, uma das linguagens de modelagem mais populares devido a sua versatilidade. De acordo com [6], o BPMN, entre todas as linguagens de modelagem de processos disponíveis foi amplamente aceito na indústria e na academia. Desta forma, o BPMN pode ser definido como uma ferramenta, na qual processos são definidos como uma sequência de atividades, pontos de decisão (caracterizados por gateways do tipo OR) e de paralelização (caracterizados por gateways do tipo AND), reguladas por mecanismos, como avaliações (decisões) ou eventos (situações que podem ocorrer em determinado momento) que direcionam o processo para determinada rota a fim de atingir um objetivo específico [22].

O BPMN é uma linguagem composta por diversos elementos, tais como, atividades, eventos, pools, lanes, gateways, artefatos e conectores. Porém, esta é uma linguagem simples e de fácil entendimento, capaz de mostrar o fluxo de execução das atividades, bem como proporcionar suporte a informação [23]. A **Fig. 1** apresenta um exemplo de um fragmento do processo desenvolvido em BPMN aplicado ao processo de infusão de rt-PA em pacientes com AVC isquêmico [24]. O AVC isquêmico acontece devido à formação de trombos em um dos vasos sanguíneos, interrompendo assim o fluxo sanguíneo em parte do cérebro [25]. Um dos tratamentos para o AVC isquêmico refere-se a infusão de trombolíticos (também chamado de infusão de rt-PA), os quais são capazes de dissolver os coágulos sanguíneos e podem ser utilizados até 4 horas e 30 minutos após o início dos sintomas.

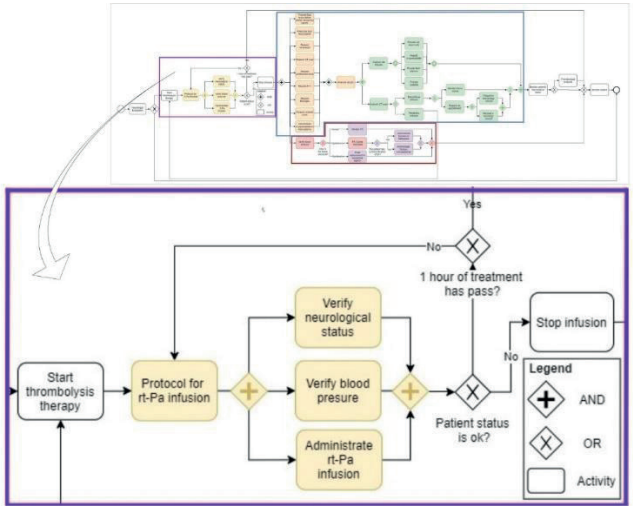

Fig. 1. Processo de infusão de rt-PA em BPMN. Adaptado de Detro *et al* (2019)

O processo apresentado na **Fig. 1.** é composto por diversas atividades (representados por retângulos), *gateways* (representados por losangos) do tipo OR (X) e AND (+). Em gateways do tipo OR, uma decisão deve ser tomada com base em alguma informação obtida ou resultado esperado. Tal decisão vai desencadear a execução de uma das sequências de atividades conectadas, ou seja, na seleção de um caminho, ou até mesmo no fim do processo. Por outro lado, *gateways* do tipo AND representam que as próximas atividades devem ser executadas em paralelo. Como exemplo, na figura, após a execução da atividade "*Protocol for rt-PA infusion*", encontra-se um *gateway* AND, mostrando que três atividades ("*Verify Neurological status*", "*Verify blood pressure*" e "*Administrate rt-PA infusion")* são executadas em paralelo. Após a execução destas atividades, encontra-se um gateway do tipo OR, no qual uma decisão deve ser feita levando ao fim da infusão ou a outro gateway do tipo OR (ou ponto de decisão).

Processos desenvolvidos em BPMN apresentam, muitas vezes, lógicas de decisões em seus diagramas, o que pode gerar modelos complexos e insustentáveis [17]. Em adição, processos em BPMN quando complexos não são escaláveis para múltiplas atividades devido a problemas de performance computacional [26]. Segundo [17], a metodologia BPMN não é feita para representar processos lógicos de decisão de forma detalhada, resultando em modelos "spaghetti", o qual representam uma situação em que muitos arcos se cruzam, tornando a interpretação complexa. Entretanto, para processos com menor quantidade de ramificações, o BPMN se apresenta mais simples para compreensão. Também, é fundamental destacar que, tal problema existe, muitas vezes, por que muitas pesquisas focam no aspecto de controle usando BPMN, e a análise do fluxo de dados acaba sendo menos estudada [8].

Conforme mencionado anteriormente, o BPMN em conjunto com a abordagem de questionário pode dar suporte à tomada de decisão. A abordagem do modelo de questionário quando aplicada ao modelo de processo desenvolvido em BPMN, permite uma maior compreensão a respeito da lógica do processo, bem como um maior controle no

que diz respeito a ordem em que as opções são apresentadas aos usuários durante a configuração do processo. Para tal, a abordagem de modelo de questionário pode ser aplicada para auxiliar o usuário final. Além disso, esta abordagem limita as opções nos pontos de decisão, impedindo escolhas inconsistentes [12].

Dessa forma, [27] ressaltam que um modelo de questionário compreende um conjunto de fatos correspondentes a um conjunto de perguntas que são expressas em linguagem natural, de modo que, cada um desses fatos corresponde a uma variável booleana que representa uma característica particular. Por sua vez, [12] também apresenta o desenvolvimento de um modelo de questionário que considera a variabilidade do processo. Tal variabilidade de informações deve ser organizada de modo a possibilitar uma estrutura de escolhas. Essa estrutura determina as ações que devem ser seguidas no processo. Então, o sistema associa que cada questão se refere a um conjunto de fatos que podem ser verdadeiros ou falsos. Tais fatos se traduzem na variabilidade do sistema (valores de parâmetros). Assim, conforme o questionário é respondido, os valores são associados a fatos. E por sua vez, define-se automaticamente quais serão as próximas questões, de modo a não exibir questões irrelevantes. A **Fig. 2** mostra um fragmento referente a aplicação da abordagem do modelo de questionário no modelo de processo desenvolvido em BPMN referente ao tratamento de infusão de rt-PA para pacientes diagnosticados com AVC isquêmico.

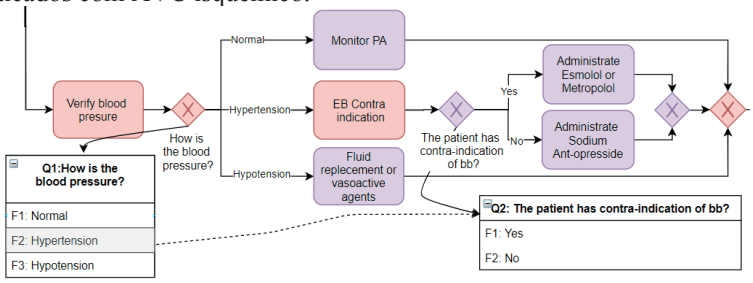

Fig. 2. Monitoramento do paciente em BPMN com modelo de questionário

Este fragmento do processo apresenta dois pontos de decisão (representados por gateways do tipo OR). O primeiro ponto de decisão, referente à questão Q1 "*How is the blood pressure*?", possui três opções possíveis. Caso o usuário selecione as opções "F1:Normal" ou "F3:Hypotension", as atividades executadas serão '*Monitor Pa'* ou '*Fluid replacement'*, respectivamente. Neste caso, nenhuma nova pergunta é habilitada. Porém, se a opção selecionada for "F2:Hypertension", então a pergunta Q2 "*The patient has contra-indication of bb (beta blockers*)?" é habilitada a fim de direcionar o tratamento correto. Por sua vez, em termos lógicos, se Q1 = F1 ou Q1 = F3 então o questionário é finalizado. Se Q1 = F2, então Q2 é habilitado e uma nova seleção deve ser feita pelo usuário. Assim, nota-se que a abordagem de questionário quando aplicada em modelos desenvolvidos em BPMN facilita a tomada de decisão e, conforme mencionado, esta abordagem permite que apenas as perguntas relevantes sejam apresentadas ao usuário. A próxima seção apresenta a aplicação da abordagem de questionário com modelos desenvolvidos em DMN.

4 Decisão com Domain Model and Notation (DMN)

Esta seção apresenta o desenvolvimento do modelo de processo em DMN referente ao tratamento de infusão de rt-PA em pacientes diagnosticados com AVC isquêmico, bem como a transcrição do modelo BPMN para DMN. Além disso, também é apresentado a aplicação da abordagem de questionário com um modelo de processo desenvolvido em DMN.

4.1 Funcionamento do DMN

Como visto na seção anterior, o BPMN não leva em consideração a lógica da informação dos processos [8]. [17] complementa que o modelo de decisão lógico está fora de escopo do BPMN. Assim, tabelas de decisão e outros conceitos de modelagem de decisões são um método razoável e compacto para descrever decisões em cenários com muitos parâmetros de entradas. [28] afirmam que o DMN pode ser usado também a fim de automatizar decisões e até mesmo automatizar análises para equipes de *business analytics*. Desse modo, o DMN é uma solução razoável para preencher o vazio da representação das decisões no aspecto de modelagem de processos [19].

O método DMN foi desenvolvido para modelar decisões e ser usado como complemento do BPMN para design de decisões. [29] apresenta o DMN como uma ferramenta cujo principal objetivo da sua notação é mostrar uma visão lógica e orientada por objetos. Entretanto, tal como aponta [30], a modelagem de decisões é desafiadora e definir como a modelagem será feita é um fator crucial para o resultado. [19] explica que o processo para desenvolvimento do DMN possui dois níveis que devem ser usados em conjunto, conforme mostra a **Fig. 3**.

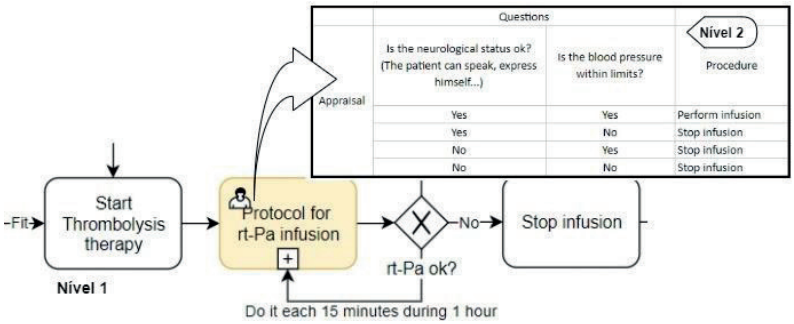

Fig. 3. Processo de infusão de rt-PA em DMN com seus dois níveis.

O primeiro nível é o de solicitação da decisão que apresenta as decisões no modelo, conforme apresentado na **Fig. 3**, a qual apresenta o fragmento referente ao processo para a infusão de rt-PA para o tratamento de pacientes com AVC. O nível 1 deste processo em DMN, assim como no BPMN apresenta as atividades em retângulos. Porém, de forma geral, as atividades no DMN são concentradas em uma só. Assim, por mais que no BPMN as atividades também possam ser concentradas em subprocessos, no DMN elas se transformam, visualmente, em tabelas e não em uma segunda camada do

diagrama. Assim, no DMN, a atividade "Protocol for rt-PA infusion" concentra as micro atividades de "Verify Neurological Status", "Verify Pressure", "Administrate rt-Pa infusion" junto a ela. Estas três atividades são executadas em paralelo.

Já no segundo nível do modelo lógico, são apresentadas as maneiras de especificar a lógica de decisão subjacente. E, por sua vez, podem ser exibidos para o usuário final em forma de modelo de questionário para auxiliar na decisão. A tabela apresenta as opções para o primeiro ponto de decisão considerando todas as possibilidades. Assim, as micro atividades podem ser condensadas em uma tabela de decisão. Deixando, no DMN, as possibilidades mais claras que no BPMN, mesmo com o questionário aplicado. Para a elaboração do DMN, geralmente realizado por transição de um BPMN, é necessário explicitar, tal como afirma [18], que não é claro qual informação/processo carrega valor de decisão e como a variabilidade de processos deve ser diferenciada quando externalizada para um modelo de decisão.

4.2 Transcrição do processo em BPMN para DMN

Na aplicação do DMN, todo o processo, representado em BPMN por meio de diagramas e gateways de decisão, deve estar presente no DMN, devidamente traduzido em sua própria linguagem. Entretanto, deve ser dado destaque aos pontos de decisão. Referente ao primeiro nível, que é constituído primeiro, é fundamental analisar a estrutura em BPMN e identificar: 1. Quais pontos de decisão podem ser simplificados/unidos; 2. Quais pontos de decisão devem ser mantidos; 3. Quais pontos de decisão devem ser reorganizados; 4. Quais critérios são avaliados em cada momento de decisão; 5. Quais critérios são avaliados ao mesmo tempo; 6. Quais critérios são dependentes entre si;

Então, com o mapeamento realizado e feito a análise da estrutura em BPMN, deve-se criar o diagrama, o qual é apresentado na **Fig. 4**. O diagrama, anteriormente em BPMN, com 38 pontos de atividade e 13 pontos de decisão e/ou paralelização; é composto por apenas 10 blocos de processo e 5 pontos de decisão. De modo que as transformações para adequação do modelo, em termos do primeiro nível, são destacadas nos próximos parágrafos.

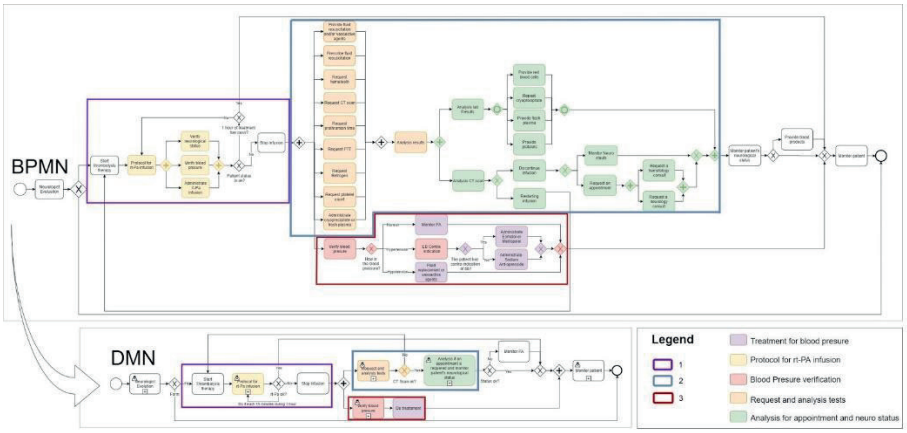

Fig. 4. Resumo das transcrições do Processo de AVC em BPMN para DMN.

Primeiramente, tem-se o subprocesso de infusão de rt-PA que inicia com a atividade "*Protocol rt-Pa infusion*". Após sua execução, as atividades "*Verify neurological* status", "*Verify blood pressure*", "*Administrate rt-Pa infusion*" são realizadas em paralelo. Na sequência existe um gateway do tipo OR(X). Neste gateway, deve-se verificar o resultado dos três processos realizados no paciente e identificar se o mesmo é capaz de continuar o processo. Se o paciente apresentar sintomas de hemorragia ou pressão alta, a infusão deve ser encerrada ("*Stop infusion*"). Caso contrário, o segundo *gateway* OR é verificado. Neste gateway, deve-se verificar o tempo de infusão. Se o tempo for menor que o prescrito pelo neurologista, a infusão e a verificação do status do paciente continuam. Caso contrário, a infusão é finalizada. Este fragmento do processo contém 5 blocos de atividades, dois símbolos de AND e dois símbolos de OR e, podem ser simplificados para duas atividades: "*Protocol for rt-Pa infusion*" e "*Stop Infusion*". Neste caso, as atividades de verificação do status do paciente são simplificadas na atividade "*Protocol for rt-Pa infusion*" e se referem a apenas 1 bloco de OR;

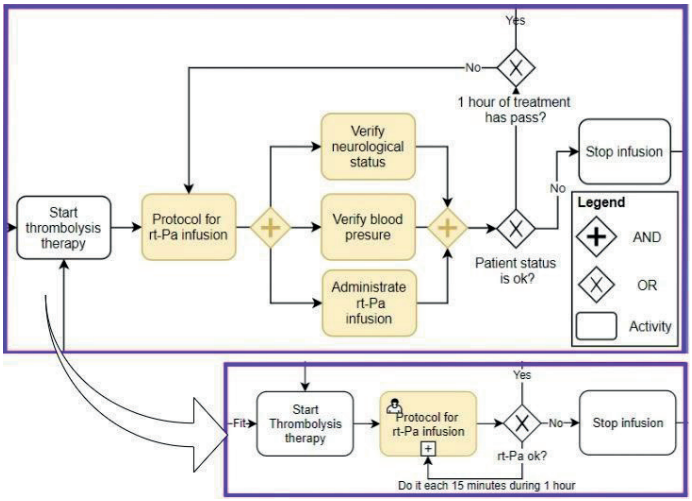

Fig. 5. Transcrição do processo de infusão de rt-PA

Já, se a atividade "*Stop infusion*" for executada, então, serão executadas atividades referentes a requisição de exames, bem como as análises destes exames. De modo que, no BPMN, o processo é composto por nove blocos de requisições médicas, seguido de um bloco de análise de resultados que, por meio do gateway AND, divide em mais cinco blocos as análises dos resultados do laboratório e outros sete blocos as análises da tomografia computadorizada e, em caso de necessidade, o agendamento de consulta com médico (neurologista ou hematologista). Totalizando vinte e dois blocos de atividades, seis blocos de AND, dois blocos de EVENT e três blocos de decisão. Estes blocos podem ser reduzidos no DMN para quatro blocos de atividades, três blocos de decisão e um bloco AND. De modo que os nove blocos de requisições médicas, os blocos de análises em laboratório e os blocos de análises da tomografia computadorizada foram agregados em "*Request and analysis tests*", de forma que, como output, a decisão sobre a necessidade de continuar a infusão e solicitar consulta gera um bloco OR (de

decisão) e define a necessidade de realizar uma consulta ou então de refazer o processo de infusão de rt-Pa.

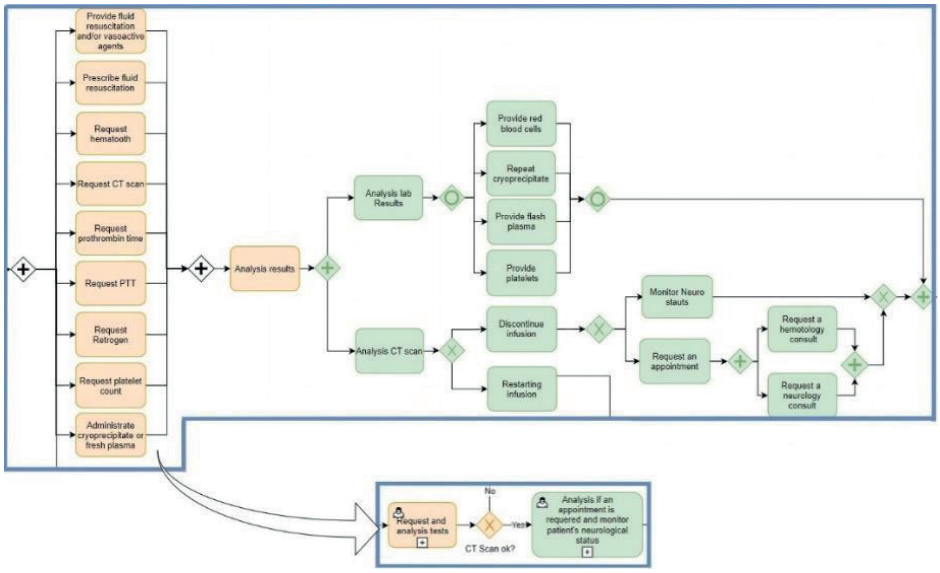

Fig. 6. Transcrição do processo de avaliação

Por sua vez, o subprocesso de monitoramento de infusão em BPMN é composto por seis blocos de atividades e quatro blocos OR de decisão, que podem ser agregados em 2 blocos de atividades. Um "*Verify blood pressure*" e na sequência as atividades de "*Monitor PA*", "*EB Contra indication*" (que gera "*Administrate Esmolol or Metropolol*" e "*Administrate Sodium ant-opresside*"), e "*Fluid replacement or vasoactive agents*" podem ser agregadas em "*Do treatment*";

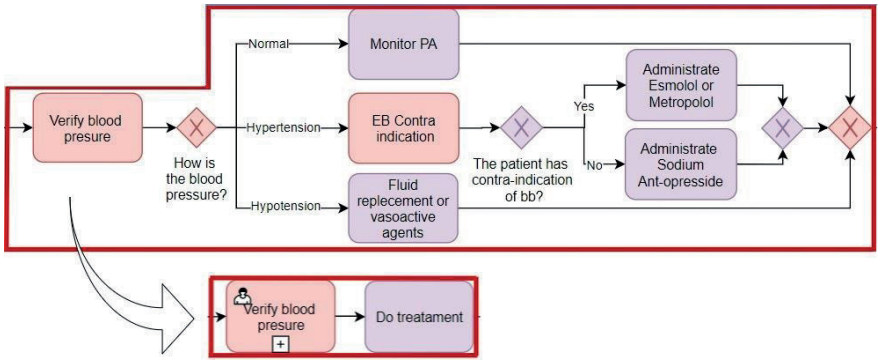

Fig. 7. Transcrição do processo de monitoramento de infusão

Também, os processos de "*Monitor PA*", "*Monitor Patient*" e "*Neurologist Evolution*" são mantidos. E por fim, é fundamental citar que no processo de "*Neurologist*

Evolution" o formulário referente a qualificação do paciente para o tratamento foi adicionado como input para a decisão do procedimento.

Após a criação do diagrama, o próximo passo é a sua validação. Se validado, é possível então, partir para o segundo nível que se refere a composição das tabelas de decisão. Tabelas essas, que são compostas por diversas perguntas (*inputs)* que retornam uma resposta (*output)*. De modo que, tal resposta define o caminho que o DMN vai seguir no DRD. Nesta segunda etapa, com o mapeamento feito anteriormente e com o diagrama construído é possível desenvolver as tabelas que contêm o detalhamento dos *inputs* e *outputs* para cada ponto de decisão. De modo que, como padrão, para *n* colunas, cada uma dessas colunas (de 1 até *n*-1) é referente a uma pergunta (*input)* e a última (*n*) é referente a resposta (*output)*. Assim, cada linha na tabela é referente a uma combinação de perguntas e sua respectiva resposta.

Além disso, é fundamental comentar que a complexidade dessas tabelas cresce de acordo com alguns fatores. O processo estudado possui tabelas com 20 colunas, com o número suficiente de linhas para todas as combinações possíveis. Entretanto, devido a seu tamanho, a sua complexidade aumenta. Tal complexidade, muitas vezes geradora de atrasos em termos computacionais, pode crescer nos seguintes casos: 1. Resposta da pergunta não ser binária ("Sim" ou "Não', 0 ou 1); 2. A resposta ter que ser segmentada em intervalos ("de 100 a 200" e de "250 a 300"), consumindo mais de uma coluna; 3. Número de *inputs;* 4. Número de opções de resposta para cada pergunta (muitas vezes as respostas podem ser uma lista).

Por sua vez, o modelo de questionário aplicado ao DMN também apresenta diversas simplificações e mudanças. Em sua aplicação, o modelo de questionário é aplicado nos pontos de atividade (retângulos) que possuem tabelas, como o "*Protocol for rt-Pa infusion*" citado em exemplos anteriores, enquanto que os questionários para o BPMN são resolvidos nos gateways OR(X). Portanto, como no DMN as decisões são coletadas nos retângulos de atividades, os pontos de decisão (XOR), neste trabalho, apenas representam diferentes caminhos que tal processo pode seguir. Além disso, a construção do diagrama do DMN tem como parte fundamental a construção das tabelas, conforme já citado anteriormente. Esse nível pode ser diretamente traduzido para o modelo de questionário, não necessitando a elaboração de lógicas para o questionário, conforme a Fig. 8.

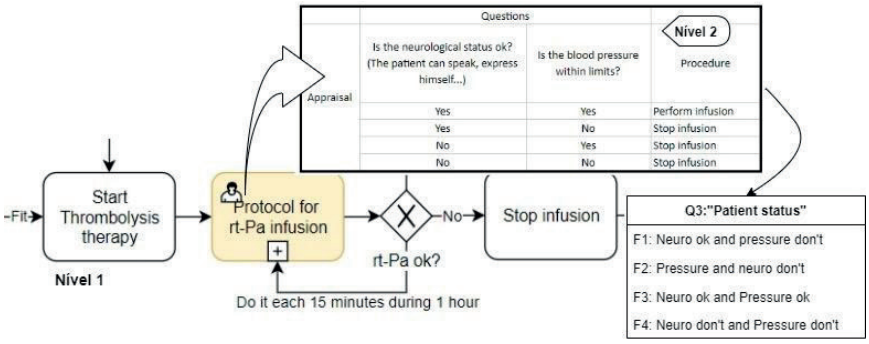

Fig. 8. Processo de infusão de rt-PA com questionário

5 Discussão

No estudo realizado, foi configurado um modelo em DMN suportado por uma abordagem de questionário, e então comparado com um modelo em BPMN também apoiado pela abordagem de questionário. Em tal comparação foi realizada a análise entre ambas as abordagens em relação a suas aplicabilidades e restrições. Para tal, foi usado o estudo de caso do processo do acidente vascular cerebral desenvolvido por [16]. De forma que, como notado na literatura, poucos autores tratam do uso de DMN na área da saúde devido tal técnica ser recente. Muitos dos trabalhos a respeito do DMN focam na transformação do processo desenvolvido em BPMN para DMN ou na integração de ambos modelos. Por outro lado, a abordagem de questionário, que pode ser utilizada em conjunto com o BPMN e o DMN, fornece suporte ao usuário na tomada de decisão. Além disso, devido às diferenças entre o BPMN e o DMN, a aplicação da abordagem de questionário pode mudar a forma como a decisão é tomada. E assim, esse trabalho é capaz de preencher o vazio encontrado referente a aplicação da técnica do DMN em processos na área de saúde e também da comparação entre processos de BPMN e DMN aplicados com modelos de questionário.

Então, ao comparar as técnicas, primeiramente verifica-se uma grande simplificação do diagrama do BPMN quando transformado para seu equivalente em DMN. Tal simplificação, para o processo aplicado, significou uma redução do fluxo, em BPMN, com 38 nós de processo e 13 pontos de decisão ou paralelização, para um estado, em DMN, de 10 nós de processo e 6 pontos de decisão no processo. Ou seja, uma diminuição de aproximadamente 73% na complexidade visual do processo e de aproximadamente 53% na redução do número de pontos de decisão que deveriam ser tomados. Também a simplificação, ao converter de BPMN para DMN, no desenvolvimento de modelos de questionários destinados a customização do processo é significativa. Pois, enquanto que em BPMN é necessário o desenvolvimento de lógica para cada possível resposta em cada nó de decisão para configuração do modelo. Em DMN, cada tabela se traduz diretamente em um questionário a ser respondido. Não necessitando assim de configurações lógicas mais elaboradas.

Por sua vez, a literatura apresenta um grande valor de resultados de busca em termos de desenvolvimento de suporte à decisão na área da saúde. Entretanto, poucos usam notações como BPMN e apenas uma pesquisa apresentou resultados sobre aplicação de DMN na saúde. [20] desenvolve uma ferramenta visual para suporte à decisão aplicada para a gestão de infecções baseado em BPMN e DMN. Sendo assim notável, tal como [17] expõem que o modelo lógico está fora de escopo do BPMN. E [31], complementa que o DMN não é um processo de modelagem padrão por si, é feito para modelagem da lógica do negócio. De modo que, torna-se evidente sua aplicação para processos orientados a decisão. Tal como [14] mostram, ao apresentar que o DMN, como técnica para o suporte de decisões, em seu uso clínico de sistemas de suporte a decisão está crescendo. De modo que, técnicas de suporte de decisão, levam a um aumento na adesão das diretrizes sobre prevenção de AVC. Porém, é fundamental ressaltar que o DMN ainda possui algumas contra partidas. [31] mostra que, como uma nova aplicação, o DMN requer um know-how novo sobre tal técnica. Afirma também que, tal técnica ainda não é tão conhecida como as demais e que sozinho não é capaz de definir um

processo. Sendo assim, como processos em DMN são transcritos de processos desenvolvidos em BPMN, [18] ressaltam que não é claro qual informação processual carrega valor de decisão, e qual dos vários tipos de processos ligados devem ser diferenciados quando externalizados em um DMN.

Logo, a pesquisa realizada encontrou suas restrições. Em primeiro lugar, observou-se processos com muitas variáveis de decisão ao mesmo tempo, tal como longos questionários, podem gerar tabelas muito complexas para o DMN. Afinal, é necessária uma linha na tabela para cada combinação de respostas, e cada combinação de respostas é um conjunto de variáveis de cada coluna. Portanto o tamanho de cada tabela é *n*x*m* (*n* sendo total de respostas possíveis e m sendo o número de perguntas) linhas por *m* colunas. Sendo fundamental ressaltar também que, em casos de combinações não lineares de resposta (sim, não), ainda maior pode ser o tamanho dessas tabelas. Além disso, é notável que o DMN esconde subatividades, que podem ser cruciais em análises de maior granulação. Portanto, é fundamental explicitar que, muitas vezes é necessário trabalhar com o BPMN também lado a lado.

Também, é fundamental destacar que tal trabalho ainda possui muito a ser desenvolvido. Em primeiro lugar, é natural a possibilidade de uma análise multicritérios junto ao DMN aplicado a tomada de decisão, de modo que, tendo o questionário, existe a possibilidade de dar sugestões ao usuário para que ele selecione a melhor opção de acordo com um resultado específico. Assim, outro caminho possível é o uso da técnica AHP (*Analytic Hierarchy Process*) junto com o modelo de questionário e com DMN como forma de dar dicas e apoio durante o processo decisório, porém aplicados a outros processos. Também, existe a necessidade de pré análise para otimização das perguntas ou fatores decisivos no processo, avaliando assim suas reais relevâncias e impactos. Em adição, é relevante o desenvolvimento da aplicação desse trabalho em outros processos e comparação entre eles, afinal é fundamental compreender a real aplicabilidade dessa abordagem em outros cenários.

6 Conclusão

Neste trabalho foi proposto um modelo de processos focado em decisão aplicado ao processo hospitalar do Acidente Vascular Cerebral (AVC), desenvolvido em DMN, em conjunto com um modelo de questionário a fim de facilitar a usabilidade para o usuário final. Assim, a partir da compreensão e análise do modelo do processo do AVC em BPMN e do estudo da funcionalidade do DMN foi possível perceber que nesse processo, quando orientado com foco nas decisões, pode ser melhor compreendido se desenvolvido em DMN. Afinal, tal técnica simplifica a complexidade de visualização dos modelos. Também, quando aplicado junto ao modelo de questionário evidencia-se que a sua implementação se torna muito mais fácil. Pois, dessa forma, não é necessário a configuração de regras lógicas de (se-então) para os questionários. E assim, o DMN se mostra capaz de ser mais eficiente ao ser implementado.

Porém, os modelos desenvolvidos não foram comparados com outros processos a fim de avaliar se o ganho do desenvolvimento em DMN é realmente significativo para todos os casos. Ou então, para compreender em que casos que tal implementação é

relevante. Também, sistemas não foram desenvolvidos para implementar, testar e comparar ambas abordagens com outros processos. Logo, tais observações levantadas na pesquisa precisam ser validadas em pesquisas futuras.

Abstract. A precise control on the molecular structure is required to enhance the development of innovative polymers. Reversible Deactivation Radical Polymerization (RDRP) techniques allow to synthesize advanced molecular structures without stringent purity conditions, which improves their potential for industrial manufacturing. In particular, the RDRP variant Activators ReGenerated by Electron Transfer – Atom Transfer Radical Polymerization (ARGET-ATRP) presents additional advantages, such as requiring very low concentration of transition metal catalyst. This reduces significantly the need of post reaction removal of residual catalyst and consequently the polymer purification cost. In addition, ARGET-ATRP tolerates a limited amount of air in the reaction environment.

In order to enhance the cost-performance ratio it is important to optimize the production process. Mathematical modeling is a powerful tool, extensively used to improve production time and process control. Part I and Part II of this work present a very detailed mathematical model of ARGET-ATRP copolymerization of styrene and acrylonitrile (SAN). Part I is devoted to the estimation of the kinetic parameters of the model. A good agreement between model and experimental data is achieved. Part II describes in detail the modeling of the bivariate molecular weight distribution-copolymer composition distribution of the copolymer, as well as the overall molecular weight distribution and copolymer composition distribution, using parallel computing and an efficient programming language.

Keywords: Copolymerization, ARGET-ATRP, Parameter Estimation, SAN.

1 Introduction

Reversible Deactivation Radical Polymerization (RDRP) has been one of the most important developments of polymer chemistry in the last decades. This family polymerization techniques make possible the synthesis of materials with prespecified molecular structures with unique physicochemical properties.

RDRP relies on adding a control reagent that reversibly deactivates radicals. When the radical chain is in its dormant state it cannot participate in any reaction, which minimizes radical termination. In this way, the lifetime of a growing polymer chain is extended from approximately a second to hours, allowing the manipulation of its molecular structure by implementing appropriate operating policies. Moreover, RDRP combines the high degree of control on the polymer properties with the ease of large-scale implementation of a free radical polymerization. However, presumably due to the need of removing control agent residues or by-products and to the higher cost resulting from the use of expensive control reagents, the number of commercial products produced with this technology is a lot less than initially expected [1].

New RDRP mechanisms have been developed that overcome most of its drawbacks. Activators ReGenerated by Electron Transfer – Atom Transfer Radical Polymerization (ARGET-ATRP) is one of the most promising techniques. Conventional ATRP relies on adding a transition metal salt (usually CuBr or CuCl) that traps the radical and when it oxidizes acts as activator. During termination processes, Cu^{II} species are irreversibly formed and, therefore, more Cu^{I} salt is needed to continue the polymerization. In ARGET-ATRP, the Cu^{I} species are (re)generated in the reaction medium from the oxidized Cu^{II} salt using a reducing agent. In this way, only the oxidized and more stable Cu^{II} salt has to be handled, facilitating the synthesis process. Besides, the amount of Cu salt that remains as residue is drastically decreased, sometimes eliminating the need of purification procedures.

The benefits of the better performance showed by the materials obtained by RDRP in general and by ARGET-ATRP in particular may not be enough to justify the higher production costs. Moreover, many of these costs are due to the purification processes required to eliminate the control agent residues and non-reacted monomers. These process flaws can be reduced with an efficient and accurate model [2]. Modeling is a powerful tool, extensively used to improve production times and process control. Programmed feeding policies have allowed to synthetized targeted structures [3] and to improve reaction conversion [4]. In this context, a reliable set of parameters is crucial to carry out successful simulations.

Styrene-acrylonitrile (SAN) copolymer is a thermoplastic often used as structural material thanks to its processability, solvent resistance and thermal stability [5]. Moreover, these superior properties make it a good potential candidate for use in polymer blends. However, poor compatibility has been encountered in many cases due to polymers immiscibility [6]. In this regard, block or gradient copolymers have shown a promising performance since they could improve the interfacial adhesion of different phases [7]. In most cases, these types of copolymers can only be obtained by means of RDRP techniques. The course of polymerization strongly depends on the initial composition and the feeding policy [4, 8], so a mathematical model is a very important tool for the operation of the process. Few works have dealt with the modeling of ARGET-ATRP processes and most of them have relied on kinetic parameters found in the literature [9-14]. In particular, modeling studies of the RDRP of SAN polymers are scarce.

Part I and Part II of this work present a very detailed model of the ARGET-ATRP of SAN. Part II focuses on the efficient modeling of the bivariate molecular weight distribution (MWD)-copolymer composition distribution (CCD) of the copolymer, as

well as the overall molecular weight distribution and copolymer composition distributions, using parallel computing and a suitable programming language. Part I presents the estimation of the model kinetic parameters using experimental data taken from the literature [15].

2 Methods

2.1 Kinetic Mechanism.

The process under study in this work is the synthesis of poly(SAN) via ARGET-ATRP at 80ºC in solution of anisole using $CuCl_2$ as the transition metal catalyst and hexamethyl-tris(2-aminoethyl)amine (Me_6TREN) as ligand, ethyl 2-bromo iso-butyrate (EBriB) as radical initiator, and tin(II) 2-ethylhexanoate ($Sn(EH)_2$) as the reducing agent [15].

The mathematical model is based on the following kinetic mechanism:

Activation:

$$I - X + (X - Cu^I)L \xrightarrow{k_{act0}} I^* + (X_2 - Cu^{II})L \quad (1)$$

$$D^j_{n,m} + (X - Cu^I)L \xrightarrow{k_{actj}} R^j_{n,m} + (X_2 - Cu^{II})L \quad (2)$$

Deactivation:

$$I^* + (X_2 - Cu^{II})L \xrightarrow{k_{deact0}} I - X + (X - Cu^I)L \quad (3)$$

$$R^j_{n,m} + (X_2 - Cu^{II})L \xrightarrow{k_{deactj}} D^j_{n,m} + (X - Cu^I)L \quad (4)$$

Propagation:

$$I^* + M^1 \xrightarrow{k_{01}} R^1_{1,0} \quad (5)$$

$$I^* + M^2 \xrightarrow{k_{02}} R^2_{0,1} \quad (6)$$

$$R^j_{n,m} + M^1 \xrightarrow{k_{j1}} R^1_{n+1,m} \quad (7)$$

$$R^j_{n,m} + M^2 \xrightarrow{k_{j2}} R^2_{n,m+1} \quad (8)$$

Reduction:

$$(X_2 - Cu^{II})L + Sn^{II}(EH)_2 \xrightarrow{k_{r1}} (X - Cu^I)L + X - Sn^{III}(EH)_2 \quad (9)$$

$$(X_2 - Cu^{II})L + X - Sn^{III}(EH)_2 \xrightarrow{k_{r2}} (X - Cu^I)L + X_2 - Sn^{IV}(EH)_2 \quad (10)$$

Termination by Combination:

$$2I^* \xrightarrow{k_{tc00}} P_0 \quad (11)$$

$$I^* + R^j_{n,m} \xrightarrow{k_{tc0}} P_{n,m} \quad (12)$$

$$R^j_{n,m} + R^k_{d,\ t} \xrightarrow{k_{tcjk}} P_{n+d,m+t} \quad (13)$$

Chain Transfer to Monomer:

$$R_{n,m}^{j} + M^{1} \xrightarrow{k_{trm\,j1}} P_{n,m} + R_{1,0}^{1} \quad (14)$$

$$R_{n,m}^{j} + M^{2} \xrightarrow{k_{trm\,j2}} P_{n,m} + R_{0,1}^{2} \quad (15)$$

The polymerization starts with the reversible activation of the initiator EBriB (I-X) by the complexed copper catalyst in reduced state, (X-Cu^{I})L. In this reaction, the catalyst is oxidized ((X_2-Cu^{II})L) and an initiating radical (I*) is formed. Each I* will be the beginning of a polymer chain. In the propagation step the active radicals add monomer units (M^1=styrene, M^2=acrylonitrile) forming a longer radical chain ($R^j_{n,m}$) with *n* units of M^1 and *m* units of M^2 that ends in an M^j monomer unit. These propagating radicals will be periodically deactivated forming the dormant specie ($D^j_{n,m}$). Eventually, the growing chain could find another radical and undergo irreversible termination forming a "dead" polymer chain with *n* units of M^1 and *m* units of M^2 ($P_{n,m}$). The oxidized catalyst is reduced with the reducing agent ($Sn^{II}(EH)_2$) in a two-step process forming (X-$Sn^{III}(EH)_2$) and (X-$Sn^{IV}(EH)_2$), respectively.

The kinetic constant of activation and deactivation are different if the initial (I*) or a growing radical is reacting, i.e. if the reaction is the initiation activation or the core-equilibrium activation. Similarly, the kinetic constants of the propagation step are different if the reaction involves an initiating radical (I*) or a polymer radical ($R^j_{n,m}$). Chain transfer to polymer and termination by disproportionation were considered negligible [16, 17], as well as thermal initiation of styrene and terminal double bond propagation.

2.2 Mathematical Model.

The version of the mathematical model employed in Part I of this works uses the method of moments to compute average molecular properties, such as molecular weights and copolymer composition, and conversion [18]. Besides, it applies the 1D probability generating functions (pgf) technique to model the overall MWD of the copolymer. In this technique, the mass balances are transformed to the pgf domain. When doing so, the differential-algebraic equation system size is reduced leading to an easier resolution. After solving the pgf balance equations, the pgf are inverted to recover the MWD from the transformed domain using the IFG inversion method. Further details on this technique and its mathematical implementation may be found elsewhere [19, 20].

2.3 Estimation of Kinetic Parameters

The parameter estimation problem was formulated and solved in gPROMS ModelBuilder (Process Systems Enterprise, Ltd.) in a standard PC. gPROMS possess a state-of-the-art Parameter Estimation entity that maximize the probability that the model will predict the experimental data [21]. Multiple starting points were tested in order to minimize the chances of falling in a local optimum.

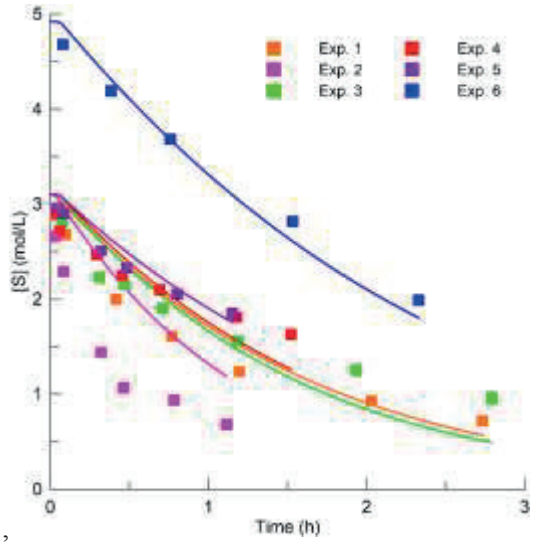
Experimental data of conversion, number-average molecular weight ($\overline{M_n}$), and dispersity ($Đ$) of six experiments taken from Pietrasik et al. [15] were used for the

parameter estimation. All the experiments were carried out with a molar ratio of S/AN of 60/40, which is the azeotropic composition for the mixture [15]. This implies that the copolymer is produced with this same composition, and that the monomer composition remains constant during the course of the reaction. Table 1 shows the experimental conditions of these experiments.

Table 1. Initial conditions of the experiments used in the parameter estimation problem. Reaction temperature: 80 °C. Solvent: anisole. Concentrations in mol/L [15].

Experiment	[S]	[AN]	[EBriB]	[$CuCl_2$]	[Me6Tren]	[$Sn(EH)_2$]
1	3.17	2.06	5.28×10^{-3}	5.28×10^{-5}	2.64×10^{-3}	2.64×10^{-3}
2	3.17	2.06	5.28×10^{-3}	1.59×10^{-4}	2.64×10^{-3}	2.64×10^{-3}
3	3.17	2.06	3.17×10^{-3}	1.59×10^{-4}	1.59×10^{-3}	1.59×10^{-3}
4	3.17	2.06	1.59×10^{-3}	2.62×10^{-4}	1.59×10^{-3}	1.59×10^{-3}
5	3.17	2.06	1.59×10^{-3}	1.59×10^{-4}	1.59×10^{-3}	1.59×10^{-3}
6	5.07	3.30	2.54×10^{-3}	7.62×10^{-5}	1.27×10^{-3}	1.27×10^{-3}

3 Results



The optimal set of kinetic parameters are shown in Table 2. There is a previous report about the rate constants of conventional ATRP of SAN [16], but, to the best of our knowledge, this is the first time that the kinetic constants of the activation/deactivation and reduction steps for the ARGET-ATRP of SAN have been obtained.

Table 2. Optimal values of the kinetic constants at 80 °C.
Units: L mol^{-1} min^{-1}

Reaction	Parameters	Optimal Value
Propagation	k_{01}	7.364×10^{3}
	k_{11}	7.364×10^{3}
	k_{02}	6.793×10^{6}
	k_{22}	3.397×10^{5}
	k_{12}	2.045×10^{4}
	k_{21}	4.354×10^{6}
Activation	k_{act0}	5.467×10^{3}
	k_{act1}	4.937×10^{3}
	k_{act2}	8.764×10^{4}
Deactivation	k_{deact0}	7.519×10^{5}
	k_{deact1}	6.278×10^{10}
	k_{deact2}	1.052×10^{15}
Reduction	k_{r1}	9.705

	k_{r2}	2.900×10^{4}
Termination by Combination	k_{tc11}	1.071×10^{8}
	k_{tc22}	9.006×10^{8}
	k_{tc12}	3.904×10^{7}
Chain Transfer to Monomer	k_{trm11}	1.987×10^{-2}
	k_{trm12}	5.977×10^{-1}
	k_{trm22}	1.351×10^{3}
	k_{trm21}	2.468×10^{3}

The mathematical model provides in general a good fit to experimental data, as shown in Figs. 1-4.

,

Fig. 1. Comparison between experimental concentration of styrene (symbol) and model prediction (line).

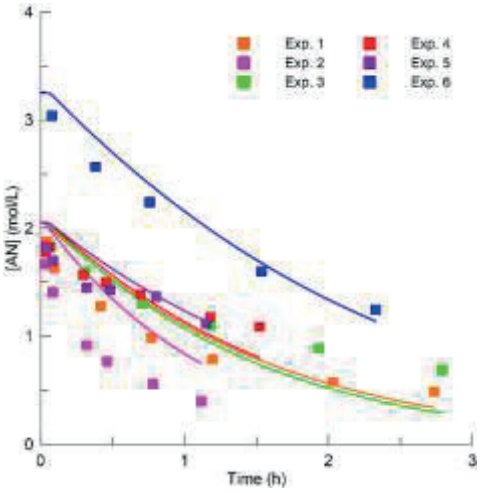


Fig. 2. Comparison between experimental concentration of acrylonitrile (symbol) and model prediction (line).

.

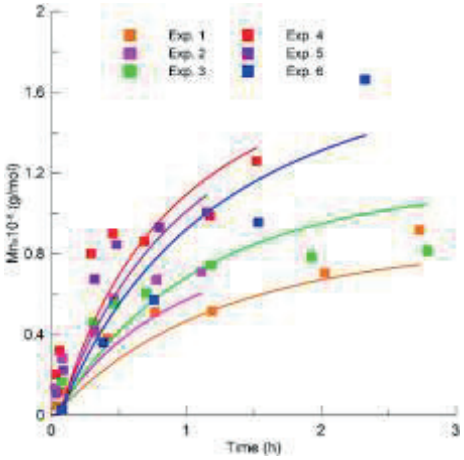

Fig. 3. Comparison between experimental number-average molecular weight (symbol) and model prediction (line).

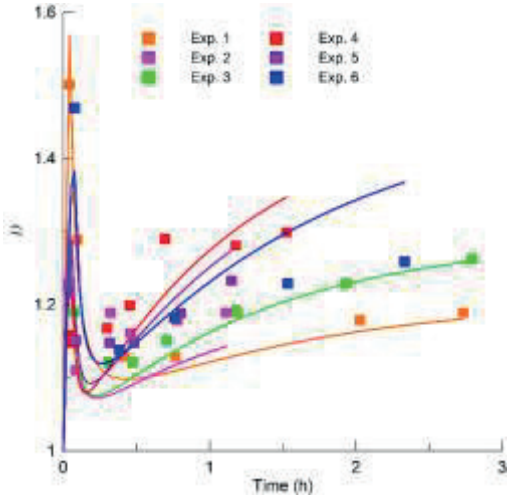

Fig. 4. Comparison between experimental dispersity (symbol) and model prediction (line).

The mathematical model may provide valuable insight on the process operation. For instance, Fig. 5 shows the average copolymer composition profile and the end-group functionality for Exp. 3 conditions. Note that the average copolymer composition remains spontaneously at the azeotropic point during the reaction, while the end-group functionality diminishes from 100 to 80 % with time. Fig. 6 presents the evolution in time of the MWD for this experiment. It shows that the MWD shifts to higher molecular weights while narrowing at the same time. However, a long low-molecular-weight tails grows at the same time, which is responsible for the increase in dispersity from 0.25 h to final time observed in Fig. 6.

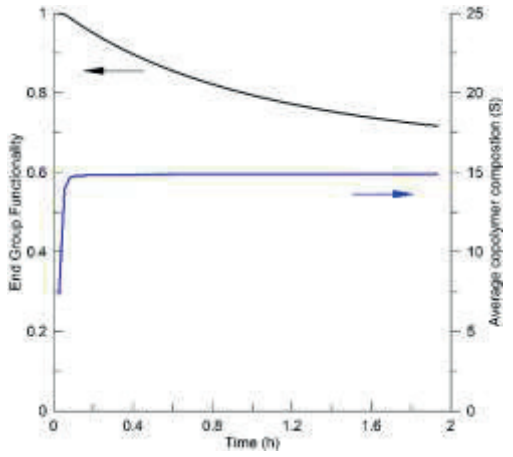

Fig. 5. Predicted average copolymer composition and end-group functionality profiles for Exp. 3 conditions.

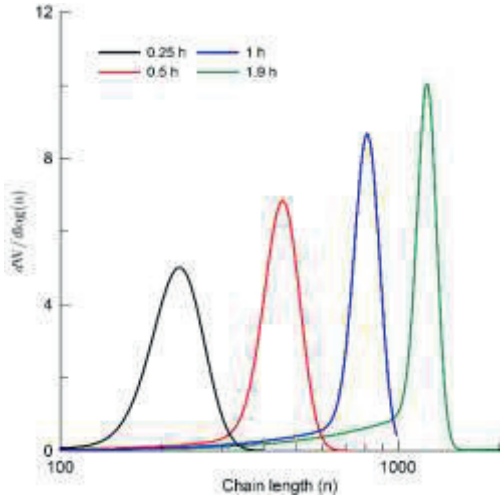

Fig. 6. Predicted MWD at different reaction time for Exp. 3 conditions.

4 Conclusion

The experimental data of MWD and average properties has been used to successfully estimate the rates constants of the ARGET-ATRP copolymerization of styrene and acrylonitrile. The set of kinetic parameters obtained allows to reproduce reasonably the experimental data. In addition, the model allowed to obtain prediction of properties that are considerably difficult to measure experimentally, such as copolymer composition and average end functionality.

The pgf technique is a powerful modeling tool of RDRP processes and can help to boost the development of innovative materials.

Abstract. The probability generating function (pgf) technique in combination with parallel computing is a very valuable tool for modeling bivariate distributions in polymerization systems. Models with this level of detail usually involve a very large system of stiff differential equations that demands efficient solution techniques. Part I of this work presented the parameter estimation of a mathematical model of the Activators ReGenerated by Electron Transfer – Atom Transfer Radical Polymerization (ARGET-ATRP) of styrene and acrylonitrile (SAN). A good agreement between model and experimental data was achieved. Part II focuses on the modeling of the bivariate molecular weight distribution (MWD)-copolymer composition distribution (CCD) of the copolymer, as well as the overall MWD and CCDs. Julia, an open-source language specifically designed for scientific computing, was used to implement the mathematical model. The parallelized implementation of the code in Julia allowed computing the bivariate distributions in relatively short times.

1 Introduction

Activators ReGenerated by Electron Transfer – Atom Transfer Radical Polymerization (ARGET-ATRP) is one of the most versatile techniques to synthesize unique polymers with prespecified molecular structure. This technique has several advantages, such as the wide range of polymerizable monomers, the low cost and availability of reagents, and the possibility of achieving high molecular weight polymers. Moreover, unlike conventional ATRP, it uses the oxidized copper salt and a reducing agent as reagents. In this way, the control agent is formed in the reaction medium from the reduction of the Cu salt, which makes the handling of reagents much easier. Additionally, the reducing agent allows carrying out the polymerization in the presence of a few ppm of

oxygen that would otherwise contaminate the reaction [1]. Reversible Deactivation Radical Polymerization (RDRP) techniques, such as ARGET-ATRP, have the capability of synthesizing polymers with tailor-made properties that may have an outstanding performance in end-use applications. However, although several polymers produced via ARGET-ATRP are already being commercialized, its industrial development has not been as wide as initially expected [2]. Many times, the improvement in material performance does not justify the increase in production cost. It is clear that the polymerization process has to be optimized and that a highly detailed understanding of the relationship between molecular structure and operation conditions needs to be developed. Mathematical modeling has been widely used to improve production times and to optimize process operation. Moreover, if the model is fitted properly to the actual experimental behavior, it is expected to predict accurately the molecular structure with a high level of detail. Simulation can be used to predict properties that are hard to measure experimentally, optimize the reaction process, and design operating feeding policies to obtain targeted structures.

However, modeling polymer growth is challenging. A growing radical could theoretically add infinite monomers to the chain which will lead to infinite mass balances. It is possible to establish a maximum chain length and therefore reduce the number of equations to a reasonable yet large number. Even so, the size of the resulting differential-algebraic equations (DAE) system is large for most polymerization systems. Furthermore, since the kinetic rates of the reactions involved differ by several orders of magnitude and the concentration of radicals relative to that of the other polymeric species is always small, the stiffness of the DAE system is high and its resolution is really difficult.

The well-known method of moments is widely used to predict polymer average properties [3]. Any distribution has infinite moments which are quantitative parameters specifics to its shape and can uniquely determine it. Since only moments of order 0, 1, and 2 are required to obtain the average properties of interest in polymer science, the technique consists of transforming the infinite mass balances into the 3 balances for the needed moments.

On the other hand, obtaining the full distribution is very complex, since the infinite set of mass balances must be solved. A polymer sample may be characterized by different types of distributions. One of the most important ones is the molecular weight distribution (MWD). It affects both processing properties (melt temperature and flow properties in molten polymers) and mechanical properties (tensile strength, impact strength, etc.). Other important molecular properties are, for example, the copolymer composition distribution (CCD), the short-chain branch distribution (SCBD), and the long-chain branch distribution (LCBD). Having a tool that allows predicting these molecular properties based on the process conditions is highly desirable.

Several methods have been proposed for modeling the MWD. In these methods, the system of equations to be solved is, in general, quite large. The extension of these methods to the computation of multivariate distributions, that is, joint distributions of more than one molecular property, is even more complex. For this reason, a reduced number of approaches have been reported [4].

One of the main problems when solving these models is not only the complexity in their formulation but also the efficiency concerning computation times, data processing, CPU and RAM memory requirements. A computational technique that has the potential to speed up the execution of mathematical models is parallel computing. Most modern computers have CPUs with more than one core (typically 4-8). However, most of the applications reported in the literature for the calculation of multivariate distributions use serial calculation, which uses a single CPU core.

To solve a particular problem using parallel computing, the problem needs to be divided into independent sections, so that each section can be solved concurrently with the other ones. Not all the methods proposed for calculating multivariate distributions meet this condition. The probability generating function (pgf) technique [5, 6] is a very efficient method for modeling multivariate distributions and is particularly suitable for use with parallel computing.

The pgf method has been used previously for modeling univariate and multivariate polymer distributions [5, 7]. This technique is based on solving the transformed pgf equations of the infinite mass balances that describe a certain process and subsequently inverting the resulting pgf to recover the desired distribution.

Developing an algorithm designed for parallel computing generally requires more effort and time than one designed for serial computing. The use of the appropriate programming language is very important to facilitate this process.

In Part I of this work [8] a model of the ARGET-ATRP copolymerization of styrene and acrylonitrile (SAN) was implemented in gPROMS ModelBuilder (Process Systems Enterprise, Ltd.) to estimate the kinetic rate constants using experimental data from the literature [9]. This model calculated conversion, average molecular properties, and the overall, univariate MWD of the copolymer. Part II of this work presents an extension of this model that calculates the bivariate MWD-CCD, the overall MWD, and the overall CCD of the copolymer. The detailed mathematical model was programmed in Julia, which is an open-source programming language easy to use and that performs very fast calculations. The pgf is used to process the infinite mass balances of the system. The code developed in Julia allowed to predict the distributed copolymer properties in a very efficient manner.

2 Mathematical Model

The experimental set up considered in this work is the synthesis of poly(SAN) via ARGET-ATRP reported by Pietrasik et al. [9]. The polymerization is carried out at 80ºC in a solution of anisole using $CuCl_2$ as transition metal catalyst and hexamethyl-tris(2-aminoethyl)amine (Me_6TREN) as ligand, ethyl 2-bromo iso-butyrate (EBriB) as radical initiator, and tin(II) 2-ethyl hexanoate ($Sn(EH)_2$) as reducing agent.

The kinetic mechanism on which the mathematical model is based is detailed in Part I of this work [8]. The mathematical description of the polymerization system involves the following entities: styrene monomer (M^1), acrylonitrile monomer (M^2), polymeric radical chains with *n* units of M^1 and *m* units of M^2 with an M^j final unit ($R^j_{n,m}$), dormant species with *n* units of M^1 and *m* units of M^2 with an M^j final unit ($D^j_{n,m}$), and terminated

polymer chains with n units of M^1 and m units of M^2 ($P_{n,m}$), initiator EbriB (I-X), complexed copper catalyst in reduced state ($X\text{-}Cu^{I}$)L, complexed copper catalyst in the oxidized state (($X_2\text{-}Cu^{II}$)L), initiating radical (I*), reducing agent ($Sn^{II}(EH)_2$), oxidized reducing agent stage 1 ($X\text{-}Sn^{III}(EH)_2$) and oxidized reducing agent stage 2 ($X\text{-}Sn^{IV}(EH)_2$).

The mass balances of the polymeric species for a batch reactor derived from the kinetic mechanism are:

$$\frac{dV\left[R^j_{n,m}\right]}{dt}=\left(\begin{array}{l}-k_{deact\,j}\left[R^j_{n,m}\right]\left[\left(X_2-Cu^{II}\right)L\right]+k_{act\,j}\left[D^j_{n,m}\right]\left[\left(X-Cu^{I}\right)L\right]\\+\left\{\left(k_{trm\,jj}\,\lambda^j_{0,0}+k_{trm\,ij}\,\lambda^i_{0,0}\right)\left[M_j\right]\right\}\delta_{n,1\delta_{j,1}}\delta_{m,1\delta_{j,2}}\\+k_{ij}\left[M^j\right]\left[R^i_{n-1\delta_{j,1},m-1\delta_{j,2}}\right]+k_{jj}\left[M^j\right]\left[R^j_{n-1\delta_{j,1},m-1\delta_{j,2}}\right]\\+k_{0\,j}\left[I^*\right]\left[M^j\right]\delta_{n,1\delta_{j,1}}\delta_{m,1\delta_{j,2}}\\-\left\{\begin{array}{l}\left(k_{jj}+k_{trm\,jj}\right)\left[M^j\right]+\left(k_{ji}+k_{trm\,ji}\right)\left[M^i\right]\\+k_{tc\,jj}\,\lambda^j_{0,0}+k_{tc\,ji}\,\lambda^i_{0,0}+k_{tc0}\left[I^*\right]\end{array}\right\}\left[R^j_{n,m}\right]\end{array}\right)V \qquad (1)$$

$$\frac{dV\left[D^j_{n,m}\right]}{dt}=\left(k_{deact\,j}\left[R^j_{n,m}\right]\left[\left(X_2-Cu^{II}\right)L\right]-k_{act\,j}\left[D^j_{n,m}\right]\left[\left(X-Cu^{I}\right)L\right]\right)V \qquad (2)$$

$$\frac{dV\left[P_{n,m}\right]}{dt}=\left(\begin{array}{l}\left(k_{trm\,11}\left[M^1\right]+k_{trm\,12}\left[M^2\right]\right)\left[R^1_{n,m}\right]\\+\left(k_{trm\,21}\left[M^1\right]+k_{trm\,22}\left[M^2\right]\right)\left[R^2_{n,m}\right]\\+k_{tc12}\sum_{l=0}^{n-l}\sum_{r=0}^{m-r}\left[R^1_{n-l,m-r}\right]\left[R^2_{l,r}\right]\\+\left(\frac{1}{2}\right)k_{tc11}\sum_{l=0}^{n-l}\sum_{r=0}^{m-r}\left[R^1_{n-l,m-r}\right]\left[R^1_{l,r}\right]\\+\left(\frac{1}{2}\right)k_{tc22}\sum_{l=0}^{n-l}\sum_{r=0}^{m-r}\left[R^2_{n-l,m-r}\right]\left[R^2_{l,r}\right]\\+k_{tc10}\left[R^1_{n,m}\right]I^*+k_{tc20}\left[R^2_{n,m}\right]I^*\end{array}\right)V \qquad (3)$$

In these equations, $\delta_{x,y}$ is the Kronecker delta ($\delta_{x,y}=1$ if $x=y$ or 0 otherwise) and $\lambda^j_{0,0}$ is the moment of order (0,0) of the distribution of $R^j_{n,m}$. This moment is a particular case of the moment of order (a,b) of the distribution of $R^j_{n,m}$, defined as:

$$\lambda_{a,b}^{j} = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} n^{a} m^{b} \left[R_{n,m}^{j} \right] \tag{4}$$

Moments of the distributions of dormant and terminated polymer species may be also defined as:

$$\beta_{a,b}^{j} = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} n^{a} m^{b} \left[D_{n,m}^{j} \right] \tag{5}$$

$$\gamma_{a,b} = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} n^{a} m^{b} \left[P_{n,m} \right] \tag{6}$$

Given that the total polymer chain population is $\mathrm{CP}_{n,m} = \sum_{j=1}^{2} R_{n,m}^{j} + \sum_{j=1}^{2} D_{n,m}^{j} + P_{n,m}$, finding the bivariate MWD of CP requires solving Eqs. (1)-(3) for the infinite possible values of $n = 1,\ldots,\infty$ and $m = 1,\ldots,\infty$. Even though the maximum values of n and m may be truncated at given points N_{max} and M_{max}, the grid of points with dimensions ($N_{max}\times M_{max}$) is still usually extremely large. Here the pgf technique is used to process these equations to obtain a finite system. This modeling technique is based on transforming the mass balances of the polymeric species into the pgf domain, which results in a finite system, solving them and finally inverting the resulting pgf to recover the desired distribution. When applying the pgf transformation to Eqs. (1)-(3), the following pgf balances result [10]:

$$\frac{dV\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right)}{dt} = \begin{pmatrix} -k_{deact\,j}\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right)\left[\left(X_2 - Cu^{II}\right)L\right] \\ +k_{act\,j}\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right)\left[\left(X - Cu^{I}\right)L\right] \\ +\left\{\left(k_{trm\,jj}\,\lambda_{0,0}^{j} + k_{trm\,ij}\,\lambda_{0,0}^{i}\right)\left[M_j\right]\right\}\left(z_1\delta_{j,1} + z_2\delta_{j,2}\right) \\ +\left(k_{ij}\left[M^{j}\right] + k_{jj}\left[M^{j}\right]\right)\left(z_1\delta_{j,1} + z_2\delta_{j,2}\right)\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right) \\ +k_{0\,j}\left[I^{*}\right]\left[M^{j}\right]\left(z_1\delta_{j,1} + z_2\delta_{j,2}\right) \\ -\left\{\begin{matrix}\left(k_{jj} + k_{trm\,jj}\right)\left[M^{j}\right] + \left(k_{ji} + k_{trm\,ji}\right)\left[M^{i}\right] \\ +k_{tc\,jj}\,\lambda_{0,0}^{j} + k_{tc\,ji}\,\lambda_{0,0}^{i} + k_{tc0}\left[I^{*}\right]\end{matrix}\right\}\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right) \end{pmatrix} V \tag{7}$$

$$\frac{dV\left(\beta_{0,0}^{j}\varphi^{j}\left(z_1,z_2\right)\right)}{dt} = \begin{pmatrix} k_{deact\,j}\left(\lambda_{0,0}^{j}\phi^{j}\left(z_1,z_2\right)\right)\left[\left(X_2 - Cu^{II}\right)L\right] \\ -k_{act\,j}\left(\beta_{0,0}^{j}\varphi^{j}\left(z_1,z_2\right)\right)\left[\left(X - Cu^{I}\right)L\right] \end{pmatrix} V \tag{8}$$

$$\frac{dV\left(\gamma_{0,0}\theta\left(z_1,z_2\right)\right)}{dt}=\begin{pmatrix}\left(k_{trm\,11}\left[M^1\right]+k_{trm\,12}\left[M^2\right]\right)\left(\lambda_{0,0}^1\phi^1\left(z_1,z_2\right)\right)\\+\left(k_{trm\,21}\left[M^1\right]+k_{trm\,22}\left[M^2\right]\right)\left(\lambda_{0,0}^2\phi^2\left(z_1,z_2\right)\right)\\+k_{tc12}\left(\lambda_{0,0}^1\phi^1\left(z_1,z_2\right)\right)\left(\lambda_{0,0}^2\phi^2\left(z_1,z_2\right)\right)\\+\left(\frac{1}{2}\right)k_{tc11}\left(\lambda_{0,0}^1\phi^1\left(z_1,z_2\right)\right)^2\\+\left(\frac{1}{2}\right)k_{tc22}\left(\lambda_{0,0}^2\phi^2\left(z_1,z_2\right)\right)^2\\+k_{tc10}\left(\lambda_{0,0}^1\phi^1\left(z_1,z_2\right)\right)I^*+k_{tc20}\left(\lambda_{0,0}^2\phi^2\left(z_1,z_2\right)\right)I^*\end{pmatrix}V \qquad (9)$$

In Eqs. (7)-(9), $\emptyset^j(z_1,z_2)$, $\varphi^j(z_1,z_2)$ and $\theta(z_1,z_2)$ are the pgf transforms of $R_{n,m}^j$, $D_{n,m}^j$ and $P_{n,m}$, respectively, and z_1 and z_2 are the dummy variables of the pgfs. Besides,

$$\Phi\left(z_1,z_2\right)=\frac{\sum_{j=1}^{2}\left(\lambda_{0,0}^j\phi\left(z_1,z_2\right)\right)+\sum_{j=1}^{2}\left(\beta_{0,0}^j\gamma\left(z_1,z_2\right)\right)+\left(\gamma_{0,0}\theta\left(z_1,z_2\right)\right)}{\sum_{j=1}^{2}\lambda_{0,0}^j+\sum_{j=1}^{2}\beta_{0,0}^j+\gamma_{0,0}} \qquad (10)$$

is the pgf transform of $\mathrm{CP}_{n,m}$. Once the pgf balances are solved, the distribution $\mathrm{CP}_{n,m}$ is recovered from the transformed domain using the 2D IFG inversion method [11]:

$$\mathrm{CP}_{n,m}=\frac{1}{N_1N_2}\sum_{j=0}^{N_1-1}\sum_{k=0}^{N-1}\begin{pmatrix}f_{\mathrm{Re}}\left(j\frac{2\pi}{N_1},k\frac{2\pi}{N_2}\right)\cos\left(nj\frac{2\pi}{N_1}+mk\frac{2\pi}{N_2}\right)\\+f_{\mathrm{Im}}\left(j\frac{2\pi}{N_1},k\frac{2\pi}{N_2}\right)\sin\left(nj\frac{2\pi}{N_1}+mk\frac{2\pi}{N_2}\right)\end{pmatrix} \qquad (11)$$

In this equation, N_1 and N_2 are user-defined parameters, and $f_{Re}\left(j\frac{2\pi}{N_1},k\frac{2\pi}{N_2}\right)$ and $f_{Im}\left(j\frac{2\pi}{N_1},k\frac{2\pi}{N_2}\right)$ are the real and imaginary parts, respectively, of the complex pgf $\Phi\left(z_1=\exp\left(Ij\frac{2\pi}{N_1}\right),z_2=\exp\left(Ik\frac{2\pi}{N_2}\right)\right)$. The pgf balances of Eqs. (7)-(9) are parameterized for all the values of z_1 and z_2 for which the 2D IFG inversion method (Eq. (11)) needs pgf values. The total number of (z_1,z_2) pairs of values is [11]:

$$n_{ev}=\frac{N_1N_2}{2}+N_2+N_1-1 \qquad (12)$$

Note that, unlike Eqs. (1)-(3) for the different values of n and m, the triad of pgf balances Eqs. (7)-(9) for the different values of z_1 and z_2 are independent of each other.

In addition to the pgf balances, the model of the polymerization system is formed by the balances of the low-molecular-weight species (M^1, M^2, I-X, X-Cu^I)L, X_2-Cu^{II})L, I*, $Sn^{II}(EH)_2$, X-$Sn^{III}(EH)_2$, X-$Sn^{IV}(EH)_2$, reaction volume V, and moments $\lambda_{a,b}^j$, $\beta_{a,b}^j$ and $\gamma_{a,b}$ of orders $(a,b) = (0,0)$, (1,0), (0,1), (2,0), (1,1) and (2,0) required to compute the average molecular weights and copolymer composition [7]. Hence, the total number of balances for the different species is 50; these balances have to be solved for each pair of (z_1,z_2) values at which the inversion formula of Eq. (11) requires pgf evaluations. The sets of 50 balances for the different (z_1,z_2) pairs are independent of each other. The number of these independent blocks is given by n_{ev} in Eq. (12), and the total number of differential equations in the model is then $n_{ev}\times 50$.

3 Parallelization of the model execution

The version of the model employed in Part I of this work was much smaller in number of equations because it computed the overall, univariate MWD instead of the bivariate MWD, that is, $\mathrm{CP}_{l(l=n+m)}$ instead of $\mathrm{CP}_{n,m}$. The software gPROMS ModelBuilder was used because it is very convenient for solving parameter estimation problems and can handle a model of the size of Part I model. However, gPROMS ModelBuilder cannot support a model as large as the one of Part II of this work. Here, Julia was selected as the programming language [12]. This is a modern, free and open-source programming language, with high-level dynamic typing and specifically designed to obtain high performance in technical applications, numerical analysis, and scientific computing. The language combines several modern technologies from the field of programming and has native support for parallel computing. The process of parallelization of a certain code is quite straightforward compared to other languages where parallelization is not native and it is necessary to use other applications or libraries to do it.

The parallelization of the code involved two steps. The first one involved solving the independent blocks of the 50 model equations for each of the (z_1,z_2) pairs required by the inversion method. The execution of the solution process was parallelized using the built-in function *pmap* of Julia. This function maps the call to the numerical solver for the model equations to an array containing the (z_1,z_2) pairs in a parallel fashion among the CPU processors. The total set of pgf values was gathered from this parallel execution to be used as input to Eq. (11). Note that this equation gives the distribution for given values of n and m. The second step of the parallelization involved the calculation of $\mathrm{CP}_{n,m}$ for all (n,m) pairs at which it is desired to compute the distribution. This was accomplished mapping a function that computes Eq. (11) to an array containing the (n,m) pairs using the *pmap* function.

After obtaining $\mathrm{CP}_{n,m}$, this distribution was interpolated using built-in functions in Julia and processed to calculate the bivariate MWD-CCD of the copolymer, that is, $\mathrm{CP}_{l=n+m,c=n/(n+m)}$. Besides, the overall MWD ($\mathrm{CP}_l = \sum_c \mathrm{CP}_{l,c}$) and CCD ($\mathrm{CP}_c = \sum_l \mathrm{CP}_{l,c}$) were also computed.

4 Results and Discussion

The above mathematical model was used to calculate the bivariate MWD-CCD as well as the overall copolymer composition and molecular weight distributions for Experiments 3 and 6 reported in Part I of this work [8]. Parameters N_1 and N_2 of the 2D IFG inversion method were set at $N_1 = 2410$ $N_2 = 1950$ to satisfy the error control requirements of the inversion method [5]. This results in 2 352 904 equal, independent blocks of 50 pgf equations each. Therefore, the total model size is 2 352 904×50 = 117 645 200 differential equations. The solution of a model of this size, using an implicit DAE solver as required by the stiff system of equations, is infeasible in a regular PC. On the other hand, the parallelized implementation of the solution of the independent blocks in Julia, using a laptop equipped with an Intel Core i5-8250U processor and 12 GB RAM, demanded about 6 h CPU time. The grid of the MWD-CCD was divided into 150 points in each dimension so as to obtain a very smooth surface. The number of points of the distribution grid does not affect the number of differential equations of the model and has a small influence on the simulation time.

The final conversion is similar in Experiments 3 (75 %) and 6 (70 %). However, the ratio of monomer concentration/initiator concentration is higher in the second case (1649 for Exp. 3 and 3295 for Exp. 6.). Figs. 1 and 2 show the predicted bivariate MWD-CCD for these experiments. As expected, due to the higher ratio of monomer to initiator, the MWD-CCD of experiment 6 is shifted to higher molecular weights than in Experiment 6.

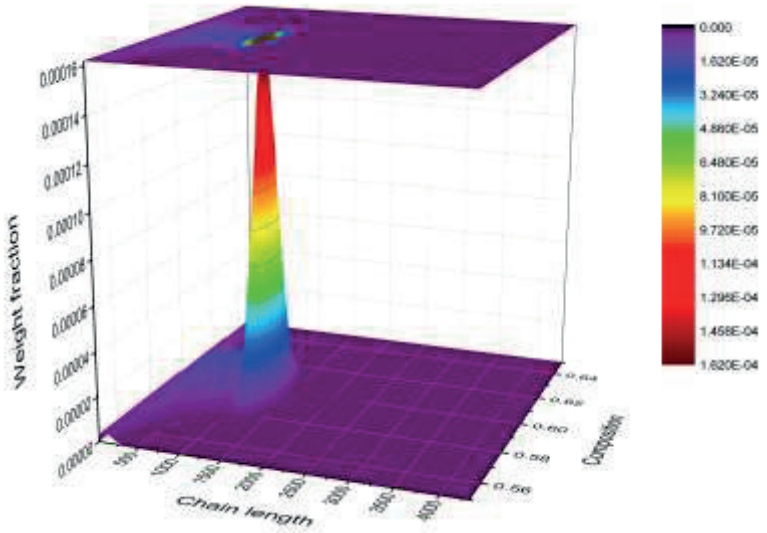

Fig. 1. MWD-CCD for Experiment 3.

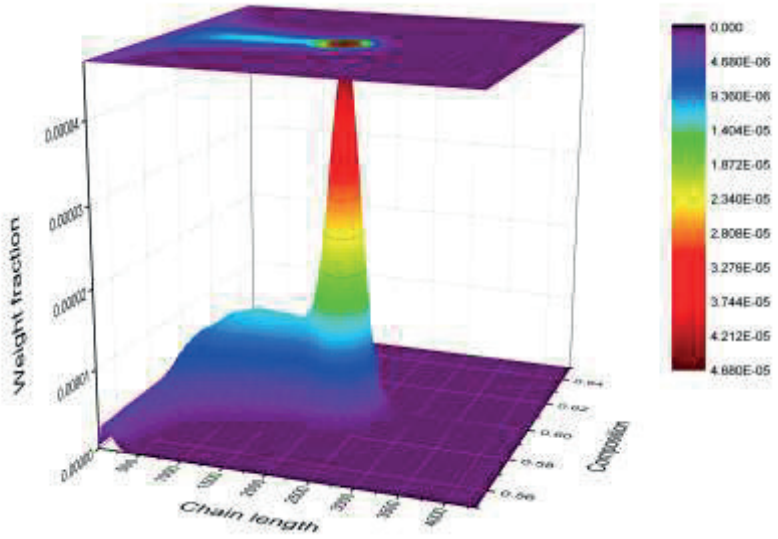

Fig. 2. MWD-CCD for Experiment 6.

These figures also show that the distribution in composition is narrow around the azeotropic value of 60 % for both experiments. On the other hand, the distribution in molecular weight is wider for experiment 6 presenting a long low-molecular-weight tail. These two features are also appreciated in the overall CCD and MWD presented in Figs. 3 and 4, respectively.

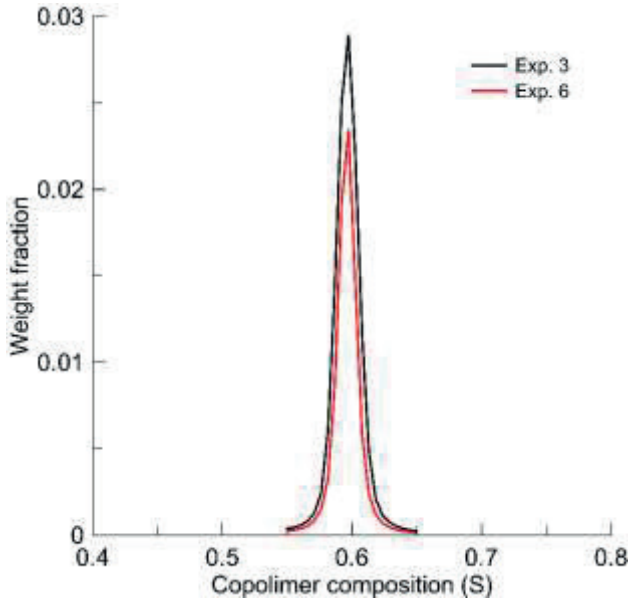

Fig. 3. Overall CCDs for experiments 3 and 6.

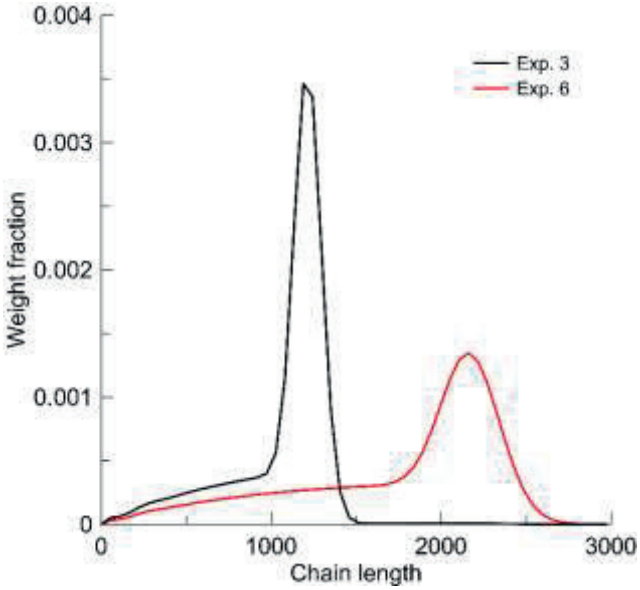

Fig. 4. Overall MWDs for experiments 3 and 6.

5 Conclusion

The pgf technique was successfully implemented to obtain the full 2D MWD-CCD of copolymers of SAN synthesized via ARGET-ATRP. The code developed in Julia allowed to significantly reduce the computational time while calculating a very detailed description of polymer molecular structure.

Abstract. Enterprise Resource Planning (ERP) systems have considerably become traditional as a part of organizations' IT systems in the last decades. ERP systems' research field have involved technology, project management and organizational learning since its birth. With the new big data era, ERP systems have been also progressively exposed to an extensive volume and variety of data in a short amount of time. Since then, a new study field regarding the linkage of these commercial systems with performance analytics to improve decision directions has emerged. Based on a systematic literature review methodology, the purpose of the present paper is to analyze recent research studies connecting ERP Systems to performance analytics. Proknow-C method was applied for a first iteration in Scopus. Results present a bibliographic portfolio analysis composed by 30 papers, being 70% journals and 30% conference papers. The interaction of both themes revealed that diverse environments have integrated analytics in ERP Systems to achieve smart management decisions. Although most studies have not reached many citations over time, the conjunction of both themes has been an important research issue worldwide. Author key-word analysis directed further research suggestions, identifying some possible extra key-words for ProKnow-C following iteration. The contribution of this paper is two-fold, a bibliometric analysis of the current scenario of ERP systems with performance analytics along with a summarized lessons learned of the present portfolio, connecting emergent technologies to cyber-security, organizational learning, hidden knowledge findings, active communication and multiple audit facilities as common output drivers for competitive performance.

Keywords: ERP Systems, Data Analytics, Performance Analytics, Decision-making, Systematic Literature Review.

1 Introduction

Organizations are increasingly investing in a competitive database with the capability to provide assertive decision-making processes. Investment in corporate management systems, also known as ERP Systems, aims to optimize operations, integrate internal departments and unite corporate databases. Over time, they have been associated to their ability to provide directions for decision support, since ERP became intensively exposed to expansive and diversified data structures in a fast environment and demanded the exploration of analytical features such as Business Intelligence (Holsap-

ple *et al.*, 2019). This connection between ERP and big data analytics has enabled faster decision making by providing near real-time statistical data and consistent dashboards of the organizations' current scenario as well as reporting historical events (Cadersaib *et al.*, 2018).

The scientific literature on ERP systems has focused on diverse fields of study since its birth in the end of the last century, exploring implementation challenges (Ismail and Zamre, 2015), implementation approaches (Nordin and Adegoke, 2015), ERP learning and performance (Plaza and Rohlf, 2008) and also technological, structural, behavioral changes and benefits experienced by organizations during ERP projects (Nwankpka, 2015). With the new technological field, some studies have investigated the connection between ERP Systems and performance analytics, exploring the benefits of ERP commercial packages on decision support (Shi and Wang, 2018; Holsapple *et al.*, 2019). Based on the described context, this paper proposes to explore both themes with a systematic literature review and answers the following research question: how is the current scientific scenario of ERP Systems integration with Performance Analytics?

The research question was used as a guidance for this investigation to find the linkages between ERP and performance analytics through a systematic literature review with Proknow-C method (Essnlin *et al.*, 2010).

2 Literature review

This chapter shows the literature review, starting with ERP Systems and Performance Analytics individual definitions, the chosen axes for this study.

2.1 ERP Systems

Historically, ERP Systems originated with MRP, Material Requirements Planning, in the early 1970s, which made it possible to calculate the amount of materials needed at each point in the production stage according to backlog orders. In the 80s, computers and the technological universe remarkably increased and, following this evolution, MRP I turned Material Resource Planning, commonly known as MRP II, providing complementary modules such as purchase control, shop floor control and capability resource planning. ERP is MRP II successor, because in addition to the manufacturing process, it encompasses the integrated planning of all other organizational departments (Correa *et al.*, 2011).

ERP Systems facilitate information flow among company activities, simplify processes and eliminate the need for parallel and inefficient controls. Benefits are not limited to process optimization, because they also improve risk management and business process security through transactions' traceability along with profiles consistent with their respective accesses and usage permissions (Nordin and Adegoke, 2015, Holsapple *et al*., 2019). Despite benefits diversity, ERP systems face complex implementation projects demanding rigid structural changes and companies are usually directed towards a department hierarchical view. The transition from a functional to a process-based view is a great challenge. However, with the proper implementation

approach, encompassing organizational cultural aspects, it is possible to increase successful cases (Al-mashari, 2003; Shi and Wang, 2018).

Technological developments have made it possible for organizations to use enterprise resource without infrastructure high costs. Cloud ERP has an extra advantage for being online with organizational data stored in the cloud. This measure not only guarantees the information security, but also allows the system to be accessed from anywhere. Thus, business performance indicators can be monitored more closely and provide efficient external sales. According to Gupta *et al*. (2018) cloud ERP has led to a constant creation of large data of structured and unstructured natures and consequently defended there has been a need to analyze such complex data sets within the integration of cloud ERP and big data predictive analytics.

2.2 Performance analytics

Big data analytics examines massive amounts of data to uncover hidden patterns, correlations and other analyses. Individual data can possibly be considered not extremely relevant for business strategies, however, big data analytics cases are progressively increasing, since a collection of spread individual data can provide competitive information, which any hidden knowledge can be found once collected into large volumes (Kim and Yu, 2015). Data analytics are also commonly divided into descriptive, diagnostic, predictive and prescriptive (Appelbaum *et al.*, 2017).

The term big data is commonly introduced as a technology for analyzing results from a large amount of structured and unstructured data set beyond the ability of reporting, saving and simulating decisions with traditional database administration resources (Holsapple *et al.,* 2019). Big Data term is also referred as a set capable of handling data generated within the 3V concept: variety, velocity and volume, structured or not with different formats. The challenge is directed to capture, treat and examine this mountain of information sources fast enough to provide strategic decisions. With the current technology, organizations have also used another famous approach for analytics named as business intelligence, an effort that is slower and gets forthwith analyzes with instantly reports (Nofal and Yusof, 2016).

Big data analytics is mostly related as an organizational tool with the ability to provide competitive knowledge for smart business decisions or even a system that supplies data architecture as an input and transforms information as output strategic guidelines (Olszak, 2016; Karimanzira and Rauschenbach, 2020).

Performance analytics has contributed to multidisciplinary environments, providing faster and more effective diagnostics in healthcare systems (Charleonnan *et al.*, 2016; Raglio *et al.*, 2020) and bringing competitive knowledge in organizational setting (Sabbeh, 2018; Jayadi *et al.*, 2019). However, big data analytics demand structured project plans involving cross-functional teams, innovative visualization technologies and leadership involvement to change management processes (Dutta and Bose, 2015). The present research investigates the current scientific scenario of data analytics linkage to ERP projects.

3 Research Design

The method selected to achieve the research purpose is Knowledge Development Process-Constructivist, also known as ProKnow-C (Ensslin *et al*., 2010). The process approach, simplified by Figure 1 with an overview of the main steps, consists on a complete structured process for bibliographic portfolio selection and literature analysis.

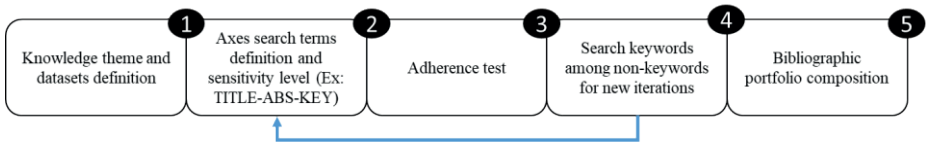

Figure 1. ProKnow-C main steps.

ProKnow-C methodology begins with the research theme definition within its field of study and the respective search databases. Secondly, search terms are defined to obtain the desired theme through axes' interaction along with search sensitivity level. An adherence test is following applied to test if search results matched its intended target. If the match is positively verified, the first bibliographic composition is available. The method involves extended iterations involving the search of new keywords in the first iteration's research papers for bibliographic composition continuously improvement.

The present study used ProKnow-C method to build exclusively the first literature composition of the both research themes: ERP Systems and Data analytics and limited Scopus database for this first iteration. Bibliometric analysis followed the sequential steps: publication over the years, citation overview, portfolio subject areas, predominant authors and finally, the key-word analysis.

4 Results

This chapter presents the research results, which is segmented by bibliographic portfolio composition and its sequential bibliographic analysis.

4.1 Bibliographic portfolio composition

The research themes used in the axes consisted of "ERP" and "analytics", respectively. The following search expression presented by Table 1.

Table 1. Search expression.

1st axis: ERP	Boolean Operator	2nd axis: analytics
("enterprise resource planning" OR "ERP system*" OR "Cloud ERP")	AND	("analytics" OR "business intelligence" OR "big data")

The search, made on July 14th at 11:25 a.m., was restricted for open access articles, Journals and Conferences, written in English and published between 2015 and 2019, considering exclusively Scopus database for bibliographic analysis. The search expression insertion in their respective database provided a preliminary result of 188 articles.

Table 2. Adherence test.

	Articles description
1	APPELBAUM, D., KOGAN, A., VASARHEYLI, M., YAN, Z.: Impact of business analytics and enterprise systems on managerial accounting", International Journal of Accounting Information Systems, v. 25 (No.March), pp. 29–44 (2017).
2	SHI, Z., WANG, G.: Integration of big-data ERP and business analytics (BA). Journal of High Technology Management Research, v.29 No., pp. 141-150 (2018).
3	DUSSOYE, H., CADERSAIB, Z.: Sentiment analytics framework integrating Twitter and Odoo ERP", 2017 International Conference on Infocom Technologies and Unmanned Systems: Trends and Future Directions, ICTUS 2017, v.2018(n.jan), pp. 145–151. (2018).
4	NYCZ, M., PÓLKOWSKI, Z.: The ERP system as a basic system for business analyses, Proceedings of the 2014 6th International Conference on Electronics, Computers and Artificial Intelligence, ECAI 2014, IEEE, pp. 63–66 (2015).
5	ROUHANI, S., MEHRI, M.: Does ERP have benefits on the business intelligence readiness? An empirical study. International Journal of Information Systems and Change Management, v. 8 (n.2), p. 81 (2016).

A considerable number of these articles were rejected for being book chapters, since the intended restriction was specified to limit Journals or Conferences studies and some others were also excluded due to availability, presenting as non-open access. On the next step, to verify if the selected search expression is adequate or if there was the need to find substitute terms that better represent the research themes, the recommendation of five articles reading was applied, as presented by Table 2.

Positive adherence by search expression could be observed, resulting in articles dealing with both research themes simultaneously, besides similar key words with the search expressions. Therefore, the raw bibliographic portfolio of 74 papers was originated. Sequentially, the refinement phase was applied reading the 74 articles titles and abstracts discarding 44 considered either non-aligned or not specifically addressing both topics, resulting in 30 final articles presented by Appendix Section.

4.2 Bibliographic portfolio analysis

The selected portfolio is predominantly composed by journals, counting 70% with the other remaining 30% composed by international conferences. In addition, bibliographic portfolio over the years, exhibited by Figure 2, reveals a noticeable stronger impact in the researched field in 2015 and 2016 comparing to other yeas.

Year	2015	2016	2017	2018	2019	Total	% Total
Journal	5	6	3	3	4	21	70%
Conference	3	4	0	2	0	9	30%

Figure 2. Bibliographic portfolio over the years.

Regarding scientific relevance, it was perceived few citation quantity, with most of the papers counting less than five citations. Figure 3 indicates only two articles have exceeded 20 citations. One possible explanation for the low impact is search restriction for studies written between 2015 and 2019 and therefore time exposition is still relatively short.

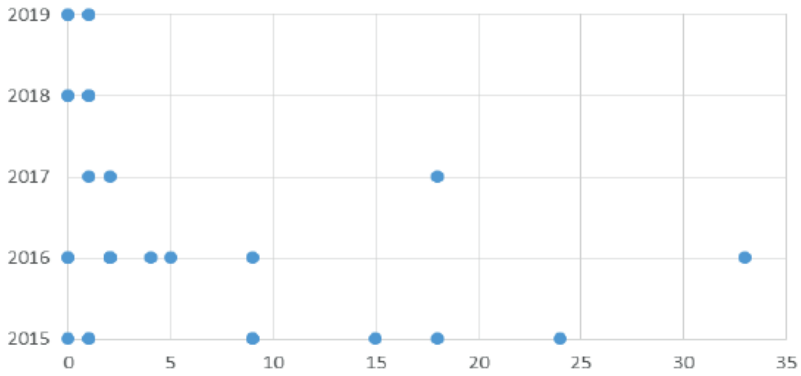

Figure 3. Citation overview.

Sequentially examining scientific relevance, the journals composed in the portfolio were also analyzed according to their respective SJR indicators, Table 3. There is no specific journal dominating the bibliographic portfolio composition, presenting consistent diversity. However, some journals are high rated regarding their SJR qualifications, increasing the portfolio scientific value.

Table 3. SJR indicators.

Journal	SJR
Journal of Information Technology	2,1
International Journal of Operations and Production Management	2,1
Journal of Business Research	1,7
Computers in Industry	1,2
International Journal of Advanced Manufacturing Technology	1,0
Computers and Electronics in Agriculture	1,0
Management Decision	0,7
Information Processing in Agriculture	0,6
Business Process Management Journal	0,6
Information Systems Management	0,5
International Journal of Accounting Information Systems	0,5
Information Technology and Management	0,4
Journal of Supercomputing	0,4
Kybernetes	0,3
International Journal of Business Information Systems	0,3
Journal of High Technology Management Research	0,3
Library Hi Tech News	0,3
International Journal of Software Engineering and its Applications	0,2
International Journal of Information Systems and Change Management	0,1
International Journal of Internet Manufacturing and Services	0,1
International Journal of Intelligent Information and Database Systems	0,1

The remaining conference papers in portfolio composition are also diverse, counting International Conference on Enterprise Systems, International Advanced Computing Conference, Global Conference on Communication Technologies and many others involving industrial engineering and computational intelligence.

Examining the studies' scope classified by subject areas presented by Figure 4, it can be observed that most of papers addressing data analytics with ERP Systems deal with Computer Science (34,4%), Business, Management and Accounting (17,2%) and Decision Sciences impacts specifically (15,6%) research fields. The specificity and diversity involving the remaining subject areas can be explained by the specificity of some contributions involving agricultural, social sciences and energy environments.

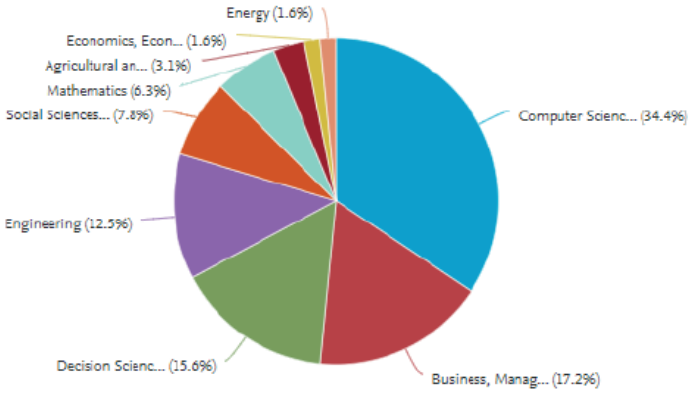

Figure 4. Portfolio subject areas.

In respect of the authorship 83 different authors appeared. Of these, only a single author had incidence of two publications in the portfolio, the Portuguese management researcher Oliveira T., and all the remaining stayed with one frequency. Analyzing the portfolio regarding their country, as exhibited by Figure 5, it is perceptible a domain in India, although United States remained a single paper behind and Germany together with Taiwan had a noticeable contribution. This fact indicates that the conjunction of the two themes have been researched worldwide by all continents.

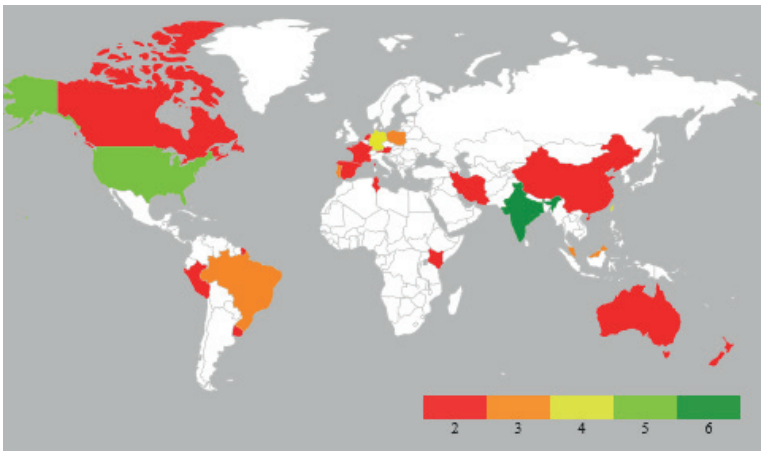

Figure 5. Portfolio geographic heat map.

Author keywords' analysis, Figure 6, revealed most of the common key-words among portfolio authors were defined by search axes.

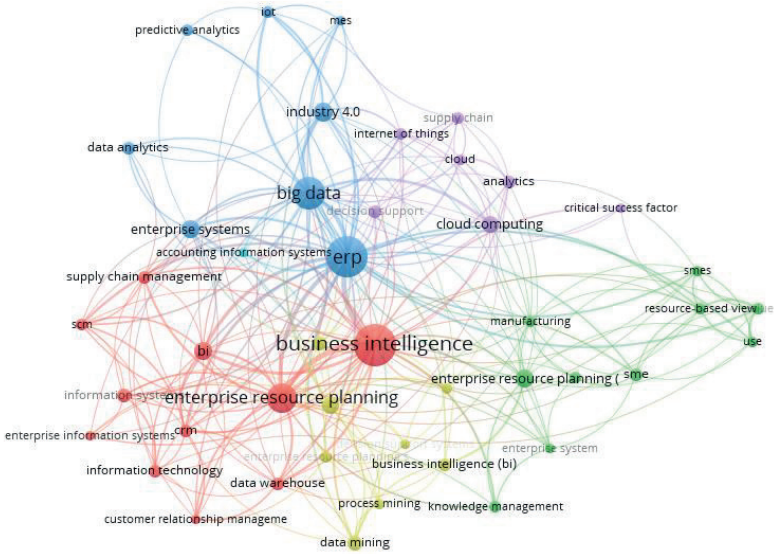

Figure 6. Author keyword analysis.

Some of non-keywords among author keywords, such as data mining, cloud computing and data warehouse, are considered relatively important for a second search iteration, following Proknow-C method steps.

4.3 Lessons Learned Portfolio Summary

The present bibliographic portfolio composition reveals diversity not only among study centers, authors and multi-sector organizations, but also of the emergent technologies connected to ERP systems. Figure 7 presents some contributions identified on ProKnow-C first iteration.

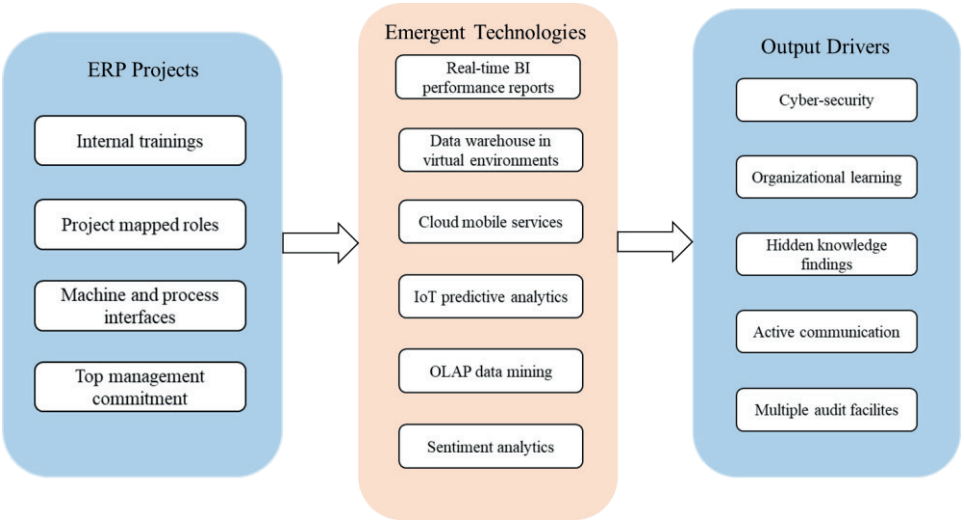

Figure 7. Summary of lessons learned.

The interaction of both axes presents a summary of common best practices among ERP projects, such as internal trainings, mapped roles, process interfaces and top management involvement. Regarding emergent technologies, business intelligence reports are the most predominant object of study (Kim and Yu, 2015; Shi and Wang, 2018, Ranjan *et al.*, 2017). On the other hand, some approaches are more unusual with distinct perspectives, revealing new trends, such as sentiment analytics using microblogging to find social media feelings (Dussoye and Cadersaib, 2018) and IoT predictive analytics for aquaponics management (Karimanzira and Rauschenbach, 2020).

Summary of lessons learned also connects the emergent technologies to competitive outputs that have supported organizations to find hidden knowledge (Kim and Yu, 2015; Nycz and Pólkowsky, 2015; Shi and Wang, 2018), build cyber-security (Tai *et al.*, 2016), organizational learning (Labonte-LeMoyne, 2017), active communication (Nofal and Yusof, 2016) and multiple audit facilities (Werner and Gehrke, 2015; Gambetta *et al.*, 2016).

5 Conclusion

The present systematic literature review have successfully achieved a first iteration with assertive keywords that brought relevant recent papers interacting ERP Systems with data analytics. The following step is to continue Proknow-C method trying new keywords among non-keywords to extend bibliographic portfolio composition, since this study was limited to a single first step in Proknow-C process. Another limitation is related to search restriction to Scopus, since the present first iteration can possibly be extended once new databases are included.

The interaction of performance analytics term relating to ERP Systems have reached distinct areas and contributed to management decisions for near real-time data analysis in medical institutions (Kim and Yu, 2015), bank's audit (Gambetta *et al.*, 2016), manufacturing enterprises (Ranjan *et al.*, 2017) and agriculture environment (Junior *et al.*, 2019; Karimanzira and Rauschenbach, 2019). Curiously, even polish water parks (Nycz and Pólkowsky, 2015) have been improving decision-making integrating analytics with their ERP systems.

Regarding analytics and some of its classifications, some papers specify their studies, such as sentiment analytics (Dussoye and Cadersaib, 2018) or predictive analytics (Karimanzira and Rauschenbach, 2019) while others explore the theme without explicitly classifying along their studies. The main contribution of this paper consisted on identifying the diversity integration of ERP systems with performance analytics. Common emergent technologies were listed in lessons learned, connecting to cybersecurity, organizational learning, hidden knowledge findings, active communication and multiple audit facilities as performance output drivers. This briefly summarized interrelationship can be linked to a further research with a more extensive content analysis. Complementarily, a secondary study could also enhance additional relevance and dialogue to recent research, such as the effects of capabilities and policies of strategic decision areas on manufacturing high performance (Okoshi *et al*., 2019) or even management frameworks (Giordani da Silveira *et al*., 2018), since performance analytics has brought a new scenario of management.

Avaliação de Interoperabilidade Empresarial: Uma revisão sistemática da literatura

Angélica Duarte Lima[1] and Eduardo de Freitas Rocha Loures [2]

[1] Instituto Federal do Paraná – IFPR - Brasil
[2] Pontifícia Universidade Católica do Paraná – PUCPR, Brasil

Abstract. Interoperability is a necessity for organizations to achieve their business objectives and remain in the market. For this, it must be continuously measured and improved. This paper aims to show a systematic literature review about interoperability assessment, using the methodology Proknow-C, with the objective of raising the main aspects of the researchs. Two phases of the method were made. On the first phase was made the selection of the bibliographic portfolio (BP), were found 21 papers related to the subject. In sequence on the second phase was made a bibliometric analysis. The more expressive areas on the BP are the engineering and computer science. Is perceived a preponderance from studies focused on supply chain and government area assessment.

Keywords: Enterprise Interoperability Assessment, Organizational interoperability, systematic literature review, Proknow-C.

1 Introdução

Atualmente, para atuarem de maneira competitiva, as empresas precisam monitorar em tempo real seus recursos e controlar com eficiência suas operações, reagindo com rapidez ao mercado dinâmico [1]. Outro fator que determina o sucesso das organizações no mercado globalizado é a sua capacidade de desenvolver parcerias. Para isso é importante a capacidade de comunicação e interação [2].

Neste sentido, a concepção de interoperabilidade se apresenta como um meio para melhorar a comunicação e interação, tanto interna, como também entre as organizações. Interoperabilidade tem conceito amplo e com muitas definições [2]. O Institute of Electrical and Electronics Engineers [3] define como a "capacidade de dois ou mais sistemas ou elementos trocarem informações entre si e usarem as informações trocadas".

Um fator que impede a interoperabilidade são as barreiras, definidas por Chen [4] como incompatibilidades de vários tipos e em vários níveis da empresa. Para evitar problemas de interoperabilidade as empresas devem conhecer as barreiras existentes, para desenvolver soluções e removê-las [4]. Neste contexto, a avaliação da interoperabilidade pode beneficiar as organizações [5].

Na literatura, há diversos modelos de avaliação de interoperabilidade com diferentes abordagens, escalas e aplicações. O objetivo deste estudo é apresentar uma visão geral dos modelos existentes por meio de uma revisão sistemática da literatura utilizando o método ProKnow-C.

2. Referencial Teórico

2.1. Interoperabilidade

A European Interoperability Framework in the eGovernment domain [6] define três tipos de interoperabilidade: a semântica, a técnica e a organizacional. Marcondes e Sayão [7] acrescentam mais três tipos: a política, a internacional e a legal. Alguns autores chamam os tipos de camadas da interoperabilidade.

A interoperabilidade apresenta três dimensões. A primeira são as barreiras, classificadas em três tipos: Conceitual (diferenças sintáticas e semânticas das informações a serem trocadas), Tecnológica (incompatibilidade de tecnologias da informação) e Organizacional (incompatibilidade das estruturas da organização). A segunda dimensão se refere às diferentes áreas de preocupação da empresa (dados, serviço, processo, negócios). A terceira são as abordagens, que consistem nas diferentes maneiras pelas quais as barreiras podem ser removidas (integrada, unificada e federada) [4].

O conhecimento sobre interoperabilidade fornece soluções para remover as barreiras em quatro áreas específicas: Dados (encontrar e compartilhar informações provenientes de bases heterogêneas e máquinas diferentes); Serviço (identificar, compor e fazer funcionar juntos vários serviços); Processo (fazer com que vários processos funcionem juntos) e Negócios (trabalhar de maneira harmonizada nos níveis da organização, para que os negócios possam ser desenvolvidos e compartilhados entre empresas) [4].

2.2. Avaliação de desempenho organizacional

O desempenho é abordado por muitos campos do conhecimento, tais como, contabilidade, recursos humanos, marketing entre outros. Avaliação deixou de olhar apenas para medidas de desempenho financeiro e de produtividade, passou também a medir aspectos qualitativos e intangíveis de desempenho [8].

Definir corretamente os indicadores que refletem os objetivos da organização é um desafio, pois os indicadores de desempenho assumem papel central, por se apresentarem como instrumentos capazes de fornecer informações para o processo de tomada de decisão [9].

A literatura apresenta diversos métodos para a medição de desempenho das organizações entre os mais conhecidos estão o Balanced Scorecard (BSC) [39], Performance Prism [40], ECOGRAI [41] entre outros.

2.2. Avaliação da Interoperabilidade

Os modelos para avaliar a interoperabilidade existentes se propõem a medir a potencialidade, compatibilidade e desempenho. A avaliação da potencialidade mede a capacidade da organização se adaptar e superar possíveis barreiras, ao interagir com um parceiro em potencial.

A avaliação de compatibilidade analisa o estado atual dos sistemas envolvidos, para identificar conflitos que causam, ou podem causar problemas. A avaliação de des-

empenho mede os custos para a implementação de aplicativos interoperáveis e a qualidade durante todo o tempo de execução [22].

A avaliação de potencialidade está ligada a modelos de maturidade, pois a maturidade pode ser entendida como potencial de interoperação [22]. Alguns exemplos são o Extended Enterprise Architecture Maturity Model, o Organisational Interoperability Maturity Model e o Enterprise Interoperability Maturity Model [10].

Com relação à compatibilidade o INTEROP framework avalia a interoperabilidade nas três dimensões: as barreiras, preocupações e abordagens [11]. Outros modelos conhecidos são o ERISA [42], IDEAS [43] ATHENA framework[44].

2 Metodologia

Este estudo pode ser classificado como de natureza conceitual aplicado, por seu interesse em aplicação prática. Quanto aos objetivos é exploratório, pois busca evidenciar o problema de pesquisa utilizando pesquisa bibliográfica. A abordagem é qualitativa e quantitativa e o procedimento utilizado foi a pesquisa bibliográfica [12]

Para a realização da revisão bibliográfica foi utilizado o ProKnow-C, metodologia desenvolvida por Ensslin e Ensslin [13]. O método é composto por quatro etapas: (1) Seleção do Portfólio Bibliográfico (PB), (2) Análise Bibliométrica, (3) Análise sistêmica, (4) Identificação de uma pergunta de pesquisa e do objetivo para futuras pesquisas [13].

O Proknow-C apresenta um processo estruturado para a construção de conhecimento, fornece um panorama da área investigada e aponta questões para novos estudos [13]. Foram realizadas duas etapas do Proknow-C: (1) Seleção do Portfólio Bibliográfico, (2) Análise Bibliométrica.

3.1. Etapa 1 - Seleção do Portfólio

Foram delimitados dois eixos de estudo “interoperabilidade” e “avaliação de desempenho”, sendo que as palavras-chave destes eixos foram usadas em uma pesquisa preliminar na base de artigos Science Direct para verificar a aderência.

Foram encontradas novas palavras-chave e incluídas na pesquisa. As bases utilizadas foram Science Direct, Emerald Insight e Scopus. A Tabela 1 apresenta a definição final das palavras-chave.

Tabela 1. Eixos da pesquisa e Palavras-chave

Eixo I: Interoperabilidade	Eixo II: Indicadores
Enterprise Interoperability Assessment	*Performance Measurement*
Interoperability Assessment	*Performance Indicators*
Business interoperability	*Performance Evaluation*
Organizational interoperability	*Performance Assessment*

3.2. Etapa 2 - Análise Bibliométrica

A etapa de análise bibliométrica dos artigos consiste em um levantamento e análise quantitativa das características do PB de artigos da etapa anterior, com objetivo de evidenciar as informações relevantes para a área de estudo [13].

A análise bibliográfica foi realizada em seis passos: (1) Levantar os periódicos nos quais os artigos foram publicados e verificar o grau relevância destes, (2) Estimar o grau de relevância dos artigos, (3) Estimar o grau de relevância dos autores, (4) Verificar as palavras-chave mais utilizada e verificar a relação entre elas, (5) Analisar a referência dos artigos do PB e (6) Analisar a relevância dos artigos para o PB.

3 Resultados

Os artigos encontrados foram filtrados de 2011 a 2020 e exportados para análise para o EndNote Web. Foram encontrados 64 artigos. Destes foram excluídos três por duplicação, 19 após a leitura dos títulos e 16 após a leitura dos resumos. Dos 26 artigos lidos, 21 contemplam o objetivo da pesquisa, a Tabela 2 apresenta os artigos que compõem o PB.

3.1. Análise Bibliométrica

Dos 21 artigos analisados, 18 foram publicados em periódicos e 3 em anais de eventos. Nesta etapa foi levantado o nome dos periódicos, a quantidade de artigos que cada um tinha no PB e o fator de impacto de cada periódico.

Pode se perceber um predomínio de publicações no Computers in Industry, que concentra 7 publicações. Em segundo lugar, mas bem menos expressivo o Transforming Government: People, Process and Policy, com duas publicações. Os demais tiveram um artigo cada. A Figura 1 apresenta gráfico com números de artigos por periódico no PB.

O fator de impacto foi consultado no Journal Citation Reports (JCR). O índice é publicado anualmente, com dados das publicações do ano anterior e citações dos dois anos imediatamente anteriores. A grande parte dos artigos não constava na base, por não serem periódicos indexados a Web of Science. O periódico de maior fator de impacto foi o Computers in Industry, com 4,769.

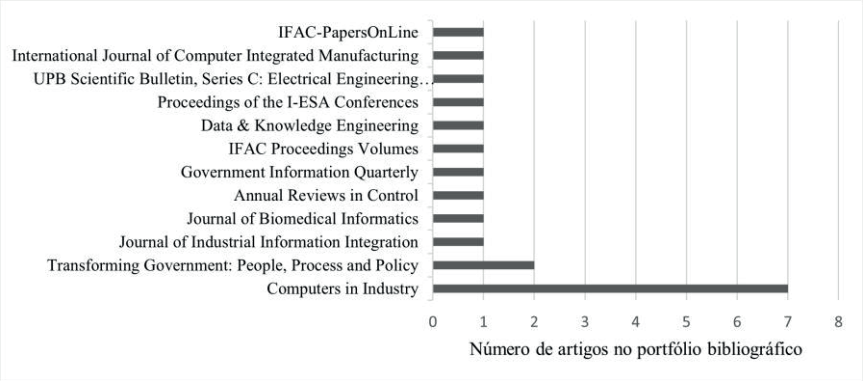

Fig. 1. Números de artigos por periódico

Para a estimativa da relevância acadêmica dos artigos do PB foi considerado o número de citações indicados no Google Acadêmico e na base Scopus. No Google acadêmico os artigos do PB apresentam um total de 1249 e na Scopus 707.

O artigo "Industry 4.0: A survey on technologies, applications and open research issues" possui o número de citação bem acima dos demais, possuindo 886 citações (Google acadêmico) e 492 (Scopus). Três artigos tiveram apenas uma citação, e um artigo não teve nenhuma citação, no entanto este artigo é de 2019.

O ano com mais publicações no PB bibliográfico foi 2012, com 5 publicações. Não constam publicações no ano de 2013.

Quanto a citação dos artigos do PB, o ano com mais citações foi 2019 com 565, no entanto esse número está um pouco distorcido devido ao artigo do Lu, Y. que tem citações muito acima dos demais, sendo responsável por 499 citações em 2019.

Os 21 artigos do PB contaram com a participação de 40 autores. O autor com mais artigos, foi Ducq, Y. com 6 publicações, seguido de Grilo, A. com 5. A Figura 2 ilustra o gráfico com a quantidade de artigo por autores. Os demais autores, que possuem um artigo, não constam no gráfico.

O índice h é uma maneira de medir a produtividade e o impacto das publicações acumuladas de um pesquisador. Os autores terão o índice h, se h de seus trabalhos tiverem pelo menos h citações, por exemplo, um autor terá índice h=2, se possuir 2 artigos, com pelo menos 2 citações [36]. O autor com maior índice h foi o Janssen, M., com h=39 e 433 publicações. A Figura 3 apresenta um gráfico com os autores que apresentam maiores índice h no PB.

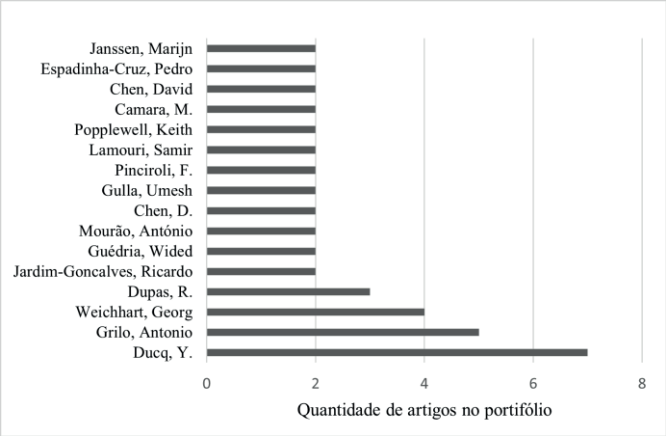

Fig. 2. Número de artigos do PB por autor

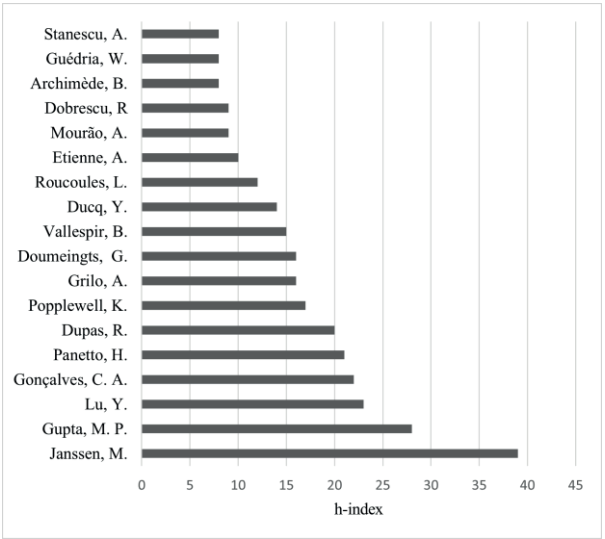

Fig. 3. Índice h dos autores do PB

A análise apontou para a ocorrência de 95 palavras-chave. Destas as mais frequentes foram Interoperability e Enterprise interoperability, as duas com cinco ocorrências. As palavras-chave mais utilizadas estão indicadas no gráfico da Figura 4 e a sua relação estão apresentadas na Figura 5.

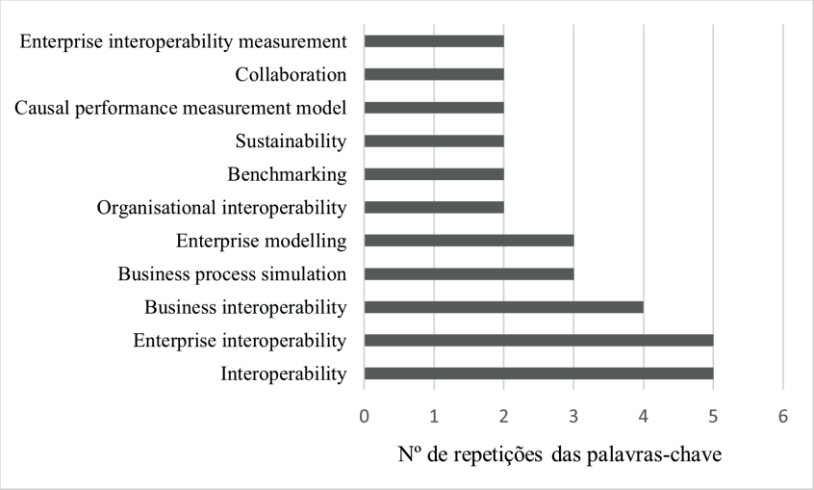

Fig. 4. Quantidade de ocorrência das palavras-chave

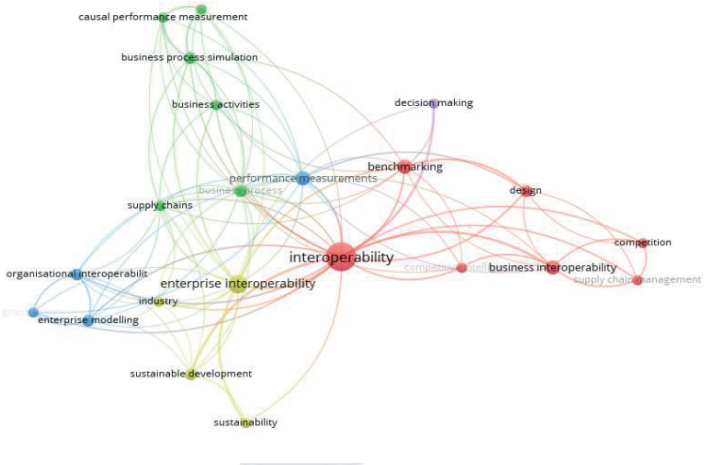

Fig. 5. Relação entre as palavras-chave utilizadas no artigo do PB

3.2.5 Análise da referência dos artigos do portfólio

Os artigos do PB analisado citam 1439 autores, deste o mais citado é Chen, D. com 68 citações, seguido de Jardim, G. R. com 34. A Figura 6 apresenta um gráfico com os autores mais citados do PB e a Figura 7 a relação entre estes autores citados.

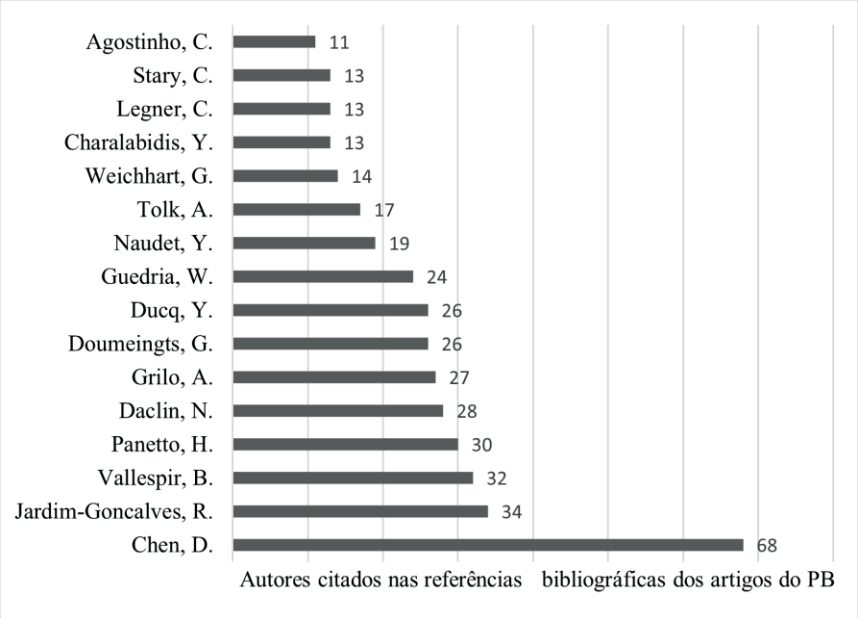

Fig. 6. Artigos citados nas referências do PB

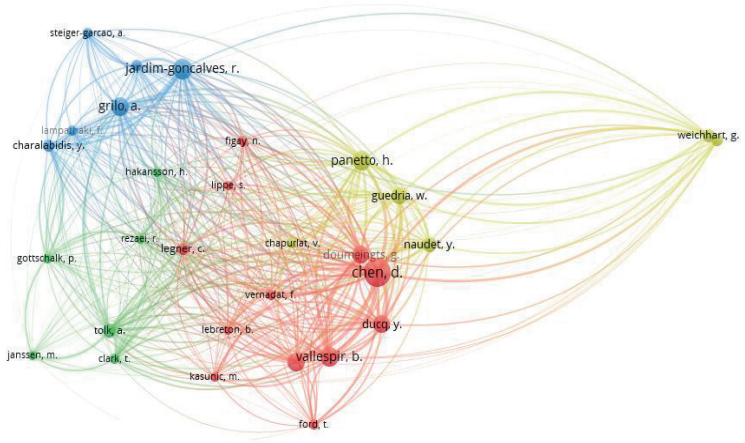

Fig. 7. Relação entre os autores citados nas referências dos artigos do PB

O país com maior quantidade de publicações foi a França, seguido de Portugal com 9 e 5 artigos respectivamente. O Brasil possui uma publicação, o artigo 19. As áreas de estudo predominantes são a engenharia e ciência da computação.

Os artigos destaques foram o 9, o 8 e o 10, respectivamente com 46, 35 e 31 citações na base Scopus. O artigo 8 foi um artigo destaque realizado por um autor

destaque, o autor deste artigo mais citado no PB foi o Chen com 68 citações. A Figura 8 apresenta um gráfico de dispersão para evidenciar a relevância dos artigos do PB, o artigo 17 não foi incluído no gráfico, pois ele possui o número de citações muito superior aos demais e distorceria a visualização dos dados, além disso, o artigo não foi citado nos demais artigos do PB.

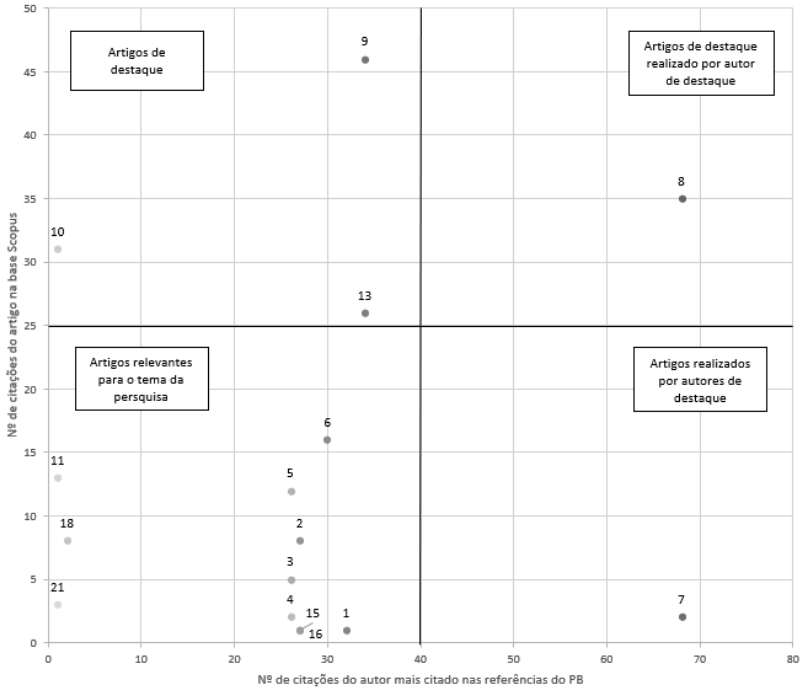

Fig. 8 Artigos com maior destaque no PB

3.4. Discussão sobre os artigos do portfólio bibliográfico

A interoperação em redes de colaboração trouxe vantagens competitivas para as empresas e tornou-se um ponto crítico para alcançar os objetivos do negócio [38]. No PB, 6 artigos apresentam modelos voltados a medir e melhorar a interoperabilidade entre empresas parceiras. Os estudos 3, 4, 15 e 16 seus modelos são aplicados à cadeia de suprimentos. E os artigos 2 e 5 apresentam estudos voltados à empresas que cooperam.

Os governos de diversos lugares também estão adotando estratégias para alcançar a interoperabilidade, para enfrentar o problema da heterogeneidade entre sistemas de informação do governo [25]. Nessa perspectiva o artigo 10 apresenta modelo de medição de interoperabilidade em governo inteligente. O artigo 11 propõe uma estrutura analítica para avaliação, classificação e comparação qualitativa dos Frameworks de interoperabilidade governamental. O artigo 19 propõe um sistema para avaliar o nível de maturidade de interoperabilidade técnica do governo.

Outro tema abordado é a interoperabilidade contribuindo para a sustentabilidade das organizações. Nesse sentido o artigo 8 discute como a teoria dos sistemas, aplicada à sistema de sistemas, é capaz de apoiar o desenvolvimento da interoperabilidade empresarial sustentável. Os artigos 20 e 21 abordam conceitos de interoperabilidade para ajudar a alcançar níveis de sustentabilidade no contexto de sistemas adaptativos complexos.

Alguns artigos apresentam seus estudos da avaliação de interoperabilidade organizacional de forma ampla, sem especificar um grupo específico, como é o caso do artigo 1 e 13. O artigo 16 propõe uma estrutura para apoiar a análise das condições de interoperabilidade na relação comprador-fornecedor.

Os artigos apresentam variados contextos e propósitos. No artigo 1 o foco da avaliação está na detecção da falta de interoperabilidade e avaliação dos esforços necessário atingir ou manter o nível de interoperabilidade alvo.

O artigo 2 tem o objetivo de simular a maneira pela qual as empresas interoperam em redes industriais cooperativas e como distância entre o nível real e o necessário de interoperabilidade podem afetar o desempenho dessas empresas.

Nos artigos 3, 4 e 5 os autores buscam avaliar como os investimentos em interoperabilidade participam na obtenção dos objetivos da empresa. O artigo 13 apresenta modelo BIQMM - Medição de Quociente de Interoperabilidade de Negócios baseado em pesquisa como ATHENA, ECOLEAD e COIN, buscando capturar os fatores responsáveis pela interoperabilidade. No artigo 14 os autores apresentam um conjunto de características que podem apoiar a tomada de decisão e a avaliação da interoperabilidade no domínio de sistemas sensíveis ao contexto aplicado à gestão de sistemas de transporte inteligentes.

No artigo 17 os autores realizam uma revisão abrangente sobre a indústria 4.0, mesmo que a avaliação de interoperabilidade não seja o tema central do artigo, foi mantido no no PB, pois dedica boa parte ao tema. Os autores descrevem questões críticas da interoperabilidade da Indústria 4.0, propõem um quadro conceitual e apresentam alguns frameworks para avaliação de interoperabilidade.

Quanto aos métodos e ferramentas, os estudos utilizam variados. Os artigos 7 e 9 apresentam uma revisão literatura sobre avaliação da interoperabilidade e o artigo 6 exibe uma revisão sistemática da literatura. Dos 21 artigos do PB 12 apresentam estudo de caso. O artigo 1 utiliza modelagem corporativa, gráfico verificação de teoria e regras. O artigo 2, 5, 12 e 15 realiza simulação. Os artigos 3 e 8 usam a metodologia GRAI. O artigo 19 utiliza regras Fuzzy no modelo proposto.

4 Considerações Finais

Este trabalho teve por objetivo apresentar informações relevantes para área de pesquisa de avaliação de interoperabilidade. Por meio da aplicação do Proknow-C, se chegou a um PB com 21 artigos relevantes.

A análise bibliométrica dos artigos do PB apontou os seguintes resultados: (i) o periódico mais destacado para o tema é o Computers in Industry, com 7 artigos no PB, o periódico também é o de maior fator de impacto com JCR 4,769; (ii) o artigo 17 é o com maior reconhecimento científico com 886 citações (Google acadêmico) e 492 (Scopus) (iii) o autor com maior índice h é o Janssen, M., com h=39 e 433 publi-

cações; (iv) A palavra-chave mais usada foi Interoperability e Enterprise interoperability, ambas com cinco ocorrências; (v) O autor mais citado nas referências foi o Chen, D. com 68 citações (vi) o artigo mais relevante para o PB é o 8.

O artigo 8 é apontado como o mais relevante do PB para o estudo, pois o artigo e o autor são destaques quanto a quantidade de citações. O artigo analisa a interoperabilidade considerando a teoria de sistemas, considera problemas de interoperabilidade entre diferentes tipos de sistemas (ecológicos, econômicos, de pesquisa etc). O estudo propõe um modelo de avaliação e aplica em um estudo de caso.

Entre os artigos encontrados 3 se dedicam a revisão da literatura apresentando diversos métodos de avaliação de interoperabilidade. Dos artigos do PB 11 propõem modelos de avaliação, o que manifesta a importância de criar critérios de avaliação da interoperabilidade. Outro aspecto importante foi à aplicação prática dos métodos, pois 12 artigos apresentam estudo de caso e 1 demonstra em uma situação hipotética deixando como lacuna a aplicação.

Abstract. La problemática que se genera en la actualidad como consecuencia de la generación de desechos es de una complicación creciente en todo el mundo. En este marco existe uno en particular que es la acumulación totalmente descontrolada y desatendida de neumáticos inservibles y sus residuos.
El presente trabajo está orientado a la evaluación del desempeño de hormigones con la utilización de estos residuos como agregados alternativos en reemplazo de algunos tradicionalmente utilizados, buscando atenuar el impacto ambiental y social generado por los desechos mencionados.
Se moldearon probetas de hormigón realizadas con distintos porcentajes de reemplazo de agregados pétreos por caucho molido y se evaluó la influencia en las propiedades del hormigón modificado respecto del hormigón patrón, a los fines de estudiar la posible implementación de este material en la fabricación de elementos de protección vial.
Debido a que estos elementos pueden estar sometidos al impacto de vehículos, se comprobó que la incorporación de caucho modifica el módulo de elasticidad y se profundizó el estudio en ensayos de choque o que simulen un impacto.
A partir de los resultados obtenidos en laboratorio y su discusión se ha verificado que los hormigones con la incorporación de caucho mejoran su respuesta frente a un impacto respecto al patrón al absorber una mayor cantidad de energía.

Keywords: Hormigón, Caucho, Energía.

1 Introducción

El sostenido crecimiento anual del parque automotor, sin la existencia de una legislación que controle la disposición final de las cubiertas, plantea un escenario ambiental complejo. El Instituto Nacional de Tecnología Industrial (INTI), expuso que en Argentina la generación de neumáticos inservibles superaba las 100.000 toneladas anuales en el año 2010 [1]. Se puede estimar que dicha cifra alcanza las 130.000 toneladas en la actualidad. La disposición final de neumáticos inservibles descontrolada y fuera de cualquier criterio de reciclaje en cualquiera de sus formas, representa un grave peligro para la salud humana al convertirse en lugar de resguardo y fuente de reproducción de

insectos y animales transmisores de enfermedades graves y hasta letales para la población humana.

De igual manera, constituye un potencial riesgo de incendio incontrolable, que liberaría a la atmósfera grandes cantidades de gases y partículas nocivas para el medio ambiente y la salud de todos sus habitantes. Por otro lado, se estima que el tiempo de su descomposición natural o biodegradación supera los 600 años y, por su forma constructiva de aro, abarcan grandes extensiones de tierras aprovechables para otros usos más eficientes. Además, se genera una contaminación visual del entorno y comienza una incipiente, lenta y peligrosa degradación química de los neumáticos.

La industria de la construcción, al utilizar grandes volúmenes de recursos naturales, produce un impacto ambiental importante por lo que la cuantificación de ese impacto es fundamental para que sean posibles las acciones de mejoras. Este conocimiento permite analizar como los materiales pueden tener un mejor aprovechamiento de manera de causar menos perjuicios ambientales [2].

En ese mismo sentido, existen variadas posibilidades de reciclaje de los neumáticos inservibles, algunas son la reutilización, revalorización y recuperación energética. Hay múltiples ejemplos de ello y uno es la adición de partículas de caucho a hormigones, tema de estudio del presente trabajo. Su objetivo principal es analizar la influencia de la utilización de caucho de neumáticos inservibles molido en hormigones, como sustituto de los agregados inertes, en sus propiedades para su empleo en elementos de protección vial.

En una primera etapa, el trabajo consistió en el estudio de hormigones con distintos porcentajes de remplazo de agregados por caucho molido, realizando ensayos tanto en hormigón en estado fresco como en estado endurecido. Los resultados de este plan experimental permitieron definir las características más sobresalientes de cada mezcla.

Posteriormente, y a partir de la elección de la mezcla óptima, se realizaron sobre ésta los ensayos para evaluar su comportamiento frente a impactos y de allí se realizó teóricamente la deducción del comportamiento energético. Esto que permitió determinar las posibles ventajas de su utilización para la elaboración de elementos de la industria de la construcción, en especial de protección vial.

Se propone una opción atractiva técnica, económica y sustentable que es el uso de caucho reciclado para neumáticos en hormigones de cemento portland siempre que se usen porcentajes apropiados de caucho molido en tales mezclas.

2 Materiales

2.1 Ligantes

Para este trabajo se utilizó Cemento Portland con Filler Calcáreo CPF40, contemplado en la Norma IRAM 50000[3]. Para caracterizarlo se siguieron los procedimientos establecidos en las Normas IRAM 1623[4] e IRAM 1624[5], obteniéndose una densidad relativa de 2,99 y una superficie específica de 347 m^2/kg.

2.2 Agregados pétreos

Los agregados seleccionados fueron triturados pétreos provenientes de canteras de la provincia de Córdoba, Argentina, de tres tipos: Fino Hidrolavado (FH), Arena Gruesa (AG) y Binder. Se realizó el análisis granulométrico (Norma IRAM 1505 [6] y Norma IRAM 1627 [7]), determinación del porcentaje de material que pasa por el tamiz IRAM 75 µm (Norma IRAM 1540 [8] y determinación de la densidad relativa real, densidad relativa aparente y absorción de agua (Norma IRAM 1520 [9] o Norma IRAM 1533 [10]), cuyos resultados se indican en la Tabla 1 y en las Figuras 1,2 y 3.

Table 1. Caracterización agregados pétreos

Ensayo	FH	AG	Binder
Material fino que pasa por el tamiz 75µm [%]	2,60	1,10	-

2.3 Caucho Molido (CM)

Para el reemplazo de los agregados pétreos se utilizó caucho vulcanizado molido, proveniente de neumáticos inservibles, Figura 4, caracterizado por medio del análisis granulométrico (Norma IRAM 1505 [6] -Figura 5- y Norma IRAM 1627 [7]), determinación del porcentaje de material que pasa por el tamiz IRAM 75 µm (Norma IRAM 1540 [8]) y determinación de la densidad relativa real y densidad relativa aparente (Norma IRAM 1520 [9]) cuyos resultados se presentan en la Tabla 2.

3 Dosificaciones

El reemplazo de los agregados pétreos por caucho se realizó en volumen. Se proponen diferentes porcentajes de reemplazo del volumen total de agregados (0, 10, 17.5 y 30).

Las dosificaciones utilizadas se presentan en las Tablas 3 y 4, todas con una relación agua/cemento 0,40.

4 Métodos de ensayo

En estado fresco se realizaron los ensayos de:

- Peso Unitario (IRAM 1562[11])
- Consistencia mediante el asentamiento en el cono (IRAM 1536[12])
- Exudación (IRAM 1604[13])

En estado endurecido se realizaron para todas las mezclas:

- Resistencia a compresión (IRAM 1546[14]) a 7, 14, 28 y 90 días
- Módulo de elasticidad (IRAM 1865[15]) a 28 días

- Absorción por inmersión (ASTM C 642 [16]) a 28 días

Luego de la realización de estos ensayos, se seleccionó la mezcla con las mejores condiciones según los resultados obtenidos y sobre sobre ésta se realizaron los ensayos de esclerometría (IRAM 1694[17])) en probetas de 15 por 30 cm y choque o impacto.

Para evaluar el comportamiento frente a choque, luego de analizar diferentes alternativas, se optó por adaptar un equipo ya disponible en el laboratorio, el equipo para la determinación del ensayo de choque en baldosas, según Norma IRAM 1522 "Baldosas aglomeradas con cemento con cara vista plana" [18]. Se moldearon placas de 20 por 20 cm de lado y 5 cm de espesor del hormigón patrón y del que contenía un 17.5 % de reemplazo de CM por agregado.

El método empleado es una adaptación de la Norma IRAM 1522; este ensayo permite determinar la capacidad de soportar impactos que puedan causar daños a la cara vista de las baldosas, tanto en sus aspectos estéticos como en su vida útil.

El ensayo consiste en dejar caer sobre la cara vista de la probeta la esfera de acero, desde una altura determinada e ir aumentando esta altura en (100 +- 5) mm hasta la rotura de la muestra, o si ésta no se produce, hasta alcanzar la altura máxima de 1000 mm. La altura de caída se determina entre plano definido por la cara vista de la baldosa y el centro de la bola de acero.

Cabe destacar que para este trabajo se modificó la masa, la dimensión y el sistema de sujeción de la esfera al soporte; la esfera que se utilizó para el ensayo tenía una masa de 2.295 gr y un diámetro de 59 mm.

La probeta se consideró rota cuando apareció una fisura que atravesaba la probeta de lado a lado.

En la Figura 5 se presenta el equipo modificado.

Fig. 6. Equipo de choque modificado.

5 Resultados

5.1 Ensayos en estado fresco

Los resultados de los ensayos realizados en estado fresco se encuentran resumidos en la Tabla 5.

Table 5. Ensayos en estado fresco

Ensayo		Unidades	HFP	HF10	HF17,5	HF30
Peso unitario	Peso unidad volumen	[kg/m3]	2460	2211	22156	1727
Trabajabilidad	Asentamiento	[cm]	3,0	2,1	2,1	2,1
Exudación	Volumen de agua exudada por unidad de superficie	[cm3/cm2]	0,02	0,04	0,04	0,07
	Porcentaje de exudación respecto volumen de agua de mezclado [%]	[%]	2,3	2,2	4,8	4,2

Las mezclas con incorporación de CM presentan menor peso unitario. Con respecto a la trabajabilidad, de acuerdo con el asentamiento del cono de Abrams, las mezclas con caucho presentan una pequeña disminución del asentamiento, sin embargo, ésta no fue significativa al momento del moldeado de las probetas, permitiendo una correcta colocación y compactación de la mezcla.

Los valores de volumen de agua exudada por unidad de superficie y porcentaje de exudación también varían respecto del patrón, pero se mantienen dentro de parámetros aceptables.

5.2 Ensayos en estado endurecido

Los resultados de estos ensayos se encuentran resumidos en la Tabla 6 y en la Figura 7 se presenta la evolución de la resistencia a compresión en función de la edad de ensayo.

Table 6. Resultados de ensayos en estado endurecido

Ensayo		Unidades	HFP	HF10	HF17,5	HF30
Resistencia a la compresión	7 días	[MPa]	21,80	6,80	8,30	1,60
	14 días		24,30	7,00	11,10	1,60
	28 días		26,30	7,60	10,50	1,90
	90 días		35,80	9,50	14,00	2,10

Módulo de elasticidad	-	[GPa]	33,80	14,60	12,40	3,70
Absorción por inmersión	Absorción después de inmersión y hervor	[%]	6,10	12,00	9,10	20,00
	Peso específico aparente	-	2,58	2,47	2,46	2,27
	Volumen de vacíos	[%]	13,70	22,90	18,20	31,90

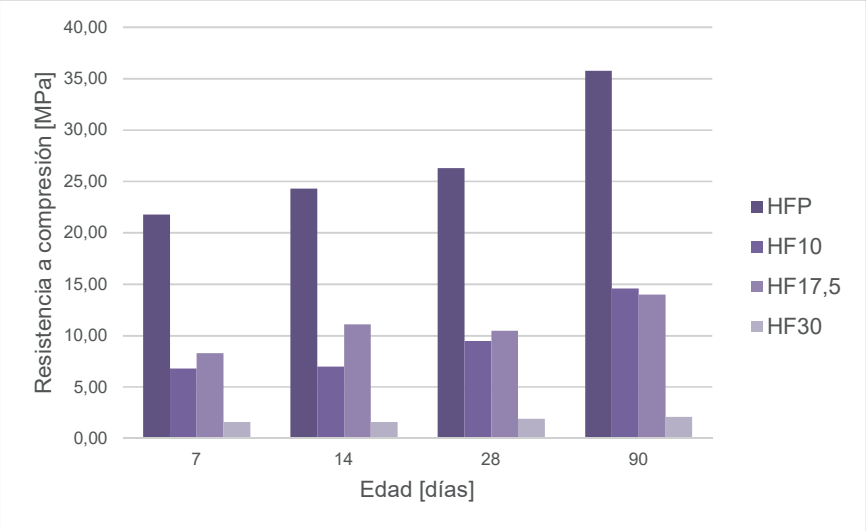

Fig. 7. Evolución de la resistencia a la compresión en función de la edad

De acuerdo con los resultados de resistencia a compresión, este material, que se podría calificar de ecoeficiente debido a que aprovecha un residuo industrial, no es apto para fines estructurales con los porcentajes de caucho incorporados ya que presenta una disminución significativa de la resistencia a la compresión, lo que imposibilita su uso en estructuras y/o elementos estructurales.

Coincidente con los resultados obtenidos en los ensayos de compresión axial, las mezclas con caucho molido presentan una mayor absorción lo que se traduce en un mayor porcentaje de vacíos.

El alto porcentaje de vacíos indica que la disminución de la resistencia mecánica es debida a la presencia de zonas débiles en la masa del compuesto, aunque también puede verse influida por una mala adherencia entre la pasta de cemento y los agregados de caucho molido.

De acuerdo con los resultados obtenidos en el ensayo del módulo de elasticidad con agregado de CM se obtienen valores menores a los de la mezcla patrón, lo que indica que para tensiones similares, los hormigones con agregado de CM presentarán mayores

deformaciones y esto puede traducirse en una mayor disipación de energía frente al impacto.

A partir de este último concepto, se evaluó el comportamiento al choque de la mezcla con un reemplazo del 17.5 % del agregado por CM al considerarse esta mezcla la más apropiada por su resistencia a la compresión y módulo de elasticidad. Los resultados de ambos ensayos, realizados a la edad de 28 días, se presentan en la Tabla 8.

Table 7. Resultados de ensayos de esclerometría y choque

Ensayo	Unidades	HFP	HF17.5
Choque	[cm]	57	60
Esclerometría	N°	31	31

En los resultados del ensayo de esclerometría no se encuentran diferencias significativas entre el hormigón patrón y el que contiene caucho, mostrando los resultados obtenidos, que el método no permite evaluar el comportamiento frente impactos.

Los resultados obtenidos en el ensayo de choque permiten observar que el hormigón con reemplazo de agregados por CM, soporta una mayor altura de caída antes de la fisuración. Con el objetivo de obtener una estimación de la mejora que representa este resultado, se utiliza la siguiente ecuación para calcular la energía absorbida por las piezas ensayadas:

$$E_i = \sum_{i=1}^{i=rotura} m_i * g * h_i = m * g * \sum_{i=1}^{i=rotura} h_i$$

Donde:

- E_i = Energía acumulada absorbida por la placa
- $m_{(i)}$= Masa del cuerpo que impacta (2295 gr)
- g = Aceleración de la gravedad (9,81 m/s^2)
- h_i = Alturas desde las cuales se produce la caída

Se tiene en cuenta una altura inicial de caída de 30 cm y una variación entre cada ensayo de 3 cm hasta llegar a la altura de rotura.

Se obtienen los resultados presentados en la Tabla 8.

Table 8. Energía acumulada absorbida por las placas de Hormigón.

	Unidades	HFP	HF17.5
Energía acumulada absorbida	[J]	97,94	111,44
Variación	[%]	-	+ 13,79

Si bien los valores obtenidos no son significativamente mayores, al considerar que el hormigón con CM tiene menor resistencia, este hecho indicaría una mejora en el comportamiento del hormigón que posee reemplazo de agregados inertes por caucho molido frente al choque.

6 Conclusiones

El material desarrollado, además de proponer un nuevo destino a los neumáticos inservibles, disminuyendo así sus impactos negativos, responde de la manera esperada en los aspectos evaluados.

Uno de los principales desafíos ambientales que enfrentan los municipios de todo el mundo es la eliminación de neumáticos fuera de uso. Para abordar este problema global, en este trabajo se ha avanzado en aplicaciones del caucho de neumáticos reciclado, para su aplicación en elementos de usos vial.

En estado fresco los resultados obtenidos del hormigón con CM han permitido lograr similar trabajabilidad y valores de exudación aceptables para los porcentajes de reemplazo propuestos.

En estado endurecido para el hormigón con CM se verifica una disminución de la resistencia a compresión, un aumento de la absorción de agua y una disminución del módulo de elasticidad.

La disminución que presenta la masa en hormigones con reemplazo de agregado por caucho molido, junto con la mayor capacidad de deformación, permitiría una reducción en los efectos negativos generados en los pasajeros de los vehículos ante un choque con un elemento fabricado con este material.

Según resultados obtenidos, tanto experimental como teóricamente, se verifica un comportamiento que permite mejorar la absorción de energía frente a impactos debido a su mayor capacidad de deformación respecto a la de hormigones convencionales.

Por este motivo podemos considerar al hormigón desarrollado como un material apto para la elaboración de elementos de protección vial, quedando abierta la determinación del valor óptimo de reemplazo de agregados inertes por CM de acuerdo con las características del elemento a diseñar.

Abstract. Accelerated population growth and increased purchasing power lead to develop continuous improvements and new technological developments in the meat industry to meet the increasing demand for processed food worldwide. Although Lean Six Sigma has been widely used in manufacturing, its use in food processing is scarce, and the Chilean context is not an exception. The company under study recognized the need to transform itself and use continuous improvement tools such as Lean Six Sigma. This study was applied to the line of frozen meat patties in order to enhance product quality and standardize the production process, hence improving the operational excellence of the company in a business of global competitiveness. After analyzing the root causes for high variability and waste generation, solutions were produced, and countermeasures implemented at the production line. Main results include an increase in productivity of 18.8%, an 83% reduction of rework, an operating time reduction of 22%, and improvements in sigma levels for key variables.

Keywords: Lean Six Sigma, Processed food, Productivity, Efficiency, Quality.

1 Introduction

In the past decades, several efforts have been made to improve the quality of beef production driven by the increase in meat consumption trends; some elements influencing those patterns are changes in lifestyle, income, urban development, demography, food prices, improvement in meat processing, migration and the effect the mass media has on customers [1].

Beef attributes that add value to meat products are most appreciated by consumers willing to pay more for them. Buying some type of beef is strongly linked to its sensory properties; hence, consistent eating quality is one of the most important attributes [2]. Customers worldwide have preferences for extrinsic attributes such as price and certification, labels, brands, and information; and for intrinsic attributes like visible fat, meat color, and appearance [3].

Intrinsic attributes such as taste, tenderness and juiciness are highly valued, being tenderness the preferred one [4]. Such desirable sensory characteristics, such as juiciness and mouth feel of meat patties are associated with fat content [5] another important beef attribute; even though some consumers prefer lean meat, fat acts like a carrier for flavor compounds and contributes to the texture of the product. Reducing the fat content may alter product quality by causing the product to become firmer, rubberier, less juicy and darker in color [6], making muscle color a characteristic associated to fresh and palatable beef [7].

The choice behavior of the Chilean's consumer of bovine meat, analyzing factors such as price, origin, production method, and quality assurance [8] resulted in a purchase decision influenced by price, being it the least important for the majority of consumers, and the quality assurance attribute the most relevant. Other studies confirm color [9, 10], tenderness [10-12], juiciness [10], taste [12], freshness [9], price [12], and fat [9] as relevant attributes. Similar to international studies, sensorial attributes and low fat are highly desired by Chilean's consumers, being flavor [11] the key attribute justified for spending more in bovine meat for more than 2/3 of them [13]. Quality, as state by consumers, is relevant to deciding if a product is bought, and as such, it needs to be improved to remain in the competitive market.

In the following years, it is expected to have an increase in the demand for food worldwide, and meat consumption is not an exception. Beef burger patties are seldomly prepared from meat at home, but commonly purchased frozen from supermarkets or eaten at fast food restaurants, who are large consumers of Individual Quality Freezing beef patties. Emerging countries, which started with low meat consumption will eventually urbanize and change their lifestyles as their population and *per capita* income continuously grows. This could result in the population demanding more animal protein.

Southern Chile has a long tradition of beef production and related food processing industries. Its beef production increased in 2019 by 4.5% compared to previous year and about 10% of the production was exported. The export volume of beef has increased by 97.2% compared to 2018, being the main cause, China's demand, which increased by 161.2% in terms of volume; China represented in the year 2019, 77.6% of the total export value [14] for this industry. This growing trend indicates the importance of improving the productive system of bovine meat, in order to increase national and international competitiveness.

Productivity is an indicator widely used to assess business performance. The use of Quality Management techniques could help improving the production capacity and reduce waste by maintaining the attributes most valued by customers. Among those, Six Sigma, focused on reducing variation and defects, and Lean Manufacturing, focused on eliminating waste and increasing speed, aiming both to increase the quality, productivity, cost-effectiveness and competitiveness of companies.

Lean Six Sigma –LSS– combines approaches consisting of several tools and techniques. Six Sigma provides a way to measure the quality level to obtain 3.4 defects per million opportunities –DPMO– and identifies the number of opportunities within a process that could result in defects, so that possible causes of quality problems can be addressed and producing defects is avoided [15]; for many companies, this represents

a process for everyday continuous improvement to increase customer satisfaction [16]. Lean offers tools to reduce operating times and eliminate waste. Standardization has the goal of reducing the waste of products and increasing the productivity level, and as a consequence, the competitive position of the company in the market. Waste is produced mainly by returns, rework, second quality products, or customer attrition. Hence, some of the key benefits achieved by LSS implementation [17] such as cost saving, increased customer satisfaction, productivity improvement, higher quality and agility, and reduction in defects, were expected to be achieved in this case study application.

In the food industry, there is a lack of literature on how to implement Lean Six Sigma [18], representing only 2.1% for Agro/Food industries articles in a recent LSS literature review [19], and one article on a LSS implementation review [17]; some authors have researched on the practical implication of an LSS model in a food processing environment [20]. Previous studies on Six Sigma articles indicated that 63.3% were focused on manufacturing in contexts such as semiconductor, automotive, aerospace, chemical, software, pharmaceutical, steel, and aluminum industries [21]. Lean studies have focused on flow and speed up of processing by decreasing or eliminating waste in the seven forms of transport, inventory, motion, waiting, overproduction, over-processing and defects [17].

This work uses Lean Six Sigma applied through a DMAIC –Define, Measure, Analyze, Improve, Control– model to control the main variables of a frozen burger patty meat line, identified as critical for the production process. The contribution of this study for LLS in food processing is a suitable approach to improve quality and productivity, since performance enhancement and waste reduction continue to be critical subjects of such manufacturing companies.

2 Materials and methods

2.1 Materials

The case study was applied to a beef processing industry located in southern Chile. The company fulfills all national and international requirements regarding quality, food safety, hygiene, and health related to products manufactured for human consumption. The production line selected was the frozen burger patty line given the increasing number of kilograms being returned and the drop on monthly sales for that product. Data for the past three years was used to analyze the sales and defects behavior. For the preliminary analysis, data collected for nine months was used. After implementation of improvements, new data for three months was gathered, and results compared to prelim data. For each variable, authors followed the sampling size and random procedure already established by the company to collect data and statistically control the process. Media, standard deviation and variance measures were estimated for sample sizes.

2.2 Methods

This was the first LSS project in the company, so the approach used was a pilot deployment. In the pilot phase, specific problems are addressed to understand the methodology and to gain confidence on it [22]. Literature review was conducted on LSS implementation in the food industry with emphasis on meat processing.

To analyze the original process, the team meant to identify the main causes of process variation based on historical available data. Creating a learning environment for the team helped employees to understand the various phases of LSS; training them in the use of appropriate tools for each DMAIC phase [18] facilitated the implementation process.

Secondary data was obtained for a nine-month period using established procedures by the company for collecting information. Direct process observation provided in-depth knowledge to elaborate a SIPOC –Supplier, Input, Process, Output, Customer– diagram. The production process was documented through a flow diagram, and operating time was gathered to help constructing a Value Stream Map –VSM–. For each stage, different tools were applied. Data regarding sale volumes, returns, defects, rework, shrinkage and forfeiture were analyzed with trend graphics; a cause-effect diagram was elaborated after several brainstorming sessions to identify root cause.

Critical to Quality –CTQ– variables were identified through focus groups and interviews conducted with internal and external customers to define their needs regarding quality, service and price. All variables were analyzed in the company's laboratories through descriptive statistics in the form of histograms or pareto diagrams when needed. Control limits were estimated for critical variables of interest and compared to specifications; for those, defects were counted, and DPMO and process capacity indexes were calculated. The main wastes were classified and measured in percentages. Estimations of utilization, productivity and quality were calculated.

After implementation of countermeasures, new control and check sheets were designed to collect data for three additional months and to compare results. Hypothesis tests were conducted after implementation of changes to determine any statistical variation of media values and estimate new control limits if needed for critical variables.

2.3 Define

This phase was used to identify the process being studied, the CTQs, and the background of the problem. The SIPOC diagram and the VSM –not shown due to space limitations– required targeting time processes and identification of possible variation sources. A short version of the flow production process is shown in figure 1.

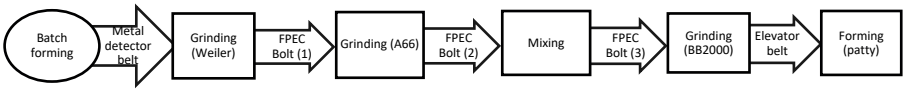

Fig. 1. Sub-process for burger patty line forming.

In order to understand sales behavior, data from the last 2 ½ years was analyzed. Table 1 shows monthly sales of the burger patty production line subprocess. As it can be observed, sales were decreasing. When this study initiated, sales of Year 3 represented 15% of sales from the same six-month period in Year 2.

Table 1. Yearly Sales (in kilograms)

Month	Year 1	Year 2	Year 3
1	62 230	124 876	18 900
2	17 150	62 314	0
3	17 150	105 679	31 500
4	19 040	83 466	15 750
5	135 900	174 992	15 750
6	137 327	84 808	15 750
7	96 264	104 540	
8	124 394	83 718	
9	121 150	4 213	
10	123 023	163 324	
11	119 620	123 916	
12	142 558	60 602	
Total	*1 115 807*	*1 226 446*	*97 650*

As well as sales were decreasing, returns were on the rise as presented in Table 2. Since no returns were registered for Year 3, data for Year 0 was used as reference. Converted to money, returns represent a cost of quality of 3.4% for Year 1 and 3.5% for Year 2 of the annual sales, respectively. Returns were related to quality problems, mainly out of customer's specification.

Table 2. Returns (in kilograms)

Month	Year 0	Year 1	Year 2
1			
2	14 939		17 975
3			1 295
4	189		
5	3 801		1 707
6		22 016	
7	25 071		
8			21 772
9		1 015	
10	2 855		760
11	626		
12	245	14 824	310
Total	*47 726*	*37 855*	*43 819*
% of Sales	*n/a*	*3.4%*	*3.5%*

In order to estimate the productivity of the sub-process line, production capacity – real versus theoretical – was observed for a nine-month period. The cost summary shown in Table 3 indicated 79% of cost was related to raw material, giving hints about the need to further analyze the mixing, grinding and forming stages of the frozen burger patty forming process shown previously in Figure 1.

Table 3. Cost distribution of burger patty line production

	Raw material	Operational	Distribution	Variable
Chilean pesos/Kg	2 175	484	63	42
Percentage	79	17	2	2

After analyzing the data, along with the SIPOC and VSM charts within the team, two-fold goals were defined: to standardize two main variables, temperature and fat percentage; and to increase the production process capacity by 5% in the mixing-grinding-forming line for a three-month period. To help achieve the objectives, a team of 10 people, including the general manager, was set up to address this problem. Since this was the first LSS approach taken by the company, the team leader and manager of continuous improvement and control, trained the team members in basic principles of LSS before continuing with the following phases. Meetings were set up to be held every other week, and each team member was assigned a role, responsibilities and resources.

To define internal customer's needs, specifications were reviewed, and meetings were held. It helped identify requirements for: temperature at the Forming patty machine, average fat percentage, and the absence of foreign elements in the raw material. Through brief interviews with main external customers, their needs were collected and specifications re-defined, as shown in Table 4.

Table 4. Burger patty specification's variables to be controlled

Weight (gr)	Thickness (mm)	Diameter (mm)	Cooking T °Celsius	Sensorial assessment
112.5–115.3	11.2–12.6	115–123	69–74	>85%

2.4 **Measure**

Historical data was collected for each one of the different stages of the subprocess regarding: ticket control, temperature control by batch, defects by variables of interest, machine preventive and corrective maintenance, belt functioning, equipment life control sheet, tools control sheet, shift times, statistical process control charts for selected variables, sensorial evaluation, and meat condition. This was consistent with factors identified by several authors to use LSS, such as process variation, waste elimination, competitiveness increase, cost decrease, inventory reduction, and process efficiency

improvement. In the food industry, product weight and size variability are commonly associated with process variation [20, 23].

Data gathered was used to construct histograms for each variable to be studied and to calculate the DPMO and sigma level for fat percentage and variables affected by fat variation, such as weight, thickness and diameter, as shown on Table 5. The burger patty size chosen, named AMD, represents the majority of the sales. Fat percentage of raw material in the batch was obtained through analysis on the *Food Scan* equipment located in the company's lab.

Table 5. Critical to Quality "As Is", Burger patty size 114 gr –AMD–

	Fat %	Weight	Thickness	Diameter
Spec. limits	22.0 –24.0	112.50–115.30	11.2–12.6	115–123
Sample size	182	482	1 928	410
Opp./batch	27	11	11	8
DPMO	20 960	31 686	46 444	62 500
Sigma level	3.55	3.38	3.14	3.03
Performance	97.9%	96.83%	95.36%	93.75%

As an example of descriptive statistics used by the team, a histogram for the diameter's variable is presented in Figure 2, where control limits were calculated and compared with specifications. All diagrams constructed for other variables are not shown due to lack of space. As it can be seen for this variable, the process is able to comply with specifications –wider curve– and variation is lower than expected, although the process is slightly uncentered, as confirmed by its Cpk value.

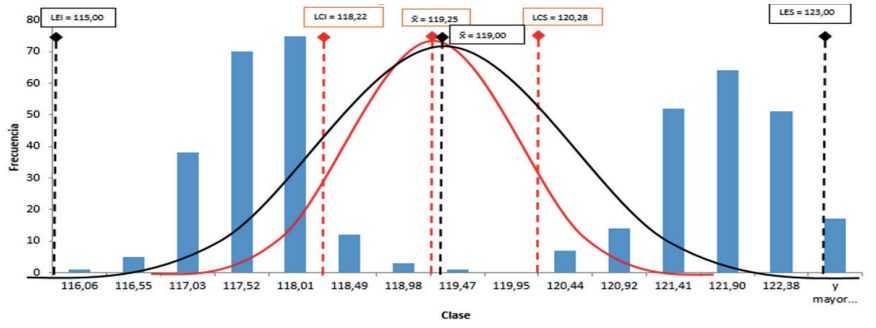

Fig. 2. Histogram for diameter of burger patty.

Later on, three additional quality attributes were studied: cooking temperature, storage temperature, and the absence of unwanted elements in raw material. Histograms were drawn for each case and control limits compared to specifications. For cooking temperature, only 0.2% of burger patty samples were found to be out of specifications, meaning a sigma level of 5.6. Thus, it was not further investigated.

Regarding storage temperature, data was collected from months 7 through 9. The temperature varied according to the fat percentage in the mix. A histogram was elaborated, and data compared to specifications, showing excessive variation for frozen raw material; the average was -8.5°C while the media specification indicates -4.5°C. Temperature is relevant to forming the patty burgers, thus it needed to be addressed.

A sensorial assessment [24] named Cutting was performed of Batch AMD 157540, in the first month of this study, obtaining a sensorial approval of 89.2% –85% was the minimum expected value–. Since some variables measured by this analysis –flavor, tastiness, texture defects, juiciness, tenderness, unscrambling, appearance, seal conformance– are intrinsic and relevant to customers; this evaluation had to be repeated after implementing changes.

No foreign material was found in the process line; thus, it was not further addressed by this study.

Average production times for all stages of the subprocess shown on Figure 1 were estimated, adding to an average of 02:28:58 hours per batch.

Regarding waste, Table 6 shows data for a nine-month period of study. Waste mainly occurs at the Forming stage of the subprocess. From the data it was clear that waste should be reduced to increase productivity.

Table 6. Waste in kilograms for burger patty forming line.

Month	Production	Forfeiture	Rework	Shrinkage
1	406 754	1 629	4 304	10 060
2	435 552	1 630	3 778	6 945
3	455 137	1 303	2 761	7 403
4	324 020	1 474	2 849	7 193
5	289 127	1 716	3 633	6 687
6	308 260	1 673	4 971	7 356
7	405 203	1 562	5 154	7 936
8	446 043	1 527	4 821	10 248
9	292 349	1 210	4 416	4 772
Total	**3 362 443**	**13 724**	**36 686**	**68 600**
Average %		0.4%	1.1%	2.0%
Chilean pesos*		**41 460 808**	**30 999 890**	**207 240 521**

**Estimated value / 1 USD = 665 Chilean pesos in year of study*

The estimated quality loss for a nine-month period was valued at 420 603 USD due to shrinkage, rework, and forfeiture. This data was a key element to promote improvements to reduce waste and was consistent with literature, which considers cost, defects, value and time to be drivers for implementing LSS in the food industry [18].

2.5 **Analyze**

A data collection sheet was designed to gather all desired information: batch number, production date, code, temperature, fat percentage, weight, diameter, and thickness. A cause-effect diagram was elaborated. From it, main causes of possible variability on the final product were detected for machines –Weiler, A66, Mixer, Conveyor belt, and Forming–, people –training–, methods –unknown, outdated–, materials –inventory conditions–. Details for each machine were documented, discussed with the team members, and solutions proposed. Several options were analyzed to reduce the variability of the fat percentage in the product, regarding formulation adjustments and new methods to form the batch. Operational time was analyzed as well as the type of mold being used to form the patty burger.

The bottleneck of the subprocess is the Forming Stage, composed of Machine F16 and F19. They have a design capacity of 2 160 kg/hr. and 972 kg/hr.; shift times of 11.5 hours and 9.5 hours 5 days per week; and number of people per shift of 12 and 3, respectively. Combined, Forming has a design capacity of 3 132 kg/hr. and a planned production time, also known as maximum rated capacity of 95% the design capacity, equals to 2 975.4 kg/hr. The output rate is calculated dividing the production volume by the run time. Finally, productivity is estimated by multiplying utilization and efficiency. Calculations are shown in Table 7.

Table 7. Frozen burger patty production line (nine months)

Production volume	Available run time	Run time	Utilization	Efficiency	Productivity
3 362 443 kg	1 723	1 424	82.3%	79.3%	65.2%

Regarding the Overall Equipment Effectiveness –OEE–, which includes quality loss to estimate the fully productive time, it can be calculated as,

$$OEE = \%Performance \times \%Availability \times \%Quality \quad (1)$$

Performance is the speed at which the machine or workstation runs expressed as a percentage of the speed it is designed to run. It is synonymous of efficiency. Availability is the asset operating time expressed as a percentage of available operating time. Quality is the total number of good units produced expressed as a percentage of the total number of units that were started.

The theoretical time needed to produce 3 362 443 kilograms was 1 130 hours –performance time–. Performance is equal to 79.3% and availability is equal to 82.3%, same as utilization. Of the 3 362 443 kilograms produced, only 96.5% were of good enough quality. The other units had to be reworked, before sale or scrapped. This means the good kilograms expressed as time is 1 090 hours, and the quality is 95.1%. Hence, OEE_{before} equals to 62.1%.

This calculation shows that the total losses during the day for this machine were 37.9% of production time. Eventually, this represents a large amount of time loss, decreasing the profits if the productivity of the Forming stage was higher. Therefore, it

was important to identify the main root causes of this loss and to implement the necessary actions to reduce or eliminate waste.

2.6 **Implement-Improve**

New working procedures were standardized, documented, and implemented. Employees received training; possible causes of failures were identified and addressed properly for each stage of the subprocess. Measures were taken to reduce process time. Raw material temperature handling and storage were strictly controlled.

In order to stabilize the fat percentage, the ingredients and formulation were prepared the day before production; this new method allowed to have adequate quantities and to load the fat raw material in alternative ways into the batch. This change reduced the deviation for fat percentage from the media to 0.4%, and the DPMO from 20 960 to 137, improving the sigma level from 3.55 to 5.14 as presented on Table 8.

Regarding weight, thickness and diameter of burger patties, analyses performed previously showed a close relationship between weight and the mixing time. The type of mold used in the Forming Stage affected all three variables. New molds were bought, a mold matrix was constructed with diameters and codes for the size and type of each burger patty used in the machines.

After implementing the changes, new samples were taken and statistics compared to the previous data; from those, DPMO for weight was reduced from 31 686 to 16 142 and the sigma level was improved by 5.5%. Data taken for comparing thickness shows an reduction in DPMO from 46 444 to 22 727; however, such number is still high and more efforts need to be done; its sigma level was increased from 3.14 to 3.37. The other CTQ, diameter, had a significant improvement: from 45 454 DPMO to 3 504 for the new sample taken. This represents an improvement in the sigma level from 3.14 to 4.25. All results are presented on Table 8.

Even though all four CTQs were improved, the process was still not centered in regard to specifications; yet three variables had $Cp < 1$ and $Cpk < 1$, except for diameter, indicating room for improvement on those variables.

Table 8. Critical to Quality "After Implementation"

	Fat %	Weight	Thickness	Diameter
Spec. limits	22.0 – 24.0	112.50–115.30	11.2–12.6	115–123
Sample size	270	107	428	214
Opportunities/batch	27	11	11	8
DPMO	137	16 142	22 727	3 504
Sigma level	5.14	3.56	3.38	4.25
Performance	99.99%	98.39%	97.73%	99.65%

Burger patty quality. As discussed earlier, cooking time does affect the quality of the product. Data analysis showed that the operational cooking time was not complying

with specifications, being skewed to the left. After studying the process, a new procedure was written and implemented.

Later on, as changes were implemented a new sensorial evaluation –Cutting– was performed. The panel responses evaluating the burgers on batch AMD 160348 gave them a 91.3% acceptance, an increase of 2.1 % in quality perception from the previous evaluation.

In order to stabilize the temperature of raw material in cooler rooms at -5°C, several tests were performed with the goal of reducing mixing times and achieving the optimal temperature needed by the burger patty maker. Figure 3 shows the values registered. Frozen raw material should have an average temperature of -4.5°C. Table 9 shows the summary of the results. For fresh products, 1.0°C was the minimum average temperature expected. From the figure and the results, it can be seen temperature was set under control with the measures taken.

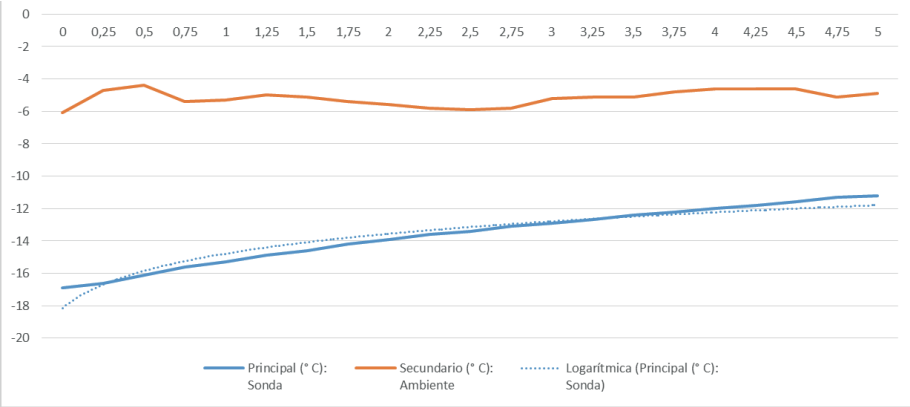

Fig. 3. Tempering curve for raw material

Table 9. Average raw material temperatures °C

Raw material	Meat block 1	Meat block 2	Meat block 3	Meat block 4
A85SGP fresh	2.0	1.9	2.0	1.7
A90SCB frozen	-3.6	-4.0	-4.7	-5.6
B50SCB frozen	-3.3	-3.6	-4.2	-5.1
M30ECB frozen	-5.6	-5.3	-5.7	-5.1
2M70CB frozen	-4.4	-5.5	-5.0	-4.2

Processing time. As shown in Table 10, operating times were reduced by reprogramming the production line, applying changes to the temperature of the raw material storage, regulating the fat percentage addition to the mix, and controlling better the block meat temperatures. Time estimations were supported by the VSM chart elements. All

changes were documented and standardized in written procedures. Total processing time was reduced by 22.7%.

Table 10. Average patty burger line operating time

Steps	Before	After
Batch forming	0:04:20	0:03:30
FPEC1	0:05:05	0:04:40
FPEC2	0:06:29	0:06:50
Loading mixer	0:08:32	0:07:29
Unloading mixer	0:14:02	0:14:10
Loading FPEC3	0:24:30	0:18:00
Loading BB2000	0:39:00	0:28:00
F16 /719	0:47:00	0:34:00
Total time	***2:28:58***	***1:56:39***

Waste reduction. Regarding waste in the form of forfeiture, rework and shrinkage occurred in the Forming line, after improvement new data was collected. A comparison is shown in Table 11, with reduction in the types of waste targeted by the changes implemented: rework and shrinkage. Rework was reduced by 83% and shrinkage by 25%. Estimated monthly quality loss due to rework and shrinkage was estimated at 46 733 USD. After implementation, this loss was reduced to an average of 12 020 USD per month, and 75% reduction.

Table 11. Waste Before (January-September) and After (October-December)

	Production	Forfeiture	Rework	Shrinkage
Before	**3 362 443**	**13 724**	**36 686**	**68 600**
		0.4%	1.1%	2.0%
After	**397 840**	**1 881**	**2 390**	**7 278**
		0.4%	0.6%	1.8%

Productivity improvement. Instead of running both machines at the same time, Forming equipment F19 and F16 were programmed to work at different periods of time. The results from data taken after changes were implemented, indicate an improvement in efficiency and productivity. Data for the last three months had an average daily combined production of 21 610 kilograms, with an effective capacity of 2 975 kg/hr. and a real capacity of 2 507.6 kgs/hr. Most of the production was processed on the Forming machine F16, leaving F19 for small batches. New results compared to data from Table 7 show that efficiency was improved from 79.3% to 97%, utilization increased from 82.3% to 86.7%, and productivity from 65.2% to 84%.

Of the 21 610 average kilograms produced daily, only 97.2% were of good enough quality. The other units had to be reworked before sale or scrapped. Hence, OEE_{after} was estimated to be 81.7%. Compared to 62.1% from the previous nine months, there was an increase of almost 19.6% in OEE for the processing line.

2.7 **Act**

Data taken at the beginning of the process showed a utilization of 92.8%, efficiency of 55.2% and productivity of 51%. Since machine F19 was being underutilized, it was discontinued. By using only F16, labor force was reduced by 17%.

In order to verify the changes for the media of the variables, a hypothesis test was performed for each one. Results are shown on table 12. Each hypothesis test was associated with a probability and a type-I error rate of 5%, under the assumption that the variables had a Normal distribution, with unknown mean μ, and known standard deviation σ; random samples were obtained, and sample means and Z_0 values were calculated.

Table 12. Hypothesis test for media with known sigma value

	Fat %	Weight	Thickness	Diameter
	21.45	111.44	11.16	119.25
σ	0.33	0.5	0.23	1.16
n	27	107	428	214
$\bar{x}$	23.8	113.93	11.25	119.25
Z_0	-23.9	-46.6	-7.2	0
Decision	Reject	Reject	Reject	No reject

Since the media changed for three variables, new control limits were calculated for those. Given the fact that variation remained high for some variables, further improvements is needed. Those efforts were beyond the scope of this work. To maintain the changes, strict procedures were implemented to control the critical CTQs and keep waste level and processing times at the new rates. Those aspects in no need of change, such as absence of foreign material, were kept being monitored. Temperature needed in storage of raw material was controlled by regular preventive maintenance of equipment.

3 Conclusions

This study had a two-fold objective: to standardize two main variables, temperature and fat percentage; and to increase the production process capacity by 5% in mixing-grinding-forming for a 3 month-period. Through the study, it was necessary to analyze variables, such as weight, diameter and thickness of the burger patty, all affected by the percentage of fat and the temperature it was kept in the storage room. Several Lean and Six Sigma tools were utilized while implementing the DMAIC model. With the solutions provided by the team, fat percentage was stabilized and DPMOS were reduced for weight, thickness and diameter of burger patties, gaining improvements at the sigma level of 5.5%, 7.5% and 35%. However, the process is still not centered in regard to specifications, indicating room for improvement on those variables. Overall line efficiency was improved from 79.3% to 97%, utilization increased from 82.3% to 86.7%, and productivity from 65.2% to 84%. Those results are well above the goal of 5% increase. Production time per batch was reduced from 2:28:58 to 1:56:39 hours, representing a 22% improvement. OEE for the line increased from 62.1% to 81.7%. Sensorial assessment, which measures the quality perception of customers was increased by 2.1 % for burgers patties; this was achieved as storage temperature allowed fat percentage to stabilize. Rework was reduced by 83% and shrinkage by 25%, representing estimated annual savings of 416 448 USD. New procedures were settled to ensure changes are kept in time.

Future research includes identification of non value-added activities and 5S implementation. The application of LSS in the processing food industry is scarce, being this work, to the best of the author's knowledge, the first of its kind in the Chilean context of beef food processing.

COVID-19 Pandemic Effects on the Idiosyncratic Risk of the Brazilian and Emerging Markets

Andre Assis de Salles[0000-0001-5218-4006]

Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil
as@ufrj.br

Abstract. The Covid-19 Pandemic affects social and economic relations in all national economies and the world economy, and their financial markets. Investment and production financing in economies take place through these markets, in particular in the capital market. The idiosyncratic risk represents the risk associated only with a specific productive project, with an economic sector, or with a specific national economy. This work aims to estimate the idiosyncratic risk of the Brazilian economy, through heteroscedastic conditional models, to verify the initial impact of the Covid-19 Pandemic on the risk associated with productive projects developed in the Brazilian and emerging economies, and to their financing and investments. Daily data in US$ covering the period from June 30, 2017 to July 1, 2020 were used.

Keywords: Covid-19 Pandemic, Idiosyncratic Risk, Brazilian Economy.

1 Introduction

The sanitary crisis caused by the Covid-19 Pandemic is compared to the 1918 crisis caused by the H1N1 Influenza Pandemic. The sanitary crisis that triggered the Covid-19 Pandemic began with news of a public health problem that started in Wuhan, capital of Hubei province in China, caused by a virus identified as SARS-CoV-2, a new Coronavirus, which quickly spread over 180 countries causing high mortality. Compared to the 1918 crisis caused by the H1N1 Influenza Pandemic that haunted the humanity in the beginning of the twentieth century, Covid-19 Pandemic has also triggered many studies and research in the most diverse areas of knowledge.

The great crises repercussions which spread throughout the world during the last centuries have been the object of studies and researches over time. Most of these researches were aimed to verify the immediate effects and the influence of these crises on the world population welfare and the economic and social behavior and relations in the world. Among these researches, [1] can be mentioned. In a broad study on the economic impacts of the Influenza Pandemic, [1] highlights that the loss is more human than material. The economic impacts of this Pandemic, according to [1], can be classified as direct and indirect. The study includes hospital costs, lost days of work, medicine costs, the decrease in tax revenue and the increase in health and economic aid expenditures to sectors in difficulty, followed by government fiscal deficits as direct

impacts. Among the indirect economic impacts [1] includes the economic multiplier effects of direct costs and the behavior of consumers, affecting consumption relationships.

The crisis caused by the Covid-19 Pandemic had a direct impact on social and economic relations in all regions of the world affecting national economies and the world economy as well as world financial markets. These financial markets signal the expectations of national economies and the world economy, through money, foreign exchange, credit and capital markets. While in the public health area, efforts are being made to minimize the serious problems in public health systems, economic agents seeks to verify the problems that the Covid-19 Pandemic has caused and should cause in the years to come, with the growing disorder in the costs and the production chains.

The financing and investment of production in economies happen, generally, through the financial market, in particular via the capital market. The productive projects that provide the necessary infrastructure for the development of economies and maintenance of jobs and the income growth have in the capital market the source of resources for investments and financing. In this way, one of the important advanced indicators of the economy is the performance of the capital market, whose first indicator is the stock market profitability index. This index reflects the expectations of economic agents regarding the economy, and allows estimates of the volatility or risk associated with productive projects, sectors of national economies, a national economy and the global economy. The volatility or the total risk has two components, the market risk and the idiosyncratic or unique risk. The market risk refers to the risk of exposure of productive projects, sectors of national economies, and a national economy, to the behavior of the respective market portfolios, respectively, the sector project portfolio associated to the productive project concerned, the portfolio that represents the national economy, and the portfolio that represents everything that is produced in all national economies. The idiosyncratic risk is the unique risk associated only with a specific productive project, or the project portfolio of a sector, or of a sector of a national economy, or of a national economy. Thus, each national economy has as an indicator that represents the portfolio that encompasses most of the productive projects of each of the national economies, that is, the indicator closest to a market portfolio which is the equity market profitability index of each national economy. These economies are part of the world economy, which has a profitability index of the global stock market as a proxy for the market portfolio. Some agencies or market institutions calculate and make available some profitability indexes of the nationals and global stock markets.

Many studies and researches started with the objective of verifying and mitigating the pressing public health and economic problems that present themselves during the Covid-19 Pandemic and the possible problems that will be originated. Among these studies it must be mentioned: [2], which deals with idiosyncratic and systematic shocks caused by pandemics in financial markets; [3], who discusses the economic impact of the Covid-19 Pandemic; the study by [4], which deals with the influence of the Covid-19 Pandemic on the global economy through the capital market using the global market share profitability index to study the long term relationship between the markets of actions and the effects of the Covid-19 Pandemic; the research by [5], which deals with the influence of the Covid-19 Pandemic in the capital markets of selected countries; the

work by [6], which presents a study on the effect of the lockdown period on the Indian capital market through a sample of 31 companies listed on the Bombay Stock Exchange; and other researches related to this topic, such as [7], [8], [9], [10], [11] and [12].

With regards to the risk, based on the seminal work of [13], many researches have been carried out seeking, in an appropriate way, to determine the total risk and its components: systematic risk and idiosyncratic risk. The estimation of the market model, or the Single Index Model, suggested by [13] allows the determination of the main indicator of market risk, the beta coefficient, and the idiosyncratic risk, also called specific risk or unique risk. In a pioneering work [14] seek to forecast the systematic risk and the specific risk of stocks and propose stochastic models for deter-mining the beta coefficient and the idiosyncratic risk using the Single Index Model. From this work, many researches were developed. [15] estimated the idiosyncratic risk and its relationship with the monthly stock returns using the three-factor model, suggested by [16]. Besides that [15] employed some of the ARCH family for volatility models derived from the Autoregressive Conditional Heteroscedasticity Models available in the finance literature developed from the seminal work of [17] and the work of [18]. In another relevant work [19] note that the idiosyncratic risk has been neglected to the detriment of a greater emphasis given to the systematic or market risk in determining the risk premium. In turn, [20] emphasized the importance of assessing specific or idiosyncratic risk. In general, market volatility increases in the periods leading up to these crises and during crises periods, as observed by [21] in the recent period of the world economy with the subprime crisis. Among the most recent studies that attempt to estimate idiosyncratic risk, we can mention [22], which deals with this risk as an anomaly, [23], with data from the Japanese economy, and [24], that verify the idiosyncratic risk of the Chinese stock market.

This work aims to estimate the idiosyncratic risk or unique risk of the Brazilian economy and the emerging economies, using heteroscedastic conditional models of the ARCH family models in order to verify the impact of the Covid-19 Pandemic on the risk associated with productive projects developed in the Brazilian economy and the other emerging countries as well as on the risk associated with investments and financing.

Besides this introduction in Section 2 the methodological approach implemented in the research is presented. Section 3 presents the data or the sample used. The analysis of the results obtained in this research are reported in Section 4. Finally, Section 5 presents the conclusions and final comments of this work followed by the bibliographic references used.

2 Methodological Approach

In the development of this work, models were estimated according to the classical statistical inference procedures, which are described in econometrics and time series handbooks such as [25], [26], [27], among others.

The concept and the determination of the total risk and its portions, systematic risk and idiosyncratic risk, were established from the Single Index Model, or the market model proposed by [13], which explain the risk asset portfolio returns through the returns of market portfolio. In the scope of this work, the risk asset portfolio is characterized by the Brazilian stock market profitability index represented by the MSCI Brazil index while the emerging stock market profitability index was represented by the MSCI Emerging index and the world stock market portfolio is characterized by the global equity market profitability index, represented by the MSCI ACWorld index. These indices are calculated by Morgan Stanley Financial Services (MSCI) and will be described in this work in the section dealing with the data used. The market model can be described as follows:

$$R_t = \alpha + \beta R_{Mt} + e_t \tag{1}$$

Where: R_t = the return of MSCI-Brazil index or MSCI-Emerging index in period t; R_{Mt} = the return of ACWorld index in period t. Thus, the conditional average and conditional variance of the financial asset returns can be determined as follows:

$$\textit{Mean}: \quad E(R_t|R_{Mt}) = \alpha + \beta R_{Mt} \tag{2}$$

$$\textit{Variance}: \quad V(R_t|R_{Mt}) = \beta^2 V(R_{Mt}) + V(e_t) \tag{3}$$

The estimation of the beta coefficient, the main indicator of market risk, takes place through linear regression models, as for example in the works elaborated by [28], using corrections from a classic univariate model, and by [29], using a multivariate Bayesian model. The estimation of the idiosyncratic risk time series can be done through volatility models such as the ARCH family models, in particular, the GARCH model proposed by [18]. The GARCH model seeks to capture a common behavior in financial asset return time series, in which high values are also followed by high values in the following periods, not necessarily in the same direction, following a predictable process. Therefore, a market model that allows obtaining estimates of the two components of the total risk can be built. Additionally to the GARCH model, some of the main models of the ARCH family were tested, such as ARCH, IGARCH, EGARCH and TGARCH, as described in [25]. Using the model selection criterion suggested by Akaike, the AIC, which can be seen in detail in [26] or [27], the market model to estimate the idiosyncratic risk was selected. With the alpha and betas parameters greater than zero, the volatility models estimated in this work have their general form given by the expressions shown below: the ARCH (q) model represented by the expression (4); the GARCH (p, q) model represented by expression (5); the IGARCH (p, q) model represented by expression (6); the EGARCH (p, q, r) model represented by the expression (7); and TGARCH (p, q, r) model represented by the expression (8).

$$\sigma_t^2 = \alpha_0 + \sum_{j=1}^{q} \alpha_j e_{t-j}^2 \quad (4)$$

$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i e_{t-i}^2 + \sum_{j=1}^{p} \beta_j \sigma_{t-j}^2 \quad (5)$$

$$\sigma_t^2 = \sum_{i=1}^{q} \alpha_i e_{t-i}^2 + \sum_{j=1}^{p} \beta_j \sigma_{t-j}^2 \quad (6)$$

$$ln\sigma_t^2 = \alpha_0 + \sum_{j=1}^{p} \beta_j ln\sigma_{t-j}^2 + \sum_{i=1}^{q} \alpha_i \left| \frac{e_{t-i}}{\sigma_{t-i}} - E\left(\frac{e_{t-i}}{\sigma_{t-i}}\right) \right| + \sum_{k=1}^{r} \gamma_k \frac{e_{t-i}}{\sigma_{t-i}} \quad (7)$$

$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i e_{t-i}^2 + \sum_{j=1}^{p} \beta_j \sigma_{t-j}^2 + \sum_{k=1}^{r} \gamma_k d_{(e_{t-k} \leq 0)} |e_{t-k}|^2 \quad (8)$$

Thus, the model used in this work to estimate idiosyncratic risk was a heteroscedastic linear regression model, where the stochastic terms are distributed according to a Student's t distribution and the variance given by a GARCH (1, 1) model which can be described as follows:

$$R_t = \alpha + \beta R_{Mt} + e_t \ , \ e_t \sim Student\ (0; \sigma_t^2; \nu) \quad (9)$$

$$\sigma_t^2 = \alpha_0 + \alpha e_{t-1}^2 + \beta \sigma_{t-1}^2 \quad (10)$$

3 Data Used

The primary data referring to the stock market indices that form the sample used in this work were collected on the Investing.com website. These indices are calculated and released by the financial services company Morgan Stanley Capital International (MSCI). These indicators were: the profitability index of the Brazilian stock market - MSCI Brazil; the profitability index of the stock market of emerging countries - MSCI Emerging Markets; and the worldwide stock market profitability index - MSCI All-Country World Equity - or simply the MSCI ACWI Index. The Brazilian stock market index is made up of 56 shares and represents 85% of the equities traded in the country and includes the main sectors of the Brazilian economy and is detailed at https://www.msci.com/search?keywords=brazil. The emerging markets index is composed of equities traded in China (33.00%), South Korea (13.02%), Taiwan (11.35%), India (9.16%), Brazil (7, 73%), South Africa (5.89%), Russia (3.77%), Mexico (2.55%), Thailand (2.34%) and others (11.59%). Further details on the composition of the emerging countries stock markets indicator are at https://www.msci.com/search?keywords=Emerging+Markets. And the global stock market index used is composed of equities from 11 sectors of the economy traded on the markets: from developed countries in the Americas, 2 countries, from Europe and the Middle East, 16 countries, and from the Pacific, 5 countries; and from emerging countries in the Americas, 6 countries, Africa, Europe and the Middle East, 11 countries, and Asia, 9 countries. Further details about the description of this index can be seen https://www.msci.com/acwi. All

information collected was daily data in US$, covering the period from June 30, 2017 to July 1, 2020.

Table 1, below, presents the time series statistical summary of interest to obtain this research results, that is, an estimate of the idiosyncratic risk time series using the market model. It can be seen that the time series location measures are disparate and do not have a symmetry. With regard to the volatility of the return time series it is high, as expected from market price returns or variations. As for the asymmetry and kurtosis coefficients: it can be seen that all the asymmetry coefficients shown in Table 1 differ from the asymmetry coefficient of a normal probability distribution, the same happens with regard to the kurtosis coefficients calculated for all series used. The Jarque-Bera test confirms the inferences made from observing the coefficients of asymmetry and kurtosis, that is, for every of the time series used, the normality hypothesis cannot be accepted. With regard to the stationarity hypothesis of the time series summarized in Table 1, the stationarity possibility of the time series of the quotes of the MSCI-ACWorld index according to the results of the ADF test cannot be rejected. However it should be noted that the extensions to the ADF test do not allow acceptance of the stationary hypothesis of the quotes of the global stock index MSCI-ACWorld.

Regarding the time series of the quotes of the MSCI-Brazil index, the hypothesis of stationarity for the ADF test and its variations cannot be accepted. Regards the MSCI-Emerging markets index, although stationarity is not rejected at the level of significance of 8%, for the ADF test the alternatives of the ADF test, without the constant or the trend component of the series, point to a contrary decision , that is, the stationarity hypothesis of the index corresponding to the portfolio of equities traded in emerging countries is not accepted.

Table 1: Statistical Summary of Time Series

4 Analysis of Results Obtained

With regards the idiosyncratic risk of the Brazilian market, the time series was estimated using the market model for mean and an EGARCH (p, q, r) model for variance.

In this market model, according to the descriptions in Section 3, the returns of the profitability index of the Brazilian stock markets, given by the stock profitability index MSCI-Brazil (MSCI-Br) as a response variable and the market portfolio given by the MSCI-ACWorld (ACW) index as a regressor. The market model selected was the model without intercept. Thus, the selected model was similar to that described by the expressions in (9), without the α parameter, with the EGARCH (1,1,1) model replacing the expression (10), since this model was selected using the criterion AIC. This model was selected among the 18 models with all the significant parameters among the 175 models estimated with different combinations, that is, varying: the estimation of the constant parameter in the average model; the probability distribution of stochastic terms, normal or Student's t; inclusion of dummy variables, in the average and or variance; and the volatility model. Additionally, as observed from the Pan American Health Organization (PAHO) information at https://www.paho.org/bra, these variable dummies considers the follow dates: January 23rd, the day of the first lockdown in Wuhan in China; January 30th, the day of outbreak declaration from the World Health Organization - WHO, that declares that the outbreak of the new corona-virus is a Public Health Emergency of International Importance (ESPII) and it is spreads for 19 countries; February 26th, the day of the first case of Covid-19 in the São Paulo city -- Brazil, a patient coming from Italy; and March 11th, the day of the characterization of the Covid-19 Pandemic by the World Health Organization - WHO. The variable dummies were added to the market model in the mean and / or variance, however none of these models were selected to estimate the idiosyncratic risk of the Brazilian economic activity.

Therefore the idiosyncratic risk used, hereafter IDR, was obtained by estimating the market model without intercept term in the average, where the stochastic terms adjusted to a Student's t distribution with approximately 6 degrees of freedom and an EGARCH (1,1,1) model for the variance. The selected model is described in expressions (11) and (12), ahead, with the estimates and the necessary metrics to observe the performance of the estimates obtained listed in (13).

The market model for emerging countries was estimated, to compare with the results obtained for the IDR Brazil time series. Thus, the same methodology was used to obtain the IDR Brazil using the MSCI-Emerging index (MSCI-Em), in that way obtain estimates for IDR-Emerging. From 18 estimated models, the results pointed to the selection of the market model whose results are shown forward. The model selected, using the AIC criterion, it is described in expressions (14) and (15), respectively, for the mean and for the variance, given by a GARCH model, and the performance metrics listed in (16) in the follow.

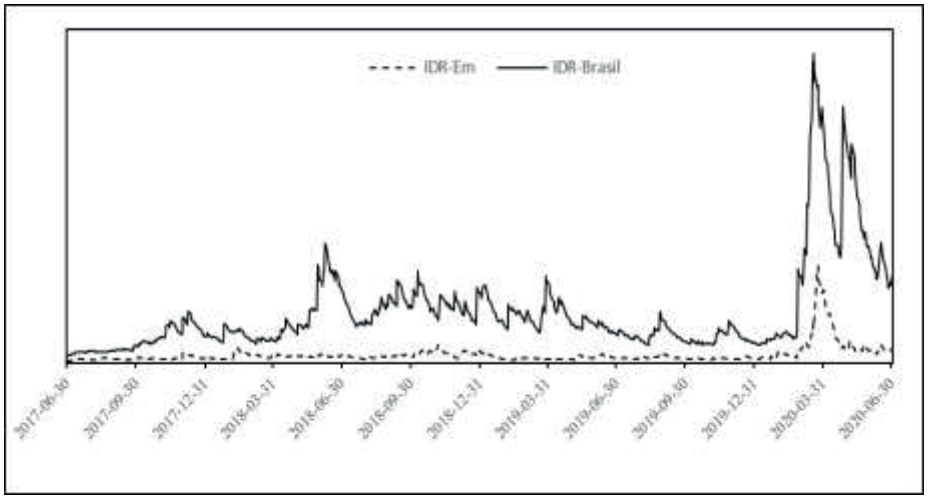

Fig. 1.The Idiosyncratic Risk of the Brazilian Market and the Emerging Markets (June 2017 July 2020)

Thus, the IDR-Brazil and the IDR-Emerging were obtained from the market model, respectively, for the Brazil and for the emerging countries. The two plots in the Fig. 1 illustrates the IDR-Brazil and the IDR-Emerging time series behavior. Regard to IDR-Brazil, it is can be to observe the risk associated with in-vestments and financing of economic activities in Brazil. In the period near the end of the first half of 2018 can be observes an increase with variations until the same period in 2019, maintaining a lower level with peaks close to the beginning of September and December 2019. At the end of February 2020, the IDR-Brazil plot shows an atypical behavior reaching a peak, the highest level in the period studied, on March 17th, 2020 after March 11th, when the Covid-19 epidemic was characterized as a Pandemic by WHO. At the end of April 2020, the IDR-Brazil decreased and then growing until the end of this month. From Fig. 1, it can be inferred that the IDR-Brazil is always above the idiosyncratic risk of the group or the portfolio of emerging countries. Another relevant inference from the observation of IDR-Brazil behavior can be done at the end of the period studied, that is, on June 30th, 2020 when the lowest level of risk in the period after the decree of the Covid-19 Pandemic by WHO was reached, which corresponds to the highest level the idiosyncratic risk of emerging countries that happened on March 23rd, 2020.

5 Conclusions and Final Remarks

This work aimed to carry out initial studies of the impacts of the Covid-19 Pandemic on national economies through idiosyncratic risk, associated with economic activity in Brazil and in emerging economies. The primary objective of this paper was to verify this impact on Brazilian economic activity. This work used a methodological approach based on the portfolio theory, a fundamental milestone of the finance theory, to obtain estimates of the idiosyncratic risk associated with the financing and investment of economic activity in Brazil, or the productive projects implemented in the Brazilian economy.

One of the two installments of the total risk of an asset portfolio, or of an economy, is the idiosyncratic risk, allowing to observe the part of the total risk that refers only to the asset portfolio or to a particular national economy. Thus, once the idiosyncratic risk can be estimated thought the market model, heteroscedastic market models were estimated for a portfolio of assets in the Brazilian economy and for a portfolio of assets traded in emerging countries. In addition to heteroscedastic conditional models, Student's t distribution was used in these models as an alternative to the normal distribution for the stochastic terms.

The idiosyncratic risk time series estimated allowed to observe the impact or influence of the Covid-19 Pandemic on the risk of the Brazilian economic activities and the emerging economies over the studied period.

It should be emphasized that the allocation of resources in productive projects, or in national economies, occurs by observing the trade-off risk and return. This way, resource managers available for applications in the international market seek to invest in projects and in national economies that can offer returns compatible with the level of risk that is externalized in the international market. The level of specific or idiosyncratic

risk associated with economic activity in Brazil demonstrated itself well above the risk of other emerging countries, in the entire period of the sample studied, which was accentuated by the Covid-19 Pandemic.

Future works can be done with other samples and methodologies that will provide more accurate results to allow for further subsidies that will contribute to minimize the Covid-19 Pandemic effects in the economic activities, particularly the financing and investment of production.

Abstract. Among the operating conditions that impact the performance of a gas turbine, the ambient conditions are the most egregious ones. Inlet air cooling systems can be used to restore these values to a level closer to the turbine's design conditions. The most used inlet cooling methods in thermal power plants are evaporative cooling, vapor-compression refrigeration systems and absorption chilling. This work investigated the application of these methods to the gas turbines used for ship propulsion in the Brazilian Navy. A mathematical model was developed and implemented on the Engineering Equation Solver for the calculation of the chilled turbines' cycle. Results were calculated respective to a design point and the inlet cooling methods were compared according to their respective effect on the gas turbines' power, efficiency and fuel consumption. Finally, a strong correlation between the ambient condition and the necessary cooling load for reaching a given temperature was detected. Therefore, this paper has great relevance to society, because the methodology presented can be used to gain efficiency in several areas of the civil and military sectors.

Keywords: Gas turbines; chilling; evaporative cooling; thermal efficiency.

1 Introduction

The study of thermal machines is usually about optimization problems: how to extract more useful work from the least energy input. The ambient conditions are so relevant for this kind of study when dealing with Gas Turbines (GT) that for commercial turbines comparison the ISO 3977-2 standard (Gas Turbines – Procurement – Part 2: Standard Reference Conditions and Ratings) defines the reference conditions. Catalog and datasheet values all account for ISO conditions, which include 15 °C temperature, sea-level atmospheric pressure and 60% relative humidity (RH).

These factors are related to the intake-air specific volume. Since power output is proportional to air mass flow and this, in turn, is inversely proportional to temperature

and greater RH results in greater heat capacity of the working fluid, which lowers the combustion exit temperature for the same energy input, the effects of variations on these conditions becomes clear, as shown in Fig. 1:

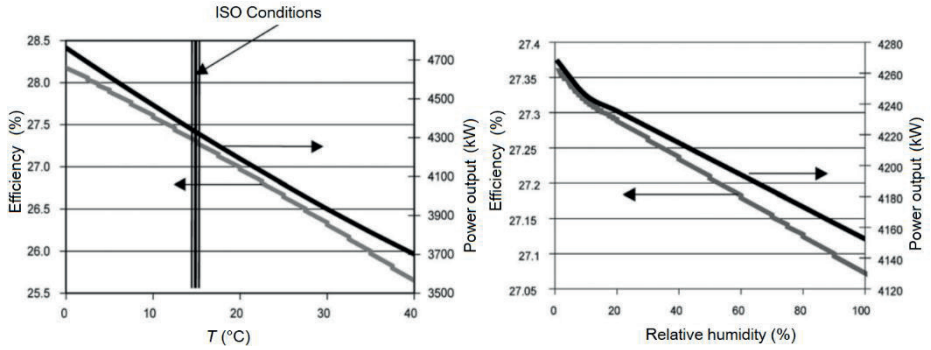

Fig. 1. Ambient conditions effects on Gas Turbines [1].

Although GT are low-efficiency machines, when compared to diesel engines or steam plants, the number of marine GT in operation around the world is on the rise, either on propulsive plants or onboard power generation. Therefore, the impact of their efficiency cannot be dismissed, because it is associated with fuel consumption in maneuvers, logistic and even strategic decisions, when the equipment life cycle is taken into account. Elevated operating costs can turn the use of GT prohibitive. Even a small increase in thermal efficiency will result in fuel economy, greater plant availability and should be taken into account not only in ships already in operation but also in the design and selection of future ships.

Ambient temperature is both the parameter which has a greater effect in a GT's efficiency and the most easily modifiable thermodynamic parameter in operating conditions, requiring only the installation of a compressor inlet air cooler, which is itself external to the GT's design.

In this study, the three main compressor inlet air cooling methods were reviewed and modeled, coupled with the Brazilian Navy's propulsion gas turbines in operation, in order to demonstrate their effects on power output and specific fuel consumption and verify their applicability in the paradigm of naval propulsion. The analysis was done through a computer simulation of the cooled GT with varying ambient temperatures.

2 Mathematical model and simulation parameters

2.1 Gas turbines and thermodynamic cycle

Gas turbine-powered vessels in the Brazilian Navy are the ones labeled as escort ships, which benefit the most from the high power and maneuverability provided by these equipments. Three types of turbines are presently in use among four classes of vessels:

• Rolls-Royce Marine Olympus TM3B: Niterói and Greenhalgh-class Frigates boost turbine;
• Rolls-Royce Marine Tyne RM1C: Greenhalgh-class Frigate cruise turbine; and
• General Electric LM2500: Inhaúma and Barroso-class Corvettes boost turbine.

The air-standard Brayton cycle is the model thermodynamic cycle in GT studies. It is thus called because assumes that the working fluid is a fixed mass of air, modeled as an ideal gas with constant specific heat, that undergoes four steady-state thermodynamic processes: adiabatic and internally reversible (isentropic) compression, isobaric heat addition, isentropic expansion at the turbine for work output and isobaric heat loss to the surroundings, thus going back to its initial state. The thermal efficiency is defined as the ratio of work output at the turbine shaft to energy input as heat. With the Brayton cycle assumptions, the effect of the intake-air temperature T_1 on the GT performance becomes evident (1):

$$\eta_{th} = \frac{W_{net}}{\dot{Q}_H} = 1 - \frac{T_1}{T_2} = 1 - \frac{1}{\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}} \tag{1}$$

k being the working fluid specific heat ratio c_p/c_v. Thermal efficiency is also dependent on the cycle's pressure ratio P_2/P_1.

A real cycle diverges from the Brayton model in the assumptions it makes about its processes. Compression and expansion are not modeled as isentropic, so the component isentropic efficiencies η_c (compressor) and η_t (turbine) must be taken into account. Modeling these processes as polytropic, their isentropic efficiencies become a function of the polytropic efficiency η_p as follows (2), (3) [2]:

$$\eta_c = \frac{(P_2/P_1)^{\frac{k-1}{k}} - 1}{(P_2/P_1)^{\frac{k-1}{\eta_{p,c} k}} - 1} \tag{2}$$

$$\eta_t = \frac{1 - (P_3/P_4)^{-\frac{\eta_{p,t}(k-1)}{k}}}{1 - (P_3/P_4)^{-\frac{k-1}{k}}} \tag{3}$$

Still using the ideal gas model for the working fluid, the temperature difference resulting from the compression/expansion processes can be found by (4) and (5):

$$\Delta T_c = T_2 - T_1 = \frac{T_1}{\eta_c}\left[(P_2/P_1)^{\frac{k-1}{k}} - 1\right] \tag{4}$$

$$\Delta T_t = T_4 - T_3 = \eta_t T_3 \left[(P_3/P_4)^{-\frac{k-1}{k}} - 1\right] \tag{5}$$

By knowing pressure and temperature before and after all processes, and therefore fully defining these thermodynamic states, the processes themselves can be modeled by the first law of thermodynamics (6), (7), (8):

$$\dot{W}_{\mathrm{C}} = \dot{m}(h_1 - h_2) \tag{6}$$

$$\dot{Q}_{\mathrm{H}} = (\dot{m} + \dot{m}_{\mathrm{f}})(h_3 - h_2) \tag{7}$$

$$\dot{W}_{\mathrm{T}} = (\dot{m} + \dot{m}_{\mathrm{f}})(h_3 - h_4) \tag{8}$$

$\dot{m}$ being the air mass flow and $\dot{m}_{\mathrm{f}}$ the mass of burnt fuel, calculated iteratively from the fuel's Lower Heating Value (LHV) and the needed energy input rate (9):

$$\dot{m}_{\mathrm{f}} = \dot{Q}_{\mathrm{H}}/LHV \tag{9}$$

The studied GT parameters are the ones from Table 1. The compressors' polytropic efficiency was taken to be 0,9 as a starting value for calculating the isentropic efficiencies, using an iterative procedure that forced the calculated quantities to converge to the GT known datasheet parameters at ISO conditions. For fuel mass flow calculations, it was used diesel oil with a LHV of 42259,41 kJ/kg.

Table 1. ISO-condition data for the studied GT [3 - 5].

	LM2500	OLYMPUS TM3B	TYNE RM1C
P_2/P_1	18,00	10,37	12,00
T_3	-	946,8 °C	1006,8 °C
T_4	566,0 °C	-	-
$\dot{m}_{\mathrm{air}}$	70,5 kg/s	103,42 kg/s	19,05 kg/s
$\dot{W}_{\mathrm{net}}$	25,06 MW	20,88 MW	4,00 MW
η	0,3709	0,2800	0,2690

Intake-air was modeled as humid air with a mass flow rate proportional to the ISO flow rate (10) and the combustion gases were modeled as a mixture of nitrogen (75,738%), oxygen (14,141%), carbon dioxide (4,128%), argon (0,902%) and water vapor (5,091%) with the typical molar ratios for a diesel GT [6]. Except for water vapor, which followed its proper thermodynamic tables, other components were modeled as ideal gases. Specific heat values used for air and combustion gases were, respectively, 1,399 (for ISO conditions) and 1,328 (for the average combustion temperature and pressure of the three studied GT).

$$\dot{m}_{\mathrm{air}} = \frac{\rho_1}{\rho_{\mathrm{iso}}} \dot{m}_{\mathrm{air,ISO}} \tag{10}$$

2.2 Cooling methods

Evaporative cooling. This is a constant wet-bulb process that takes advantage of the latent heat of vaporization to cool an air stream. This method is used on many dry-climate power plants for inlet air cooling because it can do so with a relatively low

energy cost [7]. Air temperature after the inlet cooler and the heat removal rate can be calculated as follows (11), (12):

$$T_1 = T_0 - E\left(T_0 - T_{0,\text{wet-bulb}}\right) \tag{11}$$

$$\dot{Q}_{\text{EC}} = \dot{m}_{\text{air}}(\omega_1 - \omega_0)\left(h_{\text{H2O},0} - h_{\text{H2O,wet-bulb,saturation}}\right) \tag{12}$$

The model considered an evaporative panel with constant effectivity E of 0,85 and a feedwater pump with a 15 m head, this pump's power being the only energy input in this system.

Vapor compression chilling. This is the most widely used method for producing cold. It consists of a compressor-driven plant that takes electric power to drive a refrigerant that undergoes a phase transition to absorb heat. The heat removal rate (cooling load) can be calculated as follows and, coupled with the refrigeration plant's coefficient of performance, can be used to calculate the compressor power consumption (13), (14):

$$\dot{Q}_{\text{VC}} = \dot{m}_{\text{air}}(h_0 - h_1) - \dot{m}_{\text{air}}(\omega_0 - \omega_1)h_{\text{H2O}} \tag{13}$$

$$\dot{W}_{\text{el. comp}} = \dot{Q}_{\text{VC}}/COP \tag{14}$$

The model was based on the air conditioning plant installed on Amazon-class Ocean Patrol Ships, vessels with dimensions and displacement comparable to corvettes, the parameters of which are found in Table 2. Besides the power consumed by the compressor, it was also taken into account a condensate pump, with a pressure differential of 60 kPa, and a cold-water pump with a pressure drop of 70 kPa.

Table 2. Main parameters of Amazonas-class ship refrigeration plants [8].

Condenser heat rejection (nominal):	266,0 kW	Cold water temperature:	6,5 °C
Evaporator heat absorption (nominal):	216,0 kW	Cold water return temperature:	12,5 °C
COP:	4,32	Cold water pressure:	600 kPa

Absorption chilling. Absorption cycles allow for the production of cold water from a heat source by means of a thermochemical absorption of a refrigerant by a secondary substance, called absorbent, forming a liquid solution that is then pumped to a higher pressure. Since the working fluid is an incompressible liquid, the power consumption in this process is significatively lower than for a vapor compression process. Cooling load is calculated analogously to the vapor compression cycle (15):

$$\dot{Q}_{\text{AC}} = \dot{m}_{\text{air}}(h_0 - h_1) - \dot{m}_{\text{air}}(\omega_0 - \omega_1)h_{\text{H2O}} \tag{15}$$

The model considered the installation of a Carrier Corporation 16LJ-A series industrial absorption chiller driven by hot water heated by the GT combustion gases. The refrigerators in this series vary in cooling capacity, but all operate under the same parameters, which can be found in Table 3. The refrigerator's internal pumps consume an average of 9,7 kW. The hot water pump was considered to work on a pressure drop of

30 kPa, while the cold water and condensate pump used the same parameters as the vapor compression cycle ones.

Table 3. Main parameters of 16LJ-A series absorption chillers [9].

COP:	0,78	Cold water pressure:	1 MPa
Cold water temperature:	7,0 °C	Hot water temperature:	80,0 °C
Cold water return temperature:	12,0 °C	Hot water return temperature:	90,0 °C

2.3 Heat exchanger

The chilling systems would need to employ a coil to circulate the cold water inside the compressor inlet duct to cool the intake-air. A cross-flow heat exchanger like this can have its performance estimated by the effectivity method (16) [10]:

$$\varepsilon_{\text{coil}} = \dot{Q}/\text{MIN}(\dot{m}_{\text{i}}\Delta h_{\text{max}}) \tag{16}$$

where Δh_{max} is the enthalpy difference between both fluids (air and water) initial temperature, evaluated for whichever fluid i outputs the lowest value (MIN function), because it's the fluid with the lowest heat capacity that will be able to undergo the maximum temperature variation at the heat exchanger. From a design condition, it is possible to calculate the effectivity of the heat exchanger and, with this, the real heat exchange rate outside the design point. The heat exchange rate can be used to ascertain the enthalpy (and, assuming a constant pressure process, the entire thermodynamic state) of the air after the heat exchanger, through an iterative convergence procedure (17):

$$h_1 = \frac{\dot{m}_{\text{air}}h_0 - \varepsilon_{\text{coil}}Q\text{MIN}(\dot{m}_{\text{i}}\Delta h_{\text{max}}) - \dot{m}_{\text{cond}}h_{\text{H2O}}}{\dot{m}_{\text{air}}} \tag{17}$$

2.4 Pumps

The power consumption for hydraulic pumps is comparatively low since it's proportional to the fluid's specific volume v, which is low for liquids. The pressure difference ΔP in water circulation systems will be simply the system's pressure drop. All pumps were considered to be powered by electric engines and to have a global efficiency η_{p} (considering electric, mechanical and hydraulic losses) with a value of 0,75. Considering the water to be an incompressible fluid, the consumed power for each pump will be (18):

$$\dot{W}_{\text{el, pump}} = \dot{m}v\Delta P/\eta_{\text{p}} \tag{18}$$

2.5 Ambient conditions and design point

For Rio de Janeiro's littoral, the Brazilian Navy's main area of operations, the average maximum temperature is 30,2 °C for the hottest months [11]. To guarantee an improved performance for conditions even above the average maximum, let us define the

refrigeration systems' design point as the capacity to bring the intake air's temperature to 15 °C down from 35 °C. Rio de Janeiro's relative humidity changes little around the year, so the yearly average of 79,1% was used for the simulation.

2.6 Power generation and global efficiency

The power onboard ships are provided by diesel-generators that are, in general, more efficient than the propulsion GT. The simulation considered a naval generator set with global efficiency η_{el} of 0,412. Taking into account that the fuel used for the generator is the same kind used for the GT, the fuel consumption for the powering of the electric equipments used for the chilling systems will be (19):

$$\dot{m}_{\text{f,el}} = \dot{W}_{\text{el}}/(\eta_{\text{el}} LHV) \tag{19}$$

The total fuel consumption, therefore, is the sum of the GT's consumption and the generator's consumption. With this, it is possible to calculate the global efficiency of the chilled GT and its specific fuel consumption (kg/kWh) (20), (21):

$$\eta_{\text{global}} = \frac{\dot{W}_{\text{net}}}{LHV(\dot{m}_{\text{f}}+\dot{m}_{\text{f,el}})} \tag{20}$$

$$SFC_{\text{global}} = \frac{3600(\dot{m}_{\text{f}}+\dot{m}_{\text{f,el}})}{\dot{W}_{\text{net}}} \tag{21}$$

3 The computational simulation

The metrics that were used for comparing the cooling methods were the raise in power output and efficiency compared to the non-cooled GT, fuel consumption and global efficiency. An algorithm for calculating these quantities, as well as the entire cooled GT thermodynamic cycle, was programed into the Engineering Equation Solver (EES). EES is a well-known software and programming environment for the simultaneous solution of systems of nonlinear equations, which is useful for thermodynamic and heat transfer problems because it has, natively, thermodynamic tables for a variety of substances and functions to call the desired properties, making it the obvious choice for this application, but the algorithm could easily be converted to any other programming language (e.g. MATLAB), provided the necessary thermodynamic tables are loaded.

The method used was to divide the simulation in three blocks or procedures: one for calculating the GT component efficiencies and cycle temperatures from the ISO data, one for loading and calculating a chosen cooling method and, finally, one for calculating the cycle for the GT with integrated cooling for a variety of ambient temperatures.

The algorithm, shown in flowchart form in Fig. 2, used the mathematical modeling and fixed parameters described in the preceding section. The numbers in parentheses in Fig. 2 refer to the equations used in the calculation. GT ISO data, combustion gases molar ratios and other known parameters are loaded at the beginning.

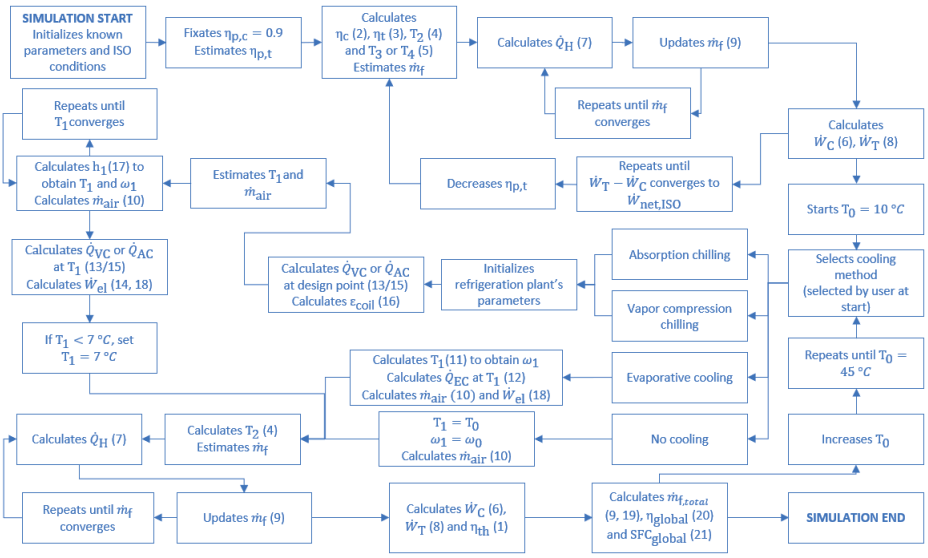

Fig. 2. Flowchart describing the simulation algorithm, with reference to the equations used.

4 Results

The heat rates of each method were calculated proportional to the airflow of each GT, to produce comparable results. The only difference in implementation for each GT would be the needed cooling load for each.

Evaporative cooling had very little effect on reducing the intake-air temperature because of the high ambient relative humidity. This is the main factor that limits its effectiveness in humid climates. The two chilling systems, on the other hand, produced equivalent cooling effects on the intake-air. The effect of this temperature drop is the rise in power output by the GT, as shown in Fig. 3 (percent nominal power).

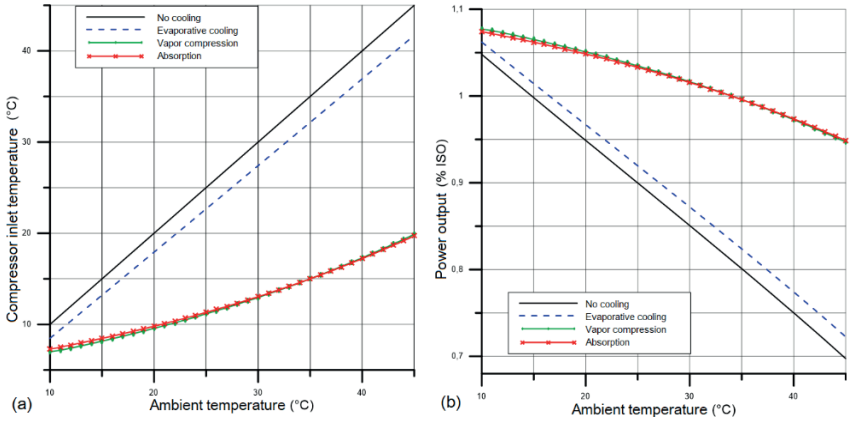

Fig. 3. Temperature drop produced by cooling methods (a) and relation to power output (b).

When considering the effect of cooling only on the GT, the efficiency curves follow the same pattern of the compressor inlet temperature curves. For global efficiency, when the entire system is considered with its energy requirements, the vapor compression and absorption curves separate drastically. As the absorption system works with fluids only in their liquid phase, the power it consumes is greatly lower than an analogous vapor compression system. Fig. 4 illustrates this result for the LM2500 GT.

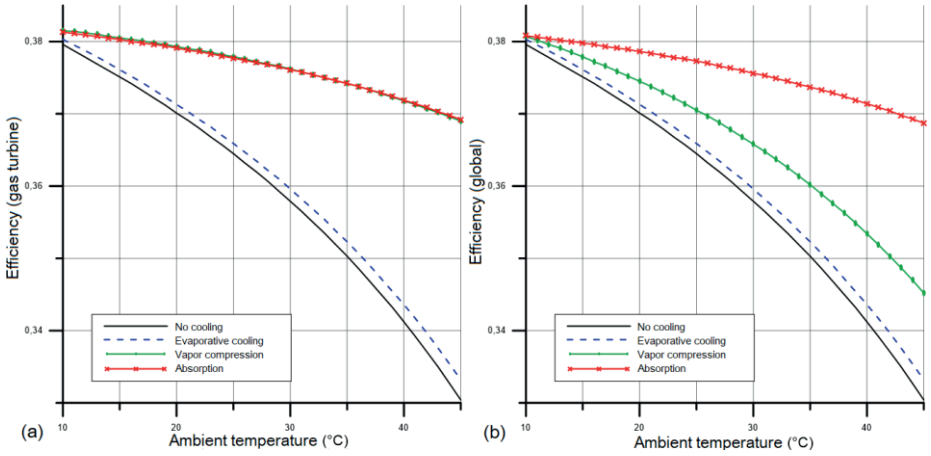

Fig. 4. GT (a) and global (b) thermal efficiency for the LM2500.

Ultimately, any deviation in the plant's efficiency will affect global fuel consumption (GT + generator). For a propulsive plant, its power output and fuel consumption are the metrics with the greatest operational relevance. Since SFC is specific per unit energy (kg/kWh), instant fuel consumption will depend on the power output in certain conditions. Fig. 5 shows both these values of consumption for the LM2500.

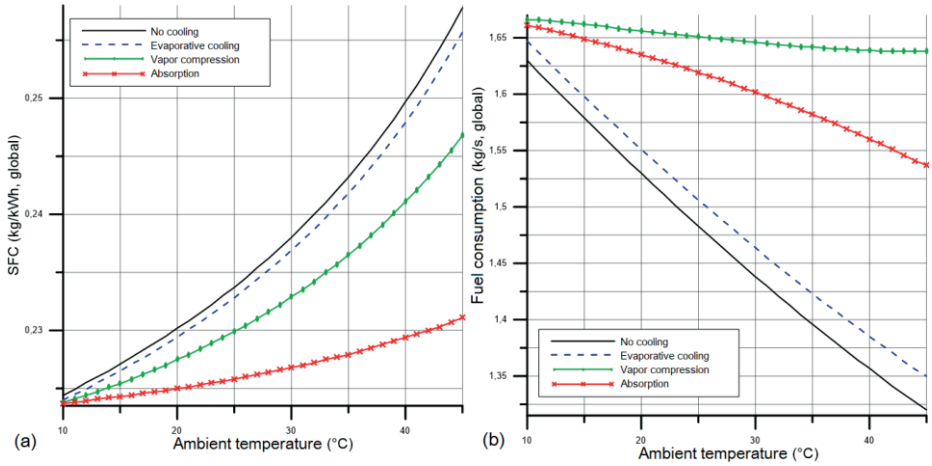

Fig. 5. Specific (a) and instant (b) chilled propulsive plant fuel consumption, for the LM2500.

Both chilling systems selected, by way of working under similar parameters for water temperature, produced equivalent gains in power output. The difference between them becomes evident when looking at their global efficiency. Despite both reaching the desired objective, the absorption system will have a lower operation cost. In a lifecycle analysis of any compressor inlet air cooling like these, in addition to the installation and maintenance costs, this is a factor that should certainly be considered.

Another important factor in military vessels is the available space for the installation of such a plant. Its dimensions will be dependent on its cooling capacity, which will be designed for a certain condition (design point). Carrier Corporation's catalogue, from which the absorption chillers parameter were taken, lists the largest in the series with a volume of 90 m³ and a nominal cooling capacity of 3956 kW, still 600 kW short of what would be needed for the LM2500 at the chosen design point.

Intake-air cooling for a GT is a much more demanding process than air conditioning, for the air mass that needs to be cooled is in constant renewal. The high demand for cooling capacity is expected and of the same order of magnitude found in literature, when the results are adjusted for the fact that the literature usually considers relative humidity of 60%. In fact, relative humidity may be the factor that affects the most the cooling load needed, owing to the condensing water latent heat. Fig. 6 shows the cooling capacity needed for a relative humidity of 79,1% (study conditions) and 60% (ISO conditions). Despite managing to produce the desired temperature drop irrespective of ambient conditions, the chilling systems are nevertheless affected by them.

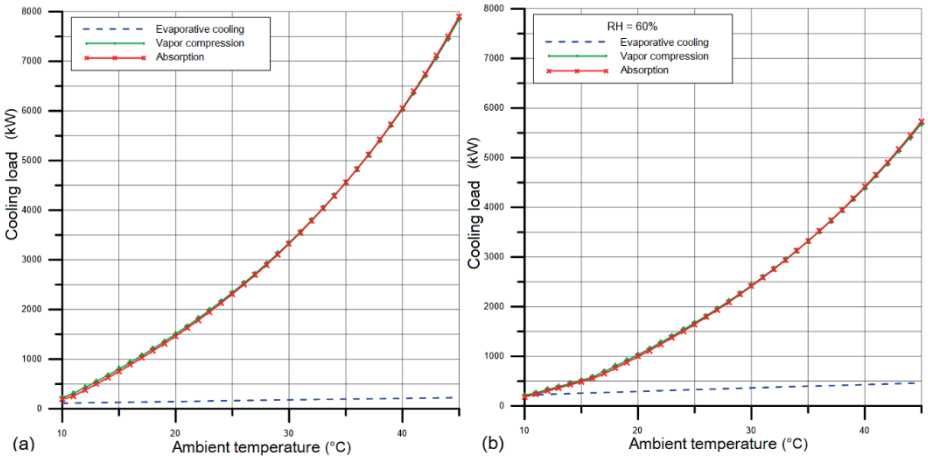

Fig. 6. Cooling load for study conditions (a) and ISO conditions (b).

The following tables summarize the results found for each of the three GT at the design point. For the evaporative cooling, even though the idea of a design point does not apply, the results shown are for T_0 = 35 °C. The values in parentheses are the percent variation over the non-cooled GT, if applicable.

$\dot{m}_{\text{f, total}}$ [kg/s]	0,3125 (1,99%)	0,3648 (19,06%)	0,3491 (13,94%)

5 Conclusion

The results were consistent with the ones found in specialized literature, adjusted for the considered ambient conditions. The effect of these ambient conditions was demonstrated not only over the GT performance, but also the compressor inlet air cooling methods.

The gains brought by the evaporative cooling system were so insignificant that may not justify the installation of a system like this in a humid climate, even when considered its low cost. The chilling systems, on the other hand, are limited by the refrigeration capacity that can be installed aboard a military vessel, the choice of a more forgiving and adequate to the local ambient conditions would lessen this demand and still benefit the plant with some power output and efficiency increase. The ideal equilibrium

point of acceptable cooling load and desired gains would depend, besides the thermodynamic analysis, also on operational considerations and operative life cycle of the vessel in which such a system would be installed. The advantages that greater power output and, therefore, greater speed and maneuverability that chilling systems would grant the ship may override the costs of installation and operation, especially with regards to boost turbines used for maneuvers, which are not used continuously. The greatest considerations for employing chilling systems in this manner, therefore, would be the operational profile of the GT (as they do not necessarily operate continuously at full-load) and the available space for the installation of such a plant. Both these factors are of low relevance for the usage most commonly found in the literature (i.e. thermoelectric power plants).

Lastly, a reliable and precise model for simulating steady-state, full-load gas turbines, coupled with a cooling system or not, was developed and successfully applied. The algorithm presented in this paper could be used for an initial calculation in the design or selection of a cooling system for gas turbines not only in the studied scenario, but also others where GT are used, such as power generation.

Abstract. This paper aims to analyze a way to decrease the temperature of exhaust gases in the discharge ducts of the Inhaúma class corvettes of the Brazilian Navy. A study was carried out of the cooling, intake and exhaust systems of the engine gases used in these ships and it was possible to determine, from the temperature and flow, the energy contained in these rejected gases. In the present article, the suggestion to lower this temperature and, thus, reduce the possibility of detection of the ship by cameras or weapons that work with infrared sensors is the reuse of this energy through the implementation of a cogeneration plant. The main focus of this plant is to harness this energy available to heat water and this is used as the hot fluid in a steam generator in a selected absorption cooling cycle from available commercial catalogs, which would have the ability to meet 25% of the ship's environmental conditioning thermal load. It was emphasized on the thermal design and sizing of the heat recuperator, as this has the essential function of transferring the initially lost energy to another heat supply process.

Keywords: Cogeneration energy, Heat transfer, Heat recovery, Exhaust gases.

1 Introduction

The combustion gases with high temperatures are used in several areas both in the industrial and tertiary sectors in systems called energy cogeneration. Cogeneration "is the combined production of work and thermal energy from the sequential use of energy from a fuel", according to the definition of the Public Utilities and Regulatory Policies Act – PURPA [1]. The more efficient use of the same primary energy source reduces the temperature of discharge gases and fuel consumption and, consequently, the cost of operation when compared to systems that produce electrical and thermal energy independently. Cogeneration systems have high global energy efficiency, usually above 70%, and lower emission of environmentally harmful substances.

The themes of energy conversion with energy recovery will have a high potential for development for naval applications. The containment of pollutant emissions can be achieved by a cycle with thermal energy cogeneration to feed the ship utilities, in place of the diesel engines currently used [2].

For some years, a few ships have been using cogeneration, however, there are several possible configurations to meet thermal, electrical and mechanical needs, making it necessary to choose the most appropriate one according to the following terms: energy use decreased temperature of exhaust gases, available space and lower emission of substances harmful to the environment.

In Brazil, the use of stealth vessels could contribute to better control of the exploitation of wealth, such as oil and fish present in the huge national maritime areas, in addition to the monitoring of maritime borders, which are fundamental for the maintenance of national sovereignty [3].

In the work, an analysis of the gases from the discharge ducts of a ship with a propulsion system similar to those used in the Inhaúma class corvettes (CCI) of the Brazilian Navy will be carried out, which present two diesel engines MTU 16V956 TB91 and a GE LM 2500 turbine. However, the use of only engines will be considered in the case under study, given that the use of the turbine is reduced and limited to situations where a large increase in power is required. However, the temperature of the discharge gases of the internal combustion engines strengthens the thermal signature and thus decreases the stealth characteristic of the vessels, as they facilitate their detection by infrared capture cameras. Also, the high temperature of these gases means fuel waste that is not renewable and has high costs.

The objective of this work is to obtain data regarding the temperature and flow of exhaust gases through the study of engines and their parameters used in the corvettes of the Brazilian Navy and, thus, to carry out a project of reuse of this energy initially discharged into the atmosphere with a high cost to supply about 25% of the total thermal load of the ship through an absorption cooling cycle.

The methodology of the work was made through an analysis of the engine design parameters. The flow of the discharge gases of the equipment was calculated by obtaining data from the operation manual and the temperature of this is data obtained directly, considering the standard working point of the engines. Through these data, it was possible to design a heat exchanger introduced at the output of the combustion gases to recover this energy and use it in a selected absorption cycle through a company catalog.

The energy recovery was designed through a cross-current core of the equipment [4]. The sizing was stipulated so that the temperature of the gases would reduce to approximately 200 °C through iterations from the area of this equipment.

2 Energy cogeneration

Cogeneration is becoming increasingly popular in energy systems with demands on electricity and heat, which is suitable for industrial use in remote areas [5]. Energy cogeneration consists of the use of the calorific value released by the fuel for the simultaneous production of mechanical, thermal or electrical energy, through the recovery

of residual heat. This increases the overall efficiency of the system. In the case of warships, with the growing search for thermal camouflage, cogeneration can also be pointed out as an effective method to reduce the temperature level of exhaust gases, making it difficult to detect by the enemy.

For the best use of residual energy, an analysis based on the second law of thermodynamics in the form of exercise balance is necessary, which may indicate away with fewer losses. The exercise balance can be used to determine the location, type and magnitude of exercise losses, and can also give us an important role in the development of strategies and provide more effective lines of action in the use of energy in existing power plants [6].

However, this work is limited to the analysis of the energies involved in the cogeneration plant by taking control volumes over the system assemblies. Thus, in this project, the concept of energy cogeneration initially presupposes the combination of three types of equipment: diesel engines already existing on the ship for the production of mechanical power responsible for propulsion, an absorption cooling system for the production of cold water and one heat recovery that enables thermal exchange between the two equipments mentioned above.

2.1 Available residual energy

The corvette propulsion system has as main components two engines and one turbine. These two equipments do not work at the same time, the combined diesel engine system (MTU 16V956 TB91) of 3,900hp is used for cruise speeds, while the gas turbine (GE LM-2500) of 27,000hp to meet high-speed demands. This type of propulsion is known as CODOG (Combined Diesel or Gas Turbine) and is quite common in warships.

CODOG propulsion allows a continuous maximum speed of 27 knots (turbine) and a maximum cruising speed of 18 knots (diesel engines). The range is about 4,000 nautical miles at 15 knots [7]. For this, the propulsion using the turbine will not be analyzed due to its low frequency of use.

The exhaust gas temperature obtained through the MTU Company Operating Manual is 550 °C for the maximum power condition (2680 kW to 1490 rot/min), but the parameters used will be in continuous power condition (2570 kW to 1470 rot/min).

In the condition of continuous power, the temperature of the residual gases is 500 °C. Another information needed to obtain the available residual energy is the flow of these gases and this data is not provided directly from the operation manual, but can be obtained by a simple calculation, since the total displacement, rotation and characteristics of the engines are known (Table 1).

Table 1. Parameters and characteristic of the engine in continuous power regime [8].

Total displacement (Cr)	152.9 liters
Rotation	1470 rot/min
Power	2570 kW
Engine type	4 times

Multiplying the total displacement by the engine speed and dividing by 2 (two), since the engine is four strokes, we determine the volumetric flow:

$$\dot{v} = \frac{C_T}{2} \tag{1}$$

Where $\dot{v} = 1{,}873\ m^3/s$.

Considering that gases leave the engine at atmospheric pressure (100 kPa), the other properties of the working fluid can be determined: Enthalpy $(h) = 793{,}1\ kJ/kg$ and Specific volume $(v) = 2{,}2\ m^3/kg$. With these properties it is possible to know the values of mass flow and energy rate of discharge gases (2), (3):

$$\dot{m} = \frac{\dot{v}}{v} = 0{,}85\ kg/s \tag{2}$$

$$\dot{Q} = \dot{m}\ h = 675{,}22\ kW \tag{3}$$

Therefore, one is aware of the rate of thermal energy available in the exhaust of an engine. As the ship understudy has two engines, the total thermal energy rate in engine exhaust is equivalent to 1350.45 kW.

2.2 Absorption cooling system

The inclusion of the absorption cooling cycle can be a viable form of energy cogeneration application, as this system uses a heat source to dissociate the refrigerant from the water inside a generator and, at the end of the cycle, a fluid can be cooled and used for environmental conditioning of the ship. This type of energy use has proved effective in other types of applications such as in the industrial and pharmaceutical sectors. For the application of this concept in this work, the residual heat from the discharge gases will become the hot source of the absorption equipment as shown in Fig. 1:

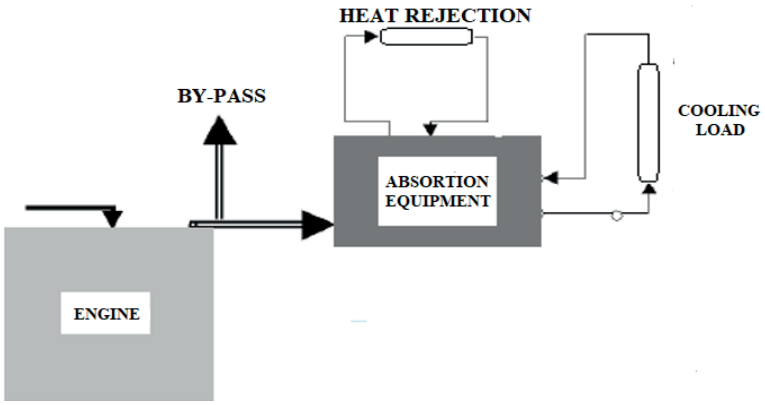

Fig. 1. Energy cogeneration scheme.

In the CCI modernization project, three URA equipments model YEWS415HA50E of Johnson Controls, with a capacity C_T of 411 tons of refrigeration (1,445.4 kW) were

installed. These URAs can operate with partial loads of 25%, 50%, 75% and 100%, and only one of these equipments can meet the need for environmental conditioning of the entire ship.

In the routine of the ship, it is observed that in a considerable period only one cooling unit is used, and with a partial load of 25 %. Due to this fact, it is plausible to select an absorption water cooling equipment with this capacity. The cooling capacity of the absorption chiller $C_t = 25\%\ C_T$; and $C_t = 380.5\ Kw$.

Through the cooling capacity, it is possible to select the cooler from catalogs of companies already established in the market. In this work, the company chiller Carrier model 16 LJA-13 was selected, whose characteristics and parameters are shown in the following table:

Table 2. Parameters of the Carrier absorption chiller model 16 LJA-13.

Equipment model	Carrier 16 LJA-13
Cooling capacity	387 kW
Ice water system	-
Mass flow	18.5 kg/s
Inlet temperature T_1	12°C
Output temperature T_2	7 °C
Hot water system	-
Mass flow	12.3 kg/s
Inlet temperature T_3	90 °C
Output temperature T_4	80 °C
Performance coefficient	0.78
Mass of equipment in operation	5200 kg (1,000 lb)

Through the catalog of the equipment already selected, some important parameters can be obtained for the sizing of the cogeneration plant, such as the required flow of hot and cold water and their respective temperatures at the inlet and outlet of the machine, and, knowing the specific heat of the water, the rate of thermal energy transferred in the generator and evaporator of the Chiller, in addition to the performance coefficient of the absorption cycle (4), (5) and (6).

$$\text{Evaporator: } \dot{Q} = \dot{m}\ c\ (T_1 - T_2) = 386{,}6\ KW \tag{4}$$

$$\text{Generator: } \dot{m} = \frac{\dot{v}}{v} = 0{,}85\ \ kg/s \tag{5}$$

$$\text{Performance coefficient (COP): } COP = \frac{\dot{Q}_{Evaporador}}{\dot{Q}_{Gerador}} = 0.75 \tag{6}$$

It appears that the calculated COP is close to that indicated by the manual. This difference is due to approximations in the value of the specific heat of the water. Other important data can also be obtained from the catalog, such as the weight of the machine, as it changes the stability of the ship and the dimensions that are critical aspects in confined environments such as ships. However, this work is limited to analyzing the energy viability of the cogeneration cycle in this system.

2.3 Heat exchanger

The design of this equipment involves many aspects. In this work, the dimensioning, heat transfer and performance evaluation will be evaluated, but the load losses and the costs of the exchanger will not be analyzed. To calculate the heat exchange area and thus select the exchanger it is necessary to know the inlet and outlet temperatures and the flow rates of the fluids.

The sizing problem refers to certain dimensions of the pipe beam to achieve the requirements of heat transfer and load loss. If we do not consider the load loss, the thermal calculation involves the determination of the total heat transfer rate to a given heat exchanger; and sizing involves determining the total heat transfer surface required to achieve the specified heat transfer rate [9].

The flow and temperature of the inlet combustion gases, as well as the flow rate and water inlet and outlet temperatures, were obtained according to (1), (2), (3) and (4).

Analyzing the data so far, it is observed that the temperature of gases after the exchanger has not yet been established. For thermal camouflage, the smaller this property, the better it would be, but exhaust gases with temperatures lower than one hundred and eighty degrees would generate other types of problems related to the environment and corrosion. Thus, initially, we can stipulate that the ideal output temperature of these components is close to two hundred degrees Celsius (Fig. 2).

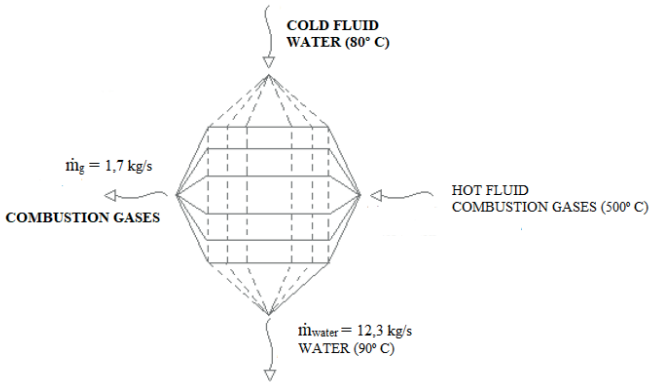

Fig.2. Heat exchanger with the indicated design parameters.

Through case studies, a compact cross current exchanger (area density greater than 700 m^{-1}) will be selected for the project due to its small size and weight. Commercially there are several configurations of heat transfer core, however, due to difficulties inherent to obtaining parameters and characteristics of commercial exchangers, in this work, an experimental exchanger studied [4] was used.

To start the calculation, we need the physical properties of the working fluids. As atmospheric air consists of approximately 79% nitrogen and ideally this element does not react in the combustion process, the properties of gases can be approximated with those of air at average temperature, but the output temperature of the gases is not known. So, we can initially estimate the temperature of the gaseous fluid at the output of the exchanger at two hundred degrees Celsius and thus the average temperature calculated would be three hundred and fifty degrees Celsius. This initial estimate can be corrected if necessary, at the end of the calculations. As the temperature of the inlet and outlet water in the exchanger is fixed, the properties were also taken in relation to the average temperature.

To calculate the coefficient of global heat transfer concerning the outside of the pipes it is necessary to know the coefficients of internal and external heat transfer and the efficiency of the fin (7).

$$\frac{1}{U_a} = \frac{1}{\dot{\eta} h_a} + \frac{1}{\left(\frac{A_w}{A_a}\right) h_w} \tag{7}$$

Where:

U_a is the global heat transfer coefficient;

$\dot{\eta}$ is the efficiency of the fin weighted by the area;

h_a is the external heat transfer coefficient; and

h_w is the internal heat transfer coefficient.

From experimental data obtained and with the value of the Reynolds number, it is possible to estimate the heat transfer coefficient [4] (8), (9).

$$Re_a = \frac{G_a D_{h\,a}}{\mu_a} \approx 2680 \tag{8}$$

$$G_a(Mass\ velocity) = \frac{m_a}{\sigma_a A_{fr}} = 24{,}25 \tag{9}$$

To determine the relationship between the Reynolds number and the heat transfer coefficient, we used the experimental data of the exchanger.

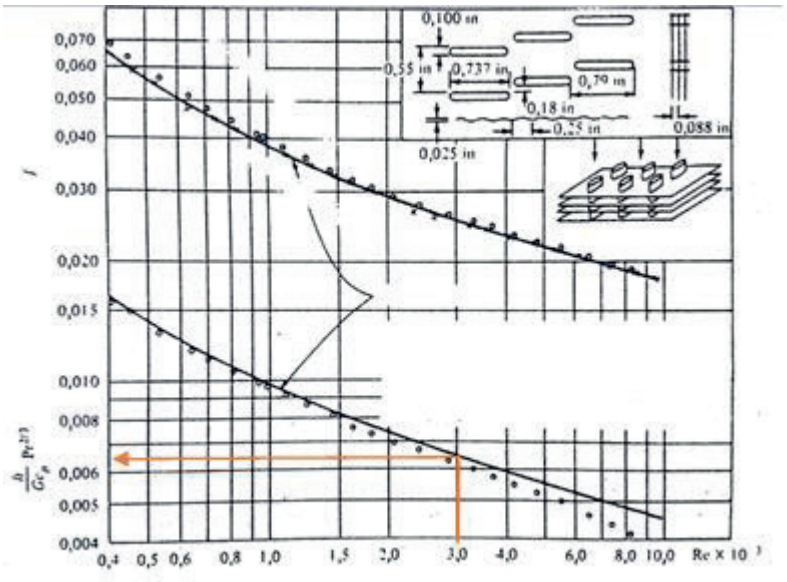

Fig.3. Heat transfer and friction factor in the flow through the heat exchanger [4].

$$\frac{h_a}{G_a c_{pa}} P_r^{\,2/3} = 0{,}0065 \tag{10}$$

Where the Internal heat transfer coefficient $h_a = 216{,}4 \frac{W}{m^{2\circ}C}$.

$$Re_w = \frac{u_{max} D_{h,w}}{v_w} = 19610 \tag{11}$$

$$u_{max}(mass\ velocity) = \frac{m_w}{\rho_w A_{fr} \sigma_w} = 1.82\ m/s \tag{12}$$

With this high value of Reynolds number, one can consider the fluid completely developed and thus use the equation, with correction due to changes in properties, to determine the relationship between the Reynolds number and the heat transfer coefficient [10] (13).

$$h_w = 0{,}027 \frac{k}{D_h} Re^{0{,}8} Pr^{\frac{1}{3}} \left(\frac{\mu_{85^\circ C}}{\mu_{90^\circ C}}\right)^{0{,}14} = 17025 \frac{W}{m^{2\circ}C} \tag{13}$$

Where:

Water viscosity (85°C) $(\mu_{85^\circ C})$: $0{,}000336 \frac{kg}{ms}$;

Water viscosity (90°C)$(\mu_{90^\circ C})$: $0{,}000318 \frac{kg}{ms}$

Therefore, in the external flow, there are flat fins and the effective difference between the temperature of the fluid and that of the fin surface is less than the difference between the fluid and the base of the fin (14), (15).

$$\eta(Fin\ thermal\ efficiency\ ) = \frac{t\ g\ h(mL_e)}{m\ L_e} = 0{,}79 \tag{14}$$

$$m = \sqrt{\frac{2h_a}{k\ t}} = 159{,}56 \tag{15}$$

With the efficiency of the fin and the ratio between the fin areas and the total area, we can calculate the efficiency of the fin weighted by the area (16).

$$\eta = \beta\eta + 1` - \beta = 0{,}82 \tag{16}$$

Once these three process parameters are known, one can then determine the overall heat transfer coefficient through (7).

After obtaining this coefficient, the flow rates and temperatures of inlet and outlet of fluids, it is possible to determine through an iterative method the value of the logarithmic average temperature difference (DTML) that satisfies the heat requirement transferred in the heat exchanger to be equal to the heat dragged by the fluid expressed by (17):

$$Q = f\ A\ U_a\ \Delta T_{ln} \tag{17}$$

Where:
f is the correction factor;
A is the heat exchanger external area.
$\Delta T_{ln} = DTML$.

Therefore, the other three parameters can be analyzed through (17).

I) Correction factor

The temperature of gas inlets is considerably higher than the water outlet temperature. Taking this into account analysis cross current heat exchangers of a pass, it is concluded that the correction factor can be considered equal to the unit [11].

II) The external area of the heat exchanger

It is a parameter that is determined iteratively along with the total heat transfer rate and the DTML. With the number of rows, the number of tubes per row and quantity of plates, the length, width and height of the equipment, and knowing the relationship between area and total volume, the iteration can take place through the distribution of rows in the exchanger.

III) Logarithmic mean temperature difference (DTML)

By an initial estimate of two hundred degrees Celsius for the gas output temperature, an initial DTML value can be determined, as shown below. With this initial value, it is possible to perform the iterative process until the values of external area, total heat transfer rate and DTML converge.

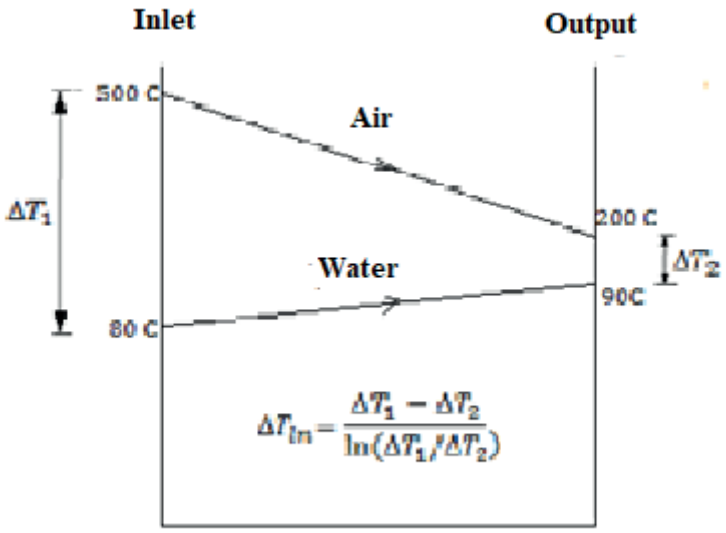

Fig. 4. Method for calculating THE DTML.

The iterative process was carried out following the following steps:

1- Estimate the gas output temperature (200 °C).

2- Calculate DTML.

3- Estimate the characteristics of the equipment (number of rows, number of tubes per row and height) and thus determine the total exchange area.

4- Determine the total heat transfer rate.

5- Determine the output temperature of the gases and compare them with the estimated in step 1.

6- If they are not close, redo the calculations at this calculated temperature.

The above steps were performed until convergence occurred. The obtained values are shown in table 3:

Table 3. Features of the designed heat exchanger and process parameters.

Heat exchanger and process feature	
Number of rows	15
Number of tubes per row	30
Number of plates (fins)	80
Heat exchanger core width	30 cm (12 in)
Length of heat exchanger kernel	30 cm (12 in)
Heat exchanger core height	17.6 cm (17.6 cm)
Total external heat exchange area	14.03 m2

Volume	0.0158 m3
Heat transfer rate	521.5 kW
DTML	224.9 °C
Heated water outlet temperature	90.1 °C
Output temperature of discharge gases	212.0 °C

The small dimensions of the equipment are due to the fact that an experimental exchanger model was used and possibly not feasible to manufacture for commercial purposes. It is also noted that the temperature is relatively close to that initially stipulated, so changes in fluid properties can be disregarded.

3 Conclusion

The study carried out in this work proposed the reduction of the temperature of exhaust gases through the implementation of an energy cogeneration plant, in which the heat contained in these gases is reused through a heat exchanger in a steam generator in an absorption cooling cycle.

As for the equipment, we studied the system and air intake and discharge of gases from internal combustion engines and through this study, it was possible to select the refrigeration equipment and then design the heat recovery that provides the thermal exchange between the gases and the water.

This proposal presented viability regarding the initial objective of reducing the temperature of gases, as well as increasing the overall efficiency of the system, as this change will be responsible for meeting 25% of the thermal load of environmental conditioning of the ship through an energy that is being wasted when being released directly into the atmosphere.

The implementation of the cogeneration plant, through this increase in efficiency, in addition to reducing the cost of operation, also reduces the consumption of non-renewable fuels making the ship more viable when considering environmental aspects.

As a suggestion for upcoming work, in addition to reducing the limitations of the previous chapter, one can also calculate the energy stored and discarded in the engine cooling and lubrication systems and reuse it in a new water heating plant used by the ship's crew.

Abstract. Organizations of all sizes and complexities are increasingly facing a challenging environment. Competition is increasingly fierce and market dynamism requires agility in emerging issues to adapt and survive. Understanding and promoting process improvements is a necessity that has troubled managers and, these use methods and tools to support their work teams in the search to eliminate losses and waste. This article aims, from a theoretical and conceptual approach, to understand VSM, its application, main positive aspects, and problems, as well as to present concepts and premises of process mining. To study two process mapping tools that are Value Stream Mapping (VSM) and Process Mining PM showing a way to improve these approaches. Seek its foundations in a quick literature review, propose a method to apply the two tools empirically and in a case study provide the authors with evidence that indicates an incremental improvement in the mapping process.

Keywords: Process mining, Value stream mapping, Process improvement.

1 Introduction

Organizations of all sizes and complexities need continuous adaptation to changes in the global, economic, and market environments. This adaptation requires solutions that consider the organization in a systemic way, that is, its role, people, knowledge, information, processes, strategy and technology [1].

A widely used tool for seeking improvement in the process is the Value Stream Mapping (VSM), which consists of an analysis performed with a pen and paper to understand the process flows and that, at the end of the analysis, a future map can be drawn, considered ideal for the process. VSM, which has an easy language, makes it possible to evaluate both the production and information flow, allowing a real view of the process.[2]. Despite the many benefits of the tool, in complex and dynamic environments the level of difficulty in the application of VSM increases. For [3] and [4], for example, the problems of applying the tool in these environments appear mainly in the collection and updating of data, as complexity can lead to a high time for the

construction of the mapping and even so some information can be neglected. Also, continuous monitoring of flows through VSM in highly dynamic environments is often not feasible.

With the rapid evolution of technology and the constant search for innovation in organizations, new perspectives and combinations of actions are developed in search of increasing business actions and executions, among them we can mention the computerization and digitalization of equipment, activities, or processes. One of the aspects of evolution, which can be considered an increase in process improvement tools, such as VSM, is Process Mining. The idea of process mining is to discover, monitor and improve real processes (that is, unassumed processes) by extracting knowledge from the event logs available in current systems [5].

This article aims, from a theoretical and conceptual approach, to understand VSM, its application, main positive aspects, and problems, as well as to present concepts and premises of process mining. Then, process mining is proposed as an incremental approach to VSM. Based on the theoretical analysis, a practical case study was then carried out to evaluate the applicability of the obtained perceptions and the proposed method.

The structure of the article has a brief review of the literature regarding the value stream mapping and process mining in section 2. In section 3, the proposed method and the framework developed for the application of process mining are demonstrated. Section 4 shows the application of the method in a case study in the automotive industry. Finally, in section 5, discussions about the work developed are presented, followed by the conclusions in section 6 of the article.

2 Literature Review

The literature review aims to provide theoretical support about value flow mapping (VSM) and process mining (PM), raising its concepts, perspectives, application, assumptions, and vulnerabilities.

2.1 Value Stream Mapping

Value stream mapping is a paper and pen tool that helps you understand the flow of material and information as a product progresses through the value stream, helping to identify waste. For mapping, one must follow the production flow of a product, from the supplier to the customer, and carefully draw a visual representation of each process in the material and information flow. Then, a future map can be drawn of how the product should flow optimally, which will serve as the basis for an action plan. VSM concerning other techniques stands out for being able to demonstrate, in an easy language, the relationship between production and information flow both within the organization and within the supply chain. Also, the tool can provide important information such as stock levels and production time, helping to make decisions regarding production flows.[2].

From the studies by [6], it can be inferred that although it has numerous advantages, VSM has some limitations. First, it can be a big challenge when it comes to

a complex product or process. The level of difficulty in preparing the VSM can be high due to the high effort involved in data collection and the time spent in building the mapping of the current state. Also, the existing complexity and possible invisibilities of the process can prevent the collection of sufficient data by direct observation. Another factor is that VSM is a static method, based on paper and pen, so its precision level and dynamic capture capacity are limited. Thus, many companies fail to apply the value flow mapping continuously, as there are always changes in products and processes. However, to obtain improvement effects, continuous monitoring is necessary for several months.

To better understand the difficulties experienced with the use of VSM, the present work brings some important information taken from a set of articles where the VSM was applied, and from which it was possible to remove some problems identified when applying the tool. These works were found through a brief survey on the problems related to VSM and brought several characteristics that were grouped into 7 categories.

1. Non-integrated processes: lack of integration between processes makes it difficult to analyze the value flow.
2. Lack of standardization and stability: processes are not clear. Existence of more than one material flow in the same line.
3. Poor understanding of the Lean principles and VSM: there is no deep understanding of the basic concepts of the tools.
4. Difficulty in measuring in-process data: problems with layout, complexity of product and process, which end up making it difficult to measure data in-process.
5. Current flow map out of date: Process that changed over time without updating documents.
6. Very flexible production: constant change to meet market demand: production mix with small batches, and many products assembled on the same line.
7. Process performed intuitively: process flow depends on the tacit knowledge of the operator, deciding in real-time how the product enters the flow.

In addition to the problems reported in the categories presented, some authors still cite possible causes for the problems encountered when applying VSM as; the increase in the product portfolio offered by the companies, the difficulty in choosing one of the products to be evaluated by the VSM, and the lack of a holistic view of the managers, who are unable to see the importance of making their processes clear to the partners. Other factors pointed out are the lack of process stability, errors in data measurements, product/process complexity and their obsolescence [3][4][7].

Table 1. *List of problems cited by authors in the application of VSM.*

Problems	Authors
Non-integrated processes	[8]; [3]; [4]; [9]; [10]; [11]; [7] [7]
Lack of standardization and stability	[3]; [12]; [10]; [13]; [11]
Poor understanding of the Lean principles and VSM	[14]; [2]; [8]; [9]; [10]; [15] [13]; [16]; [17]; [18]; [7]
Difficulty in measuring in-process data	[14]; [2]; [8]; [19]; [3]; [15]; [20]; [13]; [21]; [11]; [17]; [12]; [7]
Current flow map out of date	[2]; [3]; [13]; [7]
Very flexible production	[14]; [2]; [8]; [3]; [4]; [9]; [10]; [20]; [22]; [11]; [16] [17]; [7]
Process performed intuitively	[8]; [3]; [10]; [15]

As can be seen in the problems pointed out by the authors, for an effective VSM that can provide support for decision making, it is necessary that the company has a well-structured process and can update the VSM frequently, as today companies have an increasingly short product life cycle, which makes VSM obsolete quickly. Besides, Table 1 shows that one of the most pointed problems in the literature is the difficulty in measuring data in-process. Because of this, this article proposes the use of process mining as a tool capable of assisting in data collection and process mapping, allowing a faster and more assertive update of the value flow map.

2.2 Process Mining

Clearly, process models play an important organizational role. The modeling of processes and/or workflows, as in the case of VSM, seeks to reflect an alignment between what is modeled and what actually occurs in real age. Unfortunately, many of the "hand-made" methods do not have this desired connection, showing only an idealized view of the facts [23]. The re-design and process innovation approaches can present a failure indicator of 60-70%, since most of these approaches are subjective,

incomplete and require high availability of time and resources, since they are based on interviews and observations of actors involved in the process [24].

Organizations face constant challenges to maintain competitiveness and process improvement initiatives, such as VSM, are often conducted in search of improvement in the efficiency and effectiveness of processes. Process mining presents itself as an important facilitator of continuous process improvement, as the use of the event log can be used as information evidence of processes [25].

Process mining offers an interesting approach that seeks to solve or mitigate these problems. As organizations depend on information systems that support activities, they can record a large amount of data, for example: which activities were performed, who performed them, when they were performed. This event data can be organized as a path that contains the history of what, in fact, occurs during the execution of a process. This history can be analyzed using process mining techniques [26]. It is a relatively young research discipline, between machine learning and data mining, on the one hand, and process modeling and analysis, on the other. The idea of process mining is to discover, monitor, and improve real processes (that is, unassumed processes) by extracting knowledge from the event logs available in current systems [5].

The collection of information about the processes, from the information systems, when performed automatically reduces the time of analysis of the processes. Even so, the main benefit of process mining techniques is the possibility of analyzing a model based on the actual execution of the steps. Therefore, the insights obtained during the analysis, as well as the knowledge acquired, can be used to effectively improve the processes submitted to mining techniques. The event data can be analyzed according to different perspectives: (1) the flow-control perspective; (2) the organizational perspective; (3) the data perspective; and (4) performance perspective. The flow-control perspective is concerned with the behavior of the process, namely, the process and its order of execution. The organizational perspective focuses on the relationships between users who performed the activities, as if they belong to the same group or to different groups or organizational units. The data perspective is related to the data objects that serve as input and output for the activities in a case. The performance perspective aims to detect bottlenecks or calculate performance indicators, such as production times and, therefore, recording times [26].

Another possible use for process mining is conformity assessment, which consists of comparing a hand-drawn model (eg, VSM, BPM, VBM) with its event log. The compliance check can be used to determine efficiency and raise proposals for improvement in the face of an established process [27]. The quality of the process, generally, takes into account factors of case behavior, precision, generalization, and simplicity [23].

This mining application supports decision makers on issues such as time spent passing cases through the process, transitions and intermediary decision making, time consumed at each stage, critical activities and resources and time between activities [28]. Decision-makers in organizations show great interest in mining processes by realizing the high added value for the business and the possibility of insights brought about during process improvement studies [29].

3 Methodology

The methodology seeks to establish empirically, through a case study, improvements in the mapping of the value stream, which, despite being widespread and with satisfactory results, can still evolve with the increment of process mining. The study is carried out in two phases, being: first the execution of the VSM according to the steps in figure 1, which are: specify the customer data; place the functions and departments involved; identify units that trigger the process; record the main steps; evaluate the stages, interfaces and information flows of the process; register flows of external material and services; insert the timeline.

The second phase consists of the application of process mining in the process previously analyzed by VSM. The steps of process mining are performed according to figure 1, which are: extraction of the event log; analysis of the event log; process analysis; and results. The methodology can also be used in similar processes where it is possible to remove the event log from the database.

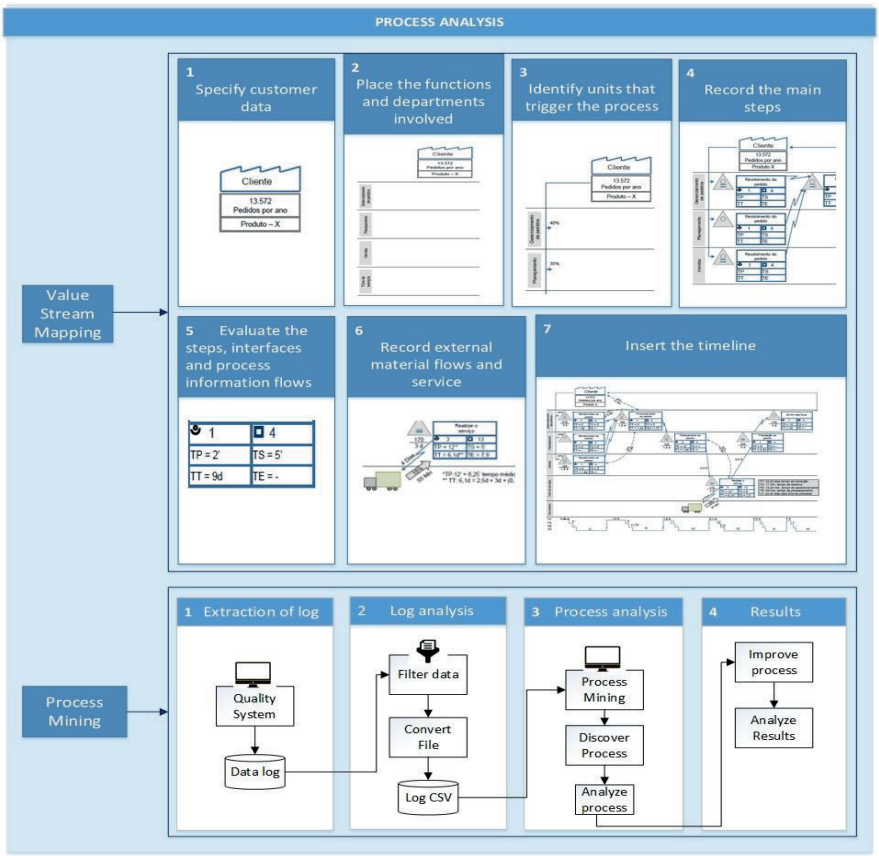

Fig. 1. Methodology

4 Case Study

The company used for the case study is part of the Brazilian automotive sector and has a good level of maturity in lean manufacturing practices. The area to which the methodology is applied is Quality, which has experience in using value stream mapping. In order to increment the VSM with the benefits of process mining, both approaches were conducted. VSM by technicians, Quality engineers, and an external consultant, and the process mining relied on Quality engineering. In both processes, there was also the accompaniment and support of the authors for understanding, applying the proposed method, and analyzing the results.

The execution had two distinct phases. In the first phase, a mapping of the value flow was carried out to handle of non-conformity, using paper and pen. The process was analyzed in-depth following the steps in figure 1, requiring five meetings of 3 hours to map the process. With this activity, it was possible to perceive the flow of the Handling of Non-Conformity (HNC) as well as to see weaknesses in the process.

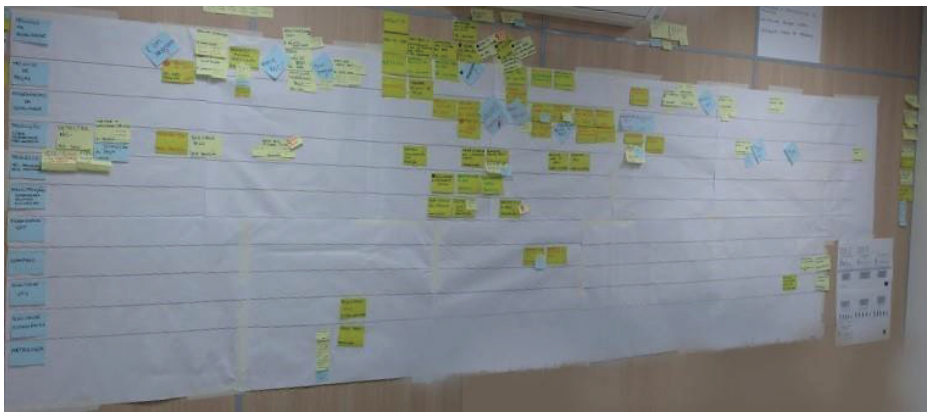

Fig. 2. Value stream mapping (VSM)

In the second phase, with the process modeled by VSM, the focus is on the existing Quality system, and the analysis is done through a log of events that was extracted via the Quality Information System. This step aims to bring the analysis under the lens of process mining in the same process analyzed by VSM, providing an increase in analysis and other possibilities for improvement.

The next subsections of the article detail the application of process mining from log extraction to processing analysis in the software. The results step, shown in Figure 1, does not apply to the scope of this article, since the present study intends to verify what the process mining can add to the VSM. However, with the analysis of the process found, the team responsible for quality management in the company will continue to improve the process and further evaluate it.

4.1 Extraction and Analysis of Log

The structure of the case study follows the methodology presented in Figure 1. It starts with the step of extracting the Quality System data log, and after the data collection, a first sorting was carried out on the file, removing unnecessary information for the study. The file was then converted and mined in the DISCO software, where the process could be analyzed by checking its adherence to the VSM model.

Although process mining is a very important tool for analyzing and understanding a process, the starting point for mining is not always easy. More than extracting data from a system, it is necessary to prepare it for the processing in question. Thus, the first stage needs the support of the IT area to filter the activities and the important attributes for analysis. For the study, the case ID and records such as date, activities, and employees were selected. After identifying the attributes of the log, it was converted to the standard format of the DISCO software.

4.2 Process Analysis

The analysis of the process included 27,181 events, which in turn were contained in 7714 cases, 4 activities, over 13 years and 11 months. The activities of the process are: Opening, Plan in execution, Analysis of effectiveness, and Completed. It is expected to observe that activities follow this order within the process model found by data mining.

Process Discovery

Through the event log, the Software automatically builds a process model, where it is already possible to find out how the process actually behaves, that is, in this case, it could analyze itself from the process flow found if what was mapped in the VSM corresponds to the reality. Process mining, therefore, allows companies to confirm or correct their ideas about the existing process. Besides, the tool allows an in-depth analysis of the process performance.

The Fuzzy Miner algorithm was used to analyze the process model, this algorithm is capable of analyzing models with a large number of events. Figure 3, shows the model of the uncovered process, indicating the real behavior of the handle of the nonconformity process. As can be seen, the process model is a spaghetti model, which contains frequent and infrequent paths. Analyzing the process, we can see that in most cases the events start with plan in execution, skipping the Open stage.

The extracted model showed differences from the proposed ideal model. Taking into account that the model phases are similar to a PDCA, where: Plan is Open, Do corresponds to Plan in execution, Check is the Effectiveness Analysis and finally, Act would be the Completed profile. We have the following situations: (1) most analyzes (6495/7714) start from the plan in execution, not making clear the study and preparation to understand and propose the appropriate action plans for the HNC; (2) 47 analyzes return from the plan in execution to Open, implying that the plans were created and deleted; (3) 56 times was looped in the Open status; (4) The stage of the Plan created for the approval and closing of the same occurs within normality, however,

1737 times the plan is not effective and returns to replan the actions, it can also be understood as the action is taken and the problem to recur; (5) The effectiveness analysis when the analysis is approved receives the status of completed. Some non-compliant flows are also observed, showing great potential for improvement in the system regarding compliance.

In summary, the model did not show the expected behavior, where the handle of non-conformity would start with the Open activity, move to the Plan in execution, after the Analysis of effectiveness, and finally, the handle would be concluded.

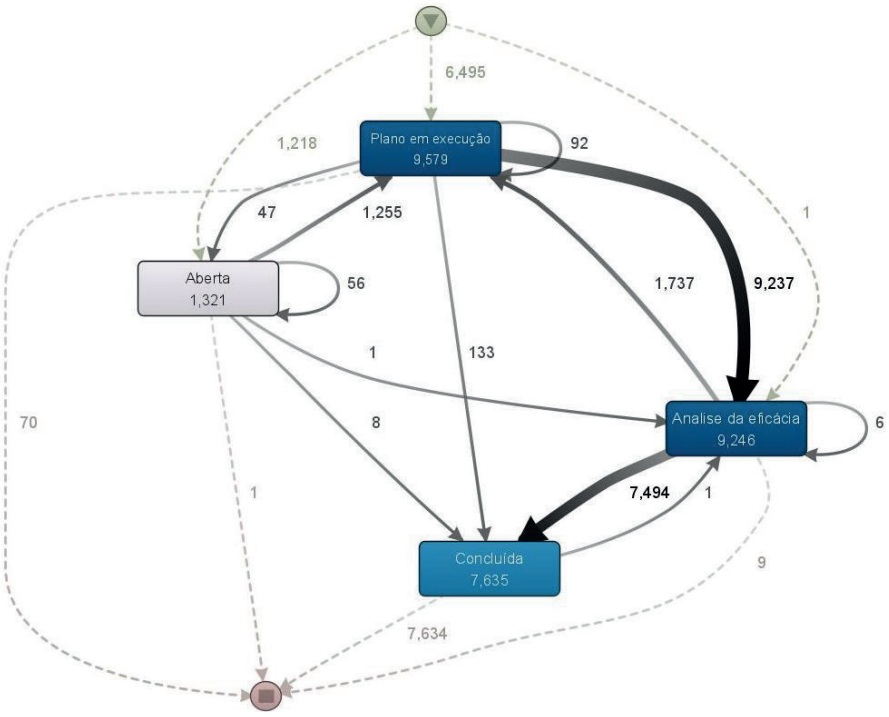

Fig. 3. Model of the non-conformity treatment process using the DISCO software.

Process Performance Analysis.

This section presents the analysis of the performance of the Quality System, which intends to discover the bottleneck of the process and whether the events presented are within the time limit estimated by VSM. It was possible to evaluate the events since when the system was created, for comparison, the average time between events was chosen. Figure 3, shows the performance of the process presented in the log, with the thickness of the arc and the color representing the average times between the activities. The thicker and stronger color indicates the bottleneck of the process. As can be seen in Figure 3, the bottleneck of the process is between the activity of Plan in execution and Analysis of effectiveness with an average of 18 weeks and with 9237 plans created. The 61.8-day effectiveness analysis shows that technicians wait this time to understand what action was effective. The accuracy of the information extracted, the

time used, as well as the ease in analyzing the data, were characteristics evaluated by practitioners as very positive in the use of process mining.

Another analysis made was in relation to the conformity of the process, which showed that of the 7714 events that started, 7635 appear finished. 1737 action plans were not effective, and in the effective analysis, they were not approved, returning to the previous phase to redo the same. One must question the importance of the Open activity, which in most cases starts with the plan being executed. Taking into account that the time taken to handle of non-conformity is aimed at 20 days, it can be seen that in most cases this time is exceeded. For a better analysis of this fact, a filter was applied based on the 20-day estimate for the resolution of the handle of non-conformity, where only the events that are within the time limit were left. As a result, 18% of the events in the log are within the stipulated time limit. Within these cases, the average time between the execution plan activities and the effective analysis was 4.8 days.

5 Discussion

During the realization of the case study, it was observed that the VSM methodology analyzed the current state of the process flow of the handle of non-conformity. The approach aimed to provide the Quality manager with a detailed mapping of activities that involve non-conformities, the human resources used, and the time consumed. In the Quality department, the main reactive activity is the problem-solving process, which includes registering the problem in the Quality system, analyzing the root cause in the Kaizen model (A3 / project), and defining and monitoring the countermeasure. The technicians are responsible for this activity and it was detected that they were overloaded, therefore, the quality of the handling was not as good as expected. VSM was able to identify and eliminate double work and waste from the process, improve performance and the workload can be revised.

However, the work mobilized the entire department with many hours of work to arrive at a photograph of the process. The energy to map the flow was so great that repeating the process with the required frequency proved to be unfeasible. The discussions for the construction of the map were based on people's intuition, which in addition to taking a long time, often generated inaccurate and unreliable data.

To conduct the activities, it was necessary to hire an external consultant, because although the methodology is quite widespread, many doubts arose on how to map the activities and mainly the fact that people often present different, but legitimate points of view. VSM achieved some of its objectives, but for the manager, it was not possible to promote more profound changes because it would be necessary to run the cycle several times, which proved to be impracticable due to the energy and resources used. The comparison of the two VSM and process mining approaches is summarized in Table 2.

In relation to VSM, it is possible to verify that process mining allows a visualization of the process as it actually occurs, thus requiring less human effort and mitigating the subjectivity existing in the discovery phase. In addition, process mining allows

for quick and constant updating of process models, as it occurs from readings, from systems, extracted in real-time and stored in an event log.

Still, to be able to execute process mining projects, there is a need for data storage, requiring computational structure and acquisition systems. These data can be extracted with dirt and found scattered in several different systems, which impacts the need for processing these data. In addition to that, structuring to collect data from systems can imposing the organization with implementation costs.

Table 2. The comparison of approaches: VSM and process mining.

	VSM	Process Mining
Numbers of people involved.	22 – the entire Quality team	2 - 1 engineer and 1 Manager
Hours used	5 meetings of 3h x 10 people = 150 hrs.	To remove the event log from the system: 8 hrs, to pass to the DISCO software: 10hrs, analysis time: 10 hrs = 28 hrs
Level of detail	Relation to people's capacity for abstraction.	Logs written to the system
Ability to repeat the process	Difficult - difficulty in bringing together all involved	Easy - whenever needed
Reliability of information	Estimated times - People have different ways of seeing the process and many disagreements regarding the duration of activities.	Times collected from the system - The data are in accordance with the process performed in the Quality system
Period analyzed	It is a photograph of the process.	It is possible to analyze different moments of the process
Ability to assess system compliance	It's not possible.	It is possible to see all occurrences, even those that have not been completed or that have not followed the required process.

6 Conclusion

This study presents a method for using process mining to increment VSM. In general, processes, such as the non-conformity approach, are dynamic and complex. Thus, the data provided by systems is highly valuable so that, when applied to process mining, and analysis of the real situation of the process is carried out, enabling a deep understanding of the behavior of the activities.

From the evaluation of the contents present in the literature, in addition to the applied case study, it is understood that currently, process mining can be an incremental tool for process improvement initiatives such as VSM. Process Mining allows the discovery and updating of models that are true to reality, supporting the analysis and decision-making phases present in the VSM. Decision making and improvement planning is not carried out by the machines and is not foreseen in mining models. Thus, the models are complementary. In the future, with greater technological maturity and mining models, they can become prognostic, making the model itself propose and set up the improvements, making the process mining complete and enabling the replacement of the VSM.

One of the objectives achieved with the use of the PM after the VSM, from the case study, was to understand the real lead time of the dealings, making it clear that the times before suggested by the people in most cases were very different from what actually happened. It was also possible to prove that many analyzes did not follow the recommended path, and worse than that, many were not even concluded, being lost in the system. It is possible to infer that this incremental approach can extend to other types of processes, as long as the system requirements and event log extraction are met.

According to Slack and Lewis (2009) the excessive "quality bureaucracy" associated with TQM is expensive and time-consuming. This affirmation with the PM was proven with a very high lead time of the negotiations and with the percentage of analyzes that were started and were not finished being lost in the system, characterizing a total waste.

Future work can be developed through event logs containing a greater wealth of details so that the additional information provides an analysis of compliance regarding the stages and times of handle of non-conformity processes, as well as the inclusion of incremental improvements in the process. Also, these works can address other types of processes to validate the proposal developed against new applications.

{renan.prado, wilson.portela, marciocatapan, portela}@ufpr.br

Abstract. As a quality improvement methodology, Six Sigma must always be seeking to improve itself, seeking tools that can help to optimize processes and generate value. Identified by the literature, Process Mining has this power, using mining techniques to improve the stages of a Six Sigma process, stages of the DMAIC cycle (Define-Measure-Analyze-Improve-Control). Proposing to unite these applications, this work aims to develop a more efficient DMAIC cycle, in terms of reliability and time, developing the agile DMAIC cycle through an approach for process mining. The aim of this study is to provide a more agile application for Six Sigma, using data from automated processes that are increasingly available, and contribute to the evolution of how continuous improvement projects are currently conducted. To verify the functionality of the agile DMAIC cycle, a case study was performed in a multinational automobile manufacturer, using data from its dealership chain, seeking to identify the main defects of the vehicles. The study is still under development, but the preliminary results are available in this work.

Keywords: Process Mining, DMAIC, Processes Improvement.

1 Introduction

Process improvement is highly dependent on the ability to identify a problem, develop solutions and implement them [7]. There are several methodologies that follows steps starting from the identification of a solution to the implementation a solution, and one of the most used methodologies in the world is the Six Sigma.

With the emergence of Six Sigma in the 1980s, and with its recognition due to several successful cases, the methodology was the most effective to achieve continuous improvement. Over the decades, the Six Sigma methodology has been adopted by many organizations, regardless its size [15].

The Six Sigma encompasses a wide range of statistical methods and quality tools, seeking to reduce eventual quality defects and costs, giving a lot of importance to the statistics of the process, becoming a method focused on measurable results and with a quick conclusion of the project [7].

The research in the process improvement area is something that is always in vogue, and one of the most emerging areas in this type of study is the Process Mining which

aims to discover, monitor and improve processes from data (also known as event logs) obtained from information systems [1]. Process Mining is not a method that replaces more classic methods like Six Sigma itself, however, it can be used to validate and accelerate process improvements [3]. This is what this research proposes, a methodology that intersects six sigma and process mining, using both in a case study that will be presented in one of the topics of this work.

One way that has been shown efficiency to use Process Mining in Six Sigma is to use mining techniques in the DMAIC cycle (method that guides the tools and steps to be proceeding in Six Sigma), with these mining techniques, it is possible to provide a visible agility at the end of the process [9;10]. Although there are already other studies in this area and some concepts from these studies are used in this work, this research has a slightly different view, bringing a new approach to the execution of the DMAIC cycle and validating its concepts in a practical way through a study of case.

This work intends to demonstrate through preliminary results the usability and improvements that can be achieved in the DMAIC cycle when process mining techniques are used. These preliminary results were obtained using the agile DMAIC cycle in logs provided by a multinational automobile manufacturer located in the state of Paraná, Brazil.

2 Contextualizing

2.1 Six Sigma

Developed at Motorola in the mid-1980s, Six Sigma is a methodology with the goal to improve the output results of a process, minimizing variations and eventual defects that may happen [16]. A trained professional leads the project using one of two typical approaches to a Six Sigma project, namely DMADV and DMAIC. DMADV is focused on product development, while DMAIC is focused on process improvement issues. for the purpose of the paper, will be studied the DMAIC approach. Figure 1 illustrates each stage of DMAIC cycle and addresses the crucial points of each.

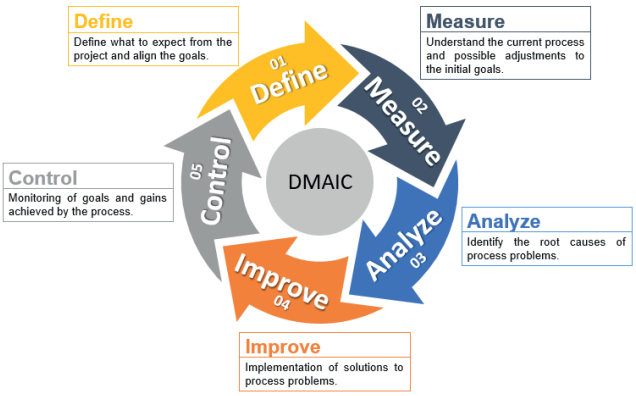

Fig. 1. DMAIC cycle.

The DMAIC cycle is one of the pillars of the success of Six Sigma, it is a structured and sequential method that seeks to emphasize the customer's voice, using tools with statistical basis to seek a better solution. DMAIC is an acronym for Define, Measure, Analyze, Improve and Control. Where each letter corresponds to a stage in the DMAIC cycle [12].

It is necessary to follow the steps in their proper order, each step has its importance and expected results after they are completed, these characteristics are detailed in table 1.

Table 1. The main objectives and expectations of DMAIC cycle. Adapted from [1;6]

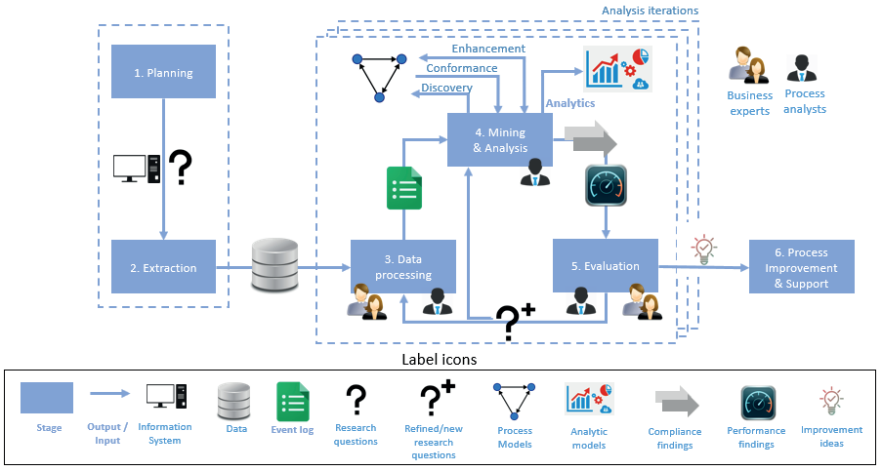
Stage	Stage importance?	What is expected at the end of the stage?
Define	Define is where the cycle begins, at this stage the scope of the project is defined, which is vitally important, because a poorly defined or superficial scope can cause the project to fail.	The project team is expected to have the objective well established, ensuring that the project's goals are aligned with those of the company, an estimate of the expected gain after the implemented project, a mapping of the entire macro process involved, and a schedule of the entire DMAIC cycle determining the estimated time for each stage of the cycle.
Measure	Measure is the step where it is possible to understand the current state of the processes and how they work, through the acquisition of indicators.	The project team is expected to have the objective well established, ensuring that the project's goals are aligned with those of the company, an estimate of the expected gain after the implemented project, a mapping of the entire macro process involved, and a schedule of the entire DMAIC cycle determining the estimated time for each stage of the cycle.
Analyze	Analyze aims to identify and select the root causes of project problems, validating through static tools.	It is necessary that the root causes of the priority problems have been identified, so that it is possible to present what is wrong with the process, and how to implement the changes that must be adopted in the next stage of the cycle.
Improve	Improve is where the solutions to the problems of the process are presented, making the necessary improvements, and checking if the specific goals have been achieved.	At the end of Improve, the project team must have made a list of solutions for each problem in the project, an action plan for the implementation of the solutions, made the necessary improvements, and evaluate through the results of the improvements if the goals were really achieved.

Control	Control is necessary to monitor the goals, ensuring that the gains made in the project are maintained.	Concluding the Control, it is expected that the project has generated new processes, well defined and aligned, that the goals have been achieved, that there is a plan to monitor the project periodically, as well as all the documentation and lessons that have been learned throughout the project

2.2 Six Sigma

Process Mining is a rising research field, that incorporates mining techniques that can be used in companies that own a mature database, providing support for process improvements [1].

The basis of Process Mining is the *event logs*, which are event records of a process, these event logs are obtained through information systems that are already available in corporations, the idea of process mining is to discover a process, monitor it, and improve it using appropriate techniques for the logs, in most of the logs it is possible to extract information about the project execution steps and the timestamps, such as when the process starting and completing. The figure 2 shows the methodology proposed by Eck et al. [6] for the execution of a typical process mining project, starting from the planning until the exhibition of results.



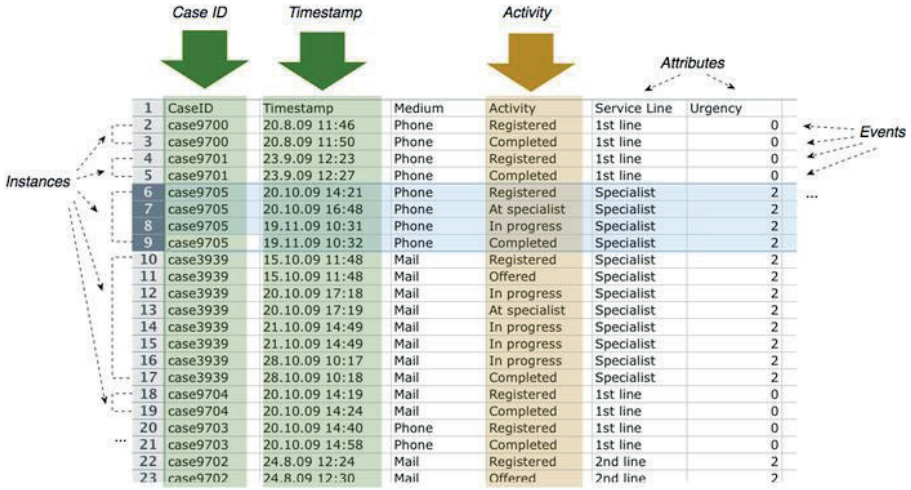


Fig. 2. Process Mining Methodology. [6]

The basis of process mining is the event logs, these logs are data acquired from information systems and are identified in tables, as the figure 3 that illustrates the elements of a log, at least three of these elements are mandatory which are Case ID, Timestamp and Activity. These elements are necessary for the mining software to generate the model that describes the process to be mined.

	CaseID	Timestamp	Medium	Activity	Service Line	Urgency
1	case9700	20.8.09 11:46	Phone	Registered	1st line	0

Fig. 3. Process mining input data. [8]

Process Mining consists of observing a process activity through its logs and using them in any of the three types of Process Mining, which are *discovery mining*, *conformance mining*, and *enhancement mining* [1;2], these characteristics are detailed in table 2.

Table 2. Types of mining and usability. Adapted from [1;6]

Mining types	Why use this type of mining?
Discovery Mining	From an event log used as input, it is possible to automatically discover (using process mining software) a process model (Petri Net, BPMN, EPC, Causal Network ...). Given this model, it is much easier to understand the process being worked on, saving time and work of having to do a traditional process mapping.
Conformance Mining	In conformance mining you can start from an already established process and with an expected behavior, it is possible to do an exploratory mining in order to detect whether the acquired event log has the expected behavior or if there is any inconsistency. When addressing to process conformance, it is possible to make gains in several areas such as quality, time, resources, and costs.
Enhancement Mining	This type of mining takes in consideration the event logs to drive improvements, based on a process performance analysis. This is a great tool to find possible bottlenecks and deviations from the process.

2.3 Process Mining in DMAIC

Six Sigma, as a quality improvement methodology, cannot remain with a static structure, if it wants to continue generating value [14]. Based on this premise, originated the idea of using another quality tool that could improve the DMAIC cycle. A

systematic review of the literature was carried out in search of something that could add value to this methodology, and it was thought that process mining could be that something from the thinking proposed by Aalst and Dustdar, where which specifies that process mining is not a method that replaces more classic methods of quality, such as Six Sigma itself, but it can be used to validate and accelerate process improvements [3].

Using the digital libraries IEEE Xplore, Google Scholar, SpringerLink and Web of Science. The literature review was made using the key words "Process Mining", "Six Sigma", "DMAIC", "Processes Improvement" and "Data Mining", so that they were combined in the search. This search resulted in 822 relevant publications, and subsequently only 4 of these researches were selected, which drew attention for bringing a process mining application within the DMAIC or notes of possible applications. These researches bring very valuable information regarding the application of these two methodologies together, like how to accelerate the design time, usefulness and possible applications of certain mining techniques in given stages of the DMAIC, usefulness of using real data from logs, and the benefits of a support tool that combines the two methodologies. Table 3 shows these researches and their main contributions.

Table 3. Most relevant research and their contributions.

Research name	Main contributions
Accelerate DMAIC using process mining [9]	After applying process mining techniques in the DMAIC phases it was possible to accelerate a process that would take an average of 9 to 12 weeks for an average duration of 4 to 6 weeks.
Data perspective of lean six sigma in industry 4.0 [5]	It was interpreted that the discovery techniques are useful for the define and analyze phases, in addition to that the Conformance techniques are applicable in the Measure and Control phases.
The future of continuous improvement [11]	It was understood that using real data from the event logs in the define phase would help to define the scope of the project, and with process mining techniques the measure and analyze phases would be streamlined, highlighting also that in the control phase it would be very useful to use process mining to assist the daily management of operations.
Process Mining for Six Sigma [10]	In order to fill a gap in a study dedicated exclusively how bridging the gap between Six Sigma and Process Mining, was developed the PMSS (Process Mining for Six Sigma), providing guidance on how to use mining techniques within the DMAIC cycle.

Taking advantage of all this shared information from these previous researches, the concept of the Agile DMAIC cycle began, bringing in a more specific way a direct application of process mining within the DMAIC cycle.

3 Agile DMAIC Cycle

The core of this research is to generate a model in which it can be followed to be applied in continuous improvement projects. Aiming as a final product a structured method for consultancy in Six Sigma projects, called Agile DMAIC Cycle.

Focusing on the approach of incorporating Process Mining along with the DMAIC cycle, without changing the progress of a standard Six Sigma project, the agile DMAIC cycle has as its main advantage the execution time, reducing the time spent in the initial stages.

Currently, this study has been limited only to discovery mining, having only direct influence in the Define, Measure and Analyze stages. However, the natural way is that the research continues to evolve and, in the future, also influences the stages of Improvement and Control, through the others mining techniques.

The Agile DMAIC Cycle has 8 phases that occur over the five stages of the classic cycle. The figure 4 shows the flow of the Agile DMAIC Cycle, as well as determinates which professionals are involved in which phases.

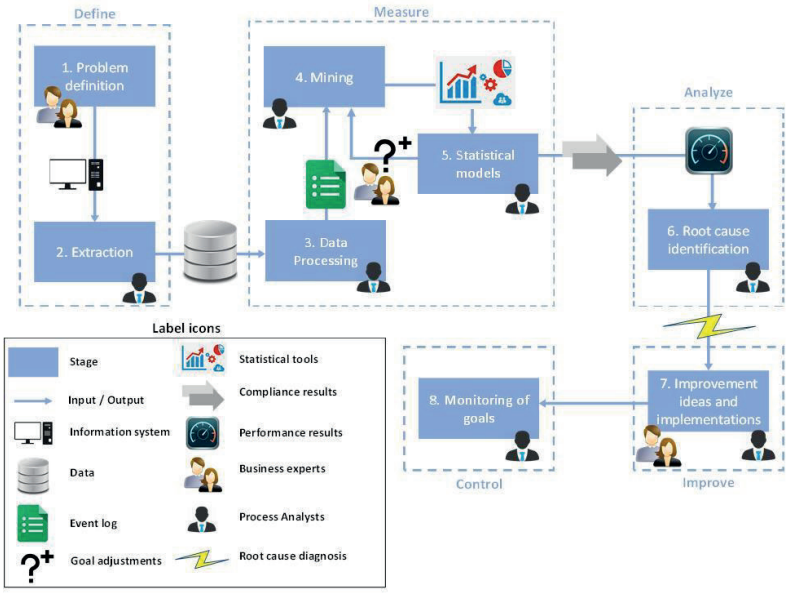

Fig. 4. Agile DMAIC Cycle methodology.

Stage 1 - In this stage, the business specialists define the problem they want to focus their efforts on solving, defining the scope and goals of the project.
Stage 2 - In this stage, data extraction occurs, process analysts based on the defined problem, analyze which information systems they could use to acquire data from the process, and make the necessary data extractions.
Stage 3 - In the Data processing stage, data is cleaned, generating event logs that can be used in mining software.

Stage 4 - This is the stage where the logs are updated in the software, generating the mapping of the process, and applying mining techniques, to obtain the statistics of the events.
Stage 5 - The statistics generated are used in this stage for the design of static models, which together with business specialists are evaluated if it is possible to reach the initial goal or if it is necessary to make any adjustments.
Stage 6 - This is the stage where the root cause of the problem is investigated, supported by statistical models, looking for variations and possible bottlenecks, generating a diagnosis with these causes.
Stage 7 - Based on the diagnosis, this stage explores the possible solutions to the problem, followed by an action plan, and the appropriate implementations.
Stage 8 - The stage that ends the cycle, is responsible for ensuring that the gains obtained with the project are maintained over time, creating a plan for monitoring the process after the project is concluded.

4 A case study and preliminary results

Proposing to test and validate the Agile DMAIC Cycle, the methodology has been applied in a case study, at the time this article was written the project is still running, however due to the evolution of the study already in this state of application, it was considered that it would be positive to expose the preliminary results of the methodology. The case study was based on data provided by a multinational automobile manufacturer located in the state of Paraná, Brazil.

4.1 The problem

The company would like to understand the main causes of the defects of its vehicles, for that they wished to make an exploratory study aiming to identify the main types of defects by models of vehicles. Subsequently intending to understand root causes, take mitigation measures, prioritizing the most significant actions first.

For this study, the company made available logs of its car dealerships chain, where from the chassis number, it is possible to identify the events and dates of these events that occur in a vehicle. These logs also have problem codes (used by the company), how many kilometers a vehicle has on a repair order and the model of the car.

The possible occurrences are vehicle manufactured, BVM registration, vehicle delivered, BIM registration, vehicle sold, and repair order. BIM and BVM registration will not be considered since they are internal company registers, and they do not have influence on the process. The information available for analysis are as follow:

i) Vehicle manufacturing is the event where the vehicle manufacturing is completed.
ii) Vehicle delivered is the event in which the vehicle is delivered from the factory to the car dealership.
iii) Vehicle sold is the event in which the vehicle is delivered to the customer.

iv) Repair order is when a technician identifies a problem and generates a repair order.

The figure 5 is an example of a log, the chassis number has been blurred due to the privacy of company data.

Chassis number	Event date	Event	Problem code	Km	Model
[redacted]	01/12/2017	Vehicle Manufactured			
[redacted]	13/01/2017	BVM Registration			
[redacted]	04/07/2018	Vehicle Delivered			
[redacted]	08/06/2019	BIM Registration			
[redacted]	15/08/2019	Vehicle Sold			
[redacted]	31/07/2019	Repair Order	GSFA-V01-CAR BODY	40462	E5
[redacted]	08/12/2019	Repair Order	GSFA-V13- INTERIOR TRIMS	41102	E5
[redacted]	08/12/2019	Repair Order	GSFA-P15-SAFETY SYSTEMS	41102	E5
[redacted]	01/08/2020	Repair Order	GSFA-V14-SEATS	48707	E5
[redacted]	01/08/2020	Repair Order	GSFA-V14-SEATS	48707	E5

Fig. 5. Event log example.

4.2 The procedure

The procedure followed in the project was as described in figure 4, where the same flow was followed and executing the steps determined within each stage of the DMAIC cycle.

4.2.1 Define

Problem definition (Stage 1): The quality sector of the company has for some time seen a high rate of defects in its vehicles, but these defects are not directly reported to this sector or to the administrative sector. These complaints and defect identifications come through the customer complaints from the car dealership chain where customers purchased their vehicles. In order to carry out an exploratory study to identify the main defects of its vehicles, the problem of the project was defined, the identification of the models that concentrate the highest number of problems, and from them prioritize the mitigation of them for each of these models, obtaining an overview of defects and already having an improvement model in progress. It was defined that the information system that could provide the data for the project would be the system of repair order registers, which the car dealership uses. This decision-making came from Business Experts.

Extraction (Stage 2): At this stage, one of the quality sector analysts extracted the data from one car dealerships, in which he judged that he would have data mature enough and that would generate a good sample.

In the extraction stage, it is intended to acquire information registered in information systems. The extracted data had a direct influence on the scope of the project, which was defined in the previous step. Searching for defects reported by customers, where in addition to defining what data would be extracted, the period to be extracted was determined. As previously stated, the data is provided by a car dealership chain, in which a .csv file was generated with the necessary information to be used in the mining

software. Figure 6 shows an example of a post-extraction log excerpt, where there is more information than is necessary for mining and that has not been used, there is no need or utility in the Damage and Customer description of the problem columns for mining, due to being non-standardized and subjective fields, the damage field is what the technician responsible for the assessment notes the identified problems in his own way and the *Customer description of the problem* field are the words of the customer to describe the problem. These two fields, besides not being standardized, make it difficult to understand for the software, they are fields that are suppressed by Problem Code, which is the code used to report the identified problems.

Chassis number	...	Event	Damage	Problem code	Customer description of the problem	KM	Model
[redacted]	...	Vehicle Manufactured					
[redacted]	...	BVM Registration					
[redacted]	...	Vehicle Delivered					
[redacted]	...	BIM Registration					
[redacted]	...	Vehicle Sold					
[redacted]	...	Repair Order	LACK OF BACK LEFT DOOR PLASTIC FILM ADHERENCE	GSFA-V07-EXTERIOR ACCESSORIES	LEFT BACK DOOR BAND TAKING OFF	42002	A1
[redacted]	...	Repair Order	LACK OF ADHERENCE; DECORATIVE BAND OF THE LEFT FRONT DOOR; UNPLUGGING	GSFA-V07-EXTERIOR ACCESSORIES	LEFT FRONT DOOR BAND TAKING OFF	42002	A1
[redacted]	...	Repair Order	LACK OF ADHESION OF THE DECORATIVE BAND DOOR FRONT RIGHT; UNPLUGGING	GSFA-V07-EXTERIOR ACCESSORIES	RIGHT FRONT DOOR BAND TAKING OFF	42002	A1
[redacted]	...	Repair Order	UNLOCKING; FRONT SEAT BELT LIMIT BUTTON LEFT; EXTRAVING	GSFA-P15-SAFETY SYSTEMS	LEFT BACK BELT BUTTON FELL	42002	A1

Fig. 6. Log post-extraction.

4.2.2 Measure

Data processing (Stage 3): The data received are prepared to become event logs, they are parameterized to a format that can be processed in the mining software, often the data comes with more information than is necessary, and which would not be relevant for the analysis, so in this step it is also defined which data has relevance, already thinking about which attributes such as case ID, activity, timestamp, resource or other relevant attribute. In the result, is expected certain similarity to the figure 5.
Mining (Stage 4): The event logs are imported into the mining software, in this project the software used was DISCO by Fluxicon, where it is necessary to identify the columns as Case, Activity, Timestamp, Resource or other. After importing the event logs, the software generated a process map. In figure 7 on the left side in blue is the process map in relation to the frequency of occurrences, considering the absolute frequency. Through the process map it is possible to identify that 33449 vehicles were registered

in the information system, and that there were 46463 repair orders, in which 11171 vehicles had more than one repair order. Still in Figure 7 on the right side in red is the process map in relation to the performance of events, considering the median duration.

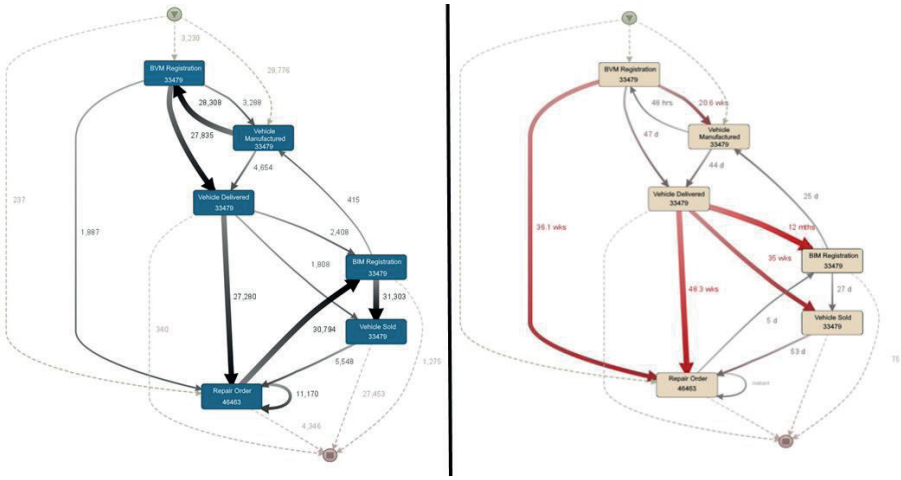

Fig. 7. Process maps.

Figure 8 shows that by the statistics generated on software Disco, within the attributes of the vehicle model and problem code, it is possible to identify that there are 57 problem codes and 10 vehicle models, which have been registered in the system. The figure shows that there is a predominance of the A1 model, being responsible for more than 60% of the repair orders, in the problem code it is also possible to have an idea of what are the most constant problems.

I9	27	0.06 %
J10	22	0.05 %

Fig. 8. Problem code and Model frequency.

Using the Disco filter tools, the three models that had the most defects were isolated, together these three models represent more than 82% of the total defects, after being

isolated, new event logs were generated. Filters were also used to measure changes in kilometer attributes and the time it takes between the sale of a vehicle and a repair order.
Statistical Models (Stage 5): From the event logs provided in the previous step, pareto diagrams were generated to better understand the distribution of defects in the A1, B2 and C3 models, which have shown the most defects, figure 10 shows these diagrams. In the A1 model the most constant defect is the code GSFA-S22 (22.4%) followed by GSFA-M07 (13.3%) and GSFA-P05 (9.06%). In the B2 model, the defect that most occurred was GSFA-V14 (14.81%), in second and third, two defect codes have a very close value, GSFA-P11 (8.09%) and GSFA-V04 (8.05%). In this model the defects are more distributed than in the A1 model. The diagram of the model C3, which is the third most defective model, the most frequent problem code is GSFA-V14 (19.46%), significantly below the codes GSFA-M06 (7.48%) and GSFA-V01 (5.35%).

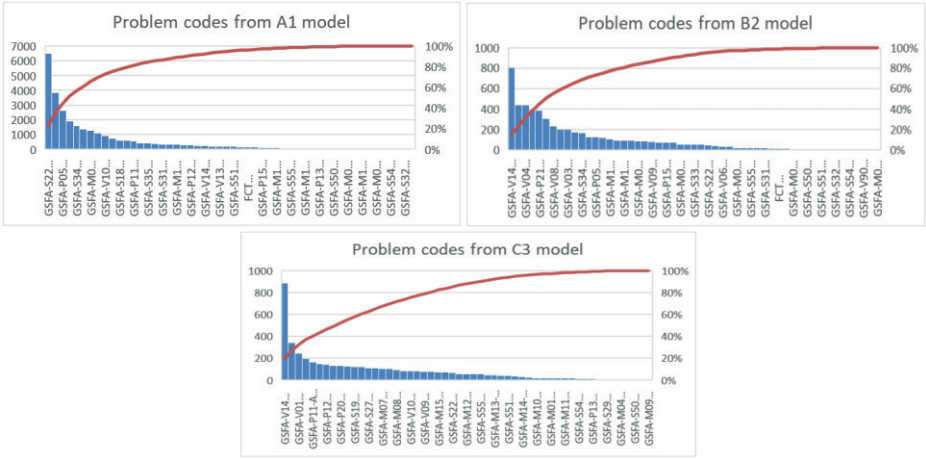

Fig. 10. Problem codes distribution.

An analysis was made focused on the following topics:

i) The time it takes a sold vehicle to return to the dealership.
ii) Repair needed, which may be a first repair order or a second repair order.
iii) Vehicle has already been previously repaired.

The analysis revealed that in both cases the defects mostly occur before completing one year. The analysis carried out was the number of kilometers traveled by the vehicle when a repair order was made, the histogram in figure 12 shows the kilometer ranges and the number of repair orders that were made, in each range. Through this histogram it is possible to reinforce the analysis of the boxplot in which the defects are occurring in the first months of use, due to the defects being more concentrated in low kilometers traveled.

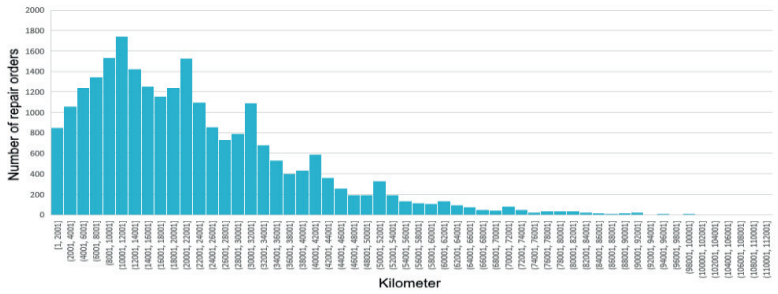

Fig. 12. Kilometers traveled on repair orders.

Also focusing on the kilometers traveled in which a repair order is initiated, an analysis was performed using a filter to isolate the problem codes in a certain time range, as the oldest repair order date is January 2019 and the data were extracted in January 2020, it was considered for analysis to divide the time range into semesters of 2019, 2020 was not considered because it has a very small sample. First, the two defect codes with the highest occurrences were analyzed, namely the GSFA-S22 and GSFA-M07, together representing more than 23% of the total defects. Figure 13 show the first and second semesters of the GSFA-S22 defect. In the first semester, this defect had 1314 occurrences, with the highest incidence between 7412Km and 11111Km.

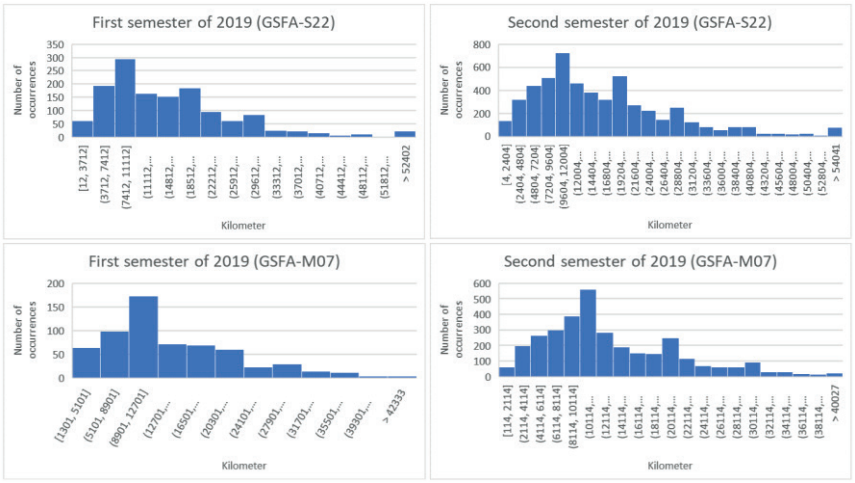

Fig. 13. Kilometers traveled in the repair order for model in the semesters.

In the second semester the defect code GSFA-S22 increased from 1314 occurrences to 5313 occurrences, an increase of just over 400%, in addition to the visible increase it is possible to notice that the apex of the problem occurred in a higher number of kilometers traveled.

Analyzing the defect code GSFA-M07, 627 occurrences were found in the first semester of 2019, with a higher incidence between 8901Km and 12701Km. As the figure 13 illustrates. In the second semester of the year, the GSFA-M07 defect code increased from 627 occurrences to 3304 occurrences, an increase of just over 520%, and as in the case of the GSFA-S22 defect, the peak of greatest occurrences was in a higher number of kilometers traveled.

The results were presented to the responsible sector of the company, who found the problems notes very consistent, and believe that what was analyzed about the problems reflect well what they experience in their daily work. It was not necessary to make any adjustment of goals, since the experts consulted gave the guarantee that the path followed was correct, and the initial goal of finding the main defects and solving them seems to be practicable. The increase in the second semester of the two main problem codes will guide the next step, Analyze, with the objective of identifying the root causes of this huge increase in the number of defects.

4.2.3 Analyze, Improve and Control

The next step would be to enter in the Analyze with the stage *Root cause identification* (stage 6), looking for the root causes, that is currently being done, however, as stated earlier, the project is still in progress and there are no consistent results to be presented about this stage at this moment.

The Improvement step is not yet intended to use process mining techniques in the Improvement ideas and implementation step (stage 7). Classic Six Sigma tools will be used, such as Poka-Yokes, Ishikawa diagram, decision matrix and brainstorm.

Control is the step in which it is intended to guarantee the functionality and stability of the improvements. This work intends to test some process mining techniques of Conformance, to ensure that these improvements continue over time.

5 Conclusion and final considerations

This work through theoretical concepts and gaps mentioned in previous studies [5; 9; 10; 11; 14], brought a contribution to a new practical approach to Six Sigma projects, aiming to bring more accurate indicators and a more agile DMAIC cycle.

Presenting encouraging and satisfactory preliminary results, the agile DMAIC cycle has shown capability in bringing a new perspective on process improvement, other case studies will be carried out in the future. At the end of this study, a new systematic methodology is expected, using process mining to make Six Sigma projects more robust.

This work continues in progress and evolution, and in this way, it is also expanding, seeking to improve Six Sigma tools together with mining techniques, just as they were already done in the Define and Measure stages of this work. As was explored in table 3, there are researches that bring the possibility of using the other process mining techniques, further of the discovery mining, the natural path of this research is to include Conformance Mining and Enhancement Mining in the Analyze, Improvement and Control steps. Conformance techniques are applicable in the Measure and Control phases

[5] and it would be very useful to use process mining to assist the daily management of operations in Control phase [11].

Despite the applicability of process mining in other process improvement methodologies, it is important to mention that the task of extracting data can be very complex [4]. The data may not be easily located and may generate logs that are not complete [13]. About data quality, although this did not happen in the case study of this work, it was evident that to succeed the process mining needs a very mature database, the higher the level of data maturity of a company, the better it is the quality of logs that can be generated. In the long term, investing in a greater discretization of data is very advantageous due to the low cost of process mining in relation to traditional projects to acquire this data.

*tinchomainardi@gmail.com

Abstract: Activities carried out by industries generate wastes which become a potential risk if there are not properly treated and well-disposed in the environment. More than two hundred industries located in the Province of Salta have been previously classified in twenty categories according to the type of product they made. However, the environmental impact of these industries is still unknown. Multicriteria decision-making analysis (MCDA) are useful methodologies to apply in this cases as they allow choosing the best from diverse alternatives based on multiple criteria, to finally make a smart decision. The aim of this work was to apply a MCDA to identify which categories of industries impact the most on the environment. The Analytical Hierarchical Process (AHP) was the MCDA selected. The alternatives were twenty categories of industries. Five criteria and sub-criteria (shown in parenthesis) were defined: 1- environmental resources (water, soil and air); 2- types of waste (physical, chemical and biological); 3- water consumption; 4- industries features (amount and size); 5- population index. AHP was solved with Expert Choice 11 Inc. Environmental resources and types of waste, were the criteria that weighed the most. Agroindustry was the alternative that impact most on the environment, due to the use of agrochemicals, emission of toxic gases and manure. In second place was the food industry which generates a variety of waste. These results will be useful on decision-making as they allow identifying the categories of industries that most impact in the environment, to propose alternatives for a better waste management.

Keywords: industrial waste, environmental impact, multicriteria decision-making analysis

Activities carried out by industries are source of different types of physical, chemical and/or biological waste, which after their treatment (or not), are usually disposed in the environment, causing sometimes, not only problems in water, soil and/or air but also on people health. The great amount of industries located in a certain area and the variety of activities carried out by them, difficult the identification of each kind of waste generated and their potential impact. Thereby, environmental surveillance organisms that control treatment and final disposal of industrial waste, need appropriate tools for the supervision and control to make better decisions towards a cleaner production. Multicriteria decision analysis (MCDA) are useful methodologies which provide a scientific decision framework for environmental management, where stakeholders participation is as important as economics, environmental impacts,

safety, health and risk, which cannot be condensed into a monetary expression. The purpose of MCDA is to choose the best from diverse alternatives based on multiple criteria. In a previous research [1] a survey was carried out in the Province of Salta (northwest Argentina) regarding industries. It was found that the Province had in that moment, more than two hundred industries spread over fifteen out of twenty-three departments. These industries were classified in twenty different categories according to the type of product made. However, the environmental impact of these industries is still unknown. The aim of this work was to apply a multicriteria methodology to assess which categories of industries that belong to the Province of Salta impact the most on the environment, related mainly to the waste generated.

The analytical hierarchical process (AHP) developed by Saaty was selected as a MCDA [2]. The purpose of AHP is to choose the best alternative among those based on multiple criteria, which are compared in pairwise (X is more important than Y). These criteria are given in an intuitive way and are based on judgments made by experts for priority scales. Saaty provides a consistent way to make such comparisons in a set of numbers representing the relative priority of each of them over another. In general, the judgments made by experts can be inconsistent and detecting the inconsistency is one of the functions of AHP (If inconsistency index is less than 0.1 is acceptable). At the end, each score is combined with the weights of each criterion to produce an overall score (Utility or objective function) for each alternative. In this work, AHP was modeled and solved using Expert Choice 11 Inc software. This decision model includes the following steps: structuring model, introduction of alternatives and prioritization of the elements of the hierarchy and sensitivity analysis.

In this case, the objective function established was to find the categories of industries in the Province of Salta that impact the most on the environment. The alternatives were twenty industries classified according to the product they made: agroindustry, food, automotive, construction, tannery, electric power, industrial equipment, slaughter, graphics, logistics, wood, leather, metallurgical, mining, petrochemical, chemical, service, tobacco, textile and treatment. Five criteria, some of them with sub-criteria (shown in parenthesis) were defined: 1- type of waste (physical, chemical and biological): chemical or biological waste was considered more harmful to the environment than a physical one; 2- environmental resources (water, soil and air): according to the industrial activities, the waste generated may impact on the resources in different ways; 3- water consumption: while greater amount of water is consumed, more effluents will be generated and thrown into the environment; 4- industries features (amount and size): considers that while more industries and larger they are, greater is the amount and types of waste dumped; and 5- population index was defined [1], which considered the number of inhabitants in the area where the different industries are located.

Results showed that type of waste and environmental resources were the two criteria that most weighed regarding the main objective defined (40%, Fig. 1). In the third place and with the same importance were the rest of the criteria: water consumption, industries features and population index (Fig. 1).

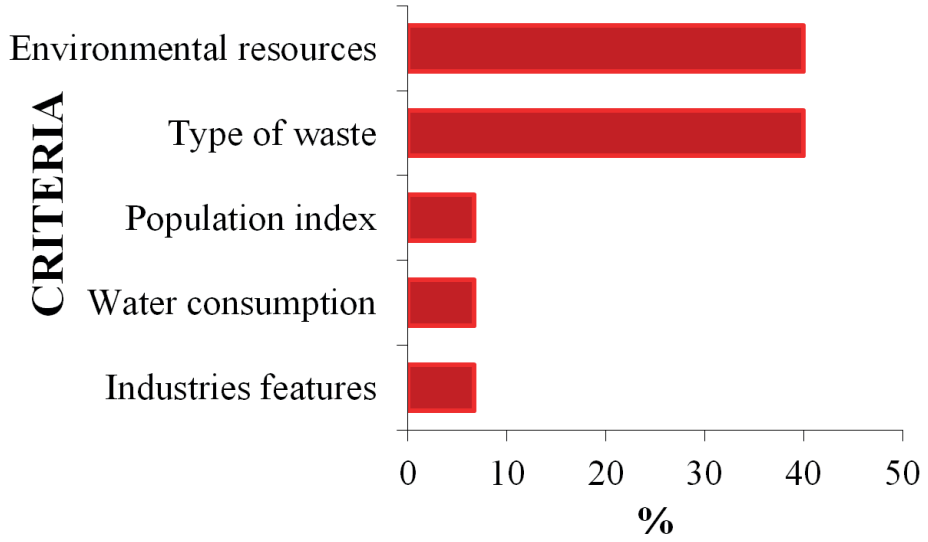

Fig. 1. Weight values (in percentage) of each of the five criteria defined to determine the categories of industries that represent the greatest impact on the environment.

Regarding categories of industries, the agroindustry seems to be the one which impacted the most on the environment (Fig. 2). This is due to the great use of agrochemicals (chemical waste) that have a highly negative impact on the soil and also can be transferred by runoff to waterbodies, causing the contamination of large volumes of water. On the other hand, this type of industry considers livestock farming, whose main waste is due to dry and/or wet manure, which can cause problems in the soil and water bodies, as well as the emission of toxic gases into the air. In this sense, the impact related to the emission of methane gas due to enteric fermentation of ruminants and soil degradation due to overgrazing were also important.

The food industry was the alternative located in the second place, which includes activities such as production of alcoholic and non-alcoholic beverages, dairy (yogurt, butter, pasteurized milk), various packaged foods (candies, cookies, potato chips), etc. All these activities include a wide variety of waste, which can range from effluents with high organic load, as in the case of the dairy industries, to dangerous goods.

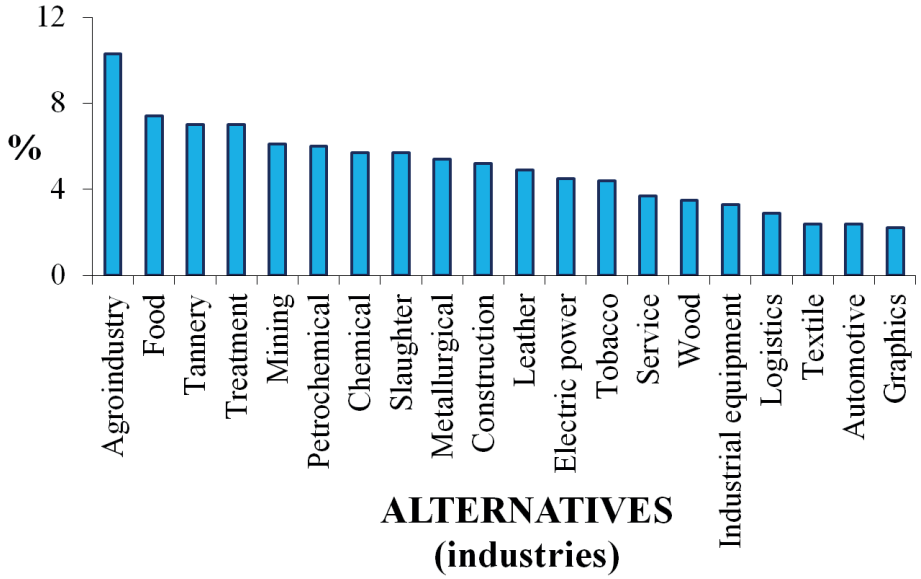

Fig. 2. Objective function values (in percentage) of each of the twenty industrial items analyzed (alternatives) that represent the greatest environmental impact.

The AHP methodology is a robust tool for decision-making. Its application allowed determining the categories of industries where changes should be made towards a better waste management and the development of sustainable industrial activity for the environment and society.

Abstract. This article presents an exact resolution of the Vehicle Routing Problem with heterogeneous fleet and flexible time windows. This problem variant extend the classical formulation by considering extended time windows for attending clients, accounting for a more realistic setting in nowadays scenarios. The proposed approach is based on a linear programming formulation implemented in CPLEX. Accurate results are reported: the proposed model is able to solve in reasonable execution times 146 out of 148 problem instances built using data from benchmarks in the related literature (16 to optimality and other 23 with lower cost than for the non-flexible problem variant).

Keywords: vehicle routing, flexible time windows, exact method, CPLEX

1 Introduction

Vehicle routing is a classical area in optimization, with many application in several domains. Vehicle Routing Problem (VRP) is a generic name given to a class of problems with the purpose of determining a set of routes for a fleet of vehicles based at one or several depots, to visit a number of geographically dispersed clients. The main goal of the VRP is to deliver the clients with known demands on the minimum cost vehicle routes originating and ending at a depot [6].

VRP is among the most studied combinatorial optimization problems in operations research. Unlike other traditional combinatorial problems, like the the Traveling Salesman Problem (TSP), where exact solvers can be applied to optimally solve instances with thousand of clients, the VRP is intrinsically more complex, as instances with more than one hundred clients can be hard to solve [1].

This article focuses on a specific variant of the VRP that considers flexible time windows for attending (i.e., delivering goods) to clients. Flexibility on the end of the time windows are included, but considering a penalization of the total cost of the route. This assumption accounts for a more realistic setting in nowadays scenarios, where it would be preferable for the decision maker to use few vehicles to complete a set of routes, even considering that a penalization must be paid for late arrivals in certain clients.

In this line of work, this article presents an exact approach for solving the VRP with heterogeneous fleet and flexible time windows. The proposed approach is based on a linear programming formulation accounting for all the relevant features of the problem, implemented in CPLEX. Realistic problem instances are solved in the experimental evaluation, built by extending existing VRP benchmarks from literature.

Accurate results are reported for the proposed model. The exact resolution approach is able to solve 146 out of 148 problem instances built using data from benchmarks in the related literature in reasonable execution times. Furthermore, 16 problem instances are solved to optimality, and other 23 solutions have lower cost than for the non-flexible problem variant.

The rest of the article is structured as follows. Section 2 describes the addressed problem and its mathematical formulation. Section 3 describes the algorithmic approach to solve the problem using CPLEX. Section 4 reports the experimental evaluation on standard scenarios and problem instances. Finally, Section 5 presents the conclusions and formulate the main lines for future work.

2 The Vehicle Routing Problem with Heterogeneous Fleet and Flexible Time Windows

This section describes the addressed problem and its mathematical formulation.

2.1 Problem description

The proposed problem is a variant of the VRP with time windows considering heterogeneous vehicles, as defined by Jiang et al. [5]. However, a relaxation of the former problem is addressed, since flexible time windows are considered. In the proposed model, early arrivals are only penalized in the waiting time, while late arrivals are allowed within a certain tolerance, suffering a penalty for the extra time that impacts the total cost of the solution included in the objective function. The elasticity given by the flexible time windows allows computing different routes accounting for different attention times withing the tolerance for each client.

The problem model differs from previous proposals since in the VRP with time windows, each client has an associated time window that is defined by the earliest and latest time in which the client is operational. The depot can also have an associated time window that defines the planning horizon for the problem. Previous models have considered that time windows can be of the "hard" or "soft" type. In the case of hard time windows, a vehicle cannot arrive before the earliest time to a client. In turn, soft time windows allow a vehicle to arrive earlier than the time window starts, but the vehicle must wait until the client is operational; however, a vehicle is not allowed to reach the client after the end of the time in which it is operative. In the case of soft type time windows considered in the proposed problem model, violations of the latest time for delivery defined by the time window are allowed, with a penalty in the objective function.

The proposed formulation is detailed in the next subsection.

2.2 Mathematical Formulation

The exact resolution of the problem is based on the linear programming formulation defined next.

The problem is defined on a complete graph $G(V, A)$, where:

- $V = \{0, 1, ..., n\}$ is the set of nodes. Node 0 represents the deposit, while nodes $N = \{1, ..., n\}$ represent the clients.
- $A = \{(i, j) : 0 \leq i, j \leq n, i \neq j\}$ is the set of edges that represent the connections between the nodes.
- t_{ij} is the travel time associated with arc (i, j).

All clients must be visited and for each client i ($i \in N$) the following information is known:

- d_i is the fixed demand of client i.
- s_i represents the service time consumed by a vehicle when servicing the client i.
- $[e_i, l_i]$ is the time window (earliest and latest respectively) of client i. The time windows are of the "soft" type (the vehicle that reaches the client after the end of its time window is penalized).
- ot_i is the "overtime" (tolerance time after the end of its time window) allowed in client i. It is calculated as $ot_i = (l_i - e_i) \times \omega$, with $0 \leq \omega \leq 1$ being a known constant. Therefore, for each client i a new extended time window is obtained, of the form $[e_i, l_i + ot_i]$. The vehicle is penalized if it reaches the client in the margin $[l_i, l_i + ot_i]$.

Regarding the deposit, it is known that:

- $[e_0, l_0] = [E, L]$ is the time window of the deposit.
- $d_0 = s_0 = 0$ since there is no demand or service time in the deposit.

The set of vehicles is modeled as $K = \{1, ..., k\}$, C represents the set of vehicle types and S_c is the set of vehicles of type c inC . For each vehicle of type $c \in C$, it is known:

- q_c is the capacity of a vehicle of type $c \in C$.
- f_c is the fixed cost of a vehicle of type $c \in C$.
- α_c is the variable cost of a vehicle of type $c \in C$.
- n_c is the number of available vehicles of type $c \in C$.

The decision variables are:

- x_{ij}^k: takes value 1 if vehicle k passes through the edge (i, j) and takes value 0 otherwise.
- a_{ik}: time of arrival of vehicle k to client i.
- o_{ik}: amount of time that the vehicle k exceeds the time range of the client i (it is called "overtime" of vehicle k in the client i").

Finally, other known data are:

- ρ: represents the penalty associated with the overtim of a vehicle in a client.
- ω: represents the percentage of deviation allowed in the time windows. It is used to define ot_i for each client i.
- the value $M = \max(l_i + ot_i + t_{ij} + s_i - e_j), (i, j \in V)$ represents the maximum possible time consumed between two clients.

The VRP with flexible time windows and heterogeneous fleet is formulated as follows:

$$\min \sum_{c \in C} f_c \sum_{k \in S_c} \sum_{j \in N} x_{0j}^k + \sum_{c \in C} \alpha_c \sum_{k \in S_c} \sum_{\substack{i,j \in V, \\ i \neq j}} t_{ij} x_{ij}^k + \sum_{k \in K, i \in N} o_{ik} * \rho \tag{1}$$

subject to:

$$\sum_{k \in K} \sum_{\substack{j \in V, \\ i \neq j}} x_{ij}^k = 1 \ \forall \ i \in N \tag{2}$$

$$\sum_{j \in N} x_{0j}^k \leq 1 \ \forall \ k \in K \tag{3}$$

$$\sum_{i \in N} x_{i0}^k \leq 1 \ \forall \ k \in K \tag{4}$$

$$\sum_{i \in V} x_{ij}^k = \sum_{i \in V} x_{ji}^k \ \forall \ j \in V, \ k \in K \tag{5}$$

$$\sum_{i \in N} d_i \sum_{\substack{j \in V, \\ i \neq j}} x_{ij}^k \leq q_c \ \forall \ k \in S_c, \ c \in C \tag{6}$$

$$a_{ik} + s_i + t_{ij} - M(1 - x_{ij}^k) \leq a_{jk} \ \forall \ k \in K, \ i \in N, \ j \in V, \ i \neq j \tag{7}$$

$$t_{0i} * x_{0i}^k \leq a_{ik} \ \forall \ k \in K, \ i \in N \tag{8}$$

$$a_{ik} \leq (l_i + ot_i) \sum_{\substack{j \in V, \\ i \neq j}} x_{ij}^k \ \forall \ k \in K, \ i \in N \tag{9}$$

$$e_i \sum_{\substack{j \in V, \\ i \neq j}} x_{ij}^k \leq a_{ik} \leq (l_i + ot_i) \sum_{\substack{j \in V, \\ i \neq j}} x_{ij}^k \ \forall \ k \in K, \ i \in N \tag{10}$$

$$E \leq a_{0k} \leq L + ot_0 \ \forall \ k \in K \tag{11}$$

$$\sum_{k \in S_c} \sum_{j \in N} x_{0j}^k \leq n_c \ \forall \ c \in C \tag{12}$$

$$o_{ik} \geq \max(0, a_{ik} - l_i) \geq 0 \ \forall \ k \in K, \ i \in V \tag{13}$$

$$a_{ik} \geq 0 \ \forall \ k \in K, \ i \in N \tag{14}$$

$$x_{ij}^k \in \{0, 1\} \ \forall \ k \in K, \ (i, j) \in A \tag{15}$$

Eq. 1 is the objective function of the problem, that is to minimize the total cost of the proposed routing. Being S_c the set of c type vehicles, the fixed cost and the variable cost of the vehicles that make up the routes are taken into account, as well as the penalties in case of overtime.

The constraint in eq. 2 guarantees that all clients are visited by only one vehicle. Then, eq. 3, eq. 4, and eq. 5 are routing constraints, they make that if a vehicle is used it leaves and returns to the depot only by one route (the vehicle must not return from the same edge and the route must be continuous). Eq. 6 is a capacity constraint and establishes that for each route, the accumulated demand for any client must not exceed the capacity of the vehicle.

The constraint in eq. 7 establishes the precedence relationship between the arrival times of the vehicles to the clients on the routes. This constraint is the linearization of $x_{ij}^k(a_{ik} + s_i + t_{ij} - a_{jk}) = 0 \; \forall \; k \in K, \; i \in N, \; j \in V, \; i \neq j$.

The constraint 8 establishes the shortest arrival time at the first node of the path. The constraints in eq. 9, eq. 10, and eq. 11 refer to the time windows for clients and the deposit, while the constraint 12 limits the number of vehicles available for each type. Finally, the constraints in eq. 13, eq. 14, and eq. 15 restrict the values that the decision variables can take.

From the formulation of the studied problem, it is possible to demonstrate that it is a relaxation of the one proposed by Jiang et al. [5]. On the one hand, the set of feasible solutions of the proposed problem is formed by the union of two sets. The first includes solutions in which vehicles serve clients only within their original time window. The second is made up of solutions where at least one client is served outside of their original time window but within the extended one. The first set corresponds to the feasible region of the problem posed by proposed by Jiang et al. Therefore, the property stating that the feasible domain of the original problem is a subset of the feasible domain of the relaxed problem is satisfied. On the other hand, the total cost of the original problem is made up of the sum of the fixed and variable costs of the solution. While the total cost of the problem raised is made up of the fixed and variable costs and also the penalties in case of overtime. The solutions belonging to the feasible region of the original problem do not present overtime, since it is not feasible to serve a client outside their original time window. This means that in the problem presented, these solutions do not present a penalty. This is why the total costs for this set of solutions coincide in both problems. Therefore, the property that establishes that the objective function of the original problem is greater than or equal to the objective function of the relaxed problem is also satisfied.

As explained above, the two properties of the relaxation definition according to Geoffrion [3] are met. It is clear then that the problem addressed is relaxation of the problem posed by Jiang et al. [5].

2.3 Related work

The classic VRP problem was introduced by Dantzig and Ramser [2] as a generalization of the TSP applied to the distribution of gasoline, looking for the optimal route of a fleet of trucks that deliver between a terminal and several

service stations supplied by that terminal. A formulation of the integer linear programming model for the traditional VRP was proposed by Golden et al. [4].

In general, VRP can be defined as the problem of determining a series of delivery routes for a fleet of vehicles, based on one or more depots, for a certain number of geographically dispersed cities or clients. The objective is then, to satisfy the known demand of the group of clients, setting up routes of vehicles of minimum cost that originate and end in a depot. Therefore, it can be seen that TSP is a particular case of VRP, when there is only one vehicle available without restrictions on capacity or total distance traveled. Given that TSP in an NP-Hard problem and VRP is a generalization of it, VRP is also a problem of the NP-Hard class [7]. In the following years, different variants and extensions have been defined, studied and combined such as heterogeneous fleet, time windows, multiple depots, stochastic demand, pickups and deliveries, multiple trips, open routes, overloads, site dependencies, multi-vehicle task assignment , green routing, single and double container loads, two-dimensional loading, time dependencies, multiple compartments, multiple stacks and collection depots.

Solomon [10] studied the performance of heuristic methods to solve the VRP with time windows, including an early method that consists of placing all clients in a single route and then dividing the route into several smaller routes to respect the time windows, and heuristics based on Waiting-Time Limit, Nearest-Neighbor, Insertion, and Sweep. Time-Oriented Insertion Heuristic was the best method, based on selecting a seed client and from there the rest of the clients are added to the route until the vehicle capacity is completed or the allowed time period is exhausted. Seed clients are the most distant from the central depot or those with the earliest time for delivering.

Regarding exact resolution of VRP and related problems, Bladacci et al. [1] presented an exact resolution framework deriving exact algorithms that allows solving different variants of the VRP (including trained VRP, VRP with time windows, the pick-up and delivery problem with time windows, etc.), provided they can be modeled as Partition Problems with additional constraints.

In turn, many articles have proposed applying heuristics and metaheuristics [8] to solve different variants of the VRP. For the reported research, it is relevant to mention the article by Jiang et al. [5], which introduced an exact formulation for the problem (used as a reference for the problem model formulated in our research by considering flexible time windows). Furthermore, Jiang et al. proposed a two-stage resolution method by extending an existing Tabu Search procedure for VRPTW with a limited number of vehicles. and a post-processing to improve the computed solution. The efficacy of the approach was evaluated for different instances of the VRP, computing accurate results. However, the search process and effectiveness must be intensified by escalating to a larger problem.

3 The proposed exact resolution approach

This section describes the main features of the proposed resolution approach for the VRP with heterogeneous fleet and flexible time windows.

The exact resolution of the proposed model was developed in Optimization Programming Language (OPL) [11]. OPL is an algebraic modeling language for mathematical optimization model, conceived to make the development of optimization algorithms simpler than using general-purpose programming languages. OPL includes features to deal with all the main concepts in real-life optimization. OPL is part of the CPLEX software package

IBM ILOG CPLEX was used as the optimization tool, over the environment defined by Optimization Studio 12.8. Optimal solutions are computed applying a branch-and-cut heuristic, considering three stop conditions for the execution:

- The time limit for the execution (parameter `CPX_PARAM_TILIM`) was set according to the problem instance dimension:
  - Test cases with 25 clients: Limit of one hour of execution time, to compute quick solutions.
  - Test cases with 50 clients: Limit of ten hours of execution times, considered a reasonable time to obtain a solution (e.g. it allows planning routes for delivering the next day).
- Branch-and-cut tree size (parameter `CPX_PARAM_TRELIM`): 51 GB limit, restricted by the computational platform used for the experiments.
- Default GAP tolerance in CPLEX (parameter `CPX_PARAM_EPGAP`): 0.01% (0.0001). It is considered the default value since, the main goal is to compare with previous solutions obtained with that specific limit. The GAP represents, in percentage terms, the distance between the solution found and the best achievable solution. It is defined as $(f(x) - bestBound)/f(x)$, where x is the solution found and $bestBound$ is the best value achievable by the objective function.

4 Experimental results and discussion

This section describes the experimental evaluation of the proposed resolution approach.

4.1 Execution platform

The experimental evaluation was performed using computing resources from two environments with the following characteristics:

- The proposed exact method was executed on an Intel Core i5 2.7 GHz server, with 3 MB shared L3 cache, 8 GB 1867 MHz DDR3, 256 GB Flash Storage.
- Reference solutions for the non-flexible problem variant were computed in a HP ProLiant DL380 G9 server with two Intel Xeon Gold 6138 processors (20 cores each) and 128 GB RAM, from National Supercomputing Center, Uruguay (Cluster-UY) [9].

4.2 Problem instances

Two sets of instances were used, with homogeneous and heterogeneous vehicles. For homogeneous problem instances, the VRPTW test cases proposed by Solomon [10] are used. These instances include data of the locations, demands, time windows, and client service times. Six classes of instances are included: C1 and C2 have grouped clients, R1 and R2 have clients with uniformly distributed locations on a square, and RC1 and RC2 have both grouped and location clients distributed. C1, R1 and RC1 have narrow time windows and small vehicle capacity while C2, R2 and RC2 have large time windows and large vehicle capacity. In turn, for the heterogeneous problem variant, the test cases generated by Jiang et al. [5] are used. Larger vehicles have higher fixed and variable costs. Client locations, demands, time windows, and service times are derived from the benchmark test cases. This way, six new classes are generated: HC1, HC2, HR1, HR2, HRC1 and HRC2 (the H in the beginning of the instance name stands for heterogeneous). Table 1 reports the data of the employed homogeneous and heterogeneous problem instances, including the number of vehicles, their type, capacities, and both fixed and variable costs.

class	*vehicle type*	*# vehicles*	*capacity*	*fixed cost*	*variable cost*
homogeneous instances					
C1	A	25	200	80	1.0
C2	A	25	700	80	1.0
R1	A	25	200	80	1.0
R2	A	25	1000	80	1.0
RC1	A	25	200	80	1.0
RC2	A	25	1000	80	1.0
heterogeneous instances					
HC1	A	20	100	30	1.0
	B	5	200	80	1.2
HC2	A	20	400	100	1.0
	B	5	500	140	1.2

	C	10	120	250	1.4
HR2	A	10	300	45	1.0
	B	5	400	70	1.2
HRC1	A	10	40	60	1.0
	B	20	80	150	1.2
	C	10	150	300	1.4
HRC2	A	10	100	150	1.0
	B	5	200	350	1.2

Table 1: Data of vehicles for the considered problem instances classes

Problem instances for both homogeneous and heterogeneous variants of the problem with 25 and 50 clients are considered. For all instances, ω, the allowed variation of the time windows, is defined as a percentage of its duration. Therefore, the overtime allowed in client i is calculated as $ot_i = (l_i - e_i) \times \omega$. In all the test cases considered, the value $\omega = 0.3$ was set, that is, the allowed variation of the time window is 30%.

4.3 Numerical results

Tables 2 and 3 reports the obtained results for homogeneous problem instances with 25 and 50 clients, respectively. The highlighted light gray cells indicate an optimal solution found by the proposed approach. In turn, the highlighted dark gray cells and bold font indicate a lower cost then the reference value for the non-flexible VRP obtained by Solomon [10].

Table 3: Results for homogeneous problem instances with 50 clients.

Regarding homogeneous problem instances with 50 clients, two optimal solutions were found, and other five solutions with lower cost then the reference value for the non-flexible VRP. The proposed model was not able to compute an exact solution in the specified time limit for two instances with 25 vehicles (C103 and RC102).

Tables 4 and 5 reports the obtained results for heterogenous problem instances with 25 and 50 clients, respectively. In this case, since there are three types of vehicles to use in the fleet (A, B, or C), column *# vehicles* indicates the type and the number of vehicles used.

Table 5: Results for heterogeneous problem instances with 50 clients.

Results in Tables 4 and 5 indicate that the problem using heterogeneous vehicles is significantly harder to solve to optimality for the proposed approach. Only six optimal solutions were found within the considered execution time limit, five for instances with 25 clients and one for instances with 50 clients. For the other instances, it is not guaranteed that the solution computed using CPLEX is the optimal (i.e., the branch and bound method stop after reaching the execution time limit with a GAP value large than the default GAP tolerance (parameter `CPXPARAMEPGAP`). However, the proposed model was able to find solutions for all problem instances solved, unlike in the case for 25 vehicles.

On the other hand, the proposed model using flexible time windows was able to compute eleven solutions with lower cost than the optimal value for the fixed time windows problem variant, for heterogeneous instances.

5 Conclusions and future work

This article presented an exact resolution approach for the VRP with heterogeneous fleet and flexible time windows. The studied problem variant extends the classical VRP formulation by considering flexible (i.e., extended) time windows for delivering products to clients, accounting for a more realistic setting in nowadays scenarios. A penalization is included in the cost function for those vehicles arriving after the end of the time window of a client.

The proposed approach is based on a linear programming formulation implemented using the OPL languaje, in CPLEX. The experimental evaluation focused on evaluating the quality of solutions for two sets of problem instances modeling homogeneous and heterogeneous fleets, built by extending benchmark test cases from the related literature.

Accurate results were reported for the proposed linear programming model. It was able to solve 146 out of the considered 148 problem instances in reasonable execution times. A total number of 16 problem instances were solved to optimality and other 23 solutions accounting for routes with lower cost than for the non-flexible problem variant.

The main lines for future work are related to extend the validation of the proposed approach, and using heuristic/metaheuristic algorithms to efficiently address larger problem instances. The problem model can be extended to a multiobjective formulation by considering trade-off solutions for the simultaneous optimization of the total cost and the quality of service offered to clients.

Determinants of Smart city commitment among citizens from Bahía Blanca, Argentina

María Verónica Alderete[1][0000-0002-9617-7526]

[1] IIESS, CONICET-UNS; Department of Economics, UNS, Bahía Blanca, CP 8000, Arg
mvalderete@iiess-conicet.gob.ar

Abstract. This paper aims to examine the determinants of smart cities activities across individuals from Bahía Blanca, Argentina. Literature has identified different factors explaining citizens' commitment with smart cities, such as education, age, labor condition; and other more subjective factors such as trust and awareness about the smart city concept. A critical determinant of smart commitment is e-readiness or digital readiness; that is, the level of preparedness to properly exploit internet opportunities such as e-government and e-commerce. To achieve this goal, we used a survey conducted on 97 citizens following Moderniza Bahía Facebook from Bahia Blanca, Argentina. By estimating a structural equation model, we obtained that higher levels of ICT use are associated with higher levels of smart city commitment, and that higher awareness of the smart city concept relates to higher levels of smart city commitment. Demographic factors such as age and labor condition also explain ICT use. These insights are useful for city stakeholders and policy makers to design properly smart city policies and strategies for citizen engagement.

Keywords: smart cities; ICT use; demographic factors.

1 Introduction

"Smart cities [which] are a new style of city providing sustainable growth and designed to encourage healthy economic activities that reduce the burden on the environment while improving QoL (Quality of Life) (JSCP, 2012)". We are witnessing a more interconnected and challenging framework that imposes the need to find better solutions for information sharing and transfer among multiple actors involved in shared environments, such as urban cities (Di Nauta et al. 2015).

Under this smart city's scenario, information and communication technology infrastructures are critical tools to improve and support social and urban growth, promoting citizens' participation and governmental efficiency. The adoption of ICT is critical for the performance of smart cities and for the performance of smart activities from the citizen perspective. Smart city services offer citizens a better living envi-

ronment and raise their quality of life (Lee et al., 2014; Piro et al. 2014; Yigitcanlar and Lee, 2014). There are many examples of smart city services such as end-to-end applications that focus on common concerns such as mobility, public services, and safety.

Since urban services are used by citizens, it is of main importance to take account their opinions and perceptions for a correct management of the services (Yeh, 2017). Nowadays, cities do not have a deep enough understanding of their citizens to actively and effectively engage them (European Commission 2013, p. 12). Scholars have highlighted that little research has focused on examining the citizens' commitment with smart cities such as smart practices or activities (Granier and Kudo, 2016). The authors concern there is a gap between the recent political approach that focus on citizens' "engagement" or "participation" in smart cities and the lack of research related to this issue. In fact, the smart city differs from the digital city in the focus given to the relationships among the actors and entities involved and their contribution to the success of all (Nam and Pardo, 2011). However, some recent empirical literature has stressed evidence on the factors that motivate citizens engagement in smart cities (Polese et al., 2018; Cardullo and Kitchin, 2017; Yeh, 2017).

The framework of this study is in line with the Innovation Diffusion Theory and incorporates the allegations in the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al. 2003). Based on UTAUT, citizens (users) with different demographic characteristics would act differently regarding the usage of technology. Building on this reflection, this study provides some understanding on factors that relate to the success or failure of citizens' engagement on smart cities initiatives through an explorative study on the smart city landscape. To achieve these goals, we utilize an online survey conducted to a group of citizens from Bahía Blanca.

In Argentina, 69.4% of individuals use the Internet (two out of three people use the Internet), but only 16.1% of inhabitants have a fixed broadband subscription. On the other side, the active mobile broadband subscription is higher than the fixed broadband reaching 67% (ITU, 2016). Bahía Blanca is a city of about 400 thousand inhabitants located in the southwest of Buenos Aires Province, Argentina. Bahía Blanca is also one of the Argentinean cities beneficiated by the program Pais Digital. Based on the latest data on ICT diffusion at household level published by INDEC in the 2017 technical report, Bahía Blanca is one of the fifth urban places in Argentina with the highest percentage of household using Internet. A better exploitation of the Internet opportunities depends on the education level of population and their digital skills. In this aspect, data based on EPH (Household Permanent Survey) 2016, shows 34% of people older than 25 holds a tertiary or university level complete in the conglomerate Bahia Blanca Cerri. Moreover, 60% of people older than 20 have at least the secondary school complete.

The paper is structured as follows. First, we describe the theoretical framework related to smart cities necessary to establish the hypotheses of the study. Secondly, the methodology and data are explained. Thirdly, we show the results obtained by estimating the structural model and finally, results and conclusions are provided Please note that the first paragraph of a section or subsection is not indented. The first paragraphs that follows a table, figure, equation etc. does not have an indent, either.

2 Theoretical Framework

During the last years, some research has emerged towards the importance of building Smart Cities. Although the concept is not new and there is plenty of definitions, we can distinguish two different approaches. On the one side, a technological view that centers on the ICT role as a mean to deepen and strengthen access to public information and turn city services more efficient (Belissent and Girón, 2013; Nam and Pardo, 2011; Washburn et al., 2010; Paskaleva, 2009; Caragliu, Del Blo and Nijkamp, 2011). On the other side, a wider approach that is related to notions of sustainable economic growth, quality of life, participatory governance, and the reduction of emissions that places the citizen at the center of analysis (Albino et al., 2015; Anthopoulos and Fitsilis, 2010; Winters, 2011; Topetta, 2010; Caragliu et al., 2011; Shapiro, 2006). "The spirit of e-governance in a smart city should be citizen-centric and citizen-driven" (Albino et al. 2015, p. 12). Most definitions of smart cities in this side coincide in five features or characteristics: smart economy, smart governance, smart mobility, smart environment and smart people.

At the same time, evaluation of citizens' perceptions in respect to urban innovations has become relevant (Macke, 2018, Marsal Llacuna, 2015). Macke (2018) focuses on the wider definition of smart cities and evaluates the perception of quality of life of Curitiba, Brazil. From a theoretical perspective, the Diffusion of Innovation theory (DOI) (Rogers, 1962) offers a model to explain the social and technological factors that affect the acceptance of innovative Information Technology (IT). This theory is broadly employed for comparison of initial adoption and continued use in a variety of technologies (Agarwal and Prasad, 1997). Later on, Moore and Benbasat (1991) have proposed the Innovation Diffusion Theory (IDT), which is an extension of DOI theory but it also includes in the ICT adoption a moderating factor termed "personal innovativeness". This term represents an individual's propensity to innovate (Agarwal and Prasad, 1998). If users are more novelty seeking, they may be more accepting innovative technologies. IDT focuses on the technological aspects and then incorporates the users' behaviour and social factors associated with an innovative technology.

Recent empirical evidence has analysed the determinants of citizens' engagement in smart cities initiatives. For instance, Cardullo and Kitchin (2017) analyse the role and context of citizens in smart cities by examining smart city initiatives in Dublin, Ireland which they titled as ''the scaffold of smart citizen participation''. Besides, Polese et al. (2018) offers an empirical investigation from a sociological and psychological perspective, on the perception of citizen services in the city of Brno, Czech Republic. The study centres on the "smart cities" issue as an example of complex service systems (CSSs) and shows how actors' perceptions (cognitive and psychological dimensions) can influence opportunities and willingness for value co-creation and collaboration. Similarly, Caputo et al. (2016c, 2017b) and Saviano et al. (2016) analyse the role of individual perceptions in the evaluation of services and in the definition of possible collaborative behaviours, with specific reference to the domain of the "smart city". On the other side, Yeh (2017) examine citizens from Taiwanese cities

that have participated in smart cities campaigns. Citizens will use smart cities services if they are innovative, high quality and secure (in terms of privacy).

2.1 SC Activities or SC commitment

Many studies show citizens from smart cities have a strong commitment with the development of sustainable and scalable practices such as trash recycling, efficient use of energy resources, among others (Chourabi et al., 2012; Khansari et al., 2014; de Jong et al., 2015; Belanche et al., 2016). Moreover, processes of political and electronic participation are a baseline in development of Smart Cities (Afzalan et al. 2017; Neirotti et al. 2014).

From an environmental perspective, Sovacool (2014) expresses citizens' participation increase democracy. Citizens perceive they are represented in environmental decision-making. Besides, public engagement and learning lead to a behavior change of environmental issues (Bull et al, 2008). Bull and Azennoud (2016) offer an example of citizen engagement in Hampshire, USA. A discussion of an adequate waste strategy was performed to engage the public in decision management of household waste in the city.

2.2 ICT use and SC Activities

By using ICT, public services can be offered online, public information can be easily accessed and citizens can organized among them to share interests and concerns. Moreover, ICT use can facilitate and promote citizens' decision-making and involvement in public life (Vázquez and Vicente, 2019). ICT plays a key role in Smart Cities to connect infrastructures, government and citizens (European Commission, 2013). Paskaleva (2009) highlights that the smart city is based on the "use" of advantages offered by information and communication technology.

Socio-economic demographics differences can give rise to a digital infrastructure gap between cities in emerging economies, such as India, asking for smart city policies implementation (Praharaj et al., 2017). However, in some countries such as India, most technologically advanced cities like Ahmedabad had only 10.3% of its household accessing internet as of the year 2011 (Praharaj et al., 2017). Therefore, ICT access has not been considered a basic infrastructure for building Smart Cities in less developed countries.

ICT have an increasing effect on different facets of people's overall quality of life (Yeh, 2017; Khankhoje, 2004; Deakin, 2014; Makee et al., 2014; Veeckman and van der Graaf, 2015). The technology trends such as mobile, personal devices; broadband connectivity; open data; urban interfaces; and, cloud computing are progressing at a rapid pace. The adoption of ICT applications in e-government is a prerequisite for the emergence of smart cities. By doing e-government, citizens can communicate with governments from different levels (national, federal, regional, local). As a result, citi-

zens' involvement in public sectors governance leads to the improvement of efficiency and effectiveness

ICT use will depend not only on connectivity (Internet access) and on access to digital devices such as computers, tablets, mobile phones, among others, but also on ICT skills. This relationship between access and use is due to the existence of complementarities in the ICT diffusion (Dewan et al., 2010). Personal computers have a stronger impact on the Internet diffusion in developing than in developed countries. Usually, the unequal access to resources and rights is correlated with both ICT appropriation and ICT intensity use. Then, we can state the first hypothesis:

Hypothesis 1: ICT use positively affects citizens' performance of SC activities.

2.3 Awareness of the SC concept and SC activities

Studies based on IDT have shown that the perceived characteristics of innovation can have a significant effect on adopters' behaviours toward the acceptance and usage of innovative ICT solutions (Plouffe et al., 2001), egovernment systems (Carter and Bélanger, 2005; Gilbert et al., 2004; Shareef et al., 2007) and SC services (Yeh, 2017). Similarly, awareness of the smart city concept is a main factor to explain a smart citizens' behaviour. However, Neirotti et al. (2014) find a negative relationship between awareness and SC activities. A possible explanation is that the most polluted cities are located in developing countries in which complete awareness of the SC concept has not yet been established.

Hypothesis 2. The awareness of the SC concept positively affects citizens' performance of SC activities.

2.4 Trust and SC activities

Trust is generally understood as the willingness of one person to count on the behaviours of others, especially when this person is under a vulnerable situation. Trust always supposes the person is ready to accept a certain degree of risk and to become vulnerable to a trusted party (Hosmer, 1995). This approval of risk is based on the expectation that the trusted party will perform actions that are important or beneficial to the vulnerable party (Eid, 2011).

If Citizens trust in the ICT-based SC services, they will positively accept and use the ICT-based SC services (Yeh, 2017). However, Vazquez and Vicente (2019) do not find trust on governments is a significant factor to explain e-participation, which is one of the dimensions of smart cities (smart governance). Therefore, we can pose hypothesis 3.

Hypothesis 3: Citizens' trust in e-goverment positively affects citizens' performance of SC activities.

2.5 Demographic factors and SC activities

Demographic characteristics affect the use of a given product or service (Webb et al., 2012), probably because the needs of citizens vary according to their educational level, gender and age. However, results on the impact of demographic factors on usage are not conclusive. Yeh (2017) show Taiwanese citizens' attitudes and behaviours toward ICT based SC services are not affected by their demographic characteristics in terms of age, gender, and education reinforcing the public nature of services, which are oriented toward the whole community. On the other side, Vázquez and Vicente (2019) observe socioeconomic factors such as age, educational attainment and labour situation are significant factors to explain citizens' e-Participation, while gender is not significant.

Citizens' education is one of the main determinants of people's digitalization level (Gutiérrez et al.,2010). The educational condition is a significant predictor of ICT use. An educated individual can access cognitive resources, digital skills and more important, social and knowledge resources. Some studies have claimed that education affects the probability of using Internet (Vicente and López, 2006) and the diffusion of Internet (Kiiski and Pohjola, 2002; Hargittai, 1999). In particular, Hargittai (1999) observes that education significantly enhanced the penetration level of Internet hosts across countries. Besides, Kiiski and Pohjola (2002) show that mean years of schooling is a significant factor to explain the growth of Internet hosts per capita. On the other side, Chinn and Fairlie (2007) did not observe a significant correlation between the variables.

Hence, education can indirectly determine the development of SC activities. In this line, Belanche, Casaló and Orús (2016) show citizens' educational level positively affects urban services usage since the more educated the people, the higher the environmental consciousness will be. The higher the educational level (human capital), the greater the probability of using ICT will be. People that are more educated have better access to information about the SC benefits and how to perform intelligent activities. Hence, the development of SC activities will be higher.

Hypothesis 4: The more educated the people, the higher the ICT use; and therefore, the higher the citizens' performance of SC activities will be.

Gender is also considered an important factor to predict the use and acceptance of technology related applications or systems. The decision-making processes are different between men and women (Tarhini, Hone, and Liu, 2014; Al-Shafi and Weerakkody, 2010; Wang et al., 2009; Dwivedi and Williams, 2008).

Hypothesis 5: Men are more likely to ICT use than women are; and therefore, they are more likely to perform more SC activities than women are.

On the other side, older people perceived lower potential profits from innovating than younger people because they attribute a higher discount rate to future profits. While young people are more prone to have ICT access (Grazzi and Vergara, 2011), older people usually use the Internet to a lesser extent (Gutiérrez et al., 2010; Barrantes, 2007). There are differential effects regarding the affect-creativity association, dependent on employees' age (Volmer et al., 2018). Therefore, age is a proxy of personal innovativeness and can be employed as a preliminary factor to understand the characteristics of adopters (Agarwal et al., 1998) and the level of Acceptance/Usage of ICT-based SC services (Yeh, 2017).

Hypothesis 6: The older people are less likely to ICT use and, therefore, to perform SC activities mediated by ICT such as e-commerce, e-government, among others.

Finally, income is an important determinant of ICT adoption as it indicates the households' budget constraint (Grazzi and Vergara, 2011; Barrantes, 2007; Vicente and Lopez, 2006). One of the users' characteristics that affect the intra-country digital divide is related to income (Zhang, 2013). The greater the household income, the higher the probability of using the Internet is (Alderete, 2018). The lack of income does not allow citizens to take part in the ICT demand. Therefore, unemployed or people with a transitory job are less likely to use ICT.

Hypothesis 7: Citizens with a permanent job are more likely to use ICT, and therefore, to perform SC activities.

Based on this research background, the model examines the causal relationship among the smart cities activities and demographic factors by describing the mediating role of ICT use. Hence, citizens' gender, age, education level and labour condition are the control variables of the proposed framework by explaining directly ICT use, and Indirectly SC activities. Figure 1 offers a graphical representation to explain the model.

3 Methodology

We use data obtained from an online survey directed to the followers of the Facebook fan page "Moderniza Bahía". The survey was conducted between April and May 2019 and was supported by the Secretary of Modernization of Bahía Blanca Town Hall. During these two months, we collected data from 97 citizens.

The questionnaire was based on several literature sources on e-government and smart cities (Weeradoky et al.2016; Alshehri et al. 2012; Chen, 2010; Teo et al., 2008). It collects information about the citizens' profile (age, education, labour condition, and ICT use), smart cities and e-government. Questions are closed and most of them are Likert scale questions.

The size of the sample is 97; we collect 97 valid observations during the two months period of diffusion of the survey. The sample size is enough for a finite popu-

lation sampling (lower or equal than 100000) (Vázquez y Trespalacios, 2002). The sample responds to the following formula:

$$n = \frac{Z^2 * N * P(1-P)}{(N-1) * K^2 + Z^2 * P(1-P)}$$

Where N is total population. In this case, followers of Moderniza Bahía Facebook., N=16400 by April 2019.

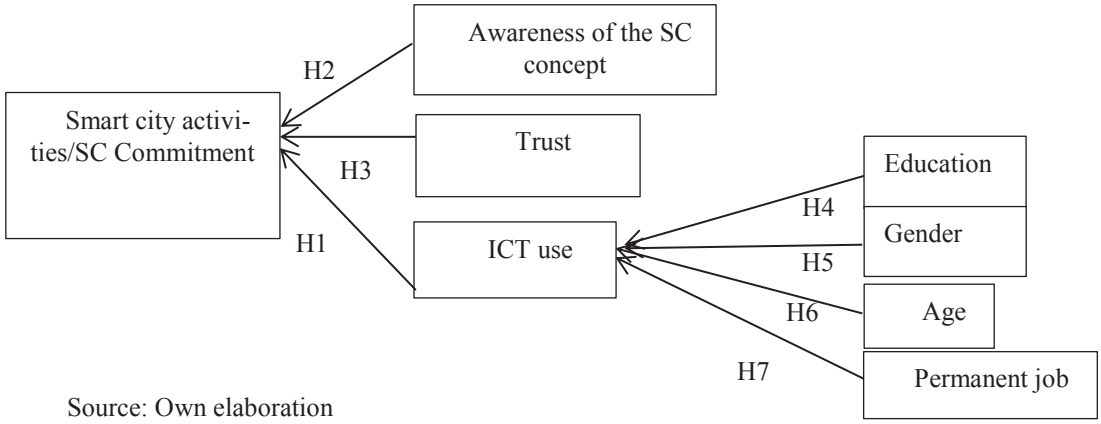
Z is the value obtained from significance levels. If population distribution is normal at a significance level of 95%, z value is 1.96. In this case, with a significance level of 90%, the corresponding z is 1.645; and so on.

K is the error or maximum difference between the sample proportion and the population proportion to be accepted based on the significance level proposed. For a significance level of 95%, k is 0.05; similarly, for a significance level of 90%, k is 0.1, as in this case.

P is the population fraction of interest. A parameter that indicates the percentage of population interested in smart cities. It can be obtained from a pilot survey; but if it is an unknown parameter, as in this case, it is suggested to use the most unfavourable value of 50%.

For each question, respondents were asked to declare their opinion using a five-point Likert scale (Matell and Jacoby, 1971) in which 1 = "strongly disagree" and 5 = "strongly agree."

We study the relationship between Smart city activities and ICT use by estimating a Structural Equation Modelling (SEM). Although there are different statistical packages, we utilize STATA 14 to perform the estimations. STATA software only uses CB-SEM (Bernardes do Nascimento and da Silva Macedo, 2016).



In this frame, SEM models are of two different types with regard to the statistical approach (non-parametric or parametric testing), the objective of the study (exploratory or confirmatory), and, especially, the algorithm employed (Generalized Least Square (GLE) or Maximum Likelihood Estimator (MLE))(Esposito, 2009). These differences lead to Variance Based Structural Equation Modeling (VB-SEM) and the Covariance Based Structural Equation Modeling (CB-SEM), respectively.

This paper uses a CB-SEM model, which is SEM based on the covariance matrix. CB-SEM goal is to test and confirm the theory by using data (exploratory model). The difference between the theoretical covariance matrix and the estimated covariance matrix (based on data) is minimized to estimate the parameters (Hair et al., 2011). Indicators of goodness of fit arise due to the difference between the empirical and theoretical covariance matrix (Hair et al., 2009),

On the other side, there are PLS (Partial Least Square) models which are SEM models based on the variance matrix (VB-SEM). However, PLS-SEM objective is building theory based on the emerging relationships (in the same way as multiple regression analysis). Thus, it is a more exploratory model. PLS-SEM emerges from the discrepancy between the observed values and/or the dependent latent variables and the values estimated by the model (Hair et al., 2011). Hence, measures or indicators of the predictive capacity of the model using PLS-SEM are of main importance to determine the quality or goodness of fit of the model, such as reliability, explained

variance, among others; which is not needed in CB-SEM models (Henseler et al., 2009). Figure 1 shows the causal relationships to be tested.

Figure 1.The model to be estimated

Source: Own elaboration

3.1 Variables

The structural model is compound of two structural equations since there are two endogenous variables: SC activities and ICT use.

SC activities: SC activities is a variable (non-observable) obtained by using a factorial analysis among a set of indicators (Table 1).

Table 1. Communalities from factor analysis among SC activities

Smart City dimension	SC activities	Initial	First extraction	Second extraction
Smart environment	Reduction of private transports (car. moto)	1.000	.597	.607
	Use of public transport	1.000	.698	.699
	Use of bike lanes	1.000	.391	
	Recycle or classify waste	1.000	.606	.760
	Rational water consumption	1.000	.723	.742
Smart government	Interaction with local government through internet (e-government)	1.000	.515	.497
Smart economy	Electronic commerce (sale-buy through internet)	1.000	.495	.509

Smart mobility	Use of SAMPEM Parking (parking app)	1.000	.562	.586
Smart people	Home-banking or financial transaction online (i.e.: pay taxes)	1.000	.738	.739
	E-learning	1.000	.617	.652

Source: Own elaboration.

To develop a construct or variable for measuring SC activities in citizens from Bahía Blanca, a set of items were included based on a thorough review of the smart city literature and mainly on the project's questionnaire. Citizens were asked to provide information about the kind of smart activities performed from reduction of public transport to e-learning.

Both the Kaiser-Meyer-Olkin Measure of Sampling Adequacy and the Bartlett's test of sphericity indicate that the factor analysis may be useful with the data. The KMO measure of sampling is nearly 0.6, if the value were less than 0.50, the results of the factor analysis probably will not be very useful. On the other side, the p value related to the Bartlett's test of sphericity is zero, indicating that these variables are related and therefore suitable for structure detection.

Table 1 shows communalities from each SC activity acquired by performing a Component Principal Analysis. We observe that the item or variable "Use of bike lane" is not relevant for explaining the variance (since communality from the first extraction is lower than 0.4). Then, we made the second extraction to define the significant items. After that, by using the components extracted, we build the SC activities index. Table 2 reports the first four factors that explain nearly 64 per cent of the variance.

Table 2. Total variance explained

Components	Initial eigenvalues			Extraction sums of squared loadings			Rotation sums of squared loadings		
	Total	% of variance	% accumulated	Total	% of variance	% accumulated	Total	% of variance	% acummulated
1	2.021	22.459	22.459	2.021	22.459	22.459	1.919	21.321	21.321
2	1.521	16.903	39.362	1.521	16.903	39.362	1.609	17.874	39.195
3	1.222	13.579	52.941	1.222	13.579	52.941	1.166	12.956	52.152
4	1.026	11.403	64.343	1.026	11.403	64.343	1.097	12.192	64.343
5	.847	9.417	73.760						
6	.754	8.375	82.135						
7	.662	7.358	89.493						
8	.530	5.890	95.383						
9	.415	4.617	100.000						

Extraction method: Principal Components analysis

To construct the SC activities index, we compute the weighted sum of the four components. Each weight represents the proportion of variance of each component related to total variance. The average value of the SC activities index reaches 0.51.

ICT use: This variable represents an independent explanatory factor of SC activities. The hypothesis is the higher the ICT use, the higher the propensity of developing SC activities such as e-commerce, e-government, among other.

ICT use is also an endogenous variable in the model, which is mainly explained by demographic factors. We use the same methodology as the SC activities index to build the variable ICT use. ICT use is a variable obtained from a factorial analysis among a set of ICT use indicators. People were asked to provide information about the places use to connect Internet as well as the devices employed. The higher the number of places and devices used to connect internet, the higher the intensity of using Internet will be.

Since we have built ICT use as an exogenous variable by using factor analysis, we show the suitability of the data for structure detection. Both the Kaiser-Meyer-Olkin Measure of Sampling Adequacy (nearly 0.52) and the Bartlett's test of sphericity (p value 0.000) indicates that the factor analysis may be useful with the data. Tables 3 and 4 shows information needed to this task.

Table 3. Communalities from factor analysis in ICT use

	Initial	First Extraction	Second Extraction
Internet Access at home	1.000	.862	.868
Internet Access at work	1.000	.581	.702
Internet Access in educational places	1.000	.572	.571
Internet access in commercial places	1.000	.625	.670
Internet Access in Public places	1.000	.701	.736
Use computer to connect Internet	1.000	.656	.689
Use mobile phones to connect internet	1.000	.870	.872
Use Tablet to connect Internet	1.000	.363	
Use TV to connect Internet	1.000	.449	.468
Use E-Reader to connect Internet	1.000	.487	.478

Extraction method: Principal Components analysis

Source: Own elaboration

Independent variables of SC Activities:

Web-Trust: trust in the web is an important factor of the willingness of citizens to doing e-commerce, e-government, among other SC activities. Web trust refers to trust in the municipality's website; is an ordinal Likert scale variable that ranges from 1 (totally disagree) to 5 (totally agree).

SC-Awareness: it related to how much local citizens are aware of the Smart Cities concept. The survey asks each citizen if he was acquainted with the smart cities concept. It's an ordinal variable that ranges from "have never heard about that" to "I have heard about it but I do not know much"; "I know the concept, what it means and how cities are implementing it"; "I am researching about smart cities ideas" and lastly, "I am planning or implementing one or more smart cities projects."

Independent variables of ICT use:

Age: Age is a scalar and continuous variable. Each participant is asked to report his or her age in the survey.

Education: High_education is a binary variable that takes value 1 if the individual has reached a tertiary or university degree and zero, otherwise (whose maximum education level is lower than tertiary).

Income: Permanent_job is a binary variable that values 1 if the individual works in a permanent job, and zero otherwise. The survey does not collect information on income. However, labour condition can be a proxy of income. We suppose citizens without a permanent job are in a more vulnerable condition to support connectivity and therefore, ICT use than the rest (people with transitory or informal jobs; unoccupied; among others).

Gender: A binary variable that takes value one if the individual is a man and zero if it is a woman.

4 Results

This SEM model does not include a measurement model since there are no latent variables. Due to the limited number of observations, we do not add latent variables but include non-observable variables (such as ICT use, SC activities) by using factorial analysis.

In this section, we test the goodness of fit of the structural model (Table 5). The Chi Square test is a test of exact fit that confirms the structural equation model estimated can explain the theoretical model. Chi square values near zero shows an adequate goodness of fit. Based on this model, Chi square is 6.4 with a p-value of 0.38. As a result, the hypothesis of a perfect correspondence between the estimated matrix and the observations matrix cannot be rejected.

On the other side, we analyse the Root Mean Square Error of Approximation (RMSEA) to provide a more sensible approach than the Chi Square test. The model fit is good if RMSEA is lower than 0.05 and does not surpass the lower bound of the 90 percent confidence interval (Steiger, 1990). We can determine the model fits well because RMSEA reaches a value zero.

Moreover, there is an overall measure of bad fit known as the Root Mean Square Residual index (RMR). This indicator is based on the fitted residuals that are scale dependent (]öreskog and Sörbom, 1981). Therefore, the Standard RMR (SRMR) is a more accurate indicator. If SRMR is lower than 0.05, it indicates a good fit of the model (Hu and Bentler, 1995).

Table 5. Goodness of fit of the structural model

Statistic	Value	Description
Likelihood Ratio		
Chi square_ms(6)	6.405	model vs. saturated
p > chi square	0.379	
Chi square_bs(13)	23.281	baseline vs. saturated
p > chi square	0.028	
Population Error		
RMSEA	0.027	Root Mean Square Error of Approximation
90% CI, lowerbound	0.000	
, upperbound	0.139	
Pclose	0.623	RMSEA probability<= 0.05
Size of residuals SRMR	0.038	Standardized root mean squared residual

Source: Own elaboration based on Stata 14.

Once the goodness of fit of the model was determined, we examine the structural model results (Table 5). Based on Table 5, ICT use positively affects the SC activities (β=0.286) (hypothesis 1). Higher levels of ICT use shows citizens are more digitized and probably have better digital skills than the rest. As the ICT use is greater, citizens can perform smart cities activities. People with fewer ICT use will not be able to develop all kind of smart cities. For instance, citizens without smartphones are less likely to use parking apps or doing e-commerce.

Besides, trust on the website directly affects SC activities (hypothesis 3). Trust significantly and positively explains SC activities (β=0.06). Therefore, citizens with a higher level of trust on the website are more likely to buy products and contact local governments. This finding contradicts Vazquez and Vicente (2019) but is in line with most of the literature (Yeah, 2017; Hosmer, 1995). Furthermore, awareness of the smart city concept is a significant predictor of doing smart city activities (hypothesis 2, β=0.049). The more aware people are about the concept of smart city, the more prone they are to do smart activities. This result confirms previous literature in the subject (Yeh, 2017; Neirotti et al., 2014).

On the other side, labour condition and age are the two significant factors of ICT use. Citizens with a permanent occupation have a greater ICT use than the rest. Besides, the younger the citizen, the more likely he will use ICT more intensively. This result follows previous studies (Volmer et al., 2018, Yeh, 2017). Hence, young citizens with a permanent job will indirectly do smart activities.

Moreover, the education level is not a significant factor of ICT use, contrary to the literature review provided (Belanche et al., 2016; Kiiski and Pohjola, 2002; Hargittai, 1999). This result is not surprising considering the sample selection bias. It is likely that respondents of an online survey have more digital skills and education than the whole population. On the other side, gender is not a significant factor of ICT use or SC activities.

Table 6. Structural models

Variable	Structural equation SC Activities	Structural equation ICT use
ICT use	.2865806**	
Trust	.0063282**	
Awareness	.0492644 ns	
Education		-.0204209 ns
Labour_condition		.075872**
Age		-.0029159**
Gender		.0039698 ns

Source: Own elaboration.
Notes: ns means not significant; ** significant at 5% level.

5 Conclusion

The main contribution of this paper is to offer some highlights about the citizens' perception on smart cities in a city from a developing country as Argentina. In particular, the paper examines the determinants of smart cities activities across individuals from Argentina. Although there is some empirical literature on this subject in developed countries, much less research has been conducted in the developing world where infrastructure and technological conditions are different. The paper also provides some insights useful for city stakeholders and policy makers to design properly smart city policies and strategies for citizen engagement.

Based on the results obtained, local governments should focus attention on performing an ex-ante process to promote ICT use and bring trust to the web. This strategy will be useful to encourage activities or initiatives of smart city among citizens, especially young citizens and those having a permanent job. Moreover, this policy seems to be more significant than motivating citizens about the benefits and opportunities related to the smart city since awareness of smart cities is not a significant factor for encouraging SC activities. Public authorities should coordinate and cooperate

with civic associations to raise trust and facilitate the understanding of Smart Cities' initiatives and projects. This policy follows the international successful experience of global cities such as London, where citizens drive change in the same way as technocrats, business or policy makers.

Some limitations of the model are the omission of some variables such as Citizens' civil engagement; the sample size that is not large enough, and the sample selection bias, since the survey was conducted to followers of the municipality's social network. Therefore, results represent that population, and not the whole citizens of Bahía Blanca. It would be useful to reproduce the survey to other citizens' profiles. For instance, a survey conducted to citizens without internet access or use.

Resumen. Asignar recursos en épocas de crisis, más en tiempos de pandemia, se torna un problema prioritario en las organizaciones actualmente, caso de los sistemas de servucción, haciendo especificidad en la industria de la hospitalidad, en la cual la demanda es escaza o nula, lo que impacta de manera significativa su sostenibilidad debido a que afecta su productividad y su rentabilidad, es así que, urge implementar metodologías agiles que conlleven a una reorganización y/o definición de procesos para establecer así con la mejor asertividad los recursos que realmente se requieren en aras de responder de manera efectiva a los requerimientos del mercado actual. Teniendo en cuenta este planteamiento el presente trabajo describe la aplicación de una metodología denominada adecuada asignación de recursos en sistemas de servucción, sobre un caso de estudio particular de una organización de servicios de hospitalidad Categoría III, en la ciudad de Cartagena de Indias Colombia, la cual para el departamento de Bolívar represente el 70,3% del PIB y de este el 4,4% lo aporta Cartagena representado en actividad turística. Para el caso de Colombia para el 2020 se esperaba un incremento del 3,5 al 3,8% de aporte del turismo al PIB, pero no se logró debido al efecto Covid – 19. De manera general se observa una empresa que se equivoca en la definición de los recursos necesarios para actividades misionales comprometiendo la eficiencia y la calidad de su operación.

Keywords: Asignación de recursos, Lean Services; servucción, industria de la hospitalidad, Covid -19

Abstract. Allocating resources in times of crisis, more in times of the pandemic, becomes a priority problem in organizations today, in the case of service systems, making specificity in the hospitality industry, in which demand is low or void, which significantly impacts its sustainability because it affects its productivity and profitability, is that, it is urgent to implement agile methodologies that led to a reorganization and / or definition of processes to establish with the best assertiveness the resources that are really required in order to respond effectively to

the requirements of the current market. Taking into account this approach the present work describes the application of a methodology called adequate allocation of resources in service systems, on a particular case study of a Category III hospitality services organization, in the city of Cartagena de Indias Colombia, which for the bolivar department represents 70.3% of GDP and of this 4.4% is provided by Cartagena represented in tourist activity. For Colombia for 2020, an increase of 3.5 to 3.8% of tourism's contribution to GDP was expected, but was not achieved due to the Covid – 19 effect. In general, there is a company that is wrong to define the re-courses necessary for missionary activities by committing the efficiency and quality of its operation.

Keywords: Resource allocation, Lean Services; servuction, hospitality industry, Covid -19.

1. Introducción

Cuando de servucción se habla nos remitimos especialmente a aquellos sistemas productivos de altísima complejidad y variabilidad, dado sus características, que tienen como misión fundamental fabricar o prestar servicios (Garzón Sáenz, Solana Garzón, Ortiz Piedrahita, & Cogollo Sepúlveda, 2017), y que se fundamenta en la aplicación de un modelo gerencial que equipara la "producción" como fabricación del producto, con la "servucción" como la fabricación del servicio (Briceño de Gómez & García de Berrios, 2008). Dentro de estos podemos citar muchos ejemplos tales como: Restaurantes; Hoteles; Bares; Instituciones de Educación Superior; Centros Comerciales; Instituciones de Educación Media y Básica; Centros de Servicios de Salud; Clínicas y Hospitales desde baja complejidad hasta alta complejidad; Centros recreacionales, entre muchos otros que en la actualidad dinamizan la economía mundial convirtiéndose así en todas las naciones en la principal fuente de generación de empleo y de aportación al producto interno bruto de las mismas (Arellano Díaz, 2017).

En entrevista realizada a Nanno Mulder Jefe de la Unidad de Comercio Internacional de la División de Comercio Internacional e Integración de la Comisión Económica para América Latina y el Caribe (CEPAL), este establece que los servicios son, por lejos, el sector predominante de las economías de América Latina y el Caribe, representando el 70% del PIB y 62% del empleo total en 2015 (Schuster, 2018), hoy en día, los servicios representan alrededor de dos tercios del valor agregado total mundial, pero el camino hacia la economía de servicios no ha sido el mismo en todos los países. Las economías desarrolladas se han estado moviendo hacia los servicios de forma continua, y hoy en día son las economías más orientadas a los servicios en el mundo, generando un 75-80 % del valor añadido en los servicios. Los servicios no constituyen una proporción tan alta en las economías en desarrollo, a excepción de algunos pequeños países que se especializan en el turismo o en los servicios públicos. En los países del Caribe, el sector servicios llega a un 74 % del valor añadido (Aboal, y otros, 2015).

Para efectos de enfocar este documento, el mismo se direccionará hacia un eslabón de la servucción como lo es, la industria de la hospitalidad también conocida como industria hotelera la cual en términos generales se encarga de fabricar y ofertar servicios

de alojamiento temporal; alimentos y bebidas, recreación entre otros relacionados a turistas de índole local; nacional e internacional (Vásquez Gómez & Osorio García, 2016). El concepto de hospitalidad puede ser definido como un proceso ritual que invoca la protección de un turista nacional o extranjero bajo la dinámica de circulación material de la propia sociedad, por lo tanto, factible de ser comercializada. Los sectores que otorgan hospedaje son aquellos económicamente y políticamente en condiciones de dar dicha protección (Korstanje, 2010). La industria de la hospitalidad en la actualidad y desde tiempos remotos ha tenido un gran auge y crecimiento dado el gran desarrollo que se ha generado como consecuencia de la globalización, el cual es un proceso económico, tecnológico, social y cultural a escala mundial de los países capitalistas desarrollados fundamentalmente, que consiste en el crecimiento de la comunicación y la interdependencia de mercados, sociedades y culturas. Y se caracteriza por la integración de las economías nacionales dominadas por las empresas multinacionales y la libre circulación del capital industrial y financiero; el incremento de la conectividad humana expresada en el desarrollo del transporte y las telecomunicaciones; el auge de las redes sociales; y la integración política en bloques regionales y globales lo cual ha establecido la necesidad irrefutable sobre todo para los inversionistas de dormir fuera de casa en aras de gestionar sus potenciales inversiones (Meza Perez, Zaldivar Puig, & Fernandez, 2016). Lo anteriormente planteado en paises como el caso de Colombia y en especial como la ciudad de Cartagena de Indias la cual además de servir como epicentro turístico y hotelero dada su historia, hoy en día por su ubicación estratégica se ha convertido en punta de lanza para el comercio internacional, para el turismo de reuniones y otras derivaciones de esta (Bustillo Castillejo & De la Espriella Mendoza , 2013), lo que ha traído consigo la llegada a la misma de muchas personas de diversas nacionalidades a gestar cualquiera de las derivaciones de turismo existentes, Cartagena está preparada para recibir todo tipo de turismo: desde el vacacional hasta el de negocios. Su ocupación hotelera en 2018 fue del 66,6 por ciento y ese mismo año se convirtió en el segundo destino del país a donde llegan más extranjeros, después de Bogotá. Mientras que en 2008 Cartagena recibió alrededor de 567.000 viajeros en vuelos nacionales, en 2017 la cifra superó los 2 millones. Según el Dane, en 2016, La Heroica representaba el 70,03 por ciento del peso relativo del PIB de Bolívar y, de ese total, el turismo simbolizaba el 4,4 por ciento del departamento (Revista Semana, 2019) En cuanto a vuelos internacionales en 2017 la cifra fue de 328.483, que equivale a un incremento del 200% en los últimos diez años. Adicionalmente, en cruceros, durante 2009 la ciudad recibió más de 270 mil turistas en cruceros y para 2017 se registraron 338.172 según cifras Corpoturismo, el aumento fue del 25% (Cartagena como vamos, 2020).

Según el reporte provisional del DANE para 2016, la participación del turismo dentro del Producto Interno Bruto de Colombia representa el 1,9%, equivalente a más de 28 billones de pesos. Si hacemos una desagregación por departamentos, para Bolívar la rama de Hoteles, restaurantes, bares y similares representaron el 3,1% del PIB departamental en 2016. El DANE muestra a precios constantes que desde el año 2000 hasta 2016 se ha registrado un incremento de esta rama en Bolívar del 119%, pasó de 372 mil millones de pesos a 815 mil millones, es decir, un crecimiento promedio anual aproximado del 5% (Cartagena como vamos, 2020). Esto ha establecido la necesidad

de fortalecer la capacidad hotelera y como consecuencia se ha permitido el acceso de nuevas cadenas hoteleras o el fortalecimiento y renovación de las ya existentes en aras de mejorar su capacidad de hospedaje, impactando a los hoteles de pequeños y de mediano nivel los cuales han tenido que hacer esfuerzos por mantenerse a flote debido el carácter estacional de dicha industria (Garzón Sáenz, Ramos Franco, & Imitola Villa, , 2018), dado también los grandes rubros que se requieren para mantener en un buen nivel los servicios ofertados, además de esto en la actualidad esta industria se ha visto impactada de manera notoria por la proliferación del Covid -19 que ha establecido la necesidad de suspender actividades dado el alto riesgo que representa su funcionamiento debido a que los servicios en la industrial de la hospitalidad requieren alto nivel de contacto persona a personal, lo que ha traído como consecuencia el despido masivo de personal y la crisis económica de muchas por no decir la totalidad de las empresas del sector más en una ciudad como Cartagena donde como lo hemos descrito el turismo y en especial la industria de la hospitalidad juega un papel importante en el PIB de la ciudad y en la calidad de vida de sus habitantes (Asociación Española de Expertos Turísticos, 2020).

Según el informe especial de la CEPAL Como se describe en este mismo informe especial de la CEPAL, para el caso de América Latina y el Caribe, esta enfrenta la pandemia desde una posición más débil que la del resto del mundo. Antes de la pandemia, la CEPAL preveía que la región crecería un máximo del 1,3% en 2020. Sin embargo, los efectos de la crisis han llevado a cambiar esa previsión y pronosticar una caída del PIB de al menos un 1,8%. Sin embargo, no es de descartar que el desarrollo que la pandemia lleve a previsiones de contracciones de entre un 3% y un 4%, o incluso más (CEPAL, 2020).

Dado lo anterior y la importancia que representa la industria de la hospitalidad para el desarrollo mundial y local de la naciones y ciudades que la conforman se hace necesario adoptar medidas conducentes a mejorar el uso de los recursos requeridos para la operatividad de este tipo de contextos y hacerlos más productivos y rentables, lo que implica identificar que actividades o que aspectos no agregan valor el que hacer de dichas empresas para así determinar con la mayor exactitud posible que es necesario para garantizar servicios hoteleros de calidad durante la pandemia y una vez se salga de los efectos de la misma, surgiendo así como alternativa el Lean Services, con la cual se pretende la mejora en la eficiencia, velocidad de respuesta y flexibilidad en servucción de las empresas de servicios por medio de la administración basada en procesos y la eliminación de desperdicios, permitiendo así que tales organizaciones oferten diversidad de servicios al menor costo con altos niveles de productividad, rapidez en entrega, niveles mínimos de stock y óptima calidad (Arango Vásquez & Rojas López, 2018). Como lo describe (Gupta, Sharma, & Sunder M., 2016), aunque las organizaciones de servicios se tardaron en asimilar y usar la metodología Lean Services la cual es una derivación del Modelo Productivo Toyota (TPS), existen grandes retos en el uso de la misma por parte de los sistemas de servucción ya que un reto clave con los servicios es gestionar la intangibilidad de los residuos que surgen debido a la dificultad para identificarlos y a la presencia del cliente como coproductor. Otro desafío para aplicar Lean

en la industria de servicios es la falta de conciencia sobre los beneficios de implementar Lean en una organización de servicios como consecuencia del desconocimiento o inexperiencia en este tipo de metodologías con la cuenta los equipos que conforman a estas organizaciones y por otro lado como lo concluye (Hadid, Mansouri, & Gallear, 2016), Es necesario seguir trabajando para establecer una mejor planificación o secuenciación de la implementación del sistema lean. En aras principalmente de contribuir con el impacto directo de las prácticas de servicio lean en el rendimiento operativo y financiero de las empresas que conforman dicho contexto lo cual sustenta de buena manera el objetivo principal del presente estudio.

2. Metodología

Para el desarrollo del presente trabajo la metodología usada fue de tipo descriptiva, y se aplicó en un caso particular de una empresa que oferta servicios de hospitalidad de categoría 3, mediante entrevistas directas y mesas de trabajo en conjunto con la alta dirección de la misma, así como, con personal ejecutivo de alta confianza de las distintas funciones gerenciales, operativas y de soporte que en esta se desarrollan. Soportado en tres etapas así:

a) Diagnóstico empresarial basado en la metodología de empresa fuerte y sostenible diseñada por el equipo de consultores asociados a la gran alianza dentro del marco del proyecto de fortalecimiento al tejido empresarial, el cual se desarrolló en aquellas regiones donde Ecopetrol tiene operaciones en aras de fortalecer el tejido empresarial de dichas regiones.
b) Diagnostico especifico basado en la metodología de árbol lógico o árbol de problema.
c) Y finalmente se aplicó el paquete viable de soluciones (PVS), Denominado adecuada asignación de recursos en actividades misionales, con un énfasis en el análisis de la cadena de valor (VSM) con el propósito de identificar desperdicios o mudas en los eslabones que conforman la cadena de valor del sistema de servucción asociado a la industria de la hospitalidad intervenido y así establecer un plan de acción orientado a mejorar la productividad, la calidad y la rentabilidad de la organización.

3. Resultados

En este apartado describiremos cada una de las etapas desarrolladas para establecer la adecuada asignación de recursos en el sistema de servucción asociado a la industria de la hospitalidad intervenido y los resultados derivados de dicha aplicación.

3.1. Diagnóstico Empresarial.

El diagnóstico empresarial consistió en verificar el estado actual de la empresa en estudio, alrededor de 5 atributos definidos por el modelo de empresa fuerte y sostenible y

derivados del proyecto de fortalecimiento del tejido empresarial colombiano (ver Figura 1) (Unión Temporal Universidad Jorge Tadeo Lozano, E. C., 2013) que fue diseñado por el equipo de trabajo de la Unión Temporal, con el apoyo de Ecopetrol, Confecámaras y las Cámaras de Comercio. La firma Caso Consultores, experta en temas de negocio desarrolló y validó los instrumentos que componen esta herramienta (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas, 2013).

Figura 1. Modelo Empresa Fuerte y Sostenible

Para la construcción de esta metodología, se definieron los atributos (5 en total) que una empresa fuerte y sostenible debería tener, así como las características (29 en total) y las variables que los componen (172 en total). Este proceso tomó como referencias teóricas y metodológicas: el documento Enfoque a una metodología para la identificación de componentes que crean condiciones de durabilidad en las empresas colombianas (escrito por un grupo de investigadores de la Universidad del Rosario en Bogotá, encabezado por el Dr. Luis Fernando Restrepo Puerta), el Modelo de Excelencia para la Competitividad de la Corporación de Calidad y más de cien textos académicos y empresariales. Con esta base conceptual se identificaron las variables que pueden tener una organización y se analizó el nivel de causalidad entre ellas y sus relaciones, para ello se utilizó Matrix Vester como herramienta (ver figura 2), una herramienta de análisis que permite evaluar la influencia y dependencia de las variables que componen el sistema empresarial (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas., 2013).

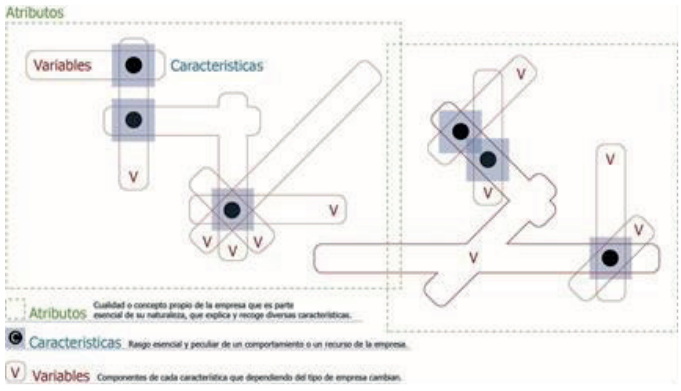

Figura 2: Relación de los atributos, características y variables.

El comportamiento de las variables se comparó con el comportamiento de 11 variables estudiadas en el mercado objetivo (que corresponde al que la empresa se encuentra actualmente, como en la que espera consolidarse en un periodo de 3 años), la aplicación de esta Metodología dio lugar al siguiente gráfico de radar (Ver Gráfico 3) (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas., 2013):

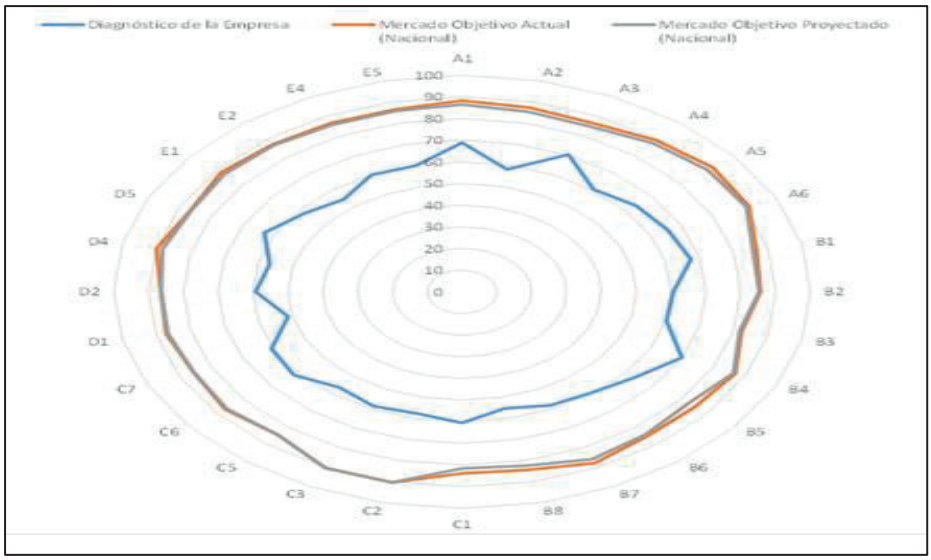

Figura 3: Resultado Diagnostico Empresarial

Como se puede ver en la Figura 3 y basado en el informe de diagnóstico empresarial (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas., 2013) y siendo coherentes con las características del sector hotelero de Cartagena y a nivel nacional, se observa una industria local y nacional muy dinámica, que está en constante evolución como resultado de la entrada de grandes cadenas hoteleras tanto a nivel nacional, como local, y hoteles boutique, que tienen una infraestructura física y tecnológica de última generación , así como una diversidad de servicios como alimentos y bebidas, recreación, lavandería, organización de eventos, ambientes confortables que garantizan una experiencia incomparable, además de personal en cantidad y con las habilidades necesarias y suficientes para satisfacer las necesidades de los turistas locales, nacionales y extranjeros de las más altas demandas, en comparación con una organización que muestra más de 30 años de existencia , posicionado a nivel local, que se evidencia en los grupos sociales de interés, muestra una infraestructura física y tecnológica, servicios como alimentos y bebidas, recreación y lavandería según su mercado actual, pero que, sin embargo, presenta grandes oportunidades de mejora, en torno a su

personal, su capacidad de generar valor, la generación de una verdadera ventaja competitiva que la diferencie competitivamente hablando y en términos de su responsabilidad social corporativa y en términos de su responsabilidad social corporativa. En consenso con el consejo de administración de la entidad y basado en el diagnóstico de negocio se determina como una importante oportunidad de mejora para hacer uso de una metodología que les permita gestionar adecuadamente sus recursos con el fin de fortalecer su trabajo y mejorar las brechas existentes entre su mercado actual y su mercado proyectado y descritos anteriormente.

3.2. Diagnostico Específico.

Como se señaló en el aspecto de la metodología una vez que se desarrolló el diagnóstico de negocio y se priorizaron las oportunidades de mejora, se aplicó un diagnóstico específico, haciendo un análisis basado en el árbol del problema, la herramienta de diagrama de Ishikawa, los 5 y el 5W - 2H (ver figura 4) y apoyado por la experiencia y el conocimiento en el tema de la hospitalidad por parte del consejo de la organización (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas. , 2013).

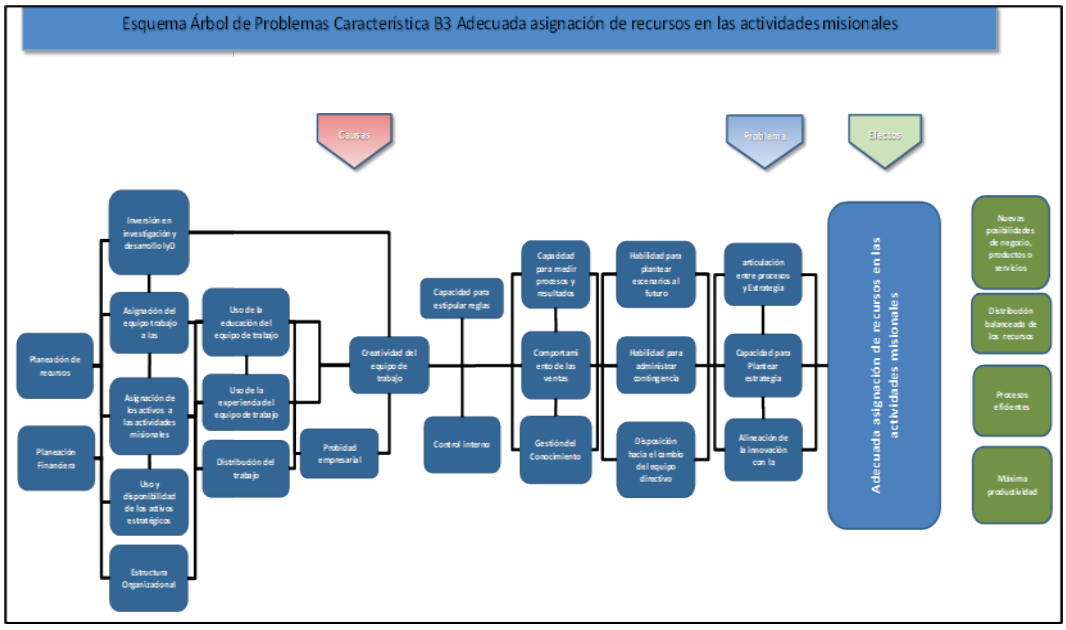

Figura 4. Árbol del Problema Maestro Para Diagnostico Especifico.

Derivado del análisis, desarrollado en conjunto con la alta directiva de la organización a partir de la metodología de lluvia de ideas y basado en el árbol de problema maestro,

se identificaron y priorizaron las siguientes oportunidades de mejora, divididas en causas y consecuencias derivadas de la misma.

Dentro de las causas establecidas en la mesa de trabajo conjunta con la junta directiva de la organización, se definen (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas., 2013):

- La planificación de los recursos es crucial para mejorar la eficiencia de las operaciones de la empresa, acortar el tiempo de entrega a los clientes y reducir los niveles de inventario, el desperdicio y la repetición del trabajo. Una asignación inadecuada de recursos afectará los resultados esperados por la empresa. En esta planificación, debe tenerse en cuenta una planificación financiera adecuada, que permita la ejecución de recursos para el desarrollo de actividades con la articulación de activos existentes y los necesarios para obtener los resultados esperados. Los recursos de investigación y desarrollo deben estar a la vanguardia del mercado.
- La empresa no puede cometer un error en la asignación del equipo de trabajo a las actividades de la misión, ya que comprometería la calidad de la operación, de esta manera es importante haber definido y alineado con la estrategia la estructura organizativa que permite identificar los activos estratégicos y el equipo definido a las actividades misioneras, ya que estas son las llamadas a ejecutar la actividad económica de la empresa. Por lo tanto, es importante medir cuánto la empresa toma el nivel de educación y experiencia del equipo de trabajo y pone a disposición el uso de activos estratégicos.
- Este equipo requiere un alto grado de identidad con la misión y los objetivos de la empresa, ya que tiene una influencia muy alta debido a su grado de experiencia, que debe ser decisiva en actuar con rectitud, honestidad e integridad. La empresa debe buscar un cambio de cultura, crear una actitud orientada al cliente y basada en procesos, para ser capaces así de adaptarse rápidamente a los cambios que le permitan abandonar las viejas estructuras o métodos de hacer las cosas.
- El propósito de distribuir los recursos siempre será obtener la máxima productividad posible de una combinación de activos.
- La asignación de recursos tiene como objetivo resolver qué empleo se dará a los diferentes factores de producción y qué cantidades de ellos se utilizarán en las diferentes actividades.
- La empresa debe ser capaz de medir de manera eficiente y eficaz sus procesos y resultados que la guíen para desarrollar las herramientas que permitan la reducción efectiva de costes, mejora de la producción, satisfacción del cliente, reducción de defectos y tiempo de ciclo y desarrollo de nuevos productos y servicios. Del mismo modo, desarrollar la capacidad de estipular reglas claras y efectivas del juego con métricas para identificar su cumplimiento. Los procesos deben tener métricas simples y deben compararse con una especificación.

Dentro de los efectos se identificaron (Unión Temporal Universidad Jorge Tadeo Lozano, Ecopetrol, Confecámaras, Asocajas., 2013):

- Identificar claramente la adecuación que se hace de los recursos a las actividades misioneras de la organización identificará claramente las acciones a desarrollar para asegurar la operación con los recursos mínimos que guíen a la empresa hacia el éxito sostenido con criterios de productividad, competitividad y sostenibilidad.
- El propósito de distribuir los recursos será siempre obtener la máxima productividad posible de una combinación de activos. Producir la mayor cantidad de bienes y/o servicios con el Mínimo de recursos.
- La asignación de recursos tiene como objetivo resolver qué empleo se dará a los diferentes factores de producción y qué cantidades de ellos se utilizarán en las diferentes actividades.
- El efecto que se obtendrá será dado por las nuevas posibilidades de negocio, productos o servicios, una distribución de recursos de forma más equilibrada y asistiendo a actividades misioneras, con procesos eficientes que lleven a la empresa a su máxima productividad.

A partir del diagnóstico específico, se determina la necesidad de planear e implementar una metodología que permita a la empresa definir sus procesos de manera adecuada, gestionarlos basados en objetivos y metas claras y poder destinar de manera eficiente y efectiva los recursos humanos, financieros, tecnológicos e infraestructuras, entre otros necesarios para ofertar una propuesta de valor competitivo en un contexto marcado por la globalización del sector , y por los efectos de una pandemia que ha debilitado la confianza del mercado objetivo actual y proyecta, lo que pone en riesgo la sostenibilidad y supervivencia del contexto en estudio.

Por lo tanto, se plantea la siguiente pregunta problemática: ¿Cómo contribuir con la mejora de la oferta de valor desde el punto de vista productivo a la organización objeto de estudio, ubicada en la ciudad desde Cartagena de Indias Colombia?

3.3. Análisis de la Cadena de Valor (VSM).

La mejor manera de entender el valor que ofrece un sistema de servucción, como es el caso del hotel, es a través del análisis de la cadena de valor; en el que, independientemente del tipo de actividad comercial a la que se dedica la organización, es capaz de generar satisfacción del cliente a través del valor recibido en el servicio. Una cadena de valor comprende toda la gama de actividades que se requieren para llevar un producto o servicio desde su concepción, a través de las diferentes fases de producción (que implican una combinación de transformación física e insumos de diversos servicios de producción) consumidor final y la disposición final después de su uso. El número de eslabones en cada cadena de valor varía según el tipo de industria (Ver figura 5) (Oddone & Padilla Perez, 2014).

Derivado del análisis de la cadena de valor actual de la organización estudiada, se puede inferir que:

• Se observa una organización que a pesar del tiempo de existencia de más de 30 años en el mercado local y poseer experiencia en el contexto, no funciona de manera armónica y sincronizada, como consecuencia de no tener implementado una gestión por procesos sino más de tipo funcional, lo que ha generado inestabilidad toda vez que no existe una clara definición de roles.

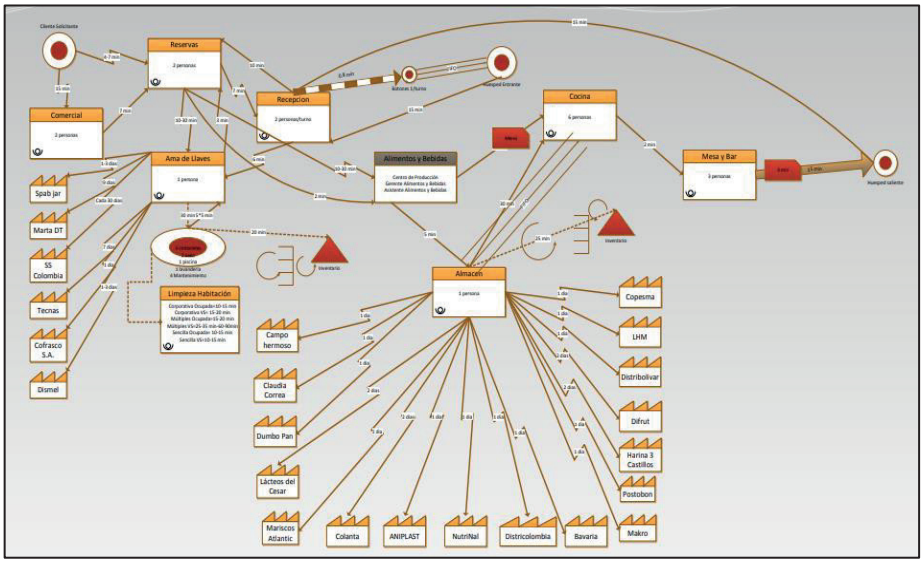

Figura 5. Mapa de la Cadena de Valor Actual Contexto Objeto de estudio.

- Se observa que al no existir roles definidos con claridad y en el afán de satisfacer y responder en el día a día con las necesidades del cliente el personal responsable de cada área desarrolla actividades de cualquier otra área abandonando sus responsabilidades generando así retraso en tareas propias y por consiguiente impactando de manera notoria en la gestión de la organización lo que sin lugar a dudas retrasa el desarrollo y adaptación de la organización ante los cambios y exigencias que establece el contexto de la industria de la hospitalidad.
- Al no tener un enfoque basado en procesos y enfocarse más hacia una estructura de tipo funcional, no se establecen tiempos tipo o tiempos estándar de servicio, lo que trae como consecuencia que algunas áreas tengan mayor asignación de recursos o basado en un análisis sistémico lo que muestra un despilfarro importante de recurso humano, así como también de recursos financieros lo cual afecta la sostenibilidad de la organización.

- A pesar de que, como organización hotelera típica se observa un ambiente agradable, espacios limpios y ordenados lo que da la impresión de tener implementado el concepto fabrica visual adecuada, operativamente hablando se percibe un ambiente laboral tenso y no armonioso como consecuencia de las múltiples tareas que deben realizar los actores y la administración tradicional que se implementa en la misma lo que muestra un alto nivel de desaprovechamiento de la experiencia del personal que en el hotel.
- Se establece a partir del análisis una organización que no basa su quehacer en hecho y datos, sino se basan en la experiencia de algunos de los miembros del equipo de trabajo, lo que dificulta la toma de decisiones asertiva y en los momentos oportunos creando así altos niveles de incertidumbre y mal uso y asignación de los recursos requeridos.

A partir de los análisis establecidos anteriormente y en conjunto con la alta dirección se determinó un plan de trabajo que llevo a definir la nueva cadena de valor y en aras de establecer de la mejor manera que recursos se requerían para ser una empresa fuerte y sostenible, así:

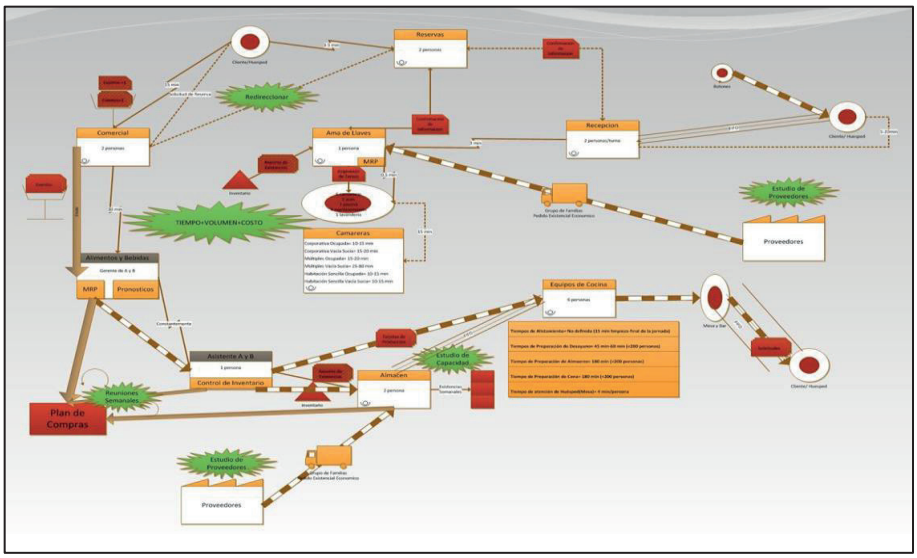

Figura 6. Mapa de la cadena de valor propuesto.

En la figura 6, se evidencia una propuesta de valor más simple, además de que se observa una secuencialidad en los procesos, lo que genera una adecuada sincronización, asignación de roles y responsabilidades.

Además de lo anteriormente planteado el definir de una manera clara los roles y responsabilidades permitió también definir qué personal se requiere, así como también la conformación de equipos de trabajos ajustados a perfiles y a la experiencia.

Al definir roles; responsabilidades y procesos se pudo establecer un sistema de medición del desempeño para la toma decisiones basada en hechos y en datos.

Y definitivamente se eliminaron despilfarros de recursos los cual estaba afectando de manera notorio la sostenibilidad de la organización.

4. Conclusiones

- Se observa un empresa que se equivoca en la definición de los recursos que se requieren para su operatividad, debido principalmente a que no cuentan con un enfoque de gestión basados en procesos, se basan mas en la experiencia de sus administradores en el sector que en hechos y datos y a que se maneja el concepto de polifuncionalidad, es decir, todos deben hace de todo en aras de garantizar el servicio y esto los ha llevado a tomar decisiones inadecuadas desde el punto de vista financiero lo que pone en riesgo la continuidad de la organización.
- Muchos de los resultados que se observan en la organización se deben en gran medida al empirismo y naturaleza formativa de la alta dirección, pero que mas sin embargo hoy les ha establecido la necesidad de mejorar y de apoyarse en personal con las habilidades necesarias para reinventar a la organización y mantenerla aun en estos momentos de crisis.
- Ante los eventos del Covid – 19, se puede establecer que la organización estudiada es altamente vulnerable y se ha visto bastante afectada, toda vez que se ha visto en la obligación de detener casi en su totalidad sus operaciones lo que ha implicado también eliminar puestos de trabajo. Pero en la medida que los efectos de la pandemia disminuyan deben determinar con la mayor exactitud posible los recursos requeridos para reinicio de operaciones de manera paulatina y además adaptar el sistema a la nueva forma de operar para garantizar el bienestar tanto de clientes internos como externos y devolver así la confianza y seguridad del mercado en el sector y estabilizarse rápidamente, lo que implica que deben contar con las tecnologías necesarias y el conocimiento pleno de sistema servuctivo para el logro de objetivos
- Dado el carácter de tipo estacional que muestra en términos generales el comportamiento de la demanda del contexto objeto de estudio, lo cual se puede traslapar a nivel de toda la industria de la hospitalidad tanto en Cartagena, como en el mundo se hace necesario que se establezca una cultura basada en hechos y datos lo que conlleva a generar un sistema de indicadores que permitan tomar decisiones de manera acertada y preparar a las organizaciones que conforman dicho sector para los momentos de alta demanda o los momentos

de baja demanda siempre pensando en el adecuado uso de los recursos tanto humanos, locativos como financieros siendo estos últimos altamente limitados en el tipo de empresas hoteleras citadas en el presente trabajo.

Aportes del enfoque multimetodológico a la gestión de problemáticas derivadas del Covid-19. Avances para una intervención sistémica en grupos poblacionales

Hernán Van Straaten[1] Melany Segarra Marinetti[1] María Alejandra Castellini[1]

[1] Universidad de Belgrano, Facultad de Ingeniería y Tecnología Informática

alejandracastellini@gmail.com

Abstract. En este artículo se reporta un avance de la propuesta del uso combinado de una gama de métodos de Investigación Operativa (IO) clásica (*hard*) y métodos de estructuración de problemas (MEP o IO *soft*) en un marco multimetodológico, a fin de estudiar algunos aspectos de la complejidad organizacional y operativa generada a partir del Covid-19. Se presentan algunas etapas de *Soft System Methodology* (SSM), método de IO *soft*, combinado con programación lineal mixta, método de IO *hard*. anclándose éstos en un marco multimetodológico sobre una propuesta de Mingers y Brockelsby para la integración de metodologías.

Se presenta un avance sobre la aplicación del marco propuesto para asistir a la gestión general de dos grupos: personal de empresas y alumnos de una institución educativa. La aplicación puede reportar pautas para los tomadores de decisiones en un nivel operativo a fin de estructurar el problema y determinar el número de personal operativo o educativo teniendo en cuenta las restricciones de prevención ante la pandemia Covid-19.

El artículo contribuye al debate actual generado por la problemática del Covid-19, mediante la práctica de múltiples paradigmas y multimetodologías en IO y se alinea con la reciente tendencia a combinar métodos *hard* con métodos *soft* de IO.

Keywords: Covid-19**,** Multimetodologías, Investigación Operativa *Hard* y *Soft. Soft System Methodology,* Programación Lineal Mixta

1 Introducción

La sociedad se enfrenta cada día a una creciente complejidad y a una constante incertidumbre, motivados por el Covid-19, manifiestos en la progresiva gama de problemas que requieren permanente atención. Las ciencias organizacionales pueden amenguar estas situaciones desarrollando métodos y metodologías que ayudan a entender estas situaciones, mejorarlas y en algunos casos solucionar la continua variedad de problemas que se presentan. En particular, la IO puede contribuir a esta tarea ofreciendo una gama de métodos y técnicas para la ayuda en la toma de decisiones.

Hasta hace algunos años, la naturaleza de las aplicaciones de la IO se caracterizaba por el uso de una técnica, método o metodología en particular y también por alinearse a un determinado único paradigma, i.e.: *hard* (modelos matemáticos), *soft* (metodologías cualitativas) o critica. Sin embargo, en las últimas dos décadas, profesionales y consultores en IO han empezado a combinar métodos, metodologías y técnicas provenientes no solo de un paradigma sino de varios. A esta modalidad de IO se la llama práctica multimetodológica en un contexto multi paradigmático (MM). Hay evidencia en la literatura de IO que las MM han sido aplicadas en varios contextos organizacionales Mingers (1997a, b); Mingers (1999); Mingers (2001) Mingers and Munro (2002). Es interesante notar que esta práctica se circunscribe a todo tipo de organizaciones, incluyendo el contexto de pequeñas y medianas empresas (PYME), Castellini y Paucar-Caceres (2018), Paucar-Caceres, et al (2015), Castellini et al (2017), Pontelli et al (2014), Silva Barros et al (2013).

Es interesante ver que el marco conceptual más usado para argumentar y justificar el uso de metodologías de IO en modo multi metodológico ha sido el propuesto por Mingers y Brocklesby (MyB) (1997); este es un marco en la forma de una matriz en la cual las distintas metodologías a usarse están ubicadas en línea con su mejor utilidad en alguna de las cuatro fases de toda intervención: Apreciación; Análisis; Evaluación y Acción. Tomando como punto de partida esta matriz se propone, una gama de metodologías/métodos. Donde la propuesta aquí presentada es una contribución al contexto problemático actual y a la buena práctica multi metodológica en IO,

En resumen, en este artículo se presenta la matriz de MyB, dejando expresadas las metodologías propuestas para algunos de sus elementos. Se expone y reporta avances en grupos afectados por la pandemia. En estas intervenciones, un equipo de tres investigadores se propone trabajar virtualmente con personas de diferentes niveles de estos grupos directamente involucrados en la problemática. La intervención se desarrollará virtualmente usando y combinando metodologías de IO *soft* (o MEP), y herramientas de IO *hard,* con el objetivo de tomar medidas que prevengan los contagios de los grupos en estudio, así como la implementación de las mejoras propuestas en los procesos de gestión organizacional a nivel operativo.

El artículo está estructurado de la siguiente manera. Después de esta introducción, en la sección 2, se presentan los fundamentos teóricos, resumiendo brevemente el papel de las metodologías *soft* y *hard* en IO y la reciente práctica de MM. En la sección 3, se introduce el esquema/marco de MyB. En la sección 4 se describe con cierto detalle la propuesta de aplicación del esquema de MyB y se discuten los posibles resultados de la intervención. Finalmente en la sección 5 se esboza las conclusiones iniciales y se sugiere una agenda de futura investigación.

2 Fundamentos teóricos

Como se menciona en la introducción, la complejidad e incertidumbre que afronta la sociedad en general y las organizaciones en particular como consecuencia de la pandemia COVID-19, incide en múltiples aspectos, siendo quizás el más relevante la

posibilidad de contagio de las personas, lo que obliga a analizar la problemática con un enfoque sistémico.

Más aun cuando los problemas de gestión en las organizaciones, en general no están claramente definidos, no hay acuerdo entre los involucrados o stakeholders (personas de adentro o fuera de la organización que pueden afectar o ser afectados por esta situación), el interés no está necesariamente en encontrar el óptimo y sí en encontrar una solución de compromiso, como lo indican Mingers y White (2010). Es en estos casos cuando las metodologías IO *soft* han sido instrumentales en ayudar a mejorar la situación considerada problemática. En estas situaciones, un equipo de IO, conjuntamente con los stakeholders de la organización pueden trabajar en el análisis de la situación compleja y en la propuesta de un plan de acción, teniendo en cuenta los aspectos socioculturales (Yolles, 2010).

2.1. La multimetodología como práctica multi paradigmática en la IO

A principios de los 90, surgió un interesante debate en la IO y las comunidades de sistemas en torno a cuestiones relacionadas con el uso de más de una metodología (combinándolas o usando partes de ellas). Los académicos y los profesionales de sistemas han estado debatiendo las posibilidades de utilizar metodologías de diferentes paradigmas reconociendo las fortalezas y debilidades de las mismas.

Paucar-Caceres (2003 a y b) ilustra cómo aplicar estas diferentes metodologías provenientes de uno o de diferentes paradigmas; esto lo hace utilizando el marco propuesto por Mingers (1997a); Mingers y Brocklesby (1997). Las diversas metodologías propuestas en este trabajo no provienen de un solo paradigma sino de un abanico multiparadigmático; es decir se propone algunas metodologías o partes de ellas, del espectro *hard-soft*. La Fig. 1 ilustra estas opciones; la opción (3) es la que más se acerca al esquema que este artículo adopta.

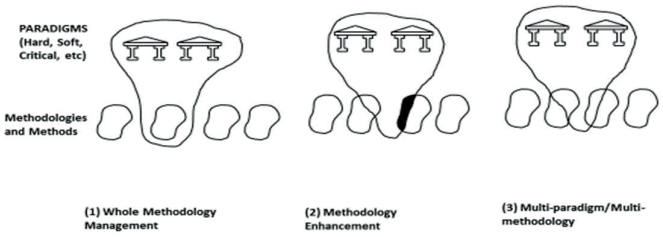

Fig.1. Intervención multimetodológica-multiparadigmática (de Mingers, 1997a)

2.2. La emergencia de los métodos de estructuración de problemas y la práctica multimetodológica

Los MEP, o IO *soft*, son aproximaciones basadas en modelos, que contribuyen de una manera constructiva y apropiada sino a la solución, al alivio de situaciones problemáticas complejas.

En general, estas metodologías cuestionan el paradigma de optimización basado en una epistemología positivista muy prevalente por muchas décadas en las ciencias de administración y se alinean más bien con un paradigma de aprendizaje y adhieren a una epistemología interpretativa y crítica. En otras palabras, son metodologías que se caracterizan por: estructurar los problemas, incorporar modelos conceptuales, considerar la subjetividad y trabajar para organizaciones, con activa participación de sus miembros, como se indica en Rosenhead (2006 y 1989), Rosenhead y Mingers, (2001), Vidal (2006).

Aun cuando en su aparición en los 80s, las metodologías IO *soft* o MEP se aplicaron en forma única e individual (SSM, SODA), como en Checkland (2000) y Eden y Ackermann (2004), en los últimos años, se han desarrollado aplicaciones con combinación entre ellas y han dado paso a la práctica de MM, en la cual IO *soft* y *hard* son aplicadas en conjunción, como puede verse en Ackermann y Eden (2011), Franco y Lord (2011), Georgiou (2012, 2008), Mingers (2000), Mingers y Gill (1997).

Esencialmente, como se explica con más detalle en la sección siguiente, la utilización de multimetodologías en un marco multi paradigmático (MM), es un área de la IO que se focaliza en la posibilidad de combinar diferentes métodos o parte de ellos, dentro de una intervención social particular, caracterizada por su complejidad, como puede verse en Henao y Franco (2016) y Small y Wainwright (2014)

Esta combinación se fundamenta en que: (a) Las situaciones problemáticas reales son multidimensionales, (b) Una intervención es un proceso llevado a cabo en etapas que tienen diferentes tareas y dificultades, que pueden ser mejor abordadas por diferentes métodos, (c) La combinación de métodos puede brindar nuevos puntos de vista y hacer más confiables los resultados.

Es un campo relativamente reciente en el que hay especial interés en los investigadores. Existen algunas publicaciones que han sido seminales y muy influyentes en el avance de esta práctica en varios foros de IO; una de ella que cabe destacar es el libro de Rosenhead y Mingers (2001) donde se analiza el mundo multidimensional, de acuerdo a la versión de Habermas (1970) (Acción, Verbalización, Emoción) en el que están incluidos los procesos de toma de decisión. Enfatizan el hecho de que se debe considerar toda intervención como proceso y analizan los aportes de cada uno de los métodos suaves cuando se utilizan de manera combinada con otros. Reseña las combinaciones *soft-soft* y *soft-hard* más utilizadas hasta ese momento. Así mismo otro artículo muy influyente ha sido el de MyB (1997) en el cual definen la terminología, las variedades de MM, el porqué de su uso, basado en la multidimensionalidad del mundo (personal, social, material), la intervención como proceso, la práctica y la factibilidad de las MM, basada en diferentes tipos de problemas: filosóficos, culturales y cognitivos, así como las dificultades que pueden surgir en su aplicación, dando un esquema de uso y sugiriendo cuál de ellas es apropiada para cada fase de intervención, lo que resume en diferentes figuras. Kotiadis y Mingers, (2006) enfatizan las limitaciones que pueden existir en el uso de las multimetodologías, citan algunos casos relevantes y explicitan un caso práctico que es la evaluación de un sistema social y de cuidados de salud, comentando la pertinencia de la multimetodología aplicada (*Discret Event Simulation* y SSM) y algunas de las dificultades encontradas.

3 Marco para posicionar distintas metodologías en la práctica multi metodológica/ multi paradigmática en IO Esquema de Mingers y Brocklesby (MyB)

En esta sección se describe sucintamente el marco desarrollado por MyB para posicionar las distintas metodologías de IO.

Como se ha expuesto en la sección anterior, el esquema planteado por MyB (1997) es el más usado para justificar y guiar la práctica multi metodológica y multi paradigmática en IO; particularmente cuando se trata de usar varias PSM en combinación.

La Tabla 1 ilustra el modo en que MyB encuadran y complementan los métodos o partes de métodos que fueron seleccionados. Este esquema contiene dos tipos de dimensiones a considerar: (1) las 4 fases de la intervención; éstas aparecen en el esquema de Mingers como 4 "As" (*Appreciation, Analysis, Assesment y Action*); y (2) tres dimensiones o mundos de Habermas, que aun cuando, en la práctica durante toda intervención, interactúan continuamente entre sí, en el esquema se las considera como discretas es decir separadas; esto para ayudar a explorar la complejidad de la situación problemática en consideración. Estas dimensiones son: *material, personal y social*. Las 4 'A's de MyB traducidas al castellano quedarían como *Apreciación; Análisis; Evaluación y Acciones* (**AAEA**).

Tabla 1. Marco para posicionar distintas metodologías en la práctica multi metodológica/ multi paradigmática en IO (MyB 1997)

Fases de la intervención multi metodológica (AAEA)				
Dimensión del problema	**Apreciación de características del problema en cuanto a:**	**Análisis de estructuras y restricciones en:**	**Evaluación de:**	**Acciones para:**
Social	prácticas sociales, relaciones de poder	distorsiones, conflictos, intereses	vías para cambiar las estructuras existentes	generar empoderamiento y alineamiento
Personal	creencias individuales, percepciones	diferencias entre las percepciones y las posturas racionales	Conceptualizaciones y construcciones alternativas	generar predisposición y consenso
Material	evidencias físicas	estructuras causales	alternativas físicas y estructurales	seleccionar e implementar alternativas adecuadas

Soft System Methodology (SSM), Checkland (1981), uno de los MEP más difundidos, combina los principios de sistemas de pensamiento con los puntos de vista individuales, reconociendo las diferentes percepciones de los problemas, e interpretándolas mediante modelos conceptuales, buscando como los sistemas podrían funcionar mejor.

Esta metodología, sobre la base de lo que se percibe como relevante, elabora conceptos abstractos que luego se interpondrán y cotejarán con el mundo real.

Los MEP requieren que el equipo de IO actúe no solo como analista, sino también como facilitador, esto es llevar a cabo la intervención juntamente con los involucrados, ayudando a estructurar y definir la naturaleza de la situación problemática y a fundamentar la evaluación de prioridades y el desarrollo de planes para la subsecuente implementación.

4 Propuesta de diseño e implementación de la Intervención Multi metodológica en dos poblaciones afectados por la pandemia

Partiendo de la premisa que todo estudio sistémico intenta aportar a la mejora de las situaciones problemáticas que se presentan en los procesos estratégicos y de gestión de todo tipo de organización, en el caso que nos ocupa, dos grupos afectados por la pandemia COVID-19, se considera necesario conocer no solo sus características, sino también el contexto en el que se encuentran. Es así que en esta sección se enumera medidas preventivas tomadas el contexto de la pandemia, para luego esbozar el diseño de la combinación de metodologías aplicadas y se reporta el avance en la ejecución del estudio.

4.1 Contexto

Medidas tomadas ante la problemática en CABA. Se han implementado medidas que pretenden disminuir la circulación de personas en el trasporte público y privado, evitando aglomeraciones y al mismo tiempo incentivando el comercio barrial.

Se restringió el uso del trasporte público exclusivamente a trabajadores esenciales y personas con permiso de circulación.

Como medida de control se dispusieron distintos centros de trasbordo, dinámicos y rotativos en los que se realizaron revisiones de síntomas y documentación necesaria y obligatoria para poder circular.

Se aumentaron las medidas y la frecuencia de los procesos de desinfección y limpieza, se establecieron protocolos y recomendaciones para asegurar una correcta higiene a nivel personal y conjunta, como por ejemplo el uso obligatorio de barbijos, marcas estipuladas para asegurar el distanciamiento social correspondiente, modalidad de viaje únicamente sentado dentro de los trasportes.

Como medidas de control se desarrollaron diversas aplicaciones como permisos de circulación que se adquieren vía web, el control de los permisos se realiza directamente desde la aplicación, se colocaron cámaras en patrulleros y cámaras detectoras de temperatura en los centros de trasbordo.

Con el objetivo de evitar aglomeraciones, se realizaron diferentes intervenciones para asegurar el distanciamiento social. Se establecieron ejes comerciales en los que se focalizó la apertura de ferias, comercios, peatonales extendidas, calles cerradas a la circulación de vehículos, veredas ampliadas, demarcaciones de distancia y prevención.

Para incentivar el comercio barrial, con el objetivo de reactivar la economía sin la necesidad de utilizar el trasporte público para recorrer grandes distancias, favorecer la movilidad peatonal y el uso de bicicletas. Los comercios deben respetar un protocolo que garantizan entre otras cosas, el uso obligatorio de barbijos tanto para el personal trabajador como para clientes, el uso de herramientas de marcación para asegurar la distancia mínima que se debe respetar dentro del establecimiento y fuera al formar filas, protocolos específicos en caso de detectar un caso sospechoso de Covid-19. Avaro et al (2020), Rodriguez Espinola et al (2020).

Algunas poblaciones involucradas. En esta fase de la cuarentena en el que cada sector de la población tiene distintos intereses, los grupos identificados y sus principales intereses, son los siguientes:

- Pequeños y medianos comerciantes, les interesa reabrir su negocio y evitar contagios en sus locales.
- Industrias no esenciales, les interesa reabrir su producción de manera segura.
- Personal de salud (trabajadores esenciales), les interesa poder realizar su trabajo minimizando el riesgo de contagio y evitar el colapso del sistema de salud.
- Industrias esenciales (logística, venta de alimentos, servicios públicos) les interesa garantizar el abastecimiento de insumos básicos a la población.
- Trabajadores esenciales (logística, venta de alimentos, servicios públicos) les interesa evitar los contagios, sin discontinuar el suministro a la población.
- Trabajadores no esenciales (artistas, gimnasios, hotelería, gastronomía, turismo), les interesa retomar la actividad laboral.
- Niños y adolescentes, les interesa realizar salidas recreativas
- Estudiantes con escasa o nula conectividad, les interesa retomar las clases presenciales
- Deportistas les interesa retomar su actividad física al aire libre en vía pública
- Deportistas de alto rendimiento, les interesa poder retomar su entrenamiento.
- Población de riesgo o adultos mayores, les interesa realizar salidas minimizando el riesgo de contagio
- Familiares de personas de riesgo o adultos mayores, les interesa minimizar el riesgo de contagio de su familia.
- Geriátricos y centros comunitarios, les interesa minimizar los riesgos de contagio en su entorno
- Barrios vulnerables y personas en situación de calle, les interesa minimizar los riesgos de contagio en su entorno
- Espacios culturales (bibliotecas, museos, iglesias, teatro), les interesa retomar la actividad.
- Transporte público, les interesa minimizar los riesgos de contagio, estableciendo reserva de asientos y mejorando la limpieza y desinfección
- Actores de los estados nacional, provincial y municipal

4.2 Diseño de la Intervención

Se seleccionaron tres de los grupos mencionados: industrias esenciales y no esenciales, y estudiantes con escasa o nula conectividad

El primer contacto es a través de representantes de los mismos que derivan en una investigación-acción desarrollada por el equipo de investigación interdisciplinario conjuntamente con los *stakeholders* de las respectivas poblaciones.

El objetivo de esta investigación-acción es proponer mejoras a las situaciones problemáticas de gestión planteados por los *stakeholders*, generadas por la pandemia. Para ello se prioriza el trabajo interactivo. Se propone una combinación de metodologías, de las áreas de IO *soft* y *hard*, considerando su potencialidad para proveer mejoras en los diferentes aspectos requeridos por las organizaciones.

Se indica en la Tabla 2. resaltado, el avance del trabajo de campo propuesto.

Tabla 2. Distintas metodologías propuestas en la práctica multi metodológica/ multi paradigmática en IO (MyB 1997)

Fases de la intervención multi metodológica (AAEA)				
Dimensión del problema	**Apreciación de características del problema en cuanto a:**	**Análisis de estructuras y restricciones en:**	**Evaluación de:**	**Acciones para:**

	Visitas de campo virtuales		**Programación Lineal**	**Programación Lineal**

Usando el esquema MyB se sitúa algunas de las metodologías que se consideran adecuadas y relevantes en cada una de las dimensiones y fases. En la Tabla 2, se resumen algunas de las diferentes herramientas y metodologías (o partes de ellos) propuestos para ser aplicados a cada dimensión y fase de la intervención multi metodológica.

Considerando las 4 fases (columnas de la matriz de MyB).

Se presentan los avances realizados en las diferentes fases, en base al esquema original de MyB, resaltados en la Tabla 2.

Fase 1: Apreciación de las características del problema desde las dimensiones social, personal y material. Se propone un workshop virtual a organizaciones representativas de los grupos seleccionados. En esta 1ª etapa se efectúa un diagnóstico general de las organizaciones a fin de definir las situaciones problemáticas, de gestión, a ser abordadas. Se busca la participación de los involucrados claves, ya sea porque tienen el poder de tomar decisiones sobre el problema tratado o porque están directamente afectados por las decisiones a tomar. A partir de éstos, se elaboran en conjunto las figuras ricas (parte del método SSM de Checkland) de la situación considerada problemática, Fig. 2 y 3.

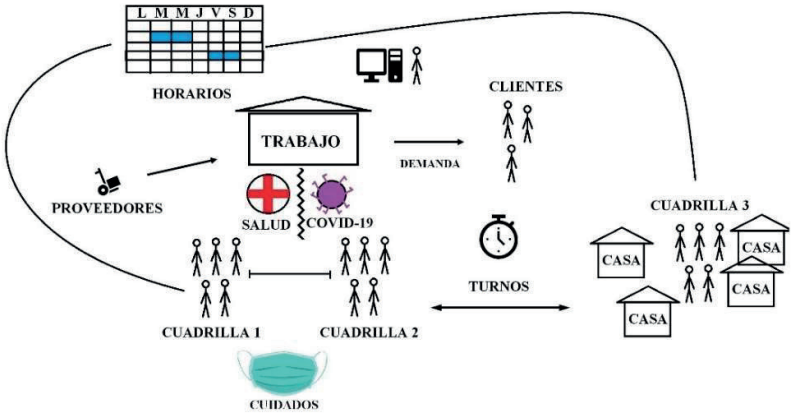

Fig. 2. Figura Rica (*Rich Picture*) de la Situación Problemática en la Industria

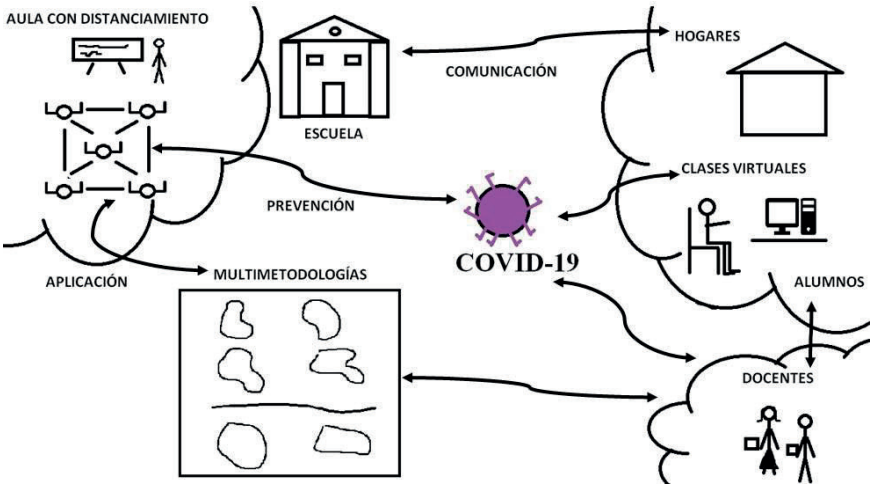

Fig. 3. Figura Rica (*Rich Picture*) de la Situación Problemática en la Institución educativa

Fase 2: Análisis de estructuras y restricciones. En esta segunda etapa se busca estructurar el problema. Analizando la figura rica, se pueden identificar las situaciones problemáticas, en un proceso participativo entre los miembros de la organización y el equipo. Se propone elaborar las correspondientes definiciones raíz (parte del método SSM de Checkland).

Fase 3: Valoración/Comparación. En esta etapa se priorizan y analizan las situaciones problemáticas. se propone realizar en la dimensión Personal y Social el Análisis 1,2,3 de SSM.

Fase 4: Definición de acciones para mejorar la situación problemática. La situación problemática se puede trabajar a diferentes niveles de las organizaciones. Para definir las acciones, en la dimensión material se propone aplicar Programación Lineal Mixta. Se presentan los programas lineales planteados para ambos grupos

Asignación de turnos laborales. En distintas actividades comerciales se tienen trabajadores asignados en diversos turnos, los cuales fueron pensados y diagramados bajo una lógica pre-pandemia. Por lo cual, existe una importante posibilidad de readecuación de los mismos mediante modelos de programación lineal mixta, de amplio uso en la programación de turnos de trabajo (JÖzder, Özcan, & Eren, 2020).

El modelo propuesto es aplicable a la actividad productiva esencial y no esencial, y se enfoca en el cuidado de las personas y minimizando la probabilidad de contagios en el ámbito laboral. La realidad de cada organización puede variar, pero se pueden esbozar una serie de lineamientos generales. La organización cuenta con *n* trabajadores y ofrece *l* tipos distintos de productos.

Se definen las siguientes variables:

$$X_{ih} = \begin{cases} 1 & \text{una persona } i \text{ trabaja en el horario } h \\ 0 & \text{una persona } i \text{ no trabaja en el horario } h \end{cases}$$

$$Y_{ij} = \begin{cases} 1 & \text{si las personas } i \text{ y } j \text{ forman parte de la misma cuadrilla} \\ 0 & \text{si las personas } i \text{ y } j \text{ no forman parte de la misma cuadrilla} \end{cases}$$

$$Z_{ijh} = \begin{cases} 1 & \text{si las personas } i \text{ y } j \text{ trabajan juntas en el horario } h \\ 0 & \text{si las personas } i \text{ y } j \text{ no trabajan juntas en el horario } h \end{cases}$$

$$P_{ph}: \text{cantidad de un producto o servicio } p \text{ a ofrecer en la hora } h$$

El problema se plantea en unidades de tiempo de horas $h \in H$ donde H representa el horizonte de planificación que pueden ser semanas, meses, trimestres, totalizando una cantidad *m* de horas. En este marco temporal se busca minimizar la exposición del personal, según la siguiente función objetivo:

$$min \sum_{i=1}^{i=n-1} \sum_{j=i+1}^{j=n} \sum_{h=1}^{h=m} Z_{ijh}$$

Se asume que se cuentan con los siguientes datos:

$Minh_i$:cantidad mínima de horas de trabajo de una persona *i* durante H

$Maxh_i$:cantidad máxima de horas de trabajo de una persona *i* durante H

D_{ph}:Demanda del producto o servicio *p* a la hora *h*

T_p:Tiempo de producción o de servicio *p*

LL_i:Duración máxima de la jornada de trabajo de la persona *i*
LC_i:Duración mínima de la jornada de trabajo de la persona *i*
P_p:cantidad de un producto o servicio *p* a ofrecer

Para terminar de conformar el modelo se establecen las restricciones que relacionan las variables entre sí, primero determinar si dos personas i y j trabajan en el mismo horario

$$2.Z_{ijh} \leq X_{ih} + X_{jh} \leq Z_{ijh} + 1 \quad \forall h,i,j \text{ con } i \neq j \tag{1}$$

Se trabaja bajo la premisa de generar turnos de cuadrillas estables, de manera de haber una persona con COVID positivo solo haya estado en contacto con su cuadrilla correspondiente y no haya posibilidad de contagio cruzado con el resto de la organización. Por eso se agrega la restricción de que si dos personas en algún momento trabajan juntas pertenecen a la misma cuadrilla:

$$Y_{ij} \leq \sum_{h=1}^{h=m} Z_{ijh} \leq m.Y_{ij} \quad \forall i,j \text{ con } i \neq j \tag{2}$$

El concepto de cuadrilla estable considera que si una persona i trabaja junto a una j, una tercer persona k trabaja con ambas o no trabaja con ninguna.

$$Y_{ij} + Y_{ik} \leq Y_{jk} + 1 \quad \forall i,j,k \text{ con } i \neq j \neq k \tag{3}$$

$$Y_{ij} + Y_{jk} \leq Y_{ik} + 1 \quad \forall i,j,k \text{ con } i \neq j \neq k \tag{4}$$

$$Y_{ik} + Y_{jk} \leq Y_{ij} + 1 \quad \forall i,j,k \text{ con } i \neq j \neq k \tag{5}$$

Es importante considerar que dependiendo de la persona se tiene la cantidad de horas máximas y mínimas que deberá trabajar dentro del horizonte de tiempo H.

$$\sum_{h=1}^{h=m} X_{ih} \geq Minh_i \quad \forall i \tag{6}$$

$$\sum_{h=1}^{h=m} X_{ih} \leq Maxh_i \quad \forall i \tag{7}$$

En el caso de personal dentro de la categoría de riesgo, se le debe dar de manera automática licencia médica con pleno goce de sus garantías laborales, asignándole $Minh_i = Maxh_i = 0$.

A su vez, se debe restringir la cantidad de horas que trabaja una persona de corrido:

$$\sum_{h=t}^{h=t+LL_i+1} X_{ih} \leq LL_i \quad \forall i,t < m - LL_i \tag{8}$$

$$LC_i.(X_{ih+1} - X_{ih}) \leq \sum_{h=t}^{h=t+LC_i} X_{ih} \; X_{ih} \leq LC_i \quad \forall i < n, t < m - LC_i + 1 \tag{9}$$

Finalmente es necesario establecer los niveles de producción horaria para satisfacer la demanda estimada.

$$\sum_{p=1}^{p=l} T_p.P_{ph} \geq \sum_{i=1}^{i=n} X_{ih} \quad \forall h \tag{10}$$

$$D_{ph} \leq P_{ph} \;\; con \; D_{ph} \geq 0 \; y \;\; P_{ph} \geq 0 \tag{11}$$

Este tipo de modelos, sirven de referencia general, sin embargo se podrían complejizar con la inclusión de flujos de stocks en el caso que se esté trabajando con productos, la apertura por especialidad necesaria del trabajador a la hora de realizar una tarea (Niknafs, Denzinger, & Ruhe, 2013), o una programación más formal de los tiempos de descanso (William S. Brownell, 1976) por mencionar algunos de los agregados posibles.

Asignación de aulas para la vuelta a clases. Se propone un modelo de asignación de alumnos a clases para asistir de manera presencial a la Institución al menos dos días a la semana, teniendo en cuenta la cantidad de alumnos total por curso y la ocupación máxima de asientos dentro del contexto de la pandemia COVID-19, tomando como hipótesis que el resto de los días los alumnos continuarán con sus clases de forma virtual.

Se definen las siguientes variables:

$$X_{ija} = \begin{cases} 1 \text{ un alumno i es asignado al día j por semana y al aula a} \\ 0 \text{ un alumno i no es asignado al día por semana j y al aula a} \end{cases}$$

$$Y_{ii'j} = \begin{cases} 1 \text{ si los alumnos i e i' concurren el mismo día j a clase} \\ 0 \text{ si los alumnos i e i' no concurren el mismo día j a clase} \end{cases}$$

A_a: *cantidad de* m^2 *del aula a*
DS: cantidad de m^2*/persona recomendados*
C: Coeficiente de beneficio extra de alinear horarios de hermanos
CDS: cantidad de días por semana que asisten los alumnos

Función objetivo:

$$max \sum_{i=1}^{i=n} \sum_{j=1}^{j=m} \sum_{a=1}^{a=l} X_{ija} + C \sum_{i=1}^{i=n-1} \sum_{i'=i+1}^{i'=n} \sum_{j=1}^{j=m} Y_{ii'j}$$

Teniendo en cuenta:

1. Cada alumno debe asistir a la institución una cantidad de días determinado a la semana.

$$\sum_{j=1}^{j=m} \sum_{a=1}^{a=l} X_{ija} = CDS \ \forall i \quad (1)$$

2. Para evitar la circulación y el contagio por superficies, el día que un alumno concurre al colegio lo hará sin cambiar de aula.

$$\sum_{a=1}^{a=l} X_{ija} = 1 \quad \forall \ i,j \quad (2)$$

3. Se deberá respetar la distancia social, por lo cual cada aula tendrá una capacidad máxima de personas a respetar según su superficie total.

$$DS. \sum_{i=1}^{i=n} X_{ija} \leq A_a \quad \forall j,a \quad (3)$$

4. Por cuestiones pedagógicas, y para evitar rotación entre los alumnos, se prefiere que en un día *j* y un aula *a* estén siempre compañeros del mismo curso. Dado un alumno

o perteneciente al conjunto E_c compuesto por los alumnos de un mismo curso, y un conjunto E'_c con los alumnos o' pertenecientes a los cursos restantes.

$$X_{oja}+X_{o'ja}\leq 1 \quad \forall j,a \tag{4}$$

5. Puede existir una ponderación para que determinados alumnos que tengan hermanos en la misma circunstancia asistan determinados días a la Institución. Donde (i,i') constituye un par de hermanos.

$$2.Y_{ii'j} \leq \sum_{a=1}^{u=1} X_{ija} + \sum_{a=1}^{u=1} X_{i'ja} \leq Y_{ii'j} + 1 \quad \forall j,(i,i')con\ i\neq i' \tag{5}$$

Por un lado esto implica un beneficio en términos de la comodidad familiar, pero desde un punto de vista epidemiológico el contagio dentro de un mismo hogar es altamente probable (Merino & Díaz,2020), así que al considerar este factor se logra minimizar la posibilidad de contagios de un día *j* a otro. El peso de esta política en el modelo dependerá del valor que tome C en la función objetivo, se recomienda que C>1.

5. Conclusiones y futuras investigaciones

En este artículo se ha argumentado que la tendencia en la actualidad en el campo de la IO es el uso de varias metodologías, métodos y técnicas en combinación conjunta. El artículo revisa brevemente la historia de las metodologías *soft* en IO. Usando como base el esquema de MyB, el artículo reporta las propuestas iniciales de una intervención sistémica efectuada en dos tipos de organizaciones, una productiva y una educativa.
Es interesante destacar la potencialidad del enfoque sistémico, pudiendo detectarse diferentes situaciones a mejorar, así como las causas que las ocasionan. Al momento se presenta la estructura de referencia en el marco de la matriz de MyB y los avances en el uso de partes de la metodología SSM y la modelización de la P L Mixta para optimizar el número de personas involucradas, bajo las restricciones que impone la situación pandémica.
El enfoque sistémico, con participación más activa de los *stakeholders*, permite relacionar las diferentes situaciones problemáticas (figura rica) detectadas, en las diferentes dimensiones planteadas por MyB y definir planes de acción para modificar las causas que las generan. Esto se potencia, por cuanto una misma causa, puede incidir en más de una situación problemática.
El uso de herramientas de fácil comprensión para los involucrados (figura rica de SSM por ejemplo), aumenta las posibilidades de darle continuidad a la propuesta y de que la misma organización pueda continuar el esquema de mejora sin el acompañamiento del equipo de investigación.
Este es un proyecto en ejecución y el siguiente paso es avanzar virtualmente en el trabajo de campo.

Modelo multicritério de apoio a tomada de decisão, baseado em Sistema de Informação Geográfico, para a gestão de acidentes de trânsito

Antônio Luiz Freitas Bezerra[1], Murilo Alves de Albuquerque Damasceno[1], Cristiany Raab de Souza[1], Joana Karolyni Cabral Peixoto[1] Thomas Edson Espíndola Gonçalo[1] and Eric Amaral Ferreira[1]

[1] Universidade Federal Rural do Semi-Árido, Mossoró RN, Brasil

Resumo. Nas últimas décadas, devido a uma explosão do crescimento demográfico das cidades e, respectivamente, de suas frotas de veículos, a violência no trânsito vem crescendo gradativamente. De acordo com a Organização Mundial da Saúde, cerca de 1,35 milhão de pessoas são vítimas fatais todos os anos. No ano de 2017, a OMS classificou o Brasil como o terceiro país em número de acidentes fatais de trânsito. Com exceção dos grandes centros urbanos, as cidades emergentes, de médio porte, enfrentam certas dificuldades na gestão do trânsito local. Com base nessa problemática, as ferramentas de apoio à decisão multicritério e os sistemas de informação geográfica (SIGs) podem apoiar o processo de tomada de decisão. Neste contexto, é proposto um modelo multicritério para tomada de decisão para classificar as vias da cidade referente a quanto estas são críticas para a segurança da população. É proposta a utilização do método PROMSORT, para classificação, e os resultados são representados em SIG. É apresentada uma aplicação numérica para o caso da cidade de Mossoró/RN, avaliando-se as vias e provendo informação para a tomada de decisão dos gestores públicos.

Palavras-chave: Métodos multicritérios de apoio à decisão, Sistema de Informação Geográfica, Acidentes de Trânsito.

1 Introdução

A frota brasileira tem crescido em ritmo acelerado nas últimas décadas. Mortaire e Euzébio [1] citam que, entre 1999 e 2009, a quantidade de veículos no Brasil cresceu de 27,1 para 55,9 milhões. No período compreendido entre 2003 e 2014, segundo Carvalho e Rabetti [2], a venda de automóveis cresceu 102,6% ao passo que a de motocicletas cresceu incríveis 269,8%. Com tantos veículos circulando diariamente pelo país, pode-se notar também um número substancial de acidentes. De acordo Almeida, et al. [3], os acidentes de trânsito no Brasil se mantém como um importante problema de saúde e demandam diferentes abordagens em ações de prevenção. Além do custo social ser elevado, esses acidentes impactam diretamente na economia nacional, sendo a causa direta dos elevados custos demandados pelo Sistema Único de Saúde, resultando, apenas entre 2010 e 2015, em mais de R$ 1,3 bilhão gastos em atendimentos. [4;5;6]

Em 2017, a Organização Mundial da Saúde (OMS) considerou que o Brasil era o terceiro país com o maior número de óbitos provocados por acidente de trânsito. Essa situação ainda é agravada devido a inexistência de ferramentas e metodologias que permitam uma intervenção efetiva. Uma análise puramente numérica pode permitir um *insight* do panorama geral da situação, mas há uma série de outras variáveis, como por exemplo características físicas da via, ou mesmo comportamentais dos condutores a serem consideradas para uma análise mais precisa. Desta forma, uma simples análise de quantitativo de acidentes pode enviesar a análise por parte do gestor, podendo levar a decisões ineficazes. Neste contexto, os métodos de apoio à decisão multicritério podem prestar suporte a este processo.

No campo das ferramentas de apoio à decisão destacam-se as abordagens multicritério, que ganham cada vez mais atenção pela sua robustez e por facilitar a análise de casos mais complexos. Segundo Vincke [7], o apoio multicritério à decisão tem por objetivo dar ao tomador de decisão ferramentas para possibilitar-lhe avanços na solução de problemas de decisão onde diversos, muitas vezes contraditórios, pontos de vista devem ser levados em consideração. O autor agrupa os métodos em três classes. (1) Métodos de critério único de síntese, vindo da Escola Americana, onde o desempenho de cada alternativa em um determinado conjunto de critérios é levado em conta para a criação de uma pontuação, cujo resultado representará o quão bem avaliadas são as alternativas. Podemos citar como exemplo dessa família, além do próprio MAUT, o SMARTS, TOPSIS e AHP. (2) Métodos de sobreclassificação, que adota uma comparação de alternativas par-a-par para definir qual delas é melhor que as demais em determinado critério. Expoentes dessa família são o PROMETHEE e o ELECTRE. (3) Métodos Interativos, que unem a preferência do decisor à uma base matemática, e assim, de maneira interativa e sucessiva, as reavaliam até que convirjam em um resultado. Nessa classe, temos como exemplos os métodos STEM, TRIMAP e Pareto Race.

Os Sistemas de Informações Geográficas (SIGs), por sua vez, unem conhecimentos da Estatística, Cartografia e Geografia na análise de dados espaciais [8]. Segundo Simões e Bastos [9], um SIG é definido como uma ferramenta de coleta, armazenamento, processamento, análise e disponibilização de informações georreferenciadas, que asseguram maior facilidade, segurança e agilidade nas atividades humanas no que diz respeito ao estudo do espaço geográfico. São ferramentas capazes de desempenhar um estudo de campo de modo a obter dados de um determinado espaço e, desse modo, incorporá-los a um sistema topográfico de mapeamento [10]. Sendo assim, a utilização de SIGs desenvolve uma estratégia de estudo promissora ao apoiar o processo de tomada de decisão, possibilitando a visualização geográfica de dados referentes à região analisada.

Diante do contexto apresentado, este artigo propõe um modelo multicritério de apoio à tomada de decisão que, utilizando representação geográfica, pode prestar suporte ao processo de gestão do trânsito em um município, permitindo uma tomada de decisão mais ampla. Além disso, a representação geográfica dos resultados obtidos pode produzir importantes *insights* para os gestores, que podem visualizar o relacionamento que pode existir entre as diversas variáveis que influenciam nesse processo. Ao levarem em consideração variáveis qualitativas ou quantitativas, permitem uma avaliação mais completa do problema, podendo fornecer direcionamentos para a gestão, permitindo uma aplicação dos recursos públicos muito

mais efetiva. A utilização de um SIG, por sua vez, pode complementar o processo de apoio à decisão, trazendo uma visão geográfica e possibilitando uma visualização de dados mais conectada com a realidade dos gestores do trânsito urbano.

O modelo proposto foi aplicado para o caso da cidade de Mossoró/RN, possibilitando a classificação das vias da cidade quanto à criticidade. Desta forma, o gestor de trânsito pode visualizar quais áreas da cidade demandam mais atenção ou, até mesmo, atuação imediata. Este artigo é composto por dizer seções: Na seção 2 é realizado um panorama sobre o problema dos acidentes de trânsito no Brasil, destacando o caso da cidade de Mossoró/RN. Na seção 3, o método desta pesquisa é apresentado, assim como o modelo multicritério proposto. Na seção 4 é desenvolvida a aplicação numérica e apresentação de resultados obtidos. Na seção 5, os comentários e análises finais são enunciados. E na seção 6, as referências bibliográficas utilizadas.

2 Acidentes de trânsito no Brasil

As estatísticas a respeito dos acidentes de trânsito em todo o mundo têm fomentado o debate nos últimos anos ao apontar esse tipo de acidentalidade como uma das principais causas de óbito anualmente. Visando a diminuição substancial dessas mortes, de aproximadamente 1,35 milhão por ano [11] , a Organização das Nações Unidas lançou, em maio de 2011, a proposta da Década de Ação pela Segurança no Trânsito, compreendendo o período entre 2011 e 2020. Para essa proposta, diversas autoridades governamentais assumiram o compromisso de adotar medidas para fortalecer a capacidade de gerenciamento da segurança rodoviária, bem como também melhorar a segurança e comportamento dos condutores [12], uma vez que são registrados de 20 a 50 milhões de acidentes em todo o mundo a cada ano [11].

A nível nacional, Waiselfisz [13] aponta que foram registrados no Brasil 960.635 óbitos por acidentes de trânsito entre 1981 e 2011. Neste período, foi avaliado um aumento de 122% no número de óbitos registrados e 39,75% na taxa de mortalidade a cada cem mil habitantes. Segundo a ONU Brasil [14], a taxa de óbitos no ano de 2019 aumentou em relação ao ano anterior, apresentando um índice de 19,7 mortes a cada cem mil habitantes. Tal índice superou o valor da média obtida para a região do Cone Sul, estimado em 18,4 mortes, e até mesmo a média para toda a região das Américas, estimado em 15,6 mortes a cada cem mil habitantes.

A Organização Mundial da Saúde estima que, apesar de concentrarem pouco mais da metade da frota mundial, os países de baixa e média renda correspondem, sozinhos, por 93% dos acidentes fatais, e que estes acidentes custam aos países cerca de 3% do seu Produto Interno Bruto [15]. A nível nacional, segundo o IPEA [16], no ano de 2014 foram registradas 167.247 acidentes nas rodovias federais, estaduais e municipais e nas áreas urbanas no Brasil, representando um custo anual de R$ 56 bilhões, incluindo atendimento médico-hospitalar, seguros de veículos, danos a infraestruturas públicas, dentre outras despesas. Desse valor, constatou-se 6.743 acidentes fatais, representando um custo anual de R$4,5 bilhões.

Quando analisa-se a cidade Mossoró, no interior do Rio Grande do Norte, as informações ficam mais escassas. Sabe-se, de acordo com as estatísticas oficiais dos órgãos de trânsito e saúde do município que morrem cerca de 60 pessoas por ano. Segundo Bezerra [17], a cidade registrou 3100 acidentes com vítimas (com algum tipo

de lesão) e 1645 acidentes sem vítimas (apenas com danos materiais) entre 2014 e 2017. Fernandes [18] complementa ao informar que, para o período analisado, foram registrados 941 Autorizações de Internação Hospitalar (AIH) referentes a fraturas identificadas como oriundas de acidentes de trânsito, conforme consta no DATASUS. Entretanto, deste total apenas 692 foram de fato acessadas para a realização de sua pesquisa. Ainda segundo Fernandes [18], as internações custaram ao município R$ 280,7 mil no ano de 2014, R$ 599,7 mil no ano de 2015, R$ 269,5 mil em 2016 e apenas R$ 22,3 mil em 2017. Diante deste cenário, conclui-se que o trânsito local traz um quadro preocupante não apenas pelas cifras financeiras, mas também pela falta de metodologias eficazes em seu monitoramento e controle.

3 Método

As etapas para a realização desta pesquisa são apresentadas na Figura 1.

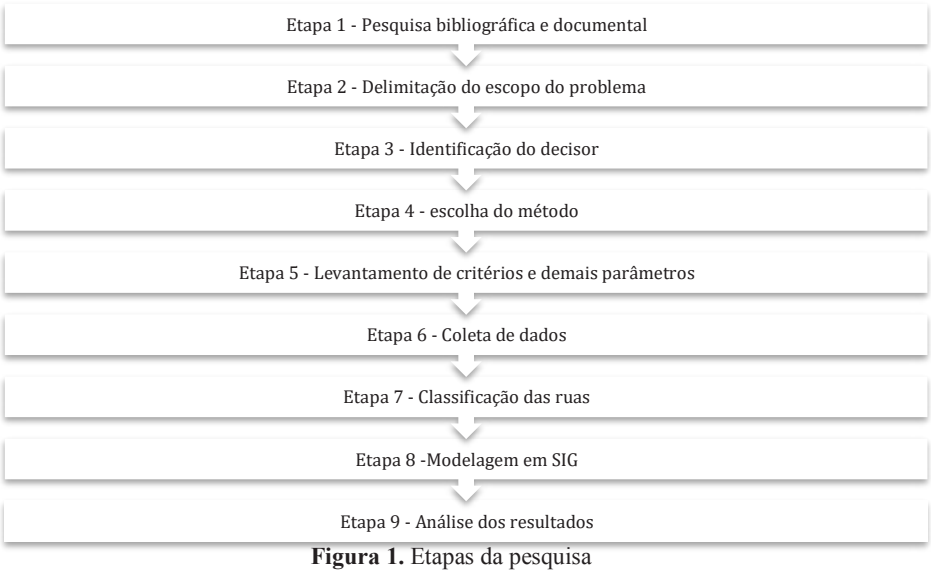

Figura 1. Etapas da pesquisa

Inicialmente, foi realizada pesquisa bibliográfica acerca dos temas relacionados ao objetivo da pesquisa. Em seguida, foi realizada uma pesquisa documental, de modo a se coletar dados relacionados a acidentes de trânsito no Mundo, no Brasil e no estado do Rio Grande do Norte. Na Etapa 2, o escopo da pesquisa foi delimitado. Desta forma, definiu-se realizar o estudo no Município de Mossoró-RN, cidade onde está localizada a Universidade. Na Etapa 3, foi identificado o tomador de decisão, cujas preferências serão consideradas no processo. O decisor escolhido foi um especialista na área, Doutor em Engenharia dos Transportes e coordenador de um projeto de pesquisa desenvolvido pela Universidade Federal Rural do Semi Árido e Universidade do Estado do Rio Grande do Norte e os órgãos de trânsito da cidade alvo. A partir de conversas com o

mesmo, definiu-se adotar a problemática de classificação, ou seja, alocar as ruas em classes, conforme sua criticidade.

A seguir, na Etapa 4, o método multicritério foi escolhido, de acordo com a estrutura de preferências do tomador de decisão. Neste ponto, foi escolhido o método PROMSORT (PROMETHEE Sorting). Considerando os pontos propostos por Roy e Slowinski [19], o método foi escolhido por fornecer solução para problemática de classificação, por considerar um grupo finito de alternativas (não há inclusão de novas alternativas após a análise dos dados), por considerar escalas verbais e numéricas, pelo caráter não compensatório (não possibilitando compensação direta de desempenhos entre critérios) e por possibilitar a consideração da hesitação dos decisores (através de funções de preferências e limiares).

Na Etapa 5, com base no método escolhido, foram levantados os critérios que o decisor considera importantes para se avaliar a criticidade em uma via, bem como parâmetros. Em seguida, na Etapa 6, foi realizada a coleta dos dados relacionados às vias. Parte dos dados foi coletada diretamente junto ao tomador de decisão, explicitando as suas preferências. Dados técnicos e de número de acidentes sem vítimas foram levantados junto a Secretaria de Mobilidade Urbana (SEMOB) do Município de Mossoró/RN. A coleta dos acidentes com vítimas, foi realizada através de uma parceria com o 2° Distrito de Polícia Rodoviária Estadual, responsável pelo município. Foram coletados dados referentes aos registros emitidos pelas instituições para cada acidente, entre os anos de 2015 e 2017, incluindo as coordenadas onde ocorreu cada acidente.

Na Etapa 7, por sua vez, o método PROMSORT foi aplicado e as vias foram classificadas em uma das três classes previamente definidas, com analogia a um semáforo: (1) Classe vermelha: as vias mais críticas, que requerem atenção imediata dos gestores; (2) Classe amarela: as vias com criticidade média, que requerem atenção assim que possível; (3) Classe verde: as vias em condição mais satisfatória e que não requerem atenção imediata. Salienta-se que, nessa etapa, 19 ruas foram excluídas, pois não apresentavam dados referentes aos critérios escolhidos. Na Etapa 8 foi elaborada a representação geográfica dos resultados obtidos, com o objetivo de se facilitar a análise dos resultados por parte dos gestores. Por fim, na Etapa 9, os resultados foram discutidos.

Para a execução do trabalho, o método PROMSORT foi escolhido, sendo ele baseado nos métodos da família PROMETHEE, utilizando o PROMETHEE I em sua primeira etapa. Desenvolvido por Araz e Ozkarahan [20], o método atribui as alternativas a categorias ordenadas predefinidas. Como destacado por Oliveira [21], para se designar uma determinada alternativa a uma das categorias, compara-se essa alternativa com valores pré-estabelecidos que servem como fronteiras de classe e também com alternativas de referência.

Segundo Araz e Ozkarahan [20], a implementação do PROMSORT se dá em três etapas definidas:

- Uso do PROMETHEE I para a elaboração das relações de sobreclassificação, encontrando nesta etapa os fluxos positivos (que representam a preferência de uma alternativa sobre as demais) e negativos (o grau de preferência de todas as outras);
- Usando as relações encontradas no passo anterior para designar as alternativas a cada categoria previamente estabelecida;

- Diante de casos de indiferença e incomparabilidade, proceder com a atribuição usando comparação por pares.

Segundo Brans, et al. [22] os métodos da família PROMETHEE destacam-se ao envolver conceitos e parâmetros que possuem alguma interpretação física ou econômica, de fácil entendimento para o tomador de decisão. Brans e Vincke [23] apontam que, designados pesos p_j, representando grau de importância para cada critério, o grau de sobreclassificação π(a,b) é computado de acordo com a equação abaixo:

$$\pi(a,b) = \frac{1}{P}\sum_{j=1}^{n} \quad p_j F_j(a,b), \quad onde\ P = \sum_{j=1}^{n} \quad p_j \qquad (1)$$

Onde $F_j(a,b)$ é um número entre 0 e 1 que aumenta quando $g_j(a) - g_j(b)$ aumenta e é igual a zero se $g_j(a) \leq g_j(b)$. Para que se encontre o valor da função $F_j(a,b)$, o tomador de decisão pode escolher, para cada critério, uma das seis formas de curvas, representadas por limiares de indiferença (q) e de preferência (p): (1) Critério usual, quando não há parâmetro a ser definido; (2) Quase-critério, para a qual define-se o parâmetro q; (3) Limite de preferência, definindo o parâmetro p; (4) Pseudo-critério, considerando os parâmetros q e p; (5) Área de indiferença, considerando, também, os parâmetros q e p; (6) Critério Gaussiano, no qual o desvio padrão deve ser fixado.

Assim, de acordo com a maneira como a preferência do tomador de decisão aumenta, com o aumento do $g_j(a) \leq g_j(b)$, o tomador de decisão escolhe, para cada critério, a forma da função e os seus parâmetros associados. Estes, por sua vez, têm simples interpretação, representando limiares de indiferença e preferência.

Uma vez obtidos os valores de $\pi(a,b)$, duas pré-ordens completas podem ser obtidas, sendo a primeira representando uma ordenação de ações seguindo ordem decrescente dos números $\varphi^+(a)$:

$$\varphi^+(a) = \frac{1}{n-1}\sum_{b\in A} \quad \pi(a,b) \quad (Fluxo\ de\ saída) \qquad (2)$$

E outro seguindo a ordem crescente dos números $\varphi^-(a)$:

$$\varphi^-(a) = \frac{1}{n-1}\sum_{b\in A} \quad \pi(b,a) \quad (Fluxo\ de\ entrada) \qquad (3)$$

A intersecção destes dois fluxos gera a pré-ordem parcial resultado da aplicação do método PROMETHEE I.

Na próxima etapa de aplicação do PROMSORT, as categorias são definidas por limites superiores e inferiores, onde as alternativas são comparadas com os perfis limite, utilizando as relações de sobreclassificação encontradas com a aplicação do PROMETHEE I. Desta forma, a comparação de uma alternativa com o perfil limite estabelece em qual classe cada alternativa será inserida, a partir das relações obtidas com as equações abaixo [20].

$$(aPb_h)\ se \begin{cases} \phi^+(a) > \phi^+(b_h)\ e\ \phi^-(a) < \phi^-(b_h)\ ou \\ \phi^+(a) = \phi^+(b_h)\ e\ \phi^-(a) < \phi^-(b_h)\ ou \\ \phi^+(a) > \phi^+(b_h)\ e\ \phi^-(a) = \phi^-(b_h) \end{cases} \qquad (4)$$

a é indiferente em relação à b_h:

$$(aIb_h)\ se\ \phi^+(a) = \phi^+(b_h)\ e\ \phi^-(a) = \phi^-(b_h) \tag{5}$$

a é incomparável a b_h:

$$(aRb_h)\ se \begin{cases} \phi^+(a) > \phi^+(b_h)\ e\ \phi^-(a) > \phi^-(b_h)\ ou \\ \phi^+(a) < \phi^+(b_h)\ e\ \phi^-(a) <\ \phi^-(b_h) \end{cases} \tag{6}$$

De acordo com Araz e Ozkarahan [20], atribuição das alternativas nas categorias escolhidas é possível com o uso dessas relações. Entretanto, é possível que alternativas possam acabar não sendo incluídas em alguma das alternativas, por incomparabilidade ou indiferença. Na etapa seguinte, o método utiliza as alternativas alocadas às categorias como referência para as que não foram incluídas.

Estabelece-se a diferença do ponto de corte d_k: tal ponto s compreende valores entre 0 e 1, usando um ponto de vista otimista ou pessimista, a critério do decisor. Se s for 0, as alternativas não classificadas serão alocadas de acordo com suas funções distância. Com s = 1, elas serão atribuídas às classes mais baixas.

$$d_k = \frac{1}{n_t} d_k^+ - \frac{1}{n_{t+1}} d_k^- \tag{7}$$

Onde:

d_k^+ : sobreclassificação de a sobre todas as alternativas alocadas a uma categoria C_t, e:

$$d_k^+ = \sum_{xeXt} \left(\Phi(a) - \Phi(x)\right) \tag{8}$$

d_k^- : sobreclassificação de a sobre todas as alternativas alocadas a uma categoria C_{t+1}, e:

$$d_k^- = \sum_{xeXt} \left(\Phi(x) - \Phi(a)\right) \tag{9}$$

n_t sendo o número de alternativas de referência da categoria C_t.

Aplicação do ponto de corte s: sendo a diferença maior que o ponto de corte s, classificar a alternativa a à categoria C_{t+1}, senão à C_t.

A seguir é apresentada a aplicação numérica para o caso da cidade de Mossoró, RN.

4 Aplicação numérica

A aplicação foi realizada considerando-se todas as ruas da cidade, desconsiderando-se as 19 excluídas, conforme apresentado na seção 3. Uma vez definidos o método e o decisor, foram levantados os critérios que tornam uma via mais crítica, sob o ponto de vista do decisor, conforme apresentado na Tabela 1.

Tabela 1. Critérios considerados pelo tomador de decisão.

Cod	Critérios	Descrição	Max/Min	Escala
C1	Sinalização vertical	Placas existentes nas vias.	Min	Likert (5 pontos)
C2	Sinalização horizontal	A sinalização pintada nas vias.	Min	Likert (5 pontos)
C3	Sinalização semafórica	Presença de sinais de trânsito nas vias.	Max	Sim/Não
C4	Velocidade	A velocidade da via. (30, 40 ou 50 km/h).	Max	Numérica
C5	Largura	A largura da via, que varia com o tipo.	Max	Numérica
C6	Acidentes sem vítimas	Nº. de ocorrências apenas com danos materiais.	Max	Numérica
C7	Acidentes com vítimas	Ocorrências com lesão corporal ou óbito.	Max	Numérica
C8	Conservação da via	Indica o estado de conservação em que se encontra a via.	Min	Likert (5 pontos)

Para a maioria dos critérios adotou-se a escala quantitativa. No entanto, para os critérios de sinalização vertical e horizontal, presença de semáforos e conservação da via foi utilizada uma escala qualitativa, que é uma escala verbal traduzida em uma escala ordinal. No que se refere ao critério Largura, tem-se diversos tipos de vias: Arterial I (20 m), Arterial II (18 m), Coletora I (15 m), Coletora II (14 m) e Arruamentos (12 m). Neste critério, segundo o decisor, quanto mais larga a rua, mais crítica pois os condutores tendem a acelerar mais.

Em seguida, o decisor estabeleceu os pesos para cada um dos critérios, representando a importância que ele atribui a cada um deles na criticidade de uma via. O decisor foi informado que ele poderia atribuir os valores livremente mas, tendo em mente que o valor 2x definido para um critério implica que ele possui duas vezes mais importância do que um critério que recebeu peso x. Os pesos definidos pelo decisor são apresentados

na Tabela 2. Quanto às funções de preferência do método PROMETHEE, foi definido utilizar a função usual para todos os critérios. Desta forma, qualquer diferença no desempenho das alternativas implica em sobreclassificação, para aquele critério. O método PROMETHEE foi, então, aplicado, obtendo-se os fluxos de entrada e de saída para cada uma das vias.

Posteriormente, foram definidos limites dos perfis b_1 e b_2, que delimitam as classes. Esses limites podem ser considerados alternativas fictícias, cujo objetivo é determinar as fronteiras das classes, sendo as alternativas de pior desempenho em relação ao perfil b_1 pertencente à classe verde, as alternativas avaliadas entre b_1 e b_2 pertencentes à classe amarela e as avaliadas como melhores que b_2 pertencentes à classe vermelha.

Para encontrar os limites de classe para o quantitativo de acidentes, o decisor analisou quais os limites que caracterizariam a classificação de uma via, para cada critério. Para os critérios de número de acidentes, este propôs a aplicação do Princípio de Pareto. A partir da base de dados, o quantitativo de acidentes que compõem os 10% das vias com mais acidentes faz a fronteira da classe vermelha com a amarela. Os 20% seguintes, separam a classe amarela da verde. Desta forma, 70% das vias com menos acidentes seriam alocadas na classe verde, para este critério.

Tabela 2. Pesos e perfis limites para aplicação do PROMSORT.

Critérios	C1	C2	C3	C4	C5	C6	C7	C8
Peso	0,0740	0,0925	0,0740	0,1851	0,1296	0,1481	0,1851	0,1111
b_1	1	1	0	30	14	2	2	2
b_2	3	4	1	50	18	39	54	4

O método PROMSORT foi aplicado. Inicialmente, 22 ruas foram alocadas na classe vermelha e 6 ruas ficaram na classe amarela. 2179 vias foram classificadas na classe verde, sendo ruas de baixa criticidade. Entretanto, 60 ruas não foram classificadas nessa primeira etapa, pois foram "Incomparáveis com b_1", o primeiro limite de classe que separa as classes verde e amarela. Esse montante representa 2,64% do total de ruas.

Foi necessário, então, definir um ponto de corte com o decisor para a próxima fase de avaliação do PROMSORT, sendo este definido como 0. Tal ponto servirá para alocar as alternativas não alocadas na primeira fase. Foi encontrado então um d_k^+, que representa a sobreclassificação da alternativa em relação a uma categoria C_t, neste caso a categoria mais baixa (Verde) e um d_k^-, por sua vez representando a sobreclassificação da alternativa perante uma categoria C_{t+1}, superior, neste caso a Amarela.

Se o resultado líquido d_k for superior ao ponto de corte, neste caso $d_k > 0$, a alternativa seria alocada à Classe Amarela. Por sua vez, se for menor que o ponto de corte, aloca-se à Classe Verde. A partir desta operação, acabou-se por classificar essas ruas na Classe Verde. Desta forma, na Figura 2 são apresentados o resultado da classificação.

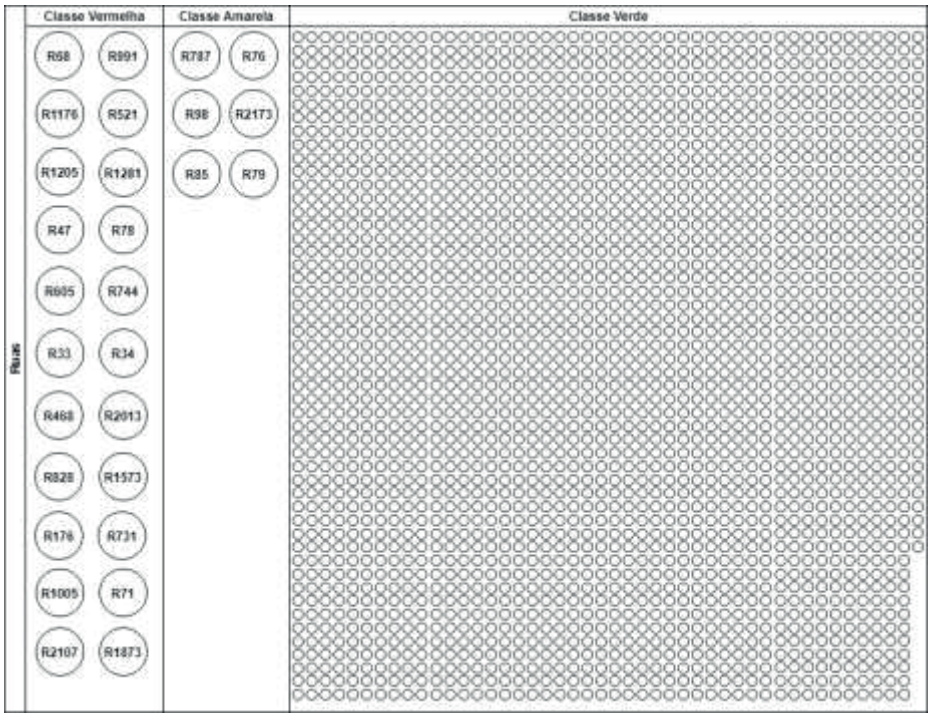

Figura 2. Representação das vias após a classificação

Conforme pode-se observar na Figura 2, a maior parte das vias ficou posicionada na classe verde, em análise comparativa com as demais vias do município. As Tabelas 3 e 4 apresentam as vias que foram classificadas nas classes vermelha e amarela.

Tabela 3. Vias alocadas na classe vermelha

Código da via	Nome
R68	Avenida Presidente Dutra
R991	Rua Francisco Solon
R1873	Rua Prudente De Morais
R1176	Rua Jeremias Da Rocha
R521	Rua Coronel Vicente Saboia
R2107	Rua Tarcísio Correia
R1205	Rua João Falcão

R1281	Rua José Damião
R71	Avenida Rio Branco
R47	Avenida Joao da Escossia
R78	Avenida Sérvulo Marcelino
R1005	Rua Frei Miguelinho
R605	Rua Delfim Moreira
R744	Rua Duodecimo Rosado
R731	Rua Doutor João Marcelino
R33	Avenida Diocesana
R34	Avenida Dix - Neuf Rosado
R176	Rua Alfredo Fernandes
R468	Rua Coelho Neto
R2013	Rua Santos Dumont
R1573	Rua Marechal Deodoro
R828	Rua Felipe Camarão

As vias apresentadas na Tabela 3 carecem de maior atenção por parte dos gestores públicos. Dessas vias, 8 são classificadas como Arteriais II, como as Avenidas Diocesanas, Dix Neuf Rosado, João da Escóssia e Presidente Dutra, algumas das vias mais movimentadas da cidade. Outras 8 são Coletoras I e 3 são Coletoras II. Com exceção de uma que é pavimentada de paralelepípedo, todas as outras são asfaltadas, sendo 9 com um pavimento com estado de conservação regular, 3 em bom estado e 7 ruins. A maior parte destas se concentram na região central da cidade. Destoa dessa distribuição a parte inicial da rua João Falcão, via de entrada de um bairro bastante populoso da cidade e a rua Tarcísio Correia, que liga o outros dois bairros. Essas ruas se destacam ainda por ter uma péssima sinalização horizontal (16 foram avaliadas com 1) e vertical (13 tiveram avaliação 1), além de serem quase todas de alta velocidade (11 tem velocidade de 50 km/h) e somarem 1357 acidentes com vítimas e 750 sem vítimas.

Tabela 4. Vias alocadas na classe amarela

Código da via	Nome

R787	Rua Epitácio Pessoa
R76	Avenida São Jerônimo
R79	Avenida Walter Wanderley
R2173	Rua Vicente Fernandes
R98	RN - 117
R85	Br - 304 - Avenida Industrial Dehuel Vieira

As vias alocadas na classe Amarela 2 são do tipo Arterial I, as Br - 304 em seu trecho de saída para Fortaleza e a RN - 117 na divisa entre os bairros Itapetinga e Bom Jesus, 1 é do tipo Arterial II (Rua Epitácio Pessoa, ligando o Bom Jardim as Barrocas) e as demais são Coletoras II, geralmente ruas importantes dentro dos bairros, captando o fluxo das Arteriais. Todas obtiveram a menor avaliação nos critérios C1, C2 e C8 (sinalização vertical, horizontal e estado de conservação respectivamente). Também possuem velocidades medianas para alta, metade com 50 km/h e metade com 40 km/h.

Foi realizada análise de sensibilidade, analisando especialmente as ruas classificadas como Vermelha e Amarela. Aumentou-se, em 20%, o valor dos pesos atribuídos a cada critério, reduzindo proporcionalmente os demais, de modo a se analisar se haveria alterações nas vias alocadas nas respectivas classes. Em linhas gerais, a variação entre as posições nos critérios foi mínima. As ruas R68, R991, R1873 e R1176 permaneceram em suas posições em todos os critérios para a classe vermelha. Apenas quando se aumentou o peso dos acidentes sem vítimas (C6), obteve-se mais ruas que os demais, totalizando 32 ruas nesta classificação, sendo 7 ruas únicas, ou seja, que não apareceram em nenhum outro critério quando foram analisados.

As posições para a classe amarela também variaram pouco. A mudança do critério de acidentes sem vítimas (C6), ocasionou redução na quantidade de ruas na classe amarela, com 4 delas indo para a classe vermelha (Epitácio Pessoa, Avenida São Jerônimo, Avenida Walter Wanderley e rua Vicente Fernandes). Quando se aumentou o peso para velocidade (C4), observou-se mais ruas sendo classificadas como classe amarela, passando para 9, sendo 3 ruas únicas, sem presença em outros critérios. Tais ruas na análise original estavam na classe verde.

Por fim, os resultados obtidos foram associados a base geoespacial original, de modo a criar um mapa temático, apresentado na Figura 3. Tais mapas permitem que o gestor facilmente assimile informações cruciais, de modo a adotar rapidamente as ações necessárias.

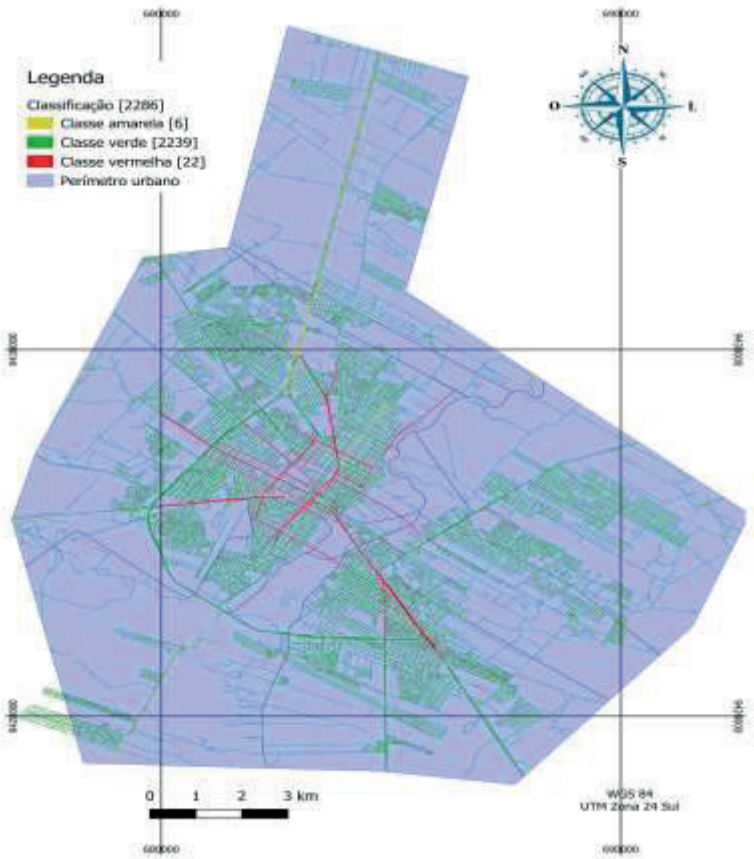

Figura 3. Mapa das vias da cidade após a classificação

A partir da análise da Figura 3, podemos ver que algumas das principais vias da cidade, como (R34) Avenida Dix Neuf Rosado, (R71) Avenida Rio Branco e (R68) Avenida Presidente Dutra, que conectam os extremos do município e tem um maior fluxo de veículos, foram classificadas como vermelha, demandando intervenção imediata. Além disso, dentro do SIG, é possível aplicar zoom no mapa e identificar visualmente quais vias estão alocadas em cada uma das classes. Isso pode ajudar o gestor a visualizar a relação entre as vias e entender como se relacionam os fatores de risco para as vias. Além disso, a representação geográfica dos resultados pode ser importante para facilitar a comunicação entre todos os envolvidos na gestão de trânsito e prover possibilidade de acompanhamento das condições das vias periodicamente.

5 Considerações finais

Os acidentes de trânsito tornaram-se uma verdadeira epidemia no Brasil, gerando prejuízos sociais, econômicos e humanos. Além disso, sobrecarregam os serviços públicos de saúde, o que prejudica o atendimento para todos. Neste sentido, melhorar o processo de tomada de decisão para priorização de onde o Poder Público deve agir, pode gerar bons resultados e maximizar os ganhos sociais com as intervenções realizadas. Diante deste contexto, é proposto um modelo multicritério para apoiar o processo de tomada de decisão, classificando as ruas em uma das três classes críticas: vermelha, amarela e verde. Para tanto, é proposta a utilização do método PROMSORT, que permitiu que fossem analisadas diversas características quantitativas e qualitativas, em uma grande quantidade de alternativas (após os processamentos, chegou-se a 2267 ruas únicas). Em seguida, os dados obtidos foram representados geograficamente e pôde-se constatar quais as áreas mais críticas para atuação dos gestores públicos.

Destacam-se algumas limitações do estudo. Em termos práticos, devido a elevada rotatividade nas pessoas que tomam decisões quanto ao trânsito, os parâmetros definidos pelo tomador de decisão podem ser alterados com certa frequência. Além disso, a própria utilização do modelo depende de um esforço dos gestores que podem passar a atuar no setor, a cada eleição, entendam a importância do mesmo. Outra limitação envolveu a consideração de apenas um tomador de decisão. Neste sentido, propõe-se, como sugestão de trabalhos futuros, a adequação do modelo para um contexto de múltiplos tomadores de decisão.

Resumo. Nos últimos anos o termo inovação encontra-se em evidência. A mudança dos ambientes corporativos e a necessidade de inserção de novas tecnologias que ficam obsolescentes cada vez mais rápidas, fazem com que decisões sobre qual destas utilizar seja bem fundamentada e baseie-se em critérios de relevância pelos diversos membros do setor. O impacto de uma decisão pode gerar uma linha tênue entre ganhos e prejuízos grandes para a empresa. A melhor maneira de contornar os impactos é tomar a decisão levando-se em consideração as principais dimensões da inovação. O artigo traz uma pesquisa sobre a preferência das camadas operacionais e de gestão de uma empresa de grande porte com relação às dimensões da inovação. A pesquisa foi realizada fazendo uso do método AHP (*Analytic Hierarchy Process*) comparando as dimensões. A ferramenta com AHP foi desenvolvida em python, sendo voltada à web, o que tornou possível a sua realização de uma forma mais rápida e de maneira remota.

Keywords: AHP, Dimensões da inovação, Tomada de decisão.

1 Introdução

A inovação, como peça determinante para o sucesso e prosperidade das organizações e países vem sendo estudada há vários anos, porém, no atual contexto de instabilidade econômica e política mundial, globalização da economia, avanços tecnológicos competição por recursos e consumidores, a inovação está tornando-se preponderante para a própria sobrevivência das organizações.

Tanto o meio acadêmico como o meio empresarial têm visto na capacidade de gerar soluções inovadoras uma fonte de diferencial estratégico para obter-se vantagem competitiva.

No entanto, desafios e pressões são apresentados às empresas para que a inovação aconteça de forma sustentável e contínua. Tempo e recursos devem ser disponibilizados para que as organizações possam vencê-los e gerar um ambiente apropriado à atividade inovadora nos diversos níveis da organização.

Diversos obstáculos se apresentam à inovação. Estes obstáculos podem ser de origem econômica, tais como, alto custo da inovação e dificuldades de financiamento. Podem também estar no campo do risco ao investimento, uma vez que inovação de-

pende da aceitação do público consumidor e até nas dificuldades de pessoal especializado e motivação para inovar. Soma-se a isto as incertezas tecnológicas, mercado e as próprias barreiras culturais e de gestão das empresas.

Desta feita, onde há obstáculos se buscam modos de suprimi-los. Diversos estudos identificam fatores ou dimensões, que se observados e mensurados, podem conduzir a organização a um caminho mais suave rumo a atividade inovativa.

Ainda assim, mesmo que o conhecimento sobre estes fatores fosse de conhecimento da camada de gestão das organizações, o conhecimento deveria ser difundido e aceito pelas camadas operacionais, geralmente quem produz a inovação. Entretanto, a comunicação entre estes níveis empresariais nem sempre é tido como satisfatório, podendo ensejar uma sequência de dificuldades.

O presente estudo pretende explanar as principais características da inovação, sua conceituação, seus obstáculos e dimensões para que a inovação aconteça. O principal propósito é observar através de método multicritério se a compreensão das dimensões e sua ordem de importância é uniforme entre as diferentes hierarquias de membros da camada gestora e depois entre esta e a camada operacional.

1.1 Referencial Teórico

1.1.1 Inovação

Muito tem se falado da necessidade da inovação para gerar diferencial estratégico para as organizações, promovendo a melhora de performance, desempenho e consequente lucratividade.

Schumpeter, em sua obra Theory of economic development (1911), já demonstrava a relação entre empreendedorismo e a inovação, reforçando a importância desta relação para as organizações. Ele cunhou o termo “destruição criativa” para demonstrar que empreendedores obsoletavam recursos e infraestrutura existentes, causando sua renovação. Este conjunto de atos, habilidades e ousadia das pessoas ensejaram o surgimento de novos produtos, processos e serviços nas organizações. Assim, as organizações surgiam, eram mantidas e cresciam de forma lucrativa (THIMÓTEO, 2020).

Assim, o capitalismo, motor da competição econômica, não poderá se manter em estado estacionário. É a inovação que “incessantemente revoluciona a estrutura econômica a partir de dentro, incessantemente destruindo a velha, incessantemente criando uma nova” (SCHUMPETER, traduzido em 2017).

Ao longo do tempo, tornou-se claro que a inovação gerando progresso tecnológico promove o incremento da produtividade, a geração de novos produtos e serviços, aumentando o desempenho e muitas vezes sendo fator decisivo para o sucesso das organizações (MOTOHASHI, 1998).

Estudos de NELSON (1992) e ROSENBERG (1982) já apontavam sobre o papel importante da inovação tecnológica para o aumento da competitividade global, na medida em que melhoravam o desempenho das organizações.

Da forma oposta, a inércia com relação ao comportamento inovador ocasiona o aprisionamento do potencial das organizações, mantendo-as cada vez mais distante das organizações que tem inovação no seu referencial estratégico e que realmente a promove. Como demonstração disto, o estudo de LEDERMAN et al (2014) informa

que o baixo índice de soluções inovadoras tem levado as organizações latino-americanas a um crescimento mais lento comparado a outras regiões.

SHUMPETER (2017) ensina que em um mundo estacionário, sem inovação e desenvolvimento econômico, a competição poderia reduzir os lucros para um nível "normal". Mas, dentro de um desenvolvimento dinâmico, lucros acima do normal são frequentemente a recompensa das organizações inovadoras.

O tema da inovação, portanto foi discutido por diversos autores e sua conceituação vem sendo desenvolvida ao longo do tempo.

SCHUMPETER (2017) já conceitua a inovação como uma ação ou conjunto de ações que é aplicado industrialmente ou mesmo no comércio na forma de produtos, formas de produção, processos, suprimentos ou outros insumos. Estas ações trazem no seu núcleo uma nova organização de negócios ou das relações de trabalho.

A Organização para Cooperação e Desenvolvimento Econômico (OCDE) também define inovação no Manual de Oslo. Para a OCDE (2006), inovação se define como "a implementação de um produto, bem ou serviço novo ou significativamente melhorado, ou ainda um processo ou um novo método de marketing ou um novo método organizacional nas práticas de negócio na organização do local de trabalho ou nas relações externas".

Já a Lei de Inovação (2004) define inovação como "introdução de novidade ou aperfeiçoamento no ambiente produtivo e social que resulte em novos produtos, serviços ou processos ou que compreenda a agregação de novas funcionalidades ou características a produto, serviço ou processo já existente que possa resultar em melhorias e em efetivo ganho de qualidade ou desempenho".

MOYSÉS & LIPPI (2003) adverte que não se deve considerar como inovação qualquer invenção advinda da mente humana. Para ele, invenção significa uma criação intelectual de algo inexistente e que pode não ter consequências econômicas, enquanto inovação consiste em uma ideia efetivamente incorporada aos sistemas produtivos levando a resultados econômicos. Tal ideia é corroborada por QUANDT (2009) que afirma ser uma invenção a concepção de algo inédito independentemente de sua aplicação comercial ou mesmo utilidade prática, enquanto inovação está atrelada à transformação de conhecimento em valor, pela introdução de novos produtos processos ou sistemas no mercado, ou seja, a inovação deve ser revestida de potencial econômico.

No mesmo bojo de ideias, a Lei do Bem (2006) definiu inovação como "a concepção de novo produto ou processo de fabricação, bem como a agregação de novas funcionalidades ou características ao produto ou processo que implique em melhorias incrementais e efetivo ganho de qualidade ou produtividade, resultando maior competitividade no mercado".

1.1.2 Obstáculos à inovação no Brasil

Se a inovação, gerada pela força do capital humano tem sido um propulsor do progresso e desenvolvimento econômico de empresas e países (DIEBOLT & HIPPE, 2019), por outro lado, esta mesma inovação encontra obstáculos à sua geração.

O manual de OSLO (2005) aponta os principais fatores dificultadores da Inovação, separando-os em 3 grupos, sendo eles: Fatores econômicos, fatores da empresa e outras razões diversas.

A tabela 1 desdobra os grupos em fatores individualizados.

Tabela 1. Obstáculos à atividade de inovação. (Adaptado OCDE, 2005)

Grupo	Itens
Fatores econômicos	Riscos excessivos percebidos
	Custo muito alto
	Falta de apropriadas de financiamento
	Prazo longo de retorno de investimento
	Potencial de inovação insuficiente
	Falta de pessoal qualificado
	Falta de informações sobre tecnologia
Fatores da empresa	Falta de informações sobre os mercados
	Dificuldade em controlar gastos com inovação
	Resistência interna às mudanças
	Deficiências na disponibilidade de serviços externos
	Falta de oportunidades para a cooperação
	Falta de oportunidade tecnológica
Outras razões	Falta de infraestrutura
	Nenhuma necessidade de inovar devido a inovações anteriores
	Fraca proteção aos direitos de propriedade
	Legislação, normas, regulamentos e padrões impostos
	Clientes indiferentes a novos produtos e processos

Os fatores apontados pelo Manual de Oslo aparecem em diversas pesquisas feitas no Brasil tanto por pesquisadores da academia, quanto por relatórios governamentais.

No Brasil, empresas pesquisadas pelo IPEA para a consolidação da nota técnica IPEA (2009) apontaram como seus principais obstáculos à inovação fatores associados ao crédito, sendo eles: Riscos econômicos excessivos, elevados custos da inovação e escassez de fontes apropriadas de financiamento.

Quandt (2009), na mesma esteira, além dos itens acima, cita: escassez de recursos próprios, falta de pessoal qualificado, resposta fraca de consumidores a novos produtos e falta de informação sobre tecnologias e mercados.

QUANDT et al (2013) estuda fatores associados à inovação dividindo-os em dimensões que podem ser relacionadas ao sucesso ou fracasso nas iniciativas de inovação. As dimensões são: Estratégia e objetivos, Liderança, Cultura e valores, Estrutura organizacional, Processos, Gestão de recursos humanos e competências, Relacionamento externo, Infraestrutura tecnológica e sistemas de informação, Medição de resultados e recompensas e Aprendizagem.

MAIA & SILVA (2016) lembram que a capacidade inovadora varia entre as empresas e pode ser determinada por um grande e complexo número de fatores. Estes fatores tanto impulsionam quanto limitam o processo de inovação empresarial.

Muitas variáveis afetam o resultado esperado referente ao processo de inovação. Estas variáveis podem ser de caráter econômico, cultural, corporativista e legal, portanto essas barreiras devem ser consideradas no momento do planejamento da gestão da inovação no âmbito empresarial (MELLO et al., 2013)

1.1.3 Dimensões da inovação

Diversos autores estudaram ferramentas para promover a inovação, seja nos aspectos da gestão da inovação ou mesmo na capacidade de inovar. Várias ferramentas e modelos conceituais foram apresentados ao longo do tempo. Neste trabalho, foram analisadas ferramentas que propõem a análise por dimensões, assim selecionamos as ferramentas a seguir:

1. (OI) Octógono da inovação proposto por Scherer & Carlomagno (2009);
2. (DI) Dimensões organizacionais da inovatividade proposto por Quandt, Ferraresi & Bezerra (2013);
3. (IIF) Integrated Innovation Framework, proposto por Nada, KHoleif, Elbadawy & Yanik (2010);

As abordagens citadas têm em comum o modelo baseado em dimensões que influenciam a inovação nas corporações, variando entre elas a quantidade e significados.

Apesar das ferramentas se basearem em dimensões de análise nota-se que entre estes autores:

1. Não há coincidência total de dimensões entre as ferramentas;
2. Nas dimensões que são coincidentes, seus significados são similares ou mesmo complementares;
3. As dimensões englobam questões típicas relacionadas à inovação, não observamos conflitos ou dimensões antagônicas.

1.1.4 Comunicação entre a alta gestão e camadas operacionais sobre inovação

As organizações, geralmente, procuram melhorar a comunicação entre a alta gestão e as camadas operacionais com o objetivo de melhorar a produtividade e se manterem no mercado.

Bueno (2007), aponta que os problemas de comunicação podem interferir negativamente na vida das organizações. Ele afirma que empregados mal informados ou descontentes podem gerar prejuízos pois expressam com mais autenticidade valores positivos ou negativos sobre a cultura organizacional, uma vez que, “afinal de contas, eles estão vivendo lá dentro”.

Por esta razão, a comunicação interna ganha destaque no sentido de promover mudanças, ajustar comportamentos e qualificar seus empregados. Ao fim, busca-se a melhoria de desempenho, produtividade e consequente lucratividade.

JACOMINI (2011) ensina que a produtividade dos empregados está diretamente ligada à qualidade da informação que recebem e consequente envolvimento com a missão. Por isto a comunicação tem papel preponderante na boa gestão operacional. A

comunicação adequada integra as pessoas e as motiva a compartilhar ideias e agregar valores à organização.

A mesma autora, no entanto, adverte que quando a comunicação não ocorre de forma correta e integrada, podem surgir transtornos que podem levar as iniciativas ao descrédito e mesmo ao fracasso. Comunicações má conduzidas e, portanto, mensagens recebidas com impedância podem gerar insegurança, desmotivação e falta de comprometimento dos empregados.

REGO (2010) adverte que, sendo uma organização de fato uma rede de comunicação, se a comunicação falha, uma parte da estrutura organizacional também falha.

O mesmo fenômeno pode ser observado nos processos de inovação. CARVALHO (2009) discute o processo de comunicação como condição essencial para que "a dinâmica interna produza e incorpore inovações". O mesmo autor ainda afirma que é a comunicação que permite que pessoas possam compartilhar conhecimento para mudar e inovar processos e produtos, sendo esta comunicação, objeto necessário para que "a cultura se renove e ocorra aprendizagem e criação".

Barañano (2005) entende a comunicação como essencial e medida básica para o sucesso dos processos de inovação. Ainda adverte que em organizações complexas, a comunicação encontra obstáculos, tornando-se um fator de suscetibilidade.

Com efeito, mesmo a comunicação das estratégias pode encontrar barreiras entre a gestão, responsável para estratégia das organizações e as unidades operacionais, responsável por levar a cabo tais estratégias. Mesmo processos estabelecidos podem encontrar barreiras devido ao isolamento das áreas multidisciplinares que atuam no mesmo processo. (GARCIA, 2011)

Desta forma, aquilo que é considerado importante para os gestores pode não ser considerado da mesma maneira pela camada operacional, criando disrupção no entendimento dos fatores essenciais, podendo levar iniciativas inovadoras ao fracasso.

2 Método Proposto

2.1 Classificação da pesquisa

Quanto à natureza, trata-se de uma pesquisa aplicada, pois busca gerar conhecimento para aplicação prática e direcionada a solução de problemas cotidianos.

A pesquisa tem características qualitativas, de caráter exploratório-descritivo, um estudo de caso, buscando compreender o comportamento e crenças de um grupo específico de pessoas, no entanto, por usar método multicritério, especificamente AHP, onde existem comparações par a par definindo um valor específico que define cada comparação, temos características quantitativas. Assim, quanto à abordagem, trata-se de uma pesquisa quali-quantitativa.

2.2 Procedimento da pesquisa

A pesquisa se deu nas áreas de tecnologia da informação (TI) de uma grande empresa situada no sul do Brasil (Empresa). Esta empresa conta com mais de 7000 em-

pregados sendo que destes, cerca de 150 trabalham diretamente com tecnologia da informação.

O "Nível operacional" está subordinado à cadeia de gestão da área em questão, que é composta por 3 níveis, sendo eles:

- "Nível gestor próximo";
- "Nível gestor intermediário";
- "Nível gestor superior";

O Nível gestor próximo se distingue por sua proximidade ao nível operacional, sendo diretamente responsável pelas funções operacionais da organização em questão.

O Nível gestor intermediário é responsável pelas ações táticas oriundas do planejamento estratégico. Tem o nível operacional e o nível gestor próximo como subordinados. Responde a Nível gestor superior.

O Nível gestor superior é responsável pelas definições estratégicas da área de tecnologia da informação. Subordina os demais níveis.

O modelo foi operacionalizado em 4 atividades distintas:

1 - A partir das descrições das dimensões da inovação foram levantadas 13 dimensões. Para cada dimensão levantou-se uma resenha baseada nas descrições.

2 - As dimensões e suas resenhas foram encaminhadas para 13 especialistas junto com uma planilha, onde estes especialistas deveriam marcar a ordem de importância, de acordo com seu entendimento, para cada uma das dimensões propostas. A classificação a ser apontada foi de 1 a 13, sendo 1 a mais importante e 13 a menos importante, não podendo haver repetição de valor.

Para cada dimensão, calculou-se a mediana das respostas dos especialistas, bem como seu desvio padrão. Isto se deu para a classificação das dimensões por ordem de importância na visão dos especialistas baseado na mediana. Caso houvesse empate, a dimensão que tivesse o menor desvio padrão teria a prevalência.

As 4 dimensões melhores classificadas foram selecionadas para a apreciação das pessoas da TI na empresa em ordem alfabética para não ocorrer qualquer tipo de influência nas respostas.

3 - As 4 dimensões foram apresentadas às pessoas da TI, posteriormente enquadradas nos níveis de gestão.

Estas receberam uma chave de acesso onde puderam classificar as 4 dimensões apontadas pelos especialistas utilizando o método AHP implementado no sistema. Os entrevistados classificaram as dimensões par a par informando o nível de relevância entre as dimensões. A relevância da dimensão "A" em relação à dimensão "B" foi classificada como:

- De igual importância;
- Um pouco mais importante;
- Muito mais importante;
- Extremamente mais importante;

O sistema disponibilizado para a pesquisa calculava de forma on-line o nível de inconsistência, solicitando ao entrevistado que corrigisse suas respostas caso esse nível fosse superior a 10%.

4 - As respostas de cada grupo foram unificadas pela mediana de seus resultados e estes resultados foram comparados.

Antes de apresentar a ferramenta aos respondentes, ela foi submetida à análise de 5 pessoas da organização para que validassem sua usabilidade. Esta fase foi útil para incrementar alguns controles e executar algumas correções.

3 Desenvolvimento

A tabela 2 mostra as escolhas dos especialistas após serem apresentadas 13 dimensões da inovação.

Tabela 2. Classificação das dimensões de acordo com os especialistas.

Ordem	Dimensão	Mediana	Desvio Padrão
1	Liderança	2	3,7296
2	Estratégia	3	3,1481
3	Pessoas	5	3,2621
4	Cultura e valores	5	3,5320
5	Infraestrutura, metodologias e ferramentas	6	3,0170
6	Estrutura organizacional	6	3,4044
7	Alocação de recursos	7	3,0234
8	Processos	7	3,3128
9	Aprendizagem	8	3,5210
10	Mensuração	9	2,7339
11	Relacionamento	9	2,8148
12	Funding	10	3,8180
13	Propriedade intelectual e comercialização	11	3,84

Conforme a aplicação da metodologia proposta, foram selecionadas as 4 dimensões mais bem classificadas.

Estas dimensões foram apresentadas aos respondentes através de e-mail, que continha a proposta do trabalho bem como uma descrição de cada uma das dimensões em ordem alfabética, além do acesso à ferramenta AHP desenvolvida para esta pesquisa. A descrição das dimensões apresentadas aos respondentes tinha o mesmo teor apresentado aos especialistas, porém com adaptação para a melhor compreensão de um público não acostumado com tema Inovação, conforme se vê na tabela 3.

Tabela 3. Descrição das dimensões apresentadas aos respondentes.

Dimensão	Descrição apresentada aos respondentes
Cultura e Valores	É a personalidade de organização. É composta pelas premissas, valores, normas e sinais tangíveis das lideranças da organização e seus comportamentos. A cultura e valores da empresa fortalecem o pensamento independente e a aplicação do conhecimento pessoal para os desafios organizacionais. Dá forte incentivo institucional ao questionamento e a quebra de paradigmas para gerar inovação. Está atrelado ao reconhecimento e recompensas.

Estratégia	O termo estratégia diz respeito à definição da "arena estratégica" para a inovação. Formulação de objetivos estratégicos de inovação, bem como o uso da inovação como instrumento estratégico para criar diferenciação. O entendimento que a inovação deve ter prioridade no planejamento estratégico da organização.
Liderança	O termo liderança no contexto deste estudo não se refere às pessoas que ocupam cargos de liderança, mas sim ao papel das lideranças para assegurar a eficácia do processo de gestão da inovação, inclusive considerando aspectos de comunicação, aprendizado e mudança, além da tolerância a riscos. Está atrelada ao grau de comprometimento que as lideranças e influenciadores tem para instituir ou propiciar a inovação.
Pessoas	O termo pessoas não se refere a um indivíduo ou mesmo ao conjunto dos indivíduos. O termo está atrelado a como a organização privilegia, estimula e recompensa seus empregados na busca da inovação. Como a organização se foca em indivíduos competentes, estimulados e dispostos ao enfrentamento dos desafios. Estas ações buscam garantir que todos os empregados conheçam os conceitos e a necessidade de inovar.

Neste mesmo e-mail, os respondentes receberam explicações básicas sobre o AHP, em especial sobre as comparações par-a-par e a necessidade de se obter um nível de inconsistência inferior a 10%.

Estas observações foram necessárias porque a ferramenta impedia que o respondente pudesse submeter suas respostas caso a inconsistência fosse superior a 10%, conforme preconizado pelo AHP.

A solução foi desenvolvida para ser executada tanto em computadores como para dispositivos móveis, fazendo uso de uma aplicação web utilizando o framework Django, escrito em python, que faz uso de linguagens javascript, CSS e HTML em modo responsivo para a interação com o usuário.

A figura 1 mostra a interface inicial que permite ao respondente comparar as dimensões propostas. O usuário faz a sua escolha deslizando o indicador em direção à sua preferência, formando assim a sua resposta.

Fig. 1. Interface da ferramenta.

Foram obtidas 51 respostas de um conjunto de 150 empregados da TI distribuídos da seguinte forma:

1. Gestor nível Superior: Posição máxima na TI, portanto 1 respondente;
2. Gestor nível intermediário: 3 respondentes;
3. Gestor nível próximo: 8 respondentes;
4. Nível operacional: 39 respondentes;

4 Resultados Observados

Após compilar os dados, encontramos os seguintes resultados seguindo os agrupamentos propostos pelo trabalho, a saber, nível operacional, nível gestor próximo, nível gestor intermediário, nível gestor superior.

As dimensões foram pontuadas e seus resultados compilados conforme a tabela 4 e apresentados no gráfico na figura 2:

Table 4. Resultados obtidos por nível.

Nível	Cultura e valores	Pessoas	Liderança	Estratégia
Operacional	0,25	0,35	0,02	0,12
Gestor Próximo	0,285	0,335	0,15	0,205
Gestor Intermediário	0,32	0,2	0,31	0,23
Gestor Superior	0,19	0,18	0,57	0,06

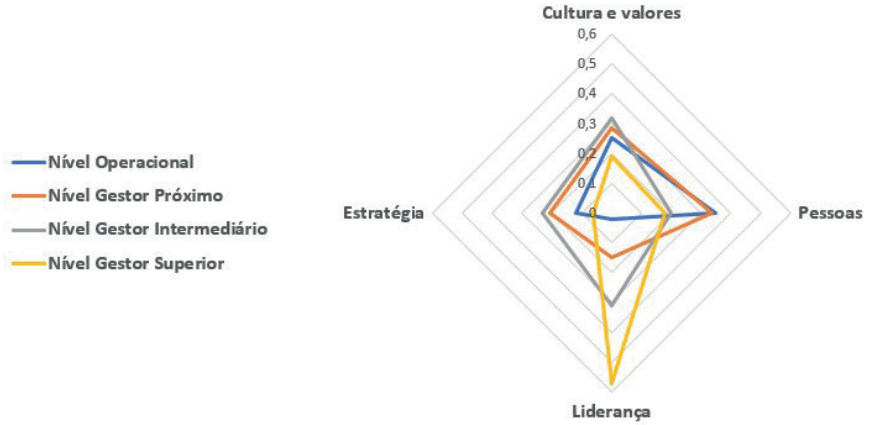

Fig. 2. Comparação das escolhas sobre as dimensões dos diferentes níveis

5 Considerações Finais

Ao observar o desenvolvimento do trabalho vê-se que a decisão por utilizar o AHP foi acertada. O AHP permitiu converter as preferências humanas em valores numéricos, não sendo mais uma simples observação da realidade. O AHP, portanto, permitiu comparar e qualificar numericamente as preferências dos respondentes e depois chegar a resultados numéricos para cada um dos grupos. Também, nota-se que a qualidade das informações recebidas tende a ser mais assertiva, visto que o método garante a consistência das respostas. Não obstante a condição humana dos respondentes, o método, apesar de apontar inconsistências, tolera o limite de 10%, o que o torna uma ferramenta adequada para trabalhar com fatores onde a percepção humana, cheia de inconsistências, pode ser aceita e mensurada.

A Ferramenta criada para este trabalho implementa o método AHP. Seu uso foi fundamental para que o trabalho fosse executado, pois facilitou e acelerou a tomada de respostas. Parte desta aceleração é devido à análise da inconsistência, não permitindo que sejam enviadas respostas inconsistentes portanto, evitando que os pesquisadores tenham que voltar aos respondentes para ajustar as respostas.

Analisando o agrupamento das respostas, observamos que existe uma divergência bastante significativa entre os diversos níveis estudados. Comparando a visão do nível de gestão superior com os demais, podemos verificar que enquanto este nível valoriza a importância da dimensão liderança em detrimento das demais, O Nível gestor intermediário se aproxima mais do nível gestor superior, enquanto o nível gestor próximo por sua vez se aproxima do nível operacional.

Diante disto, é possível entender que as mensagens relativas à compreensão da importância das dimensões da inovação, oriundas do dos níveis superiores não tem sido adequadamente compreendido ou aceito pelos níveis operacional e nível gestor próximo.

Não é objeto deste trabalho entender as razões das divergências de opinião entre os diversos grupos, portanto, este levantamento poderia ser objeto de trabalhos futuros.

Abstract. The energy transition is a process that we can observe in the history of humanity because it generates a positive impact that such process has on the population's living standards. For example, humankind has evolved from heat energy produced by wood to autonomous planes powered by solar energy. Nowadays, the transition from fossil to renewable energy pursues the maintenance of a constant improvement rate on living standards without affecting the environment. However, the current development of renewable energy does not cover global demand for energy, and the adoption costs are too high for consumers and producers as well. Thus, it is necessary a driver intermediary that facilitates the current transition. In this paper, we analyze the role of the Government as a driver intermediary for the adoption and generation of renewable energy by consumers and producers. We model the interaction through as a three-stage game where the Government sets the public policy by imposing taxes and giving subsidies to the industry after the initial stage and fully implements them in two later stages where firms compete as in the Cournot's model.

Keywords: Energy Transition, Driver Intermediary, Sub-game Perfect Nash equilibrium.

1 Introducción

En la última década, la temperatura global ha alcanzado niveles superiores a los de la época pre-industrial lo cual ha generado cambios climáticos, pérdida de ecosistemas y problemas de salud pública (Jackson et al., 2018). Debido al impacto de los gases de efecto invernadero en el incremento de la temperatura mundial, la comunidad internacional firmó el Acuerdo de París en el año 2015 con el objetivo de reducir la emisión de dichos gases (IPCC, 2018). Particularmente, los países firmantes se comprometieron a transitar hacia actividades menos contaminantes basadas en energía renovables (Hoegh-Guldberg et al., 2018).

Se conoce como Transición Energética (TE) al proceso de sustitución de fuentes de energía no renovables, como los combustibles fósiles, por fuentes de energía renovables para la generación de calor, movimiento y luz (Smil, 2010). Dados los costos asociados a dicho proceso, la comunidad internacional presenta avances heterogéneos

al respecto. Por ejemplo, los países en desarrollo no tienen recursos suficientes para desarrollar estrategias de transición energética. Sin embargo, es necesario implementar políticas públicas que aceleren dicho proceso debido a la posible irreversibilidad del cambio climático y los fenómenos que puede generar.

El presente trabajo estudia como la redistribución fiscal influye en las decisiones del oligopolio energético durante la TE. Puesto que en dicho proceso empresas y gobierno son agentes estratégicos (Loorbach et al., 2008), modelamos la transición energética tomando como base el juego de Suárez y Gibaja (2019). En el presente artículo, nos enfocamos en analizar las decisiones de las empresas cuando el gobierno implementa, o no, una política redistributiva en la tercera etapa de los ingresos fiscales obtenidos mediante impuestos durante la segunda etapa. También, analizamos el impacto de las estrategias de política pública considerando diferentes estructuras de mercado.

El presente trabajo se relaciona de manera estrecha con la literatura que reconoce los conflictos que pueden emerger en un proceso cuyo éxito depende de la cooperación de los agentes (Bridge et al., 2013). Así, la modelación de la TE parte de la interacción gobierno-empresa como un juego en el que la decisión de un agente afecta el resultado del otro (Pérez et al., 2004); es decir, soluciones cooperativas y no cooperativas dentro de los patrones de decisión de los agentes involucrados son relevantes para estudiar la adopción de nuevos productos e insumos. En este sentido, Weitzman (1993) explica las diferencias en las transiciones económicas de países comunistas hacia modelos de libre mercado a partir de la cooperación social, la cual emerge de las interacciones repetidas (Teorema del Folk).

Entre nuestras contribuciones, destaca el análisis que hacemos del gobierno como "agente conductor" de la TE. Autores como (Van Veurden, 2017) reconocen la necesidad de establecer este tipo de agentes para generar incentivos para adoptar nuevas tecnologías e insumos. Específicamente, asumios que el gobierno interviene en este proceso para evitar fallos que afecten negativamente el bienestar social durante la TE.

La competencia tipo Cournot es la base de nuestro modelo pues los mercados energéticos se caracterizan por el intercambio de bienes homogéneos en un contexto oligopólico (Borenstein et al., 1999; Ludkovski & Sircar, 2015; Villar & Rudnick, 2002). En esta rama de la literatura, el análisis de juegos se enfoca en establecer políticas regulatorias para mantener estables los precios de un insumo esencial para las actividades económicas. Nuestro principal resultado indica que, a pesar de las estructuras de costos, es posible desarrollar una transición exitosa cuando el gobierno impone impuestos en una primera etapa y después los distribuye como subsidios. Sin embargo, el considerar un espacio de acciones discreto también genera escenarios donde los agentes prefieren una estrategia mixta a una estrategia pura; es decir, la energía renovable no sustituye totalmente a la energía no renovable debido a la posible falta de cooperación de las empresas.

El artículo se encuentra estructurado de la siguiente manera. La sección 2 detalla el modelo matemático que proponemos para analizar las políticas públicas de transición energética.

2 Modelo

En esencia, el proceso de TE busca sustituir insumos que generen una gran cantidad de gases de efecto invernadero por fuentes generación de energía más limpias. Sin embargo, el éxito de la TE recae en la disposición de los agentes para cambiar sus esquemas de producción y consumo de energía. Particularmente, las empresas energéticas son renuentes a llevar cabo dicho proceso pues los insumos tradicionales les generan economías de escala (Nicholson & Snyder, 2015). Lo anterior genera barreras de entrada a otras empresas lo que permite el surgimiento de oligopolios energéticos.

Se sabe que la energía es homogénea en dichos mercados, por lo que es usual estudiar las interacciones en los mercados energéticos por medio del modelo de Cournot (Ludkovski & Sircar, 2015; Pérez et al., 2004). Con respecto a la TE, Suárez y Gibaja (2019) proponen un modelo de TE basado en la repetición del juego de Cournot añadiendo la intervención del gobierno en una primera etapa.

En el presente trabajo, consideremos una versión discreta del modelo de Suárez y Gibaja (2019) enfocada en la total redistribución, o no, de recursos fiscales. Dicha variación se describe en las siguientes subsecciones.

2.1 Elementos básicos del juego

Consideramos un mercado energético en el que el gobierno establece una política pública que busca incentivar la producción de energía mediante fuentes renovables. Denotamos por g al gobierno, y por F al conjunto de firmas productoras de energía. Por simplicidad, consideramos que $F = \{e_1, e_2\}$, donde e_i representa una firma genérica. Puesto que los consumidores no distinguen entre energía proveniente de combustibles fósiles o renovables, asumimos que los consumidores no son agentes estratégicos. Entonces, el conjunto de agentes estratégicos es $S = \{g\} \cup F$.

Cada empresa $e_i \in F$ produce energía usando insumos renovables (r) o no renovables (f). Sea $R = \{r, f\}$ el conjunto de insumos disponibles para producir energía. Denotamos por q_i^p la energía que produce e_i utilizando un insumo $p \in R$. Entonces, la producción total de energía de la firma e_i es $q_i = q_i^r + q_i^f$, mientras que $\overline{q_i} = \left(q_i^r, q_i^f\right)$ representa el plan de producción de e_i. También, consideramos que e_i tiene una función de costos C_i que depende de $\overline{q_i}$. Puesto que estamos buscando genera una TE, asumimos costos separables por las características de la energía renovable y no renovable. Así, $C_i = c_i^r \cdot q_i^r + c_i^f \cdot q_i^f$ donde c_i^p es el costo marginal de que i utilice el insumo p. Además, consideramos que $c_i^r > c_i^f$ pues producir energía con fuentes renovables es más costoso que hacerlo con fuentes no renovables debido a las economías de escala existentes en los mercados energéticos (Nicholson & Snyder, 2015).

Se asume que el gobierno es el "agente conductor" que define la política pública para incentivar la TE. Denotamos por $v = (\sigma, \tau)$ la política pública del gobierno, donde σ es un subsidio a la producción de energía con insumos renovables, mientras que τ es un impuesto al uso de combustibles fósiles.

Los consumidores demandan una cantidad total de energía $Q = Q_f + Q_r$, donde Q_f es la demanda que se cubre con insumos no renovables y Q_r es la energía que se pro-

duce con fuentes renovables. Sea P_j el precio de la energía que se produce utilizando el insumo $j \in R$.

2.2 El juego de la transición energética

Definimos el juego de la Transición Energética como un conflicto estratégico en el que intervienen los agentes en F, mientras que los consumidores no son agentes estratégicos pues no distinguen entre energía renovable y no renovable. La interacción entre gobierno y empresas se modela como un juego de tres etapas a través del cual se busca la sustitución de combustibles fósiles por combustibles más limpios mediante la intervención del gobierno. , en el cual el gobierno puede escoger entre definir una política pública no redistributiva en la cual solo implementará un impuesto al consumo que será aplicado en la etapa 2 o puede optar por una política de tipo redistributivo en la cual define un impuesto al consumo que implementa en la etapa 2 y un subsidio a la producción con fuentes renovables que implementa en una etapa 3 y que se financia a través del recaudo fiscal de la etapa 2. Considerando lo anterior se demarca que $T = \{1,2,3\}$ es el conjunto de las etapas del juego, en donde t denota una etapa genérica en el mismo, para efectos de notación explicativa se tendrá que (q_i^{tr}, q_i^{tf}) denota la producción de una firma e_i en un momento t del juego, a continuación se desglosa el desarrollo general de las etapas considerando las variantes de decisión del gobierno partiendo del escenario base de política pública redistributiva (PPR) a partir de la cual se deduce la variante no redistributiva (PPNR) :

Etapa 1: El gobierno g define una política pública (τ,σ) en la cual τ es un impuesto a la cantidad consumida de Q_f, y σ es un subsidio directo a la cantidad producida de Q_r. Se asume que el gobierno en esta etapa anuncia de manera publica su determinación y por lo tanto consumidores y productores con conocedores del tipo de medida y su momento de aplicación.

Etapa 2: Los consumidores y productores son conocedores de la medida del gobierno, y el gobierno pone en marcha un impuesto a la cantidad (τ) consumida de energía producida a través de fuentes no renovables. Todas las firmas del conjunto F observan la demanda de energía y determinan su plan de producción $q_i^2 = (q_i^{2r}, q_i^{2f})$ de manera simultánea en un marco de competencia por cantidad. Se asumen que en esta etapa aún no se da la transición y las empresas siguen produciendo un 100% de energía a través de fuentes no renovables.

Etapa 3: En la etapa 2 el gobierno obtiene un recaudo fiscal τ*O por medio del cual financia el subsidio σ para la producción de Q_r para cada firma e_i. Al igual que en la etapa anterior, todas las firmas competirán por cantidades a través de la elección simultanea de su plan de producción $q_i^3 = (q_i^{3r}, q_i^{3f})$, se asume que en esta última etapa se da la transición energética y se produce un 100% de energía a través de fuentes renovables.

La estructura del juego por etapas da cuenta del papel de "agente conductor" que lleva a cabo el gobierno, el cual a partir de un impuesto y un subsidio busca generar estímulos para la transición energética, se asume que la información es de carácter público cuando proviene del gobierno por lo tanto en la etapa de definición se informa

y en las etapas de implementación se hacen efectivas las medidas en las etapas 2 y 3 respectivamente. En el momento en que las firmas comienzan a tomar decisiones se asume que siempre decidirán simultáneamente y competirán por cantidades, por lo tanto, en las etapas 2 y 3 las firmas mantienen un estilo de competencia Cournot influidas por las medidas del gobierno dando lugar a que en el momento 2 preserven su producción a partir de fósiles y en el momento 3 pasen a una producción con fuentes renovables.

Se considera que, dentro de las posibilidades de decisión del gobierno, este también puede optar por una política pública de carácter "no redistributivo" en donde únicamente aplica un impuesto al consumo (τ), para este caso se mantiene una dinámica casi idéntica, no obstante, ante una política de este tipo dadas las condiciones de alto costo que implica pasar a la producción de energía con fuentes renovables las empresas no tendrán ningún incentivo para cambiar sus planes de producción, el único efecto esperado es un aumento de precio impulsado por el gravamen y un efecto transitorio sobre la demanda que seguirá prefiriendo el consumo de Q_f, se asume así que en el marco de una política no redistributiva el impuesto será internalizado y no habrá una transición, así las cosas, ante la decisión en el momento 1 de implementar un impuesto, se llegará únicamente a la etapa dos en donde las firmas compiten por cantidades eligiendo de manera simultánea su plan de producción que seguirá siendo dirigido a la producción a partir de fuentes no renovables. Al final de este tramo el gobierno tendrá un recaudo fiscal τ*O que no será usado para invertir en la transición; en este caso la TE se considera fallida deteniéndose en la etapa 2.

Finalmente, es importante resaltar que las empresas e_1 y e_2 en términos genéricos tienen un conjunto de acciones básicas respectivamente en donde pueden optar por una producción máxima (Max) o mínima (Min), tales acciones demarcan las variantes estratégicas de las firmas en medio de un marco de competencia ya descrito. En una sección posterior del desarrollo del juego se demarcarán algunas condiciones adicionales y necesarias para acotar el espacio de decisión a un espacio discreto, por el momento su simple demarcación es suficiente para representar el juego en su forma extensiva.

Demarcado todo lo anterior, a continuación, se procede a representar de manera general la estructura del juego de la transición energética con el fin de conocer la estructura de los nodos de decisión y lograr ver de manera gráfica las especificaciones formales desarrolladas, es preciso aclarar que esta primera representación no pretende mostrar una solución del juego, únicamente busca dejarlo descrito para posteriormente continuar especificando las condiciones para determinar los pagos y conocer posteriormente el equilibrio. La representación extensiva del juego se muestra en la Fig. 1.

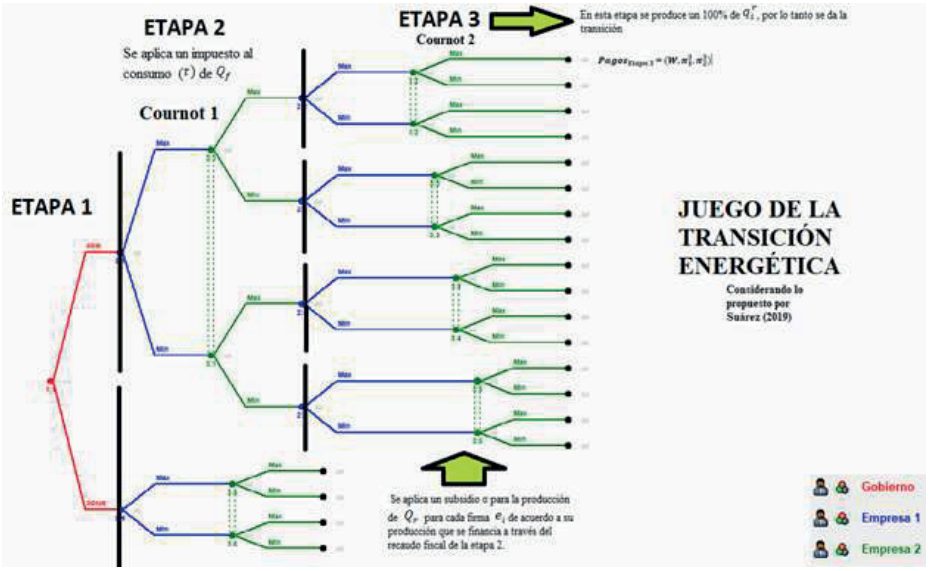

Fig. 1. Representación extensiva del juego de la transición energética considerando lo propuesto por Suarez (2019). Elaboración propia a partir del software de libre distribución Gambit 2015.

La representación extensiva del juego permite visualizar la estructura dinámica del juego. Es decir, se trata de un juego de tres etapas con información completa en el que los jugadores observan las acciones que hace cada uno de los otros jugadores. Los nodos terminales muestran los pagos en los que se resume el impacto del subsidio y de los impuestos de acuerdo con las etapas en las que son aplicados.

Al ser un juego por etapas, el equilibrio de Nash no es un concepto de solución deseable ya que permite la generación de amenazas no creíbles. Para evitar lo anterior, utilizamos como concepto de solución el Equilibrio de Nash Perfecto en Subjuegos (ENPS).

Un **Equilibrio de Nash Perfecto en Subjuegos** es un perfil de estrategias $\left((\tau^*, \sigma^*), (q_1^{1*}, q_1^{2*}), (q_2^{1*}, q_2^{2*})\right)$ que conforma un equilibrio de Nash en cada subjuego inducido por el juego descrito en la sección previa.

3 Análisis de equilibrio

El concepto de solución con el que se analiza el juego de la TE es el equilibrio de Nash Perfecto en Subjuegos. Para determinar los ENPS de la interacción entre gobierno y empresas, procedemos por inducción hacia atrás. Sin embargo, es necesario establecer los pagos que cada uno de los agentes obtiene al término del juego; a continuación describimos los parámetros (ingresos, costos, beneficios, impuestos y subsidios) que se utilizan para poder realizar el cálculo delos ENPS.

3.1 Desarrollo del juego

Los valores que se utilizan para obtener los pagos de los jugadores se construyen con base en los supuestos del modelo de Cournot. Es decir, se asume una función de costos que refleja la diferencia entre los ingresos y el costo. Además, se considera una demanda inversa lineal que depende de las acciones de las empresas generadores de energía, mientras que los costos marginales se ven impactados por la política pública implementada en cada una de las etapas del juego. A su vez se considera que la única vía para la reducción o aumento temporal de la demanda es la imposición de un impuesto o un subsidio por lo que la variación inducida por las intervenciones es independiente de las variaciones inducidas por la oferta.

Los parámetros básicos para obtener la demanda que enfrentan las empresas en cada una de las etapas son:

- En la etapa 2 se aplica un impuesto de 10 unidades monetarias (u.m) añadidas al precio de la energía fósil. Se considera que Q_f es 140 unidades energéticas (u.e). Puesto que en la etapa no se ha alcanzado la TE, se tiene que $P_f < P_r$; por consiguiente, $Q = Q_f$ y $Q_r = 0$. Es decir, los planes de producción q_i^2 son dominados por q_i^{2f} pues q_i^{2r}=0 para ambas firmas.
- En la etapa 3 se implementa un subsidio de 10 u.m a la producción Q_r , cuyo valor es de 150 u.e. Puesto que el impuesto sobre Q_f sigue activo, la implementación del subsidio implica que $P_f > P_r$. También, sabemos que las preferencias de los consumidores corresponden a un patrón de sustitución perfecta; esto implica que $Q = Q_r$ y $Q_f = 0$. Es decir, nos encontramos en un escenario de transición energética completa en el que los planes de producción q_i^3 están dominados por q_i^{3r} ya que q_i^{3f}=0 para ambas firmas.

Dadas las demandas básicas para cada una de las etapas, la fluctuación de precios se describe a continuación:

- Si $O = Q$, entonces el precio de referencia para P_f o P_r se mantiene igual al precio inicial de etapa.
- Si $O = Q$ + 10 u.e entonces hay sobreoferta. En consecuencia, se determina que por cada 10 unidades por encima de la demanda del mercado habrá una disminución de 4 u.m en el precio de referencia del tipo de energía demandado.
- Si $O = Q - 10$ u.e se genera escasez. Entonces, por cada 10 unidades por debajo de la demanda del mercado habrá un aumento de 4 u.m en el precio de referencia del tipo de energía demandado.

En otras palabras, las empresas productoras de energía tienen la capacidad de controlar los precios de energía. Por consiguiente, los consumidores toman decisiones racionalmente y no estratégicamente; es decir, los consumidores observan precios y buscan el consumo de energía que maximice su utilidad.

Puesto que el mercado energético que consideramos es un duopolio, la oferta que es generada por las empresas puede estar desequilibraba respecto a la demanda. Entonces, es necesario definir el espacio de decisión de las firmas.

Primero consideramos una situación en la que la producción es asimétrica y el mercado está vigilado por el gobierno. Dicho en otras palabras, el gobierno aplica una política regulatoria activa para el otorgamiento de subsidios e imposición de impuestos. Así, consideramos que las firmas tienen un espacio de decisión discreto, en donde el conjunto de las acciones de la empresa e_1 es E_1=$\{Max_{e1}, Min_{e1}\}$ y el conjunto de las acciones de e_2 es E_2=$\{Max_{e2}, Min_{e2}\}$; donde Max y Min cumplen la función de parámetros de producción que dependen del tamaño que se asuma para las firmas en términos de producción y que además se comportan como parámetros de expectativa. Es decir, estos valores representan la cooperación y no cooperación de las empresas para producir energía renovable. De manera análoga al Dilema del Prisionero, las mejores respuestas de las empresas se pueden describir de la siguiente manera:

- Si e_1 produce Max esperando que e_2 produzca Max entonces e_2 producirá Max esperando que e_1 produzca Max.
- Si e_1 produce Max esperando que e_2 produzca Min entonces e_2 producirá Min esperando que e_1 produzca Max.
- Si e_1 produce Min esperando que e_2 produzca Max entonces e_2 producirá Max esperando que e_1 produzca Min.
- Si e_1 produce Min esperando que e_2 produzca Min entonces e_2 producirá Min esperando que e_1 produzca Min.

Los espacios de acciones anteriores generan cuatro escenarios. En otras palabras, la transición energéticos, considerando un espacio de decisiones discreto, se limita al análisis de los escenarios Cooperar-Cooperar, Cooperar-No cooperar, No cooperar-Cooperar, y No cooperar- No cooperar. La Tabla 1 resume las acciones, pagos y características de equilibrio de cada uno de los escenarios anteriores

Tabla 1 Perfiles de decisión discreta para las firmas en el juego de la transición energética- Empresas con producción asimétrica y mercado vigilado. Elaboración propia.

Características del Mercado en la Etapa 2.						
Est. e1	Est. e2	Prod. e1	Prod. e2	Prod. total	Demanda total	Situación
Max	Max	85	65	150	140	Sobre-oferta
Max	Min	80	60	140	140	Equilibrio
Min	Max	60	80	140	140	Equilibrio
Min	Min	70	70	140	140	Equilibrio

Características del Mercado en la Etapa 3.						
Est. e1	Est. e2	Prod.	Prod. e2	Prod.	Demanda	Situación

		e1		total	total	
Max	Max	90	70	160	150	Sobre-oferta
Max	Min	90	60	150	150	Equilibrio
Min	Max	60	90	150	150	Equilibrio
Min	Min	75	75	150	150	Equilibrio

La Tabla 1 presente la estructura general del mercado (oferta y demanda), la cual es necesaria para la obtención de precios por medio de la demanda inversa lineal. Ahora, procedemos a describir los costos, que son necesarios para el cálculo del beneficio que obtienen las empresas cuando la interacción termina.

Consideramos que $c_i^f = 30$ y $c_i^r = 40$ en todas las etapas. El beneficio para la etapa 2 se calcula como $\pi_i^2 = (P_r^2 q_i^{2r} + P_f^2 q_i^{2f}) - (c_i^f q_i^{2f} + q_i^{2r} c_i^r + q_i^{2f} \tau)$. Puesto que $q_i^{2r} = 0$, podemos simplificar el beneficio a $\pi_i^2 = P_f^2 q_i^{2f} - (c_i^f q_i^{2f} + q_i^{2f} \tau)$. Por otro lado, sabemos que subsidio da lugar a un precio compensado pagado al productor durante la etapa tres; es decir, tenemos que $\pi_i^3 = P_{r\sigma}^3 q_i^{2r} - c_i^r q_i^{2r}$ ya que $q_i^{3f} = 0$.

En lo que respecta al gobierno, éste optar por una política pública redistributiva (PPR) o una política pública no redistributiva (PPNR). La PPR aplica tanto un impuesto a la energía fósil como un subsidio a la producción de energía renovable, respecto a los cuales se mantiene un presupuesto equilibrado. En otras palabras, el recaudo fiscal financia al subsidio para que el gobierno no incurra en deuda para aplicar su política. Por otro lado, al aplicar la PPNR, el gobierno no hará ningún tipo de redistribución para la producción de energía renovable y destinará el recaudo fiscal para otros fines.

En términos concretos, se considera que el impuesto al consumo Q_f será de 10 u.m por unidades energéticas. Por lo tanto, en la etapa 2 el precio de referencia de la energía de fuentes no renovables se incrementa en tal valor. Por otro lado, el subsidio se define como $\sigma = \frac{O^t}{O^{t-1}\tau}$; entonces, la oferta de la etapa 3 se divide por el total del recaudo fiscal de la etapa 2. Lo anterior asegura la condición de presupuesto equilibrado para el gobierno.

Además, es importante recordar que el gobierno juega un papel de "dictador benevolente" que busca maximizar su función de bienestar social. Esta última está dada por W= $\sum_{i=1}^{2} \pi_i^2 + \sum_{i=1}^{2} \pi_i^3$, es decir, el gobierno mide el bienestar de las empresas de manera utilitaria. La Fig. 2 resume los pagos del gobierno y las empresas cuando consideramos los diferentes valores establecidos para producción mínima, máxima, costos, impuestos y subsidios.

Comportamiento de los precios por etapa según las decisiones tomadas por las firmas

Fig. 2 Comportamiento de los precios por etapa según las decisiones tomadas por las firmas. Tabla de elaboración propia a partir de cálculos de los autores

Los aspectos señalados son suficientes para la definición de los pagos que perciben los agentes en cada uno de sus perfiles de estrategias y a lo largo de las etapas. En cada uno de los perfiles estrategicos que pueden desarrollarse, se define que los pagos corresponderán a b =(W, π_1^t, π_2^t), considerando la Ilustración 1 se sabe que del primer Cournot correspondiente a la segunda etapa en el nodo de decisión PPR tendrá 4 vectores de pagos, y del segundo Cournot se derivaran 16 vectores de pagos, a su vez del nodo de decisión PPNR únicamente se derivaran 4 vectores de pagos que pertenecen a la segunda etapa. En la tabla que se presenta a continuación se da cuenta de los pagos desglosados por cada uno los posibles perfiles estratégicos de las firmas:

Pagos de los agentes por cada conjunto de estatregias									
		Estrategias (E2[e1,e2]) y E3[e1,e2]]	ETAPA 2		ETAPA 1		Pagos Finales e1 y e2		Bienestar Utilitario (W)
			e1	e2	e1	e2	e1	e2	
GOBIERNO OPTA POR PPR	RF=Qf=1500	Max, Max y Max, Max	425	325	843,75	656,25	1268,75	981,25	2250

	RF=1400	Min y Min	630	630			630	630	1260

RF= Recaudo Fiscal - Qf= Gasto fiscal - El gobierno opta por un presupuesto equilibrado

Fig. 3 Pagos de los agentes por cada conjunto de estrategias. Tabla de elaboración propia a partir de cálculos de los autores.

3.2 Resolución del juego

Como bien se ha mencionado con anterioridad el juego de la transición energética aquí planteado es de carácter dinámico y cuenta con información completa, por lo tanto, el concepto de solución por el cual se opta es el Equilibrio de Nash Perfecto en Sub Juegos para el cual se aplica el algoritmo de inducción hacia atrás para poder llegar al concepto de solución general para el cual debe cumplirse que todos los sub-

juegos que integran al juego general deben llegar a un equilibrio de Nash de modo que el equilibrio represente el perfil estratégico no cooperativo que conduzca a la maximización de los beneficios respecto a las decisiones de los otros agentes que intervienen.

Para hallar el ENPS se ha hecho uso del software Gambit 15 en el cual se han introducido los pagos calculados y consignados para cada momento del juego en la Tabla 3, para el hallar el equilibrio se ha hecho uso del método de solución recomendado por el software usando la representación extensiva1 para la cual se ha definido encontrar un solo equilibrio el cual en su marco ideal será un ENPS en estrategias puras.

Una vez se corre el modelo en Gambit 15 se puede apreciar que el juego dinámico de la transición energética bajo las condiciones de producción asimétrica y mercado vigilado cuenta con un ENPS en estrategias puras y pertenece al conjunto de estrategias del renglón 6 de la Tabla 3 en donde en forma descriptiva se tiene que:

Juego de la transición energetica - Equilibrio de Nash Perfecto en Subjuegos- Estrategias óptimas de los agentes				
Etapa 1	Etapa 2 - Cournot 1		Etapa 3 -Cournot 2	
Estrategia Optima del gobierno	Estrategia óptima e1	Estrategia óptima e2	Estrategia óptima e1	Estrategia óptima e2
PPR	Max	Min	Max	Min

Tabla 2 ENPS del juego de la transición energética - estrategias optimas de los agentes en el equilibrio en estrategias puras. Tabla de elaboración propia

- En la etapa 1 el gobierno opta por una PPR.
- En la etapa 2 e_1 opta por producir Max esperando que e_2 produzca Min y e_2 produce Min esperando que e_1 produzca Max siendo las decisiones de producción orientadas 100% a energía producida a partir de fuentes no renovables.
- En la etapa 3 e_1 opta por producir Max esperando que e_2 produzca Min y e_2 produce Min esperando que e_1 produzca Max siendo las decisiones de producción orientadas 100% a energía producida a partir de fuentes renovables.
- Dentro de las decisiones tomadas por los agentes en el ENPS hay una tendencia a mantener siempre el mercado en un estado O=Q por lo tanto en este estado óptimo se considera no conveniente alterar el equilibrio del mercado ya que hacerlo reporte menores beneficios para los agentes.

Al final del juego el vector de pagos para los agentes es *b= (3260,1920,1340)* y representa el vector de pagos óptimo para los agentes.

4 Variaciones de la interacción

La versión principal del juego en su versión discreta cuenta con dos variantes que son relevantes y que dan muestra de otros comportamientos posibles de las firmas y

[1] Para visualizar las representaciones extensivas del juego con los pagos asignados y la solución hallada por Gambit 15 puede dirigirse al Apéndice A en donde se encuentran las representaciones extensivas de las diferentes variantes del juego.

su solución de equilibrio cuando hay variaciones en la configuración de producción de las empresas y el grado de vigilancia del mercado en el que se mueven.

Las variantes que se consideran contemplan el escenario en el que las firmas presentan producciones de carácter simétrico, es decir, cuando se asume que en los niveles de estrategias Max-Max y Min-Min aportaran niveles iguales de producción y en donde además se juega con la "regulación" y "desregulación" del mercado frente a la posibilidad de generar escasez, para presentar las variantes se optará por un desarrollo simplificado en donde se hará énfasis en los cambios de cantidad producida en los perfiles de estrategia, fluctuación de precios y los pagos de los agentes, con el fin de mostrar la solución de equilibrio en cada uno de estos casos adicionales.

Es importante resaltar que las variantes del juego preservan la mayoría de supuestos y condiciones demarcadas en las secciones anteriores, en caso de presentarse alguna variación se aclarará de manera explícita al inicio del desarrollo de la variación con el fin de tener claridad.

La intención de mostrar las variantes del juego es alimentar la discusión respecto a los escenarios y rumbos que podría tomar la política pública aplicada por el gobierno, y como la estructura de producción del mercado y el nivel de vigilancia del mismo puede afectar de manera significativa el rumbo y resultados en términos de bienestar de la política.

4.1 Juego de la transición energética con empresas con producción simétrica y mercado no vigilado

Para esta variante del juego de la transición energética se preservan los mismos elementos básicos del juego, se preservan los parámetros de preferencia de los agentes, y la dinámica de interacción entre oferta y demanda y sus parámetros, los únicos cambios que se consideran son:

- Las empresas se mueven dentro de un mercado no vigilado en donde es posible generar sobre-oferta y también es posible generar escasez sin llegar a incurrir en algún tipo de sanción.
- Las empresas producen simétricamente en sus extremos de decisión Max-Max y Min-Min, por lo tanto, la posibilidad de generar sobre oferta traerá consigo que cada empresa produzca la mitad de la oferta total y lo mismo ocurrirá en el caso de que se genere escasez, se asume que los marcos de decisión se dan en forma simultánea y sin tener plena certeza de la producción de la otra firma siguiendo los supuestos del modelo Cournot bajo una dinámica de competencia por cantidades.

Considerando los cambios anteriores los perfiles de decisión de producción discreta para esta variante son:

Conjunto de posibilidades de producción en la etapa 2 - Variante con producción simétrica y mercado no vigilado						
Estrategia e1	Estrategia e2	Producción e1	Producción e2	O= Producción total	Q=Demanda basica del mercado	Situación de mercado
Max	Max	75	75	150	140	Sobre-oferta
Max	Min	80	60	140	140	Equilibrio
Min	Max	60	80	140	140	Equilibrio
Min	Min	65	65	130	140	Escasez
Conjunto de posibilidades de producción en la etapa 3- Variante con producción simétrica y mercado no vigilado						
Estrategia e1	Estrategia e2	Producción e1	Producción e2	O= Producción total	Q= Demanda basica del mercado	Situación de mercado
Max	Max	80	80	160	150	Sobre-oferta
Max	Min	90	60	150	150	Equilibrio
Min	Max	60	90	150	150	Equilibrio
Min	Min	70	70	140	150	Escasez

Tabla 3 Perfiles de decisión discreta para las firmas en el juego de la transición energética- Empresas con producción simétrica y mercado no vigilado. Elaboración propia

Como puede observarse dado que se eliminan las restricciones en este caso se presentan escenarios en los cuales se cumple que O>C y C>O, ante esto habrá mayor variabilidad en los precios, no obstante, en esta variante se mantienen los mismos precios de referencia sin intervención y a su vez se asume que el valor del impuesto al consumo y el mecanismo de asignación del subsidio es idéntico al utilizado para el juego principal, a continuación se muestra el comportamiento de los precios ante las diferentes variantes estratégicas teniendo en cuenta las condiciones preestablecidas para los casos en el que el mercado no se encuentra en equilibrio:

Comportamiento de los precios por etapa según las decisiones tomadas por las firmas - Variante con producción simetrica y mercado no vigilado							
ETAPA 1	Estrategias (E2[e1,e2] y E3[e1,e2])	Precios sin intervención		ETAPA 2	Subsidio unitario para E3 a Qr (u.m)	ETAPA 3

Tabla 5 Pagos de los agentes por cada conjunto de estrategias en una variante con producción simétrica y mercado no vigilado. Tabla de elaboración propia a partir de cálculos de los autores.

Al igual que para el juego principal en este caso se introducen los valores de los pagos de los agentes en la representación extensiva del juego en el software Gambit 15 con el fin de hallar el ENPS, en esta ocasión nuevamente se usa el método recomendado por el software y a partir de él se obtiene que el juego cuenta con un ENPS en estrategias puras que corresponde al conjunto de estrategias de la Tabla 7 en el primer bloque en el renglón 16 en donde descriptivamente se tiene que:

Juego de la transición energetica - Equilibrio de Nash Perfecto en Subjuegos- Estrategias óptimas de los agentes - Variante con producción simétrica y mercado no vigilado				
Etapa 1	Etapa 2 - Cournot 1		Etapa 3 -Cournot 2	
Estrategia Optima del gobierno	Estrategia óptima e1	Estrategia óptima e2	Estrategia óptima e1	Estrategia óptima e2
PPR	Min	Min	Min	Min

Tabla 6 ENPS del juego de la transición energética en su variante con producción simétrica y mercado no vigilado - estrategias optimas de los agentes en el equilibrio en estrategias puras

- En la etapa 1 el gobierno opta por una PPR
- En la etapa 2 e_1 opta por producir Min esperando que e_2 produzca Min y e_2 produce Min esperando que e_1 produzca Min siendo las decisiones de producción orientadas 100% a energía producida a partir de fuentes no renovables.
- En la etapa 3 e_1 opta por producir Min esperando que e_2 produzca Min y e_2 produce Min esperando que e_1 produzca Min siendo las decisiones de producción orientadas 100% a energía producida a partir de fuentes renovables.
- Dentro de las decisiones tomadas por los agentes en el ENPS hay una tendencia a mantener siempre el mercado en un estado O<Q por lo tanto en este estado óptimo las empresas en su decisión simultanea tienden a producir cantidades bajas en aras de inducir escasez y llevar a un incremento en el precio

de la energía tanto proveniente de fuentes fósiles como de fuentes renovables.

- Al final del juego el vector de pagos para los agentes es b= (4110,2055,2055) y representa el vector de pagos óptimo para los agentes

4.2 Juego de la transición energética con empresas con producción simétrica y mercado vigilado

Para esta variante del juego de la transición energética se preservan los mismos elementos básicos del juego, preferencias de los agentes e interacciones entre oferta y demanda, los únicos cambios son el retorno al supuesto de mercado vigilado del juego principal en donde no es posible generar escasez, por otro lado se conserva el supuesto de producción simétrica de la primer variante, considerando en este caso que Min-Min corresponde a una decisión de producción en que las firmas producen la mitad de la demanda del mercado dado que no es posible producir por debajo de tal valor dada la vigilancia, a su vez dada su simetría en el caso Max-Max también producirán la mitad de la producción total.

Considerando lo anterior los perfiles de decisión de producción para las firmas en esta variante son:

Conjunto de posibilidades de producción en la etapa 2 -Variante con producción simétrica y mercado vigilado						
Estrategia e1	**Estrategia e2**	**Producción e1**	**Producción e2**	**O= Producción total**	**Q=Demanda basica del mercado**	**Situación de**
Max	Max	75	75	150	140	Sobre-oferta
Max	Min	80	60	140	140	Equilibrio
Min	Max	60	80	140	140	Equilibrio
Min	Min	70	70	140	140	Equilibrio
Conjunto de posibilidades de producción en la etapa 3 - Variante con producción simétrica y mercado vigilado						
Estrategia e1	**Estrategia e2**	**Producción e1**	**Producción e2**	**O= Producción total**	**Q= Demanda basica del mercado**	**Situación de**
Max	Max	80	80	160	150	Sobre-oferta
Max	Min	90	60	150	150	Equilibrio
Min	Max	60	90	150	150	Equilibrio
Min	Min	75	75	150	150	Equilibrio

Tabla 7 Perfiles de decisión discreta para las firmas en el juego de la transición energética- Empresas con producción simétrica y mercado vigilado. Elaboración propia

Dado que en esta variante nuevamente se tiene el supuesto de mercado vigilado solo existe un escenario en donde la oferta difiere de la demanda, considerando que se han mantenido los mismos precios de referencia sin intervención, para este caso la tabla de variación de precios será idéntica a la Tabla 2 dado que el único escenario de perturbación se da cuando las empresas deciden producir Max-Max, así las cosas, las únicas diferencias se darán en los pagos dado que ahora en los perfiles Max-Max y Min-Min la producción de las firmas resulta ser simétrica, a continuación se presentan los pagos para esta variante del juego:

		Pagos del juego por cada conjunto de estatregias - Variante con producción simétrica y mercado vigilado							
			M1		M2		Final		Bienestar
		Estrategias	E1	E2	E1	E2	E1	E2	Utilitario

	RF= 1400	Max y Min	720	540			720	540	1260
	RF=1400	Min y Max	540	720			540	720	1260
	RF= 1400	Min y Min	630	630			630	630	1260

Tabla 8 Pagos de los agentes por cada conjunto de estrategias en una variante con producción simétrica y mercado vigilado. Tabla de elaboración propia a partir de cálculos de los autores

Para esta variante del juego, al computar el valor de los pagos en Gambit 15 se halla que no hay un ENPS en estrategias puras para esta versión del juego, por lo tanto, se obtiene un equilibrio en estrategias mixtas en el cual se asume que los agentes escogen entre varias posibles estrategias puras a los cuales se les asigna una probabilidad de ocurrencia lo cual equivale a un escenario de decisión tipo lotería, en este caso los perfiles de estrategias que evidencian mayores probabilidades se muestran y describen a continuación:

	Juego de la transición energetica - Equilibrio de Nash Perfecto en Subjuegos en estrategias mixtas- Estrategias óptimas de los agentes con mayor probabilidad de ocurrecia - Variante con producción simétrica y mercado vigilado				
	Etapa 1	Etapa 2 - Cournot 1		Etapa 3 -Cournot 2	
	Estrategia Optima del gobierno	Estrategia óptima e1	Estrategia óptima e2	Estrategia óptima e1	Estrategia óptima e2
Perfil estrategico 1	PPR	Min	Min	Max	Max
Perfil estrategico 2	PPR	Max	Min	Min	Min
Probabilidad asociada Perfil 1	1	0,5884	0,5884	0,6667	0,6667
Probabilidad asociada Perfil 2	1	0,4116	0,5884	0,6667	0,6667

Tabla 9 ENPS del juego de la transición energética en su variante con producción simétrica y mercado vigilado - estrategias optimas más probables de los agentes en el equilibrio en estrategias mixtas.

- El gobierno en los dos perfiles estratégicos presenta una estrategia pura en donde la probabilidad de optar por PPR es de un 100% lo cual es consistente con su carácter de dictador benevolente.
- Es importante resaltar que los perfiles estratégicos 1 y 2 para el caso de las empresas solo representan una parte del espacio de decisión de las mismas, como bien se señala en la Tabla 11 solo son perfiles estratégicos con mayores probabilidades por lo tanto su ocurrencia no resulta ser definitiva. En esta variante el equilibrio en estrategias mixtas da muestras de incertidumbre, por lo tanto, los pagos que prevén las firmas al decidir no son fijos, sino que se perfilan como esperados dependiendo de sus elecciones de portafolio y de las elecciones de su competidora.
- El equilibrio global en estrategias mixtas lleva a que el vector de pagos este determinado por el valor esperado del pago total de cada agente, por lo tanto,

en este caso se cuenta con un vector de pagos esperados E(b)= (2919.24, 1459.62, 1459.62)

- En esta variante las empresas tienen incertidumbre respecto a la transición efectiva de su competidora hacia la producción de Q_r, por lo tanto, el panorama de decisión no resulta ser tan claro estratégicamente hablando, en especial porque la vigilancia del gobierno y la estructura simétrica reducen el potencial de maximizaciones puras en términos competitivos.

5 Discusión de resultados

La intervención gubernamental genera cambios en el mercado en la medida en que se logra influir en las decisiones de los agentes por medio de incentivos económicos. El análisis de la interacción gobierno-empresa desde la teoría de juegos alimenta el cometido de entender cómo las políticas públicas pueden impulsar la transición cuando el gobierno es el agente conductor. Las modelaciones discretas propuestas en este trabajo y sus resultados permiten vislumbrar un enfoque preventivo para la política.

De manera general, los resultados evidencian que es importante considerar el tamaño de las empresas del sector energético y también el nivel de vigilancia institucional que se ejerce para evitar situaciones de desequilibrio en el mercado. Los dos factores mencionados pueden hacer la diferencia respecto a los resultados y el nivel de bienestar logrado después de aplicar una política pública.

En el juego de la transición energética el gobierno, en su papel de dictador benevolente, opta por una PPR como estrategia pura dado que al final esto conduce a niveles de bienestar mayores para las empresas del sector. A su vez, si el gobierno tiene la transición energética como prioritaria dentro de su agenda, este tipo de política resulta ser mucho más consecuente, en especial porque la transición energética requiere también una transición en términos tecnológicos. En tal caso, los subsidios se convierten en una herramienta importante para disminuir costos de adopción tecnológica.

Es importante mencionar que la transición no debe generar traumatismos fiscales. En ese sentido, iniciar con un impuesto al consumo y luego proceder con un subsidio financiado es un mecanismo mucho más prudente de actuación que además genera desincentivos para consumir energía producida con fuentes fósiles. Si se logra que el precio percibido de la energía renovable sea mucho menor a partir de subsidios y que el precio pagado a los productores sea mayor al que se perciben por energía generada con fósiles, la transición tendrá una señal de inicio ante el incremento de la demanda de este tipo de energía.

Por otro lado, la estrategia pura del gobierno de optar por una PPR muestra que las medidas de coerción a través de impuestos sin redistribución no resultan ser compatibles con un gobierno que busca maximizar el bienestar social. A su vez, la PPNR no genera incentivos suficientes para la transición energética, por el contrario, se disminuye la demanda y el acceso al servicio ante el aumento del precio; esto deteriora los beneficios de las firmas generando una perdida irrecuperable de eficiencia (Nicholson

& Snyder, 2015). Así mismo, al conocerse previamente que no habrá redistribución, las empresas no tienen ningún incentivo para pasar a una tercera etapa de transición.

La estrategia PPR del gobierno muestra la acción del gobierno como "agente conductor." Lo que más llama la atención de la revisión de escenarios discretos para el modelo base de Suarez y Gibaja (2019) son las diferentes reacciones de las firmas de acuerdo a su capacidad de producción y al nivel de vigilancia que se ejerce en el mercado. A continuación se exponen algunas de las implicaciones de los ENPS hallados:

Empresas con producción asimétrica y mercado vigilado. Versión principal del juego en la cual las empresas no cuentan con igual capacidad de producción. El equilibrio resultante de esta versión discreta que se describe en la Tabla 4 es Max, Min y Max, Min, a su vez su vector de pagos es b= (3260,1920,1340) lo cual implica que en el transcurso del juego la empresa con producción menor (e_2) aun comportándose competitivamente tenderá a subordinarse a la empresa (e_1) prefiriendo producir cantidades "Min" antes que cantidades "Max" en especial porque al optar por la segunda opción corre el riesgo de ver disminuidos sus beneficios finales, a su vez considerado que el equilibrio de Nash es un equilibrio competitivo e_1 descartará producir cantidades "Min" ya que puede producir por encima de tales límites y además frente a un equilibrio cooperativo Min-Min preferirá un equilibrio de Nash no cooperativo en donde puede percibir beneficios mayores en un escenario en donde produce Max esperando que su competidora produzca Min, este comportamiento aplica tanto para la etapa 2 como 3 aunque se asume que la subordinación se refuerza en la etapa 3 dado que al momento en que e_1 produce en el segundo Cournot ya cuenta con la información pasada de la etapa 2.

La ventaja de este escenario de equilibrio es que dada la vigilancia los incentivos para generar escenarios de desequilibrio no son atractivos para las firmas por lo tanto se garantiza que O=Q y por lo tanto existirá estabilidad de precios y en el caso de la etapa 3 las cargas del subsidio estarán equilibradas y por lo tanto los consumidores percibirán un precio menor para Q_r y las firmas percibirán precios mayores al producir energía con fuentes renovables.

La transición energética en este modelo inicial transcurre de manera exitosa, sin embargo la dinámica de subordinación podría llevar a que en términos aplicados la empresa más grande tarde más en pasar la totalidad de su producción a Q_r mientras la empresa pequeña emprende con mayor rapidez su transición, esto partiendo del hecho de que el efecto adicional del subsidio será mayor para la empresa de menor tamaño (e_2) y será comparativamente menor para la empresa más grande (e_1) a pesar de tener pagos mayores. Esto dado que las inversiones necesarias en tecnología serán dispares y por lo tanto se esperaría que e_1 conserve por más tiempo una porción de su capacidad de producción en Q_f mientras e_2 se transforma con mayor rapidez a producción con energía de fuentes renovables, no obstante dada su mayor capacidad e_1 buscará seguir siendo dominante en la etapa 3 buscando captar el mayor beneficio del subsidio de tal forma que pueda compensar sus costos de transición, e_2 seguirá optando por Min dado que a pesar de que se transición es más rápida seguirá teniendo capacidad menor a la de e_1 y la posibilidad de forzarse y producir Max involucra

percibir menores beneficios del subsidio al esperar que e_1 produzca Max lo cual resulta inconveniente en términos de compensar sus costos de transición.

Comparativamente los pagos percibidos en esta versión principal son menores a los percibidos en la variante con producción simétrica y mercado no vigilado, sin embargo, dada la imposibilidad de generar escasez en este modelo principal los pagos percibidos son los más favorables hablando en términos competitivos.

Empresas con producción simétrica y mercado no vigilado: En esta variante las empresas cuentan con una capacidad de producción igual en sus momentos Max-Max y Min-Min, además se asume que el mercado no está vigilado, por lo tanto, es posible generar desequilibrio que dé lugar a un aumento de precios dado un escenario en donde O<Q. . El equilibrio resultante de esta versión discreta que se describe en la Tabla 8 es Min, Min y Min, Min, a su vez su vector de pagos es b= (4110,2055,2055) lo cual implica que:

En términos meramente competitivos este es el escenario más favorable para las firmas dado que pueden percibir beneficios adicionales tanto en la etapa 2 como en la etapa 3 al producir cantidades mínimas que lleven al mercado a un estado de escasez en donde los precios pagados por los consumidores sean mayores, a su vez al momento del subsidio esto también permite que se distorsione la carga del mismo dando lugar a que la disminución percibida por el consumidor sea menor tal y como se aprecia en la Tabla 6.

En esta versión del juego dado que las dos firmas producen simétricamente, los escenarios de equilibrio Max-Min y Min-Max son menos atractivos en términos de sus beneficios potenciales dado que existe el escenario Min-Min en donde se produce por debajo de Q y pueden percibirse precios mayores, dado que las firmas a pesar de decidir simultáneamente conocen las condiciones del mercado saben que reducir la oferta tendrá como resultado mayor beneficio, por lo tanto Min-Min en este caso no se considera un equilibrio cooperativo, por el contrario es un equilibrio de Nash dado que optar por este perfil estratégico conduce a maximizar el beneficio individual, a su vez este equilibrio es sub-optimo socialmente en especial porque afecta de manera significativa al consumidor.

Los consumidores van a tener que pagar más por cada unidad de energía por lo tanto sus excedentes van a ser menores teniendo en cuenta que la diferencia entre su precio de reserva y el precio pagado se hará menor, de hecho, las fluctuaciones de precios al alza pueden motivar fácilmente la generación de mercado negro tanto en la etapa 2 como en la etapa 3 ante la existencia de demanda energética insatisfecha, en el caso de la etapa 3 en el espacio de equilibrio el hecho de producir Min-Min lleva a que P_r^3 percibido por el consumidor sea de 49 u.m lo cual da lugar a que las producciones Mínimas en la etapa de transición estén relacionadas con transiciones incompletas o bien con un mercado con un alto potencial de transacciones informales.

Esta variante del juego de la transición energética es la versión menos favorable en términos de bienestar general, de hecho, en un mercado no vigilado incrementar los valores de subsidio e impuesto puede traer amplias perdidas y choques negativos para los consumidores, en el mediano plazo las problemáticas generadas por el desequilibrio del mercado pueden decantar en costos adicionales al estado derivados del combate contra la clandestinidad, degeneración de la calidad del servicio, e importantes

limitaciones al acceso; la medida se perfila poco sostenible a través del tiempo e incluso podría dar lugar a que exista un retroceso y la transición se detenga para retornar a un modelo con energías producidas con fuentes fósiles.

Empresas con producción simétrica y mercado vigilado. En esta última variante, las empresas son simétricas y el mercado está vigilado se presenta un ENPS es estrategias mixtas que da cuenta de la existencia de incertidumbre y en donde las firmas tienen portafolios de estrategias puras con cierto nivel de probabilidad ante lo cual los pagos no son esperados con exactitud como en las variantes anteriores, en este caso las firmas buscan maximizar sus pagos esperado y además a pesar el potencial de escenarios es mucho más amplio dando lugar a que los equilibrios mostrados en la Tabla 11 sean probables pero no absolutos, en términos generales el vector de pagos esperados por los agentes es E(b) = (2919.24, 1459.62, 1459.62), las implicaciones para esta variante son las siguientes:

El hecho de que las empresas sean simétricas y el mercado este estrictamente vigilado da lugar a que la posibilidad de maximizar beneficios en estrategias puras se complejice especialmente porque las decisiones tomadas considerando la producción del competidor no son claras dado que no hay diferencias en tamaño por lo tanto hay mayor incertidumbre respecto a las acciones potenciales en la elección simultanea de las firmas al punto de que en el análisis racional de su competidora la firma que decide no asume como absoluto una decisión de la otra sino que le asigna una probabilidad respecto a su portafolio de decisiones.

La incertidumbre inmersa en el juego lleva a que la dinámica de transición que se da en desde la etapa 2 a la 3 también cuente con tal característica, por lo tanto, en términos prácticos una estrategia mixta implicaría una transición parcial, es decir, ante la incertidumbre de las firmas respecto al cambio de su competidora contarán con cierto grado de aversión al riesgo por lo tanto tenderán a las mezclas en sus planes de producción, por lo tanto existirá un espacio intermedio en donde convivirán tanto las tecnologías para producir energías con fuentes fósiles, como nuevas tecnologías para la producción con fuentes renovables, así las cosas, la transición será progresiva y en un inicio no será total, no obstante, en este caso este estadio intermedio no va en detrimento del bienestar de los consumidores ya que dentro de las posibilidades de decisión de las firmas solo existirán combinaciones en donde solo es posible el equilibrio o la sobre-oferta.

Esta versión del juego de la transición energética es la que más se asemeja a lo que ocurriría potencialmente en un entorno real en donde se motiva la transición y existe estabilidad institucional, las firmas no optarán por hacer su conversión total e inmediata, sino que lo harán pensando en sus beneficios futuros sin conocer exactamente el desenlace de los pagos, en medio de esto la oferta de energía con fuentes renovables ira en ascenso mientras se logra una transición tecnológica completa, y además se logra generar mayor confianza e incentivos para que las firmas continúen en su senda de transición.

Al analizar las variantes del juego de la transición energética es posible apreciar que la política pública redistributiva debe pensarse desde las condiciones y características particulares del mercado energético, uno de los aspectos más importantes recae en el nivel de vigilancia y regulación de los mercados de energía, si la institucionali-

dad es débil y hay poca capacidad regulatoria el escenario más probable es el de la variante de mercado no vigilado en donde se afecta negativamente a los consumidores y emergen costos potenciales ante el riesgo de generación de mercado negro y limitaciones al acceso que ponen en riesgo la sostenibilidad de la transición, en este caso sería preciso primero generar los mecanismos de vigilancia necesarios desde el gobierno antes de implementar cualquier tipo de intervención, sin fortaleza institucional las medidas tradicionales para impulsar la transición pueden generar más costos que beneficios y pueden inclusive llevar al fracaso del proceso.

Por otro lado, si existe fortaleza institucional y vigilancia suficiente es importante tener en cuenta la composición y tamaño del mercado de tal forma que se puedan generar incentivos proporcionales y transiciones tecnológicas efectivas y sostenibles en el tiempo por parte de las firmas, en el caso de las empresas asimétricas será necesario generar políticas transversales que mantengan a la empresa de mayor tamaño dentro de la transición y le permitan hacer atractiva su inversión a largo plazo, en este sentido la prolongación del subsidio en el tiempo es fundamental en el horizonte futuro de la transición, en especial porque debe asegurarse que a lo largo del tiempo el sector de generación renovable se haga atractivo para inversores privados, esta situación contrasta con el caso final de empresas simétricas y mercado vigilado en donde es claro que es necesario seguir aunando acciones para la consolidación de la transición especialmente sabiendo que la producción fósil no desaparecerá en las etapas iniciales, es necesario por tanto generar políticas adicionales que continúen aumentado los incentivos tanto para los consumidores como para los productores y favorecer especialmente la desinversión en el negocio de producción de energía con fuentes no renovables, trasladándolo a empresas que aceleren su ritmo de conversión tecnológica y productiva, además de complementarlo con políticas que motiven las interacciones con la academia, y la sociedad civil.

6 Conclusiones

La transición energética es uno de los retos contemporáneos más importantes y urgentes que afronta la humanidad. Dentro de ella, los gobiernos juegan un papel fundamental para un proceso de transición exitoso en el largo plazo. Sin embargo, la política pública debe pensarse considerando los rasgos particulares y riesgos potenciales ante su aplicación; en este caso la versión discreta, aquí propuesta, del juego de Suarez y Gibaja (2019) da cuenta de que el nivel de regulación inicial del mercado energético y su estructura de producción son aspectos fundamentales a considerar antes de aplicar medidas como impuestos o subsidios.

En concordancia a lo anterior, la fortaleza de las instituciones ligadas al sector energético es un factor importante si no se quiere generar una transición lesiva con el bienestar. Además, las características del mercado son fundamentales para prever el comportamiento de las firmas dentro de la transición. Esto última traza la hoja de ruta para políticas complementarias que aumenten la gradualidad de la transición, que no se perfila como un cambio instantáneo sino progresivo en donde la generación de

confianza y la preservación de los estímulos en el tiempo son relevantes para pensar en una transición conducida desde el gobierno.

La relevancia de los elementos antes mencionados da pie para demarcar que la transición energética tiene referentes a nivel internacional. Sin embargo, al no aber una receta exitosa ya probada, es necesario que cada país que la emprenda revise de manera cuidadosa su contexto de mercado energético y capacidades institucionales antes de tomar cualquier medida, el enfoque aquí presentado da pie para pensar de forma intuitiva en esos aspectos generales que deberían ser tenidos en cuenta previamente, de tal forma que se eviten distorsiones y se logren transiciones sostenibles en el tiempo que conduzcan a economías menos contaminantes.

Abstract. Este estudo é sobre transparência de dados públicos em tempos de pandemia mundial Coronavírus Covid-19. Foi utilizada a combinação de dois eixos e de palavras-chave para selecionar os artigos publicados em 2020 nas bases de conhecimento ligada a Engenharia de produção. Devido ao curto período pesquisado houve um número pequeno de artigos selecionados, contudo os mesmos demostram que o tema já desperta a atenção de pesquisadores. A informação pública de qualidade possui duas funções determinantes: a de manter o cidadão conectado com os fatos e de combater a onda de fake news. O resultado da pesquisa propõem que no Brasil, Índia e Filipinas, há a falta de uma coordenação central de informações ocasionando desconfiança por parte da cidade e da mídia. Foi possível a identificação de dois modelos de avaliação, o primeiro oferecido pela Organização mundial da saúde (OMS) e o segundo pela OPEN KNOWLEDGE BRASIL (OKBR). Em comum foi identificado o tema granularidade.

Keywords: Transparência, Governo, Acesso a informação.

1 Introdução

A transparência de dados públicos, já vinha ganhando protagonismo na última década. Muito se deve a legislação e a cobrança dos órgãos de controle externo; também deve-se ressaltar a sociedade civil organizada. Com o advento da pandemia do Coronavírus Covid-19, diversas entidades passaram a fazer novas exigências sobre dados referentes a própria doença ou sobre informações de como está ocorrendo o enfrentamento a mesma.

A internet é um campo vasto e recheado de informações provenientes de fontes confiáveis e de sites com intensões duvidosas.

Os estudos apresentados estão sediados em dados de países como o Brasil, Filipinas e Índia. Demonstrando que o tema escolhido é de alta prioridade pois envolve a preservação de vidas humanas, a gestão de recursos públicos e a produção de informações confiáveis que combatem as fake news.

O problema a ser explorado é voltado a como e quais são as formas de estudo que estão sendo conduzidos, quais as dificuldades encontradas e se há perspectiva de pesquisas futuras.

Devido ao curto espaço de tempo encontrado entre o início da pandemia e o período em que a pesquisa foi realizada, pretende-se encontrar artigos que estejam ligados ao tema pandemia e dados abertos de governo.

2 Referencial teórico

O referencial teórico é a primeira atividade que um pesquisador deve realizar para que possa redefinir e responder a pergunta de pesquisa. Uma contribuição de valor que gera resultados deve ser fundamentada em varredura horizontal tão ampla quanto possível [1].

Os dados abertos do governo são norteados pela Open Government Partnership(OGP), essa organização padroniza a melhoria na prestação de serviços públicos integrando iniciativas sobre (1) acesso à informação, (2) participação cívica, (3) contabilidade pública e (4) alavancagem de tecnologia para fortalecer a governança [2].

A transparência nos dados de governo em relação do COVID-19, pode ser oferecida em formato de boletim diário ou de relatório [3], exportação de informações em arquivos com formato não proprietário [2] e em site do próprio governo [4].

As grandes redes sociais como Facebook, Twitter, YouTube, Reddit, Instagram, e Pinterest possuem uma forma padrão de enviar o retorno de notícias sobre o COVID-19 para os usuários. Priorizar fontes oficiais e tradicionais em detrimento dos meios de comunicação como uma maneira de controlar o “infodemia”[5].

O acesso a informação de qualidade afeta a coerência na tomada de decisões de governantes e de empresários e requer uma boa governança de dados. A fim de serem reutilizados para o geração de valor social e econômico [2].

Concorrem com os sites governamentais o acesso facilitado as mídias sociais, que são barulhentas e podem apresentar inconsistências quantos aos dados apresentados.

Nesse momento onde o isolamento social é uma das formas de conter a velocidade de expansão do vírus, as pesquisas estão sendo direcionadas para os dados oferecidos em sites governamentais federais, estaduais ou municipais.

Enquanto a informação das formas de combate e prevenção a disseminação do vírus são pilares dos governos, ocorre o compartilhamento de falsas notícias como ocorreu no Irã onde se aconselhava o uso de uísque e mel para a cura [5]. Lembrando que esse país possui rígido controle sobre o consumo de bebidas.

Os modelos de divulgação de dados apresentado pela OKBR [4] e pela OMS [3], partem de dados provenientes de sistemas voltados ao accountability [5], [4], [3] e [2].

Porém alguns dados são tratados para assegurar a privacidade dos cidadãos, assim os mesmos não passariam por discriminação; esse tratamento também é realizado com os dados dos portadores de HIV.

Devido a pandemia, diversas fragilidades na captação de informações, falta de centralização e processamento de dados, gestão de recursos humanos e organizacionais ficaram expostos [2].

3 Metodologia

Este trabalho possui base qualitativa sendo nele aplicado uma revisão sistemática de literatura voltada para a seleção de artigos. O portal de periódicos CAPES [6], dispõem de ferramenta que filtra bases do conhecimento, demonstrando na Fig. 1 possibilidade de pesquisa em 51 bases das quais foram selecionadas somente as que oferecem artigos.

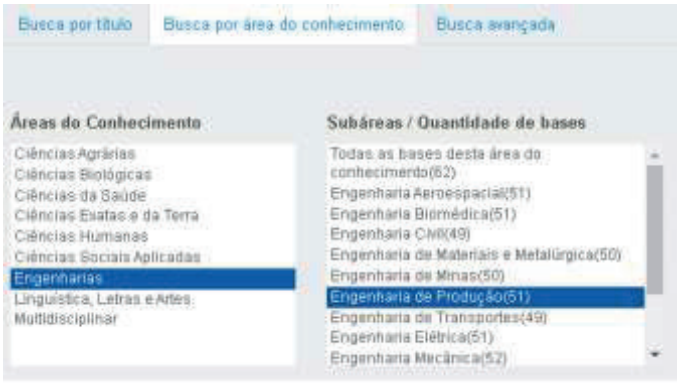

Fig. 1. Busca pela subárea do conhecimento Engenharia de Produção no portal CAPES.

Segundo [7], que nos apresenta uma técnica da revisão sistemática de literatura que em suas primeiras fases determina a seleção de palavras chave. Foi realizada a seleção das palavras chave para obter artigos que estivessem ligados a temática do eixo 1-Pandemia ("coronavirus" or "covid-19" or "pandemic" or "SARS") e do eixo 2-Dados abertos ("transparency" or "open data" or "open government data" or "accountability").

A Table 1 apresenta as bases selecionadas e o resultado obtido com o emprego do comando na pesquisa avançada disponível em cada periódico.

Table 1. Bases selecionadas para pesquisa.

As bases que possuem asterisco ao final de suas descrições não foram utilizadas por não possibilitar consulta via comando ou por não oferecer seleção por intervalo de ano.

Durante a execução da pesquisa foi aplicado o filtro de data indicando o ano das publicações que possuíssem somente ano igual a 2020. Em relação ao idioma não foi aplicado nenhuma restrição.

Foram encontrados 12 artigos no total, como pode ser observado na Table 2 a maioria dos periódicos não retornou nenhum resultado.

Table 3. Artigos selecionados

Autor(es)	Ano	Revista	Objetivo	Resultados
[8]	2020	Gestão e Sociedade	…promover reflexões sobre questões já evidentes em torno de como a transparência governamental, na atual conjuntura, tem se desenvolvido.	Futuros estudos, reflexões e analises podem sugerir uma agenda de estudos que investiguem se o aumento da transparência

				nos governos é causado pelo acentuamento da crise.
[4]	2020	Gestão e Sociedade	Analisar a construção da transparência sobre a Covid-19 pelos estados brasileiros.	Os avanços detectados neste curto e tenso período de tempo. As respostas estão sendo positivas.
[9]	2020	Cadernos de saúde pública	Quais modelos de comunicação devem embasar a narrativa oficial para criar as condições de colaboração e parceria com a mídia?	Enormes obstáculos aparecem combinados com o vácuo de informações oficiais. Cabe ao governo valer-se de sua ampla visibilidade para produzir informações seguras em seus sites.
[2]	2020	SSRN Electronic Journal	Investigar o estado dos dados abertos do governo nas Filipinas e compara o acesso a informações de saúde durante a pandemia COVID-19.	Ele tira as lições da criação do hub de dados de saúde relacionados à pandemia e o modela como uma forma de compartilhar dados mais sistemáticos no futuro.
[3]	2020	medRxiv	Responder duas perguntas, primeiro, quais são os dados mínimos que o público precisa saber para compreender a gravidade da situação e cooperar com o governo? Em segundo lugar, quão diferente é a qualidade dos relatórios de dados de um estado para outro?	Após o desenvolvendo uma estrutura sistemática para avaliar a qualidade dos relatórios de dados CO VID-19, em seguida, foi avaliada a qualidade dos relatórios feitos pelos estados da Índia. Com base nessa estrutura, forneceu-se um modelo mínimo que os estados podem usar para relatórios diários de dados COVID-19.

A Table 1, demonsta os artigos selecionados após a coleta de suas versões em arquivo .PDF, tradução em alguns casos e seu fichamento.

4 Apresentação dos resultados

Os resultados obtidos com a pesquisa horizontal apresentam uma forma de cobrança sobre a qualidade dos dados apresentados em sites governamentais.

Os modelos de avaliação são baseados na OMS, no freedom of information (FOI), OPEN KNOWLEDGE BRASIL (OKBR) dentre as 5 fontes bibliográficas encontradas.

A preocupação com a centralização dos dados e com a privacidade dos cidadãos é recorrente em [3] e [2].

A forma de acesso e a facilidade de interpretação devem ser priorizadas frente aos termos médicos e técnicos envolvidos na apresentação dos dados.

Colabora [3], com essa afirmação pois a Índia necessita de padronização dos dados apresentados, para que atraso, disparidade de informação divulgada entre os estados e o governo federal parem de causar desconfiança.

No Brasil a divulgação de dados vem sendo avaliada com base no padrão da OKBR, que é segmentada em: Conteúdo, Granularidade e Formato.

A verificação de dados e informações disseminados em redes virtuais, WhatsApp, Twitter, Instagram, entre outros é extremamente veloz frente a produção de dados oficiais [5].Ocasionando uma guerra de narrativas, sensacionalismo, senso comum, que geralmente tem cunho político e tendem a desinformação do cidadão leigo.

O modelo de avaliação aplicado pela OKBR, prioriza dados relacionados com a doença e como esses dados podem ser exportados para avaliação de terceiros.

Dimensão	Critério	Descrição	Pontuação
Conteúdo	Idade ou Faixa Etária	Idade ou faixa etária das pessoas que pertencem ao grupo de, no mínimo, casos confirmados	0 = não apresenta; 0,5 = apresenta apenas uma média geral; 1 = apresenta idade ou faixa etária.
	Sexo	Sexo das pessoas que pertencem ao grupo de, no mínimo, casos confirmados	0 = não apresenta; 0,5 = apresenta uma média geral; 1 = apresenta idade ou faixa etária.
	Status de atendimento	Especifica casos hospitalizados (internação e UTI) ou em isolamento domiciliar	0 = não apresenta; 1 = apresenta.
	Doenças preexistentes	Presença de doenças preexistentes/ comorbidades (diabetes, hipertensão etc.)	0 = não apresenta; 0,5 = apresenta em algum grupo (ex. óbitos) 1 = apresenta para todos os casos
	Ocupação de leitos	Quantidade de leitos ocupados no estado em relação ao total disponível.	0 = não apresenta; 1 = apresenta.
	Outras doenças respiratórias	Número de casos de Síndrome Respiratória Aguda Grave registrados ou outras condições que possam indicar Covid-19	0 = não apresenta; 1 = apresenta.
	Testes disponíveis	Quantidade de testes de que o estado dispõe	0 = não apresenta; 1 = apresenta.
	Testes aplicados	Quantidade de testes já realizados. A quantidade de casos descartados, que pode ser somada à de confirmados, pontua neste tópico, desde que indicado que foram descartados por critério laboratorial	0 = não apresenta; 1 = apresenta.
Granularidade	Microdado	Cada caso é um registro	0 = não apresenta; 0,5 = apresenta de um grupo de casos; 1 = apresenta.

	Localização	Nível de agregação geográfica dos casos divulgados	estado = 0;
			cidade = 0,5;
			bairro, distrito ou hospital =1

Formato	Visualização	Painel para consulta do público em geral	0 = não apresenta; 1 = apresenta.
	Formato aberto	Dados estruturados em ao menos uma planilha em formato editável, de preferência aberto (CSV, ODS)	0 = não apresenta; 1 = apresenta.
	Série histórica	Uma base de dados única e atualizada contém o histórico completo, desde o início do registro de casos	0 = não apresenta série; 0,5 = série em gráfico; 1 = série em uma base completa.

Fig. 2. Modelo de avaliação aplicado pela OKBR. Fonte:[4] .

Enquanto o modelo de avaliação aplicado pela OMS, prioriza a Acessibilidade e Granularidade.

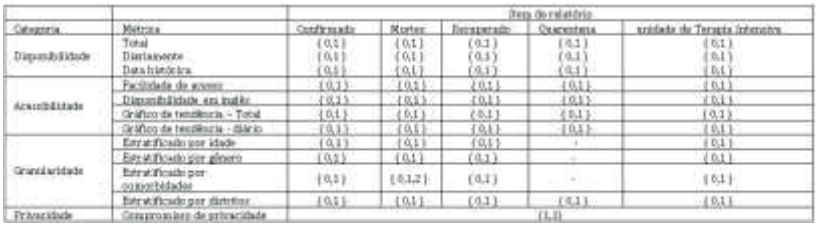

Fig. 3. Modelo de avaliação aplicado pela OMS. Fonte: Traduzido de [3]

Dentre os modelos da OMS disposto na **Fig. 2Fig. 1** e da OKBR apresentado na **Fig. 3**, observa-se que ambos possuem em comum o item Granularidade.

Como pode ser visto o tema Pandemia e Dados abertos do governo vão render diversas pesquisas, tanto voltadas para a administração de recursos financeiros, orçamentários, quanto para humanos e de saúde.

Dentro da literatura disponível não foi encontrado paralelo em outras pesquisas similares, desta forma o estudo oferece também um foco de pesquisa voltado para o combate a desinformação.

Abstract. The quest to overcome monetary challenges, competitiveness, customer demands, technological adaptation and innovation, are daily icons in the routine of the manufacturing industry, especially in this era of Industry 4.0. When dealing with logistical flows, the process becomes more complex. The amount of heterogeneous data shared, together with the diversity of domains involved in the flow, make horizontal integration in this flow more and more important. This structure concentrates and translates information in order to make the decision-making process, forecasting demands for input purchases, forecasting deliveries for customer sales much more accurate, increasing the process maturity level, thus contributing to its competitiveness in the inserted scenario. In this way, it is essential that the meaning assigned to each information is unequivocally shared. This work aims to understand the current issues involved in horizontal and vertical integration, together with knowledge related to semantic interoperability, logistical flows, decision making, demand forecasting, industry 4.0 and multiple domains. This research showed through the formalization of information and knowledge obtained about logistical flows and their routines, that even with adversities in transport, market instabilities / seasonality, it is possible to obtain greater control under the flow chain of purchase of inputs until delivery to the market customer, integrating it obtaining better forecasts, ensuring delivery time and product quality, and consequently, respecting cost, processing, quality, delivery requirements with greater precision and reliability.

Keywords: Manufacturing Systems, Semantic Interoperability, Decision-Making Support, Supply Chain, Blockchain, Horizontal Integration.

1 Introduction

The search for competitiveness and performance, brought the need to seek new ways to innovate. From this gap, the use of concepts and methodologies from Industry 4.0 were increasingly applied to structure a competitiveness strategy, development of processes and people, maturity gain, for example.

Industry 4.0 brought with it technological advances in terms of Internet of things, machine learning, connectivity, procedural independence in all existing areas: health, psychological, metallurgical, etc. As pillars of support, Industry 4.0 is based on 9

pillars: Robotics, Simulation, Systems Integration, Industrial Internet, Cyber Security, Cloud, Additive Manufacturing, Augmented Reality and Big Data and Analytics.

Its objective is to establish faster, more flexible and efficient processes, thus promoting the representation / integration of physical resources with digital ones, connecting machines, systems and real assets in order to produce items with higher quality, more profitable, lower production cost, resulting in a most performing process, consequently increasing maturity, speed in more assertive decision making and competitiveness [11][12][17].

Cultural and paradigm change has become the first barrier to be overcome for its implementation. When dealing specifically with the application perimeter in terms of the logistics of a manufacture, we can explore the theme and map its difficulties, opportunities and challenges [17].

This article provides a contribution to industrial logistics, pointing out the difficulties, challenges and problems encountered by logistics related to the lack of semantic interoperability between platforms, the absence of integration between systems, companies, suppliers and customers in the production systems when different types of parts, companies, people, production processes and sectors are involved. The main result is an overview of the existing gaps, allowing the discussion on the possibilities of dealing with the challenges faced by the complete supply chain: raw material purchase, transformation and customer sale.

This work will be structured as follows: session 2 shows the problem statement; section 3 presents the content involved; session 4 deals with the analysis of the discussion that involves the subject of this article and, finally, session 5 presents the conclusion of this research.

2 Problem Statement

Logistics in industrial companies have an important and challenging role. Its greatest difficulty is in knowing the quantity to be purchased of raw material and its delivery time to the customer. It is extremely important that the three main macro environments of logistics are clear: MRP (source), productive planning (Maker) and sales (delivery):

- **MRP (Source):** Responsible for all the planning of raw material purchase, strategy and transport costs until the raw material enters the factory, suppliers. Thus, we can highlight that its main task is planning the correct amount of raw material, without the correct deadline for not being responsible for production line stops, customer delays and increased transportation costs.
- **Productive Planning (Maker):** Responsible for planning the production of products, in the correct sequence, so as not to impact the cycle time of the line with many setups, without excess parts in order not to produce much more than the quantity sold, generating stock, according to the quantity of inputs purchased, and with flexibility of changes.
- **Sales (delivery):** Responsible for the beginning and end of the entire chain. It is through it that we receive customer input (request) or sale of products, and also that executes the delivery according to deadlines and quantities signed between company and customer.

So, the challenge is to buy the right quantity, with a time and cost of transport as planned, respecting the processing time and cost, the deadline and price agreed with the customer. In this way, we can see many challenges in its trajectory, taking into account the constant change of scenery, flexibility to adapt to new demands and cancellations. This process is explicit in Fig. 1, where it exposes the main sectors involved in the process and the requirements involved.

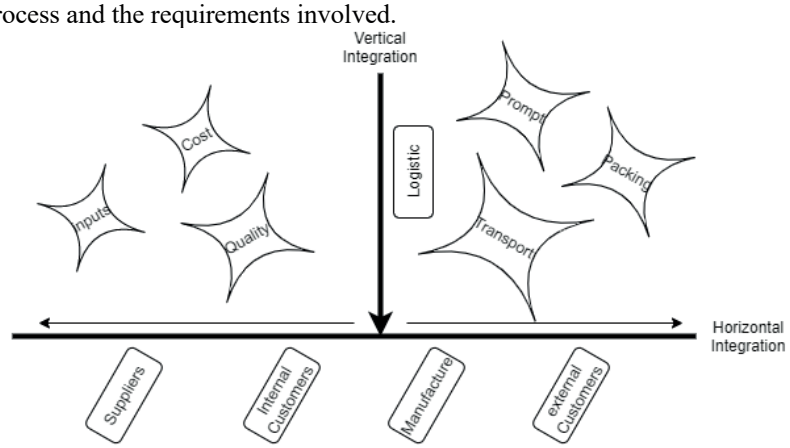

Fig 1. Logistic Environment, its influences, and information flow between sectors.

Figure 1 illustrates in its horizontal axis the need and importance of horizontal integration between sectors, so that communication occurs in a unique, centralized, interoperable way and indicates its main communication axes (suppliers, logistics, manufacturing, external customers, internal customers); in its single main axis called "Logistics" we can see the influence and importance of vertical integration under it, and the influences that are under pressure (raw material cost, taxes, transport cost, the correct delivery deadline...).

3 Current Issues

The current issues were researched and structured according to the main topics related to the research objective: I) Vertical and Horizontal integration; II) supply chain; III) smart factories.

3.1 Horizontal and Vertical Integration for the Logistics sector

The supply chain has a large extent in terms of communication between processes because it starts within the domain of the suppliers and ends with the delivery of the product to the customer. The flow of information generated, the changes along the entire logistical flow are large. Any change that has a big impact, since it is most often imported, many suppliers and customers are not located nationally, making this communication more distant and slow. Industry 4.0 has been collaborating with this problem over time, for its evolution, since it brought support tools, providing the integration of different sectors and companies, making the information homogeneous

to all interested parties, in this way we can name two types of integration: Horizontal and vertical.

The vertical and horizontal integration of production systems is directly linked to the concept of Advanced Manufacturing (Industry 4.0). This is because it aims to make the industry operate in a universal way, through a process of digital transformation. In this way, the production process starts to be optimized, reducing the moment when activities happen in the production chain.

- Vertical integration refers to the ability to integrate, reconfigure and make production processes more flexible, from product development to manufacturing. Among the advantages of vertical integration, we can mention the increased flexibility of the factory, increased reliability in production, reconfiguration of the production system, increased variety of products.
- Horizontal integration refers to the sharing of data and information between the different information systems, devices, and software that support the productive activity. In this way, the collection, processing, and analysis of data help to increase the precision and speed of decision making in the industry. This approach has a large volume of data and information that qualifies and improves the performance of the manufacturing environment. The main advantages of horizontal integration are agility in decision making, increased application of decision making through the integration and consistency of data and information, incorporation of intelligence and decision making in production systems, qualification of decision making based on systematic analysis of data in real-time [18].

In this way, the logistical flow becomes more agile for changing the scenario, type of transport used, mapping of alternative routes, roadblocks, and cargo tracking, for example.

3.2 Supply Chain

In today's competitive business environment, supply chain performance is one of the most critical issues in many industries. Because it is through it that the entire production flow is dependent, impacting productivity, product cost, added value, for example. For its performance control, measuring the performance of the supply chain is essential for efficient supply chain management. In the last two decades, several structures and systems have been developed to meet this need [1].

Supply chains are involved in the entire product life cycle, from the acquisition of materials to manufacturing and distribution, customer service, and, eventually, product recycling and disposal. Due to this fact, the need for all sectors and activities should be interconnected, occurring the interoperability of data and information are available to all.

Identify whether customer needs are met, understand business processes, make quick and accurate decisions, make progress possible, track progress, and identify bottlenecks, waste, problems, and opportunities for improvement.

To assist all this transit of information flow, which circulates along the three macro sectors of the supply chain (purchasing, production planning, and sales), we can insert technology from Industry 4.0, such as Blockchain.

Blockchain is a point-to-point distributed data infrastructure that allows for the creation of decentralized currencies (e.g. Bitcoin), self-executing digital contracts (smart contracts), and active smart contracts that can be controlled over the Internet (smart property). The technology uses a shared data infrastructure that updates in real-time and can process and settle transactions in minutes using computer algorithms, without the need for third party verification.

Integrated with other technologies, such as the Internet of Things (IoT), Blockchain can be used to create a permanent, shareable, actionable record of all moments of a product's journey through its supply chain, creating efficiencies in all the chain. Greater visibility facilitated through these technologies can also allow traceability, authenticity of the product, and legitimacy [16].

In this type of market, the definition of transport services must take into account not only the origin and destination of the elementary displacement but also the characteristics of transport resources. These characteristics must allow the transport of resources to easily identify products that can be loaded together to optimize the loading feature [6].

3.3 Smart Factories

A fourth industrial revolution is taking place today, structuring and innovating a future that will be heavily dependent on the acquisition and sharing of data in all sectors, including the supply chain. This vision of business, services, and interconnected sectors, processes, and information systems (SI) is only possible due to exceptional technological developments, especially in mobile devices. Mobility, or independence, is therefore one of the top priorities in the industrial supply chain. These developments are expected to provide a foundation for the virtual supply chain, with optimization, simulation, and decision support based on online operational data. In the Internet of Things (IoT) that the supply chain can become self-adaptive systems in which intelligent objects operate and deciding to learn autonomously [15] and execute, becoming more independent of human labor, making processes faster, optimizing the time and labor of everything and everyone involved.

Virtualization is a promising approach to deal with these challenges. Enables simulation and process optimization using systems software instead of performing physical experiments, thus being able to set up scenarios, simulate forecasts, analyzing virtually hypotheses with greater speed and agility. Consequently, supply chains can monitor, control, plan, track, and optimize remotely and in real-time using the Internet, based on virtual objects, rather than on-site observation [2].

4 Discussion

This research is working to highlight issues relevant to the knowledge requirements for semantic interoperability in the manufacturing and decision making system. These questions supported a proposed conceptual framework that aims to formalize this study, to justify its relevance to the topic addressed.

For this article, research was carried out with two groups, each group consisting of 3 people, of whom work with logistics, distributed among purchases, productive

planning, and sales. The groups were chosen because they have similar functions, are in the same company, and work with different products and manufacturing processes. The two groups were interviewed separately and at the same time by the authors of this work so that neither would interfere in the opinion of the other group. Routine issues were raised, which are the challenges, strengths, and weaknesses points and opportunities within the logistics sector in a macro way and each of the 3 sectors. Issues related to Industry 4.0 and its tools were also mentioned and presented, how technological innovation will impact and influence everyone soon.

After the interviews, all the content pointed out was discussed with the supervisor responsible for the sector. Thus, as a product of both groups, we can combine the following outputs, highlighting their main problems or difficulties:

- Decision support to strategic decision making according to forecast of prognose and sales;
- Existence of several systems bases for calculating inventory control;
- Need to create a definition regarding the minimum/maximum inventory per supplier and customer;
- Better optimization of the shipping time according to the quantity and type of cargo;
- Time optimization X Transport cost;
- Develop other local suppliers, so that they are not tied to international suppliers, often located outside the country;
- Correlate, understand and standardize the needs and visions of customers and suppliers;
- Level the production, to reduce the number of setups in the line, in the correct quantity and time, so that there is no over or missing produced parts;
- Develop a system that demonstrates the best sequence/scenario to be produced;
- Addresses the challenges of the person responsible for purchasing inputs so that they arrive in the correct quantity and time, with the transportation cost previously calculated;
- Likewise, address sales challenges, so that you can meet deadlines and prices agreed with the customer;
- Speed and interchangeability to adapt to changing market scenarios.

Based on the problems/work solutions used as basis for this work, Table 1 is proposed, which shows specific analysis by categorization, positioning each work according to its disciplines and degree of importance to the research. The classification criteria adopted were (Table 1):

1. Referring to works that address issues related to logistical interoperability problems:
   - (D1) Specific case: articles/books intended for the field of interoperability related to manufacturing.
   - (D2) Generalized case: articles/books not dealing with the field of interoperability.
2. The date of publication of the article:
   - (T1) Recent: articles/books published with date from 2014.

- (T2) Less recent: articles/books published until 2014.

3. About articles and books reporting cases and deals with specifically logistical interoperability:
   - (C1) Yes: refers to the literature of practical examples of difficulties encountered in logistics in manufacturing industries.
   - (C2) No: it refers to the literature that does not provide examples of difficulties encountered in logistics in manufacturing industries.

Table 1. Related works classification according to each research issue

Gómez, J.; Salazar, I.; Vargas, P. (2016)		X	X			X

It is observed in Table 1, that there are some unexplored flaws: in the works that deal with issues related to specific logistics problems, which bring cases, cyclical examples, difficulties encountered by the activity (C1), they were identified in only 56.25% of the articles selected, the which demonstrates, through the analyzed sample, that it is still a field to be explored. It can be noted that over the years, the theme has been growing and gaining more literature on it, with a notable increase from the year 2017. Where else can we observe certain literature reporting the application of interoperability (D1), which presented in this sample analyzed only 37.5% of the articles addressing the topic, for dealing with logistical problems, which shows a great field to be explored, even more, when we try to relate to the expansion of Industry 4.0, IoT, communication.

5 Conclusion

There are many challenges encountered by the logistics sector not only for the manufacturing industry but in its entirety. The fact that it encompasses a long path of responsibility that impacts the whole makes this perimeter even more complex and sensitive. There are many problems encountered due to the lack of interoperability and the amount of information and decision making that occur at all times, changes in political and governmental scenarios, cultures, distances, characteristics of types of transport are some of the challenges that make those responsible to quickly create scenarios and options to create solutions to problems that have occurred. Inside of Industry 4.0, many tools can be applied for a better degree of utilization, fluidity, reliability and speed, through the use of artificial intelligence, data interoperability, data collection and treatment, innovating it bringing time and cost benefits for the sector and the entire productive chain involved. Through the bibliographic analysis, we can observe that this theme is still little explored, taking into account the sample, because little more than half of the articles brought examples of logistical problems and so little about interoperability, communication networks, communication optimization, addressing issues of machine learning, artificial intelligence, for example. In this way, we highlight a vast field to be explored. As a suggestion for future work, to contribute to the improvement of these identified gaps, the application of ontological rules which will connect input items, monitoring and ensuring the output of products according to specifications. The application of artificial intelligence techniques to predict market scenarios, predict and provide paths according to changes in the global oscillation, transport crisis, lack of products at suppliers, better delivery routes based on transport cost, thus applying machine learning the system will be linked together, improving its interoperability and horizontal and vertical integration.

Acknowledgments

The authors would like to thank the Pontifical Catholic University of Parana (PUCPR) and Robert Bosch CtP for the financial support to the development of this research.

Resumen. Se propone un modelo para medir la calidad de servicio de una empresa, donde el cliente del servicio es otra empresa. Para ello se definieron seis dimensiones que contiene la percepción del servicio, estas son: experiencia en el servicio, interacción con clientes, infraestructura y repuestos, capacidad técnica del personal, tiempos de entrega e imagen corporativa. Luego basado en el concepto de *desconfirmación* de Grönroos [2], se construye un modelo que se plasma en un índice de percepción, para luego aplicarlo a una empresa de mantenimiento de motores eléctricos. El resultado del índice de percepción de calidad de servicio es de un 86% de satisfacción de clientes en la organización donde se llevó a cabo el estudio. A través de este indicador se puede inferir cuáles son los puntos altos y deficientes en la gestión de calidad de servicio mediante el análisis de las distintas dimensiones que componen el modelo.
.

Keywords: Calidad, Servicios, Modelo de medición, Motores.

1 Introducción

Los modelos de medición de la calidad de servicio representan en la actualidad un instrumento que permite a las organizaciones y empresas que ofrecen un servicio, medir la satisfacción de sus clientes con los servicios recibidos en función de ciertos factores y dimensiones propios de su naturaleza. Los modelos de medición de calidad de servicio más utilizados y de mayor aceptación corresponden al modelo *Service Quality* SERVQUAL [1], que se basa en la comparación de las expectativas versus la percepción del servicio recibido, al igual que el desarrollado por Grönroos [2] denominado modelo nórdico de calidad. Por otro lado, se encuentran los modelos cuya evaluación de la calidad se fundamentan sólo en la percepción del cliente al momento de recibir el servicio, como el modelo SERVPERF [3] y el modelo jerárquico multidimensional [4], cuyas posturas se sustentan en que no es necesario incluir las expectativas en la evaluación de la calidad del servicio, debido a que este factor se basa sólo en la percepción del resultado del servicio [5].

El modelo conceptual que se propone en este estudio, a diferencia de los modelos citados anteriormente, considera elementos propios de un servicio de tipo industrial en el cuál el cliente final no necesariamente es una persona, sino que corresponde a una organización o empresa. Debido a esto, las dimensiones que lo conforman son parte importante del proceso de producción y representan factores claves para darle una continuidad operacional al servicio. En la literatura revisada [1, 5], es posible afirmar que en la mayoría los casos, los modelos utilizados para medir la calidad de servicio son aplicados a personas como cliente final, no encontrándose ningún estudio en el cual el cliente final sea una organización o empresa, en este punto radica la diferencia esencial entre el modelo propuesto y los modelos de la literatura revisada.

En los puntos siguientes se presentará el modelo, su aplicación, resultados y conclusiones.

2 Desarrollo del modelo

El presente trabajo es del tipo cuantitativo, no experimental de corte transversal-descriptivo y busca generar un modelo que permita medir la percepción de la calidad del servicio prestado en una empresa. Para ello, se propusieron 5 etapas que se describen a continuación:

2.1. Definición de dimensiones; consiste en la definición de las dimensiones a evaluar y que serán parte integrante del modelo, para ello se consideran los componentes más críticos del servicio que se desea evaluar.

2.2. Generación del Modelo; desarrollo de un modelo con las relaciones de interdependencia y funcionalidad entre ellas. Para ello se consideró el modelo conceptual de Grönroos [2] que se basa en el paradigma de la "*desconfirmación*" el cual plantea que el nivel de calidad está dado por la diferencia entre la Expectativa del usuario (E) y lo Percibido (P) en el servicio por el usuario. Además, se consideró los modelos de Brady [5] y Lozada [6], que consideran las dimensiones sobre el cliente evalúa la calidad del servicio. En el modelo propuesto, el cliente evalúa cada dimensión por separado, esta valoración luego se pondera por el peso específico de cada una, peso que se determina mediante técnica de decisión AHP [7]. Finalmente, la suma de esas percepciones conduce a una evaluación global de la calidad del servicio.

2.3. Generación del instrumento de medición; generación del instrumento de evaluación (cuestionario) en base al modelo propuesto con una escala Likert de respuestas, el cual es aplicado a una muestra piloto en primera instancia.

2.4. Análisis de confiabilidad y validez; para verificar que el modelo de medición de calidad de servicio propuesto mide efectivamente lo que se desea medir, se realizan las siguientes pruebas estadísticas: Alpha de Cronbach [8]. y Análisis Factorial Exploratorio [9].

2.5. Evaluación de resultados; se establece el método para el cálculo del Índice de percepción de calidad de servicio, que será el indicador del nivel de la calidad de servicio, en función del cuestionario aplicado. Este indicador se expresa en el rango de 0 a 1. Luego se aplica el cuestionario definitivo a la muestra

total de clientes y finalmente se realiza un análisis de los resultados para determinar el nivel de servicio otorgado por la empresa en estudio.

3 Aplicación del modelo

La aplicación de las etapas descritas en el punto 2, se realizó a una empresa chilena de nombre Ferroman S.A., que se dedica a los servicios de asistencia técnica de motores eléctricos de media y alta tensión. En donde se seleccionaron 6 dimensiones que conformaran la base del modelo propuesto. En la Tabla Nº1, se presenta los factores y las dimensiones que las agrupa.

Tabla 1. Resumen de indicadores estadísticos

Factores	**Dimensión que los agrupa**
Años de presencia de la empresa en el mercado	Experiencia en el servicio
Experiencia en servicios	
Disposición a atender requerimientos de clientes	Interacción con clientes
Comunicación con clientes	
Infraestructura disponible	Infraestructura y repuestos
Ubicación geográfica	
Calidad de los insumos y repuestos	
Años de experiencia laboral del personal	Capacidad técnica del personal
Formación educacional del personal	
Plazos de entrega de equipos	Tiempos de entrega
Logística de transporte	
Reconocimiento de la marca en el mercado	Imagen corporativa
Certificaciones de la empresa	

Una vez obtenidos los factores y la dimensión que los agrupa, se estructura el modelo conceptual que se presenta en la Figura 2. Luego se desarrolló un cuestionario que consta con un total de 15 preguntas dividido en 6 dimensiones. El cual se validó, ya que tiene un nivel de confiabilidad y consistencia interna aceptable de acuerdo al Alpha de Cronbach obtenido, y que el modelo se ajusta a un Análisis Factorial Exploratorio. En la Tabla 2, se presentan los resultados de los indicadores estadísticos.

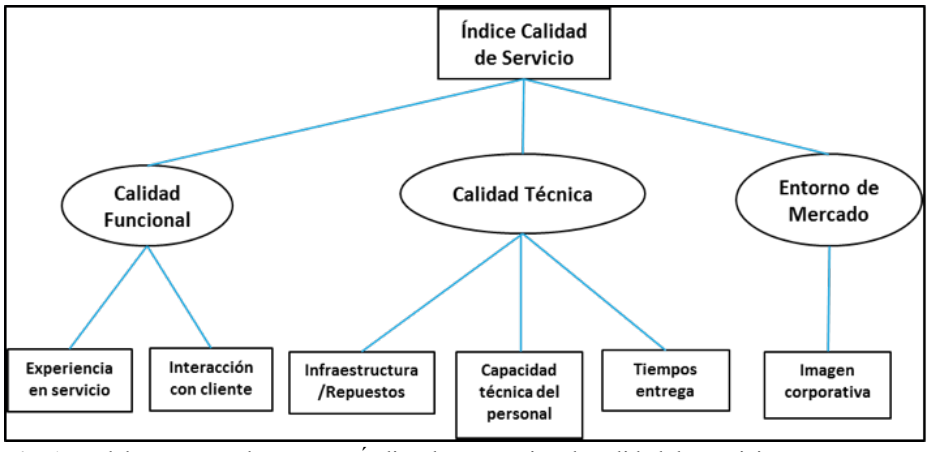

Fig. 1 Modelo conceptual propuesto Índice de percepción de calidad de servicio

Tabla 2. Resumen de indicadores estadísticos

Indicadores	Encuesta piloto
Alpha de Cronbach	0.925
Índice de KMO	0.636
Test de esfericidad	0.000
Factores representa-tivos	3
% Varianza total explicada	74.4%
Determinante de la matriz	Menor a 0.05
Comunalidades	Todas las variables mayores a 0.5

El cuestionario final se aplicó a una muestra de 70 clientes de la empresa Ferroman S.A, correspondiente al 92% del universo de clientes, y fue realizada en un lapso de 1 mes y medio (septiembre-octubre 2017) a través de encuesta presencial, telefónica y por correo electrónico. Los encuestados corresponden a representantes de las empresas que contratan los servicios de mantención de motores eléctricos de Ferroman S.A, siendo éstos de diversas regiones del país incluyendo la Región Metropolitana de Chile. El resultado global del Índice de percepción de Calidad de Servicio global (ICS) obtenido corresponde a 0,86, lo que se traduce en que el estudio presenta un 86% de satisfacción del cliente, lo que esta catalogado como “excelente” según la tabla propuesta por Praxis [10], que clasifica la saistacción de los clientes de los servicios recibidos. Los resultados por factores, se presenta en la Figura 2 y con el objeto de enriquecer la evaluación de los resultados del cuestionario, se realiza un análisis de dispersión y descriptivo de las respuestas que se presenta en la Figura Nº3, donde se muestra que el grueso de los clientes encuestados correspondiente al 83%, se

encuentran en el rango de 4 a 5, es decir, evalúan de forma satisfactoria "algo de acuerdo" y "muy de acuerdo" el servicio otorgado en todas las dimensiones medidas. El restante 17% se encuentra en el rango de 3 a 4, es decir, tienen un nivel de satisfacción menor respecto de la calidad de servicio proporcionada, presentando un cierto grado de desacuerdo con las dimensiones medidas, especialmente con lo relacionado a equipamiento e infraestructura de la empresa, la imagen de la compañía en el mercado, y los plazos de entrega de los equipos.

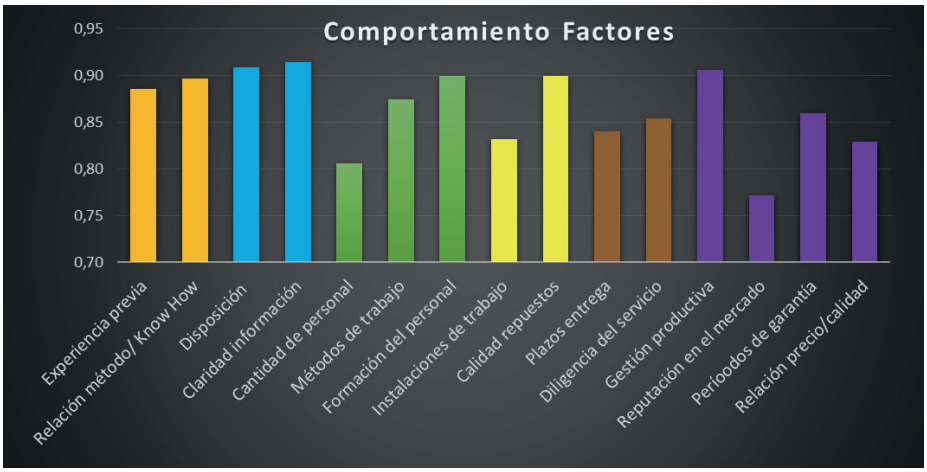

Fig. 3 Resultados obtenidos como porcentaje de satisfacción

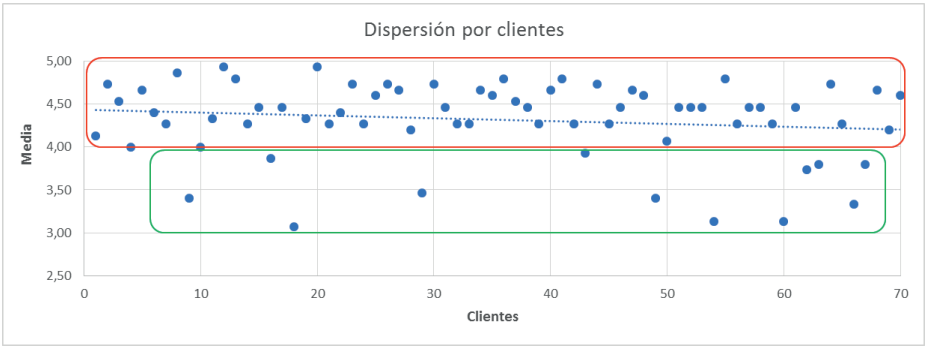

Fig. 3 Gráfico de dispersión de la media por cliente

4 Conclusiones

Al finalizar este trabajo, se concluye que los clientes de la empresa "Ferroman S.A." perciben una excelente evaluación global de los servicios ofrecidos por la empresa, con un Índice de percepción Calidad global de servicio de un 86% de satisfac-

ción. Sin embargo, se debe asumir el desafío de mejorar la experiencia de los clientes en factores como la "cantidad de personal" y "reputación en el mercado".

Del punto de vista metodológico se puede afirmar que el modelo propuesto es confiable y los factores que lo componen son idóneos, lo se validó estadísticamente mediante el indicador Alpha de Cronbach y el Análisis Factorial Exploratorio al cual se sometió el modelo.

Adicionalmente Finalmente, se espera que en futuro se pueda seguir aplicando el modelo con empresas que considere servicios similares al analizado para realizar estudios comparativos de sectores industriales.

Abstract. Este trabalho tem por objetivo analisar o impacto do agendamento de horário para refeições no tempo de espera em fila em um restaurante universitário. O estudo foi realizado com base no restaurante tipo self-service localizado na Universidade Federal do Paraná - campus Centro Politécnico, o maior polo da universidade atualmente, no qual o tempo de espera em fila externa é elevado em determinados horários. Empregou-se a metodologia de simulação de eventos discretos para reprodução do sistema, sendo os seus procedimentos implementados computacionalmente via MATLAB®. Os resultados obtidos são promissores, indicando que a adoção da política de agendamentos reduz o tempo médio em filas externas, e internas dependendo da distribuição de chegada da demanda, desde que os agendamentos nos horários de menor demanda para a refeição sejam preenchidos.

Keywords: Restaurante universitário; Filas; Simulação discreta; Implementação.

1 Introdução

O setor de prestação de serviços na área de alimentação tem tido uma crescente procura nas últimas décadas, devido o crescimento da urbanização mundial. O consumo de comida não-domiciliar aumentou devido às necessidades do cotidiano urbano-industrial que acabam por reduzir o tempo disponível para preparação do alimento ou até mesmo inviabilizando o deslocamento em decorrência da distância entre trabalho e residência. Assim, em busca da melhoria do gasto do tempo útil, os consumidores procuram um serviço que melhor se adapte a sua necessidade [1,2].

Em muitas universidades públicas brasileiras são oferecidos serviços de restaurantes universitários (RUs), que atendem a sua comunidade acadêmica. Este auxílio oferece refeições de qualidade e com valor acessível, que contribuem para a melhoria do desempenho acadêmico e redução da evasão decorrente da insuficiência de condições financeiras [3]. Na Universidade Federal do Paraná (UFPR), os RUs são do tipo *self-service*, abertos durante toda semana, onde o usuário se serve a vontade e uma única vez. Por sua vez, esse tipo de restaurante tende a apresentar filas, já que a chegada dos clientes ocorre em grupos e em um curto espaço de tempo [4]. Deste modo, reduzir o tempo de espera em fila é de extrema importância.

A adoção de políticas para a redução do tempo de espera nas filas deve ser planejada. Além dos modelos matemáticos e analíticos, uma das ferramentas utilizadas para o estudo do impacto de novas decisões é a simulação [5]. Simular torna possível o estudo do sistema sem que seja necessário construí-lo na realidade, estudando os resultados destas modificações sem que haja necessidade de alterá-lo previamente [6]. As simulações podem ser representações matemáticas, lógicas ou simbólicas, ao qual permitem a análise do modelo sem a necessidade de um sistema real, reduzindo os riscos e os custos que a mudança de um sistema pode causar [7].

Define-se como simulação a imitação de um sistema do mundo real através do tempo [8], enquanto que um sistema é definido como um conjunto de entidades, sejam pessoas ou máquinas, que agem e interagem junto para completar algum final lógico [9]. A finalidade da simulação é realizar um estudo do comportamento de um sistema, verificando o seu desenvolvimento através do tempo de acordo com suas regras/metodologias. Neste estudo, pode-se encarar dois tipos de sistemas de acordo com o tempo, denominados discretos e contínuos: num sistema discreto, o estado das variáveis muda instantaneamente para pontos separados do tempo, enquanto que o sistema contínuo a variável muda continuamente em relação ao tempo [8].

Para simular um sistema de forma efetiva, Banks et al [8] propõe alguns passos para tal: formulação do problema, definição dos objetivos, esboço de um modelo conceitual, coleta de dados reais, abstração do modelo, verificação e validação, design experimental, rodadas com análise, documentação e implementação do modelo. Almejando encontrar um sistema mais verossímil possível, é necessário assumir premissas referentes à operação do sistema que são expressas matematicamente [8], sabendo que a complexidade que um sistema real oferece pode ser mensurada em função do número de processos, filas, recursos, entidades, entre outros [10].

No âmbito de RU, Machado et al [14] objetivou-se a identificar os principais "gargalos" de um RU via *software* Arena®. Santos et al [4] desenvolveu um modelo de simulação do tipo dinâmico, discreto e estocástico, via *software* Arena®, para reproduzir a dinâmica operacional de um pequeno RU do tipo *self-service*, identificando que os *buffets* são o "gargalo" do seu sistema. Oliveira et al [15] avaliou os benefícios da aplicação da modelagem e simulação, via *software* Arena®, para melhorar a performance do sistema de um RU, otimizando os recursos e guarnições do restaurante. Os autores citados tratam o sistema sem alterar a política de organização dos usuários, focando nos recursos dos restaurantes.

Portanto, este trabalho tem por objetivo avaliar o impacto da adoção de uma nova política de organização nos RUs quanto aos seus usuários, especificamente no RU da Universidade Federal do Paraná (UFPR), campus Centro Politécnico, visando diminuir o tempo médio em fila para cada refeição. Este RU, atualmente, possui a maior concentração de alunos da UFPR. O algoritmo de simulação discreta da operação do RU foi implementado via MATLAB®, considerando eventos probabilísticos dos processos realizados pelos usuários, a fim de descrever e analisar o comportamento do sistema, de acordo com uma distribuição de chegada de clientes.

Este trabalho foi dividido em cinco seções. A seção atual retrata as motivações para o estudo. A Seção 2 apresenta uma revisão da literatura do tema. A Seção 3 descreve a modelagem conceitual e computacional adotada para o problema. A Seção 4 ilustra os resultados obtidos na simulação comparando a política atual e a proposta de filas com agendamento. A Seção 5 realiza as considerações finais do trabalho.

2 Revisão Literária

Com o aumento do poder computacional nas últimas décadas, o interesse por técnicas de simulação cresceu, considerando que é possível identificar pontos de melhorias e avaliar diversas soluções sem custo. Tal método é utilizado principalmente para encontrar resultados ótimos para sistemas que possuem filas. O fenômeno de formação de filas é algo rotineiro e ocorre em diversas aplicações, como: uma peça esperando para ser embalada, um avião esperando para decolar, um programa de computador esperando para ser executado, é principalmente e uma fila de usuários esperando um serviço [16]. Tal metodologia também é utilizada durante o desenvolvimento e implantação de um sistema, sendo uma técnica preditiva e preventiva, em que pode-se fazer o estudo de diversas situações e obter respostas para questões situacionais, auxiliando a tomada de decisão e evitando cobranças futuras quanto a situações imprevistas [9]. Assim, esse tipo de análise é uma poderosa ferramenta para a eficiência no processo de produção e pode ser empregada na redefinição de layout ou substituição de controle ou regras de operação, desenvolvimento de sistemas mais eficientes e também aprimorando a solução em problemas de sistemas complexos. O uso do modelo é uma maneira mais barata, segura e conveniente de experimentar ideias [11].

Alguns trabalhos na literatura tratam, por simulação, eventos envolvendo estudo de filas. Por exemplo Fernandes [12] implementou um modelo computacional pelo software Extend®, para simular a dinâmica operacional de uma linha industrial de abate de suínos, validando seu trabalho por meio de dados reais de uma empresa frigorífica. Já Silva [13] desenvolveu uma biblioteca, também via Extend® denominada Grain Facility, resolvendo o problema de armazenamento de grãos em silos, validando seu trabalho utilizando dados reais de uma cooperativa agroindustrial.

De acordo com Law, Hui & Zhao [17], o tempo de espera em fila afeta a frequência de retorno do cliente e é um dos principais pontos no nível de satisfação. O foco na otimização da experiência completa em relação à restaurantes universitários sujeitos à incerteza na demanda e restrições de orçamento foi estudado por Kambli, Sinha e Srinivas [18] que propuseram uma solução baseada em reconhecer onde estão as oportunidades de diminuição nas filas, incorporação de realocação em caso de atraso e a administração da capacidade das filas de acordo com os recursos disponíveis.

Estudos realizados em outros restaurantes universitários identificaram gargalos que impactam muito no tempo de espera. Silva, Gomes e Oliveira [19] concluíram que as principais influências no tempo de espera nas filas da Universidade Federal do Pampa (UNIPAMPA) é o sistema de reconhecimento dos alunos que poderia ser atualizado para um sistema biométrico, sugerindo que um computador com maior capacidade de leitura de dados ou um sistema de fila com prioridade poderá resolver o problema do tempo excessivo na espera sem que sejam necessárias grandes alterações no funcionamento.

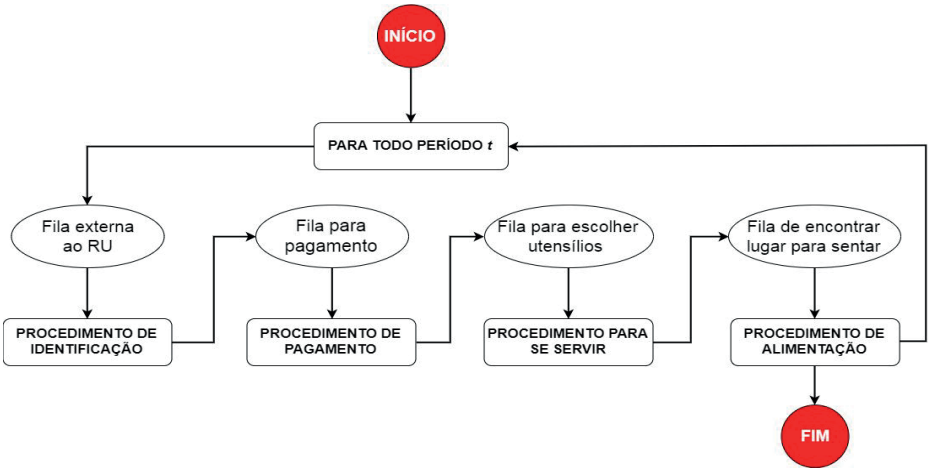
Já Oliveira e Costa [20], sugerem que para minimizar os impactos negativos das filas de espera, é necessário avaliar pelo menos três estratégias: o gerenciamento da estrutura do sistema de filas, buscando ajustar a capacidade de atendimento do sistema a demanda de usuários. Geralmente, esta estratégia demanda a expansão de

estruturas físicas e recursos humanos. Em segundo, gerenciamento da percepção de espera, que propõe uma modificação no modo em como os clientes percebem o tempo, tornando a espera mais agradável, como por exemplo, a inclusão de filas múltiplas ou filas expressas. Como o usuário associa tamanho da fila com o tempo de espera, ele pode desistir do serviço antes de perceber a rapidez no atendimento. Por último, a ocultação da percepção de espera possibilita que os usuários executem outras atividades enquanto esperam pelo serviço desejado. Esta estratégia apresenta soluções com baixo custo e resultados relevantes. Um exemplo dessa estratégia, são filas virtuais, que preveem o horário de acesso do usuário baseado no número de pessoas já alocadas na fila e da velocidade de atendimento. A solução proposta foi criar um aplicativo de fila virtual para o RU da Universidade Federal do Maranhão (UFMA).

3 Modelagem

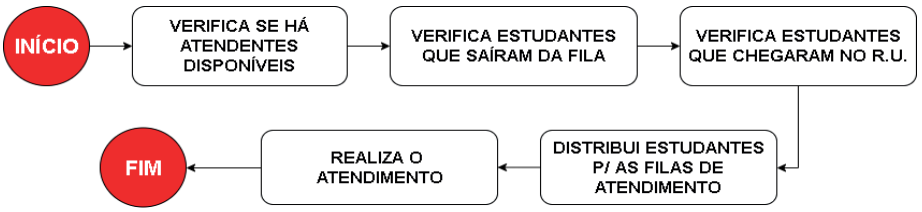
Para o desenvolvimento do modelo conceitual do RU, observou-se como os processos funcionavam na instalação. Após as observações, idealizou-se um modelo conceitual inicial que descrevesse as principais etapas que os usuários percorrem ao utilizar os serviços fornecidos pelo restaurante, como ilustrado na Fig. 1.

Fig. 1. - Modelo conceitual do funcionamento do RU.



Na Fig. 1, a primeira etapa consiste no processo de chegada. A entrada é realizada em uma fila única formada fora do restaurante, denominada de fila externa. Na segunda etapa, a de identificação pelo Cadastro de Pessoa Física (CPF), as pessoas são direcionadas para *n*-filas, no qual um funcionário verifica a identidade do usuário. É neste momento que são contabilizadas as entradas dentro do estabelecimento. A terceira etapa é o pagamento no caixa. Na quarta etapa, os usuários dirigem-se para os *buffets* de *self-service*, retirando sua bandeja com os alimentos disponíveis. Todas as filas geradas pelas etapas descritas acima serão classificadas como fila interna. Por fim, na quinta etapa, os usuários seguem para as mesas, realizando a sua alimentação e, posteriormente, deixando o local. Todas as etapas foram implementadas e serão descritas a seguir.

A modelagem computacional é baseada na comparação de políticas para entrada no RU. Atualmente, os indivíduos possuem liberdade para se dirigir ao restaurante em qualquer momento, formando uma fila única para o acesso. A proposta deste trabalho inclui a possibilidade de agendamento prévio de horário, cuja entrada no estabelecimento será prioritária em detrimento de quem não agendou, formando duas filas de acesso. Desta forma, este trabalho objetiva-se sugerir uma política para redução, ou pelo menos controle, de tempo de espera em fila externa.



A simulação segue um modelo discreto, no qual verifica-se a cada instante *t* o que está ocorrendo com cada consumidor em cada parte do RU. Antes da realização de um processo (identificação, pagamento, servir ou sentar), o usuário deve passar por uma fila em cada tarefa, como destaca a Fig. 2.

Fig. 2. – Modelo computacional de funcionamento do RU.

O procedimento de identificação possui uma série de passos para a realização, como ilustra a Fig. 3. Inicialmente, confere-se os recursos disponíveis, sendo os computadores livres para que o usuário possa informar seus dados. Em seguida, verifica-se os indivíduos que terminaram o processo de identificação. Então, os usuários seguem para a menor fila disponível, a fim de aguardar o início do atendimento. Posteriormente, os usuários que chegaram no RU são organizados conforme as duas políticas avaliadas no trabalho: filas sem agendamento (política atual) e/ou filas com agendamento (política proposta).

Fig. 3. – Etapa de identificação.

É importante evidenciar que o procedimento de identificação possui uma capacidade máxima, assim como todas as filas de espera em cada procedimento. Esta consideração é necessária para o bom funcionamento de todo o processo do

restaurante, além de ser condizente com as condições físicas no qual o restaurante foi construído. Desta forma, se o limite das *n*-filas de identificação é excedido, a entrada de mais consumidores é impedida até que algum outro usuário finalize sua identificação.

O processo de pagamento inicia-se com a verificação dos recursos necessários para a realização do atendimento dos caixas. Em seguida, confere-se os consumidores que finalizaram o procedimento de identificação no sistema e, então, o usuário se conduz para a menor fila em algum caixa disponível, efetua o pagamento e prossegue para a próxima atividade. A partir do momento que as filas internas atingem sua capacidade máxima, os procedimentos são paralisados, impedindo que os usuários nas filas externas entrem no restaurante. Assim, cria-se tempo para as filas internas diminuírem e o fluxo pode ser retomado. Refletindo o que ocorre no restaurante diariamente.

Finalizado o procedimento de pagamento, os indivíduos são direcionados aos *buffets* para se servirem. No procedimento de se servir, cada usuário aguarda o anterior terminar de se servir em cada setor do *buffet*, análogo ao processo de pagamento.

Após se servir, o indivíduo precisa encontrar um local para sentar-se e alimentar-se, sempre que houver lugar disponível. Este procedimento se inicia verificando os indivíduos que terminaram de se alimentar, liberando-os, e, posteriormente, verificando a existência de lugares disponíveis no instante para o indivíduo que terminou de se servir, destinando-o ao local. Este procedimento também possui capacidade em relação a quantidade de pessoas que podem estar sentadas: caso a capacidade de lugares do restaurante chega ao seu limite, ou seja, não possui mais lugares para os usuários se sentarem, o processo de identificação é paralisado, enquanto todos os outros processos continuam a funcionar normalmente. Deste modo, como não há novas entradas, é possível reduzir a lotação de pessoas dos demais processos até que a quantidade de pessoas em fila seja menor que a capacidade máxima de lugares para se sentar.

4 Experimentos computacionais

A modelagem computacional foi implementada no *software* MATLAB® R2019b, baseada na modelagem conceitual e nos dados disponibilizados pela Pró-Reitoria de Administração (PRA) da UFPR. Os dados, do período de março até junho do ano de 2019, contém registros da quantidade de funcionários disponíveis para realizar a identificação dos usuários, bem como a quantidade de consumidores do restaurante de maior demanda da UFPR, localizado no campus Centro Politécnico. Também foi cedida uma pesquisa, realizada no ano de 2017 pela PRA, para avaliar o tempo médio de refeição dos usuários de uma amostra piloto com 148 observações, durante uma semana nos RUs do campus Central e Jardim Botânico.

Quanto a questões de espaço, o RU adotado possui limitações físicas. Foram consideradas 5 estações para identificações, gerando 5 filas com capacidade de 8 posições cada. Foram considerados 3 caixas para realizar o pagamento, no qual geram 3 filas com 7 posições cada. Quanto aos *buffets*, foram considerados 10, ao qual no máximo 6 pessoas podem escolher cada utensílio e 8 pessoas podem se servir ao

mesmo tempo em cada ilha, respectivamente. A capacidade máxima de pessoas sentadas dentro do RU é de 800 lugares.

Conforme descrito na Seção 2, a simulação é controlada a cada instante de tempo, em que todos os processos são atualizados de acordo com os indivíduos que utilizam cada serviço (identificação, pagamento, servir e alimentação). O horário de operação do RU compreende o período das 11:00 horas até às 13:30 horas. Como alguns indivíduos chegam à fila externa próximo ao fechamento do restaurante, considera-se 30 minutos de "folga" para a simulação, no qual é feita a atualização dos estados e tempos desses indivíduos.

A discretização adotada neste estudo é definida por instantes de segundo. Neste caso, a simulação ocorre em 10800 iterações, equivalente à 3 horas de funcionamento. Esta discretização foi escolhida de forma a descrever o RU com maior precisão, dado que alguns processos dentro da cadeia são mensurados em poucos segundos. Cabe ressaltar que esta discretização é viável no presente trabalho devido ao tempo de funcionamento do RU ser limitado, o que não afeta a eficiência computacional da simulação e possibilita um nível de detalhe maior.

Para os processos de identificação por CPF, pagamento no caixa, servir-se e sentar-se, foram supostas distribuições de probabilidades que descrevessem o comportamento de cada fila, devido ao fato das informações serem escassas. A Tabela 1 destaca as expressões adotadas para geração de números.

Tabela 1. - Expressões adotadas para geração de tempos aleatórios dos processos (em segundos).

Procedimento	Expressão (apenas valores inteiros)
Identificação	TRIANGULAR(4, 6, 8)
Pagamento	TRIANGULAR(2, 3, 15)
Escolha de utensílios	UNIFORME(2,5)
Servir	NORMAL(120, 14^2)
Refeição	TRIANGULAR(420, 900, 3240)

Visto que alguns processos internos do restaurante dependem de expressões de distribuições de probabilidades, existe uma aleatoriedade nas simulações realizadas. Dessa forma, os resultados apresentados neste trabalho foram obtidos como a média de dez simulações diferentes. Cada simulação foi realizada por meio de uma semente aleatória, a fim de possibilitar a reprodução dos resultados.

Para simular a formação da fila externa na entrada do restaurante, é necessário conhecer o comportamento de chegada dos clientes. Optou-se por utilizar o histórico de atendimentos a fim de reproduzir cenários já ocorridos em meses anteriores. Assim, a quantidade de indivíduos que utilizaram os serviços do restaurante é dependente do cenário tomado na simulação, da mesma forma que o fluxo a cada instante de tempo será diferente para cada cenário. No presente trabalho, adotou-se uma série histórica do dia com maior volume de indivíduos, dia 28/03/2019 (quarta-feira), a fim de avaliar o tempo em fila em um cenário de maior utilização de recursos. É possível e foi realizado os mesmos testes com séries históricas de outros dias, porém o presente trabalho limita-se a apresentar os resultados desta única série por questões de formato.

A política proposta consiste na possibilidade do agendamento de horários para refeição. Neste caso, o cliente que agendar um horário terá acesso a uma fila preferencial, que será prioritária sobre a fila comum dos indivíduos que não agendaram. Define-se que a quantidade de vagas é distribuída em intervalos de 15 minutos, constante para os horários. Então, além de analisar o impacto desta política no funcionamento do RU, será possível também verificar o impacto de diferentes números de vagas de agendamento.

Neste estudo, supõe-se que todas as vagas disponíveis para agendamento são preenchidas, independente do instante de chegada original do cliente. No início da simulação, os indivíduos que irão agendar seu horário são sorteados de forma que todas as vagas possuam agendamento, e os instantes de chegada podem ser alterados de acordo com o agendamento. O cliente tentará agendar seu horário próximo à sua chegada original ao restaurante e, caso não exista vaga para o seu horário, escolhe agendar no próximo horário disponível.

Para a computação dos resultados das estatísticas de tempo em fila, registrou-se o instante de tempo em que o indivíduo chega e finaliza cada processo. Isto compreende desde a entrada e saída de todas as filas até o início e fim de sua refeição. Logo, é possível calcular a duração de cada processo durante a passagem do indivíduo no estabelecimento.

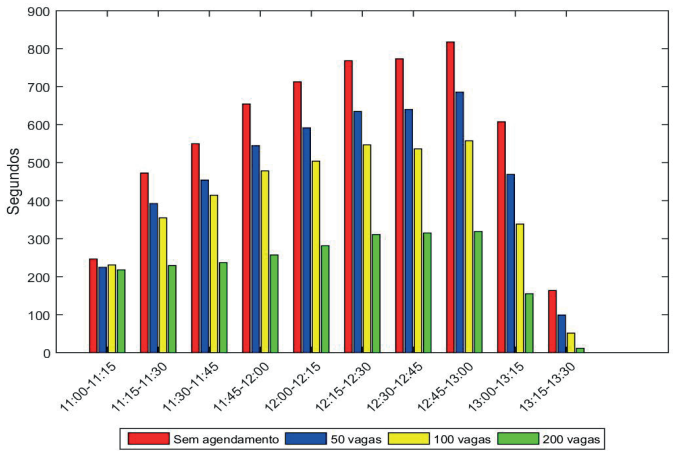
4.1 Validação do modelo computacional

A validação do modelo computacional foi realizada baseada no histórico dos dados do sistema de identificação. Neste caso, é possível calcular a quantidade de sujeitos que fazem a identificação no sistema a cada minuto do funcionamento do RU. Desta forma, a validação é feita por meio da medição de quantos indivíduos passam pelo processo de identificação na simulação.

Por meio da computação desses dados, tem-se que a quantidade de indivíduos que se identificam por minuto é constante na primeira hora de funcionamento do RU, decaindo nas horas finais. Além da medição por minuto, considera-se o agrupamento por intervalos de 15 minutos.

Conforme a Tabela 2 mostra, tem-se que a quantidade de indivíduos atendidos nos intervalos de 15 minutos na simulação é semelhante em comparação ao realizado nos cenários.

Tabela 2. - Comparação do fluxo de pessoas da série histórica 28/03/2019 adotadas e sua respectiva simulação.



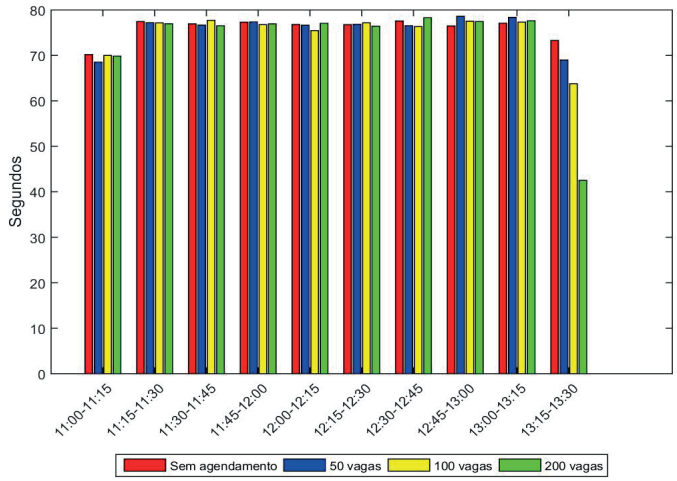
Intervalo (min)	*Real*	*Simulado (média das 10 simulações)*	Erro Relativo (%)
11:00 - 11:15	523	454,7	13,06
11:15 - 11:30	509	434,0	14,73
11:30 - 11:45	484	437,7	9,57
11:45 - 12:00	462	434,4	5,97

12:00 - 12:15	474	438,3	7,53
12:15 - 12:30	463	436,8	5,66
12:30 - 12:45	439	433,3	1,30
12:45 - 13:00	473	440,8	6,81
13:00 - 13:15	266	435,3	63,65
13:15 - 13:30	200	347,4	73,70
		Média dos erros relativos por intervalo	20,2%

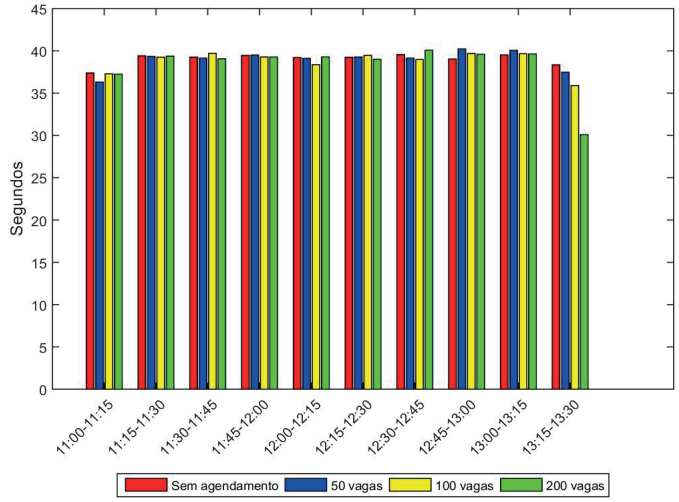
4.2 Série de 28/03/2019

Este cenário compreende o dia de maior volume de usuários segundo os dados disponíveis. A Fig. 4 apresenta os tempos médios de espera na fila externa ao RU, por intervalos de tempo e em segundos. É possível observar que houve tempo de espera em todos os intervalos. Quando não há agendamentos, o tempo médio de espera é de 246 (4,1 minutos) segundos quando o RU é aberto, tendo um maior valor de 817 segundos (13,62 minutos) de espera entre 12:45 e 13:00. Próximo ao fechamento do restaurante, no intervalo de 13:15 e 13:30, ainda havia um tempo médio de 163 segundos em fila.

Fig. 4. – Tempos médios de espera em fila externa para cada faixa de horário do dia - Série 28/03/2019.



Quando se adota a política de agendamento, observa-se que o tempo médio em fila é reduzido para todos os intervalos analisados. Para o intervalo entre 11:00 e 11:15, os tempos de espera médio são próximos, sendo que a partir de 11:15 essa diferença aumenta. Quanto mais vagas são disponibilizadas para agendamento, maior é a redução do tempo médio em fila externa quando comparado aos tempos da simulação



sem agendamento. Como este cenário é o de maior volume histórico, o agendamento não foi suficiente para eliminar a fila externa, mas houve redução no tempo.

Os tempos médios por intervalo para as filas internas do restaurante, filas para identificação, pagamento, e se servir, são ilustradas nas Figuras 5a, 5b e 5c, respectivamente.

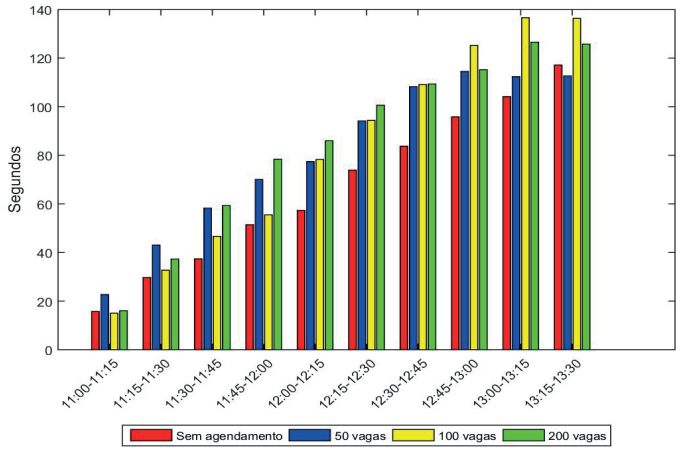


Fig. 5. – Tempos médios dos processos internos realizados pelo usuário - Série 28/03/2019.

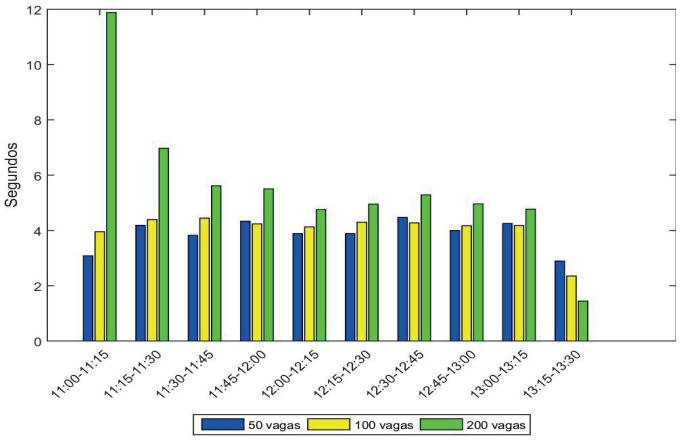
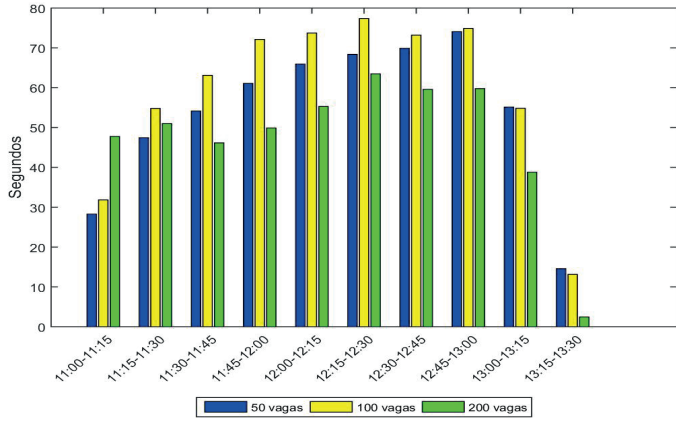
(a) Fila de identificação.

(b) Fila de pagamento.



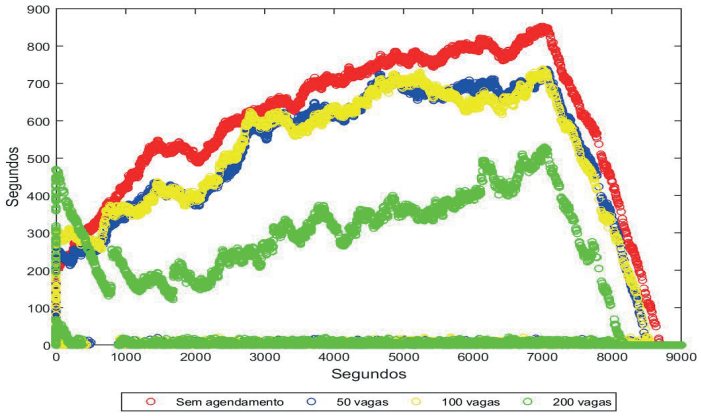
(c) Fila de servir.



Para este cenário, conclui-se que o agendamento de horários não influenciou no tempo de espera nas filas internas do RU. Isto ocorre provavelmente devido ao alto volume de usuários e a capacidade de funcionários disponíveis para identificação e pagamento não mudar, além da quantidade de *buffets* disponíveis. Nas filas para se servir no *buffet*, observa-se um aumento do tempo médio em fila conforme as faixas de horário. Para a faixa de 11:15 à 11:30, os tempos médios em fila são maiores para os casos em que se considera 100 e 200 vagas para agendamento. Conforme será discutido na próxima seção, este resultado pode ser consequência do aumento do número de indivíduos nessa faixa de horário com a política de agendamento. Além disso, este resultado pode ser um indício de que o processo de se servir obstrui o fluxo do restaurante.

A Fig. 6 compara o tempo médio na fila externa para indivíduos que chegaram com agendamento (Fig. 6a) ou sem agendamento (Fig. 6b) de horário. Neste cenário, é perceptível a diferença entre agendar ou não agendar. Existe uma maior vantagem para os indivíduos agendarem neste caso pois, em média, ficarão 4,5 segundos na fila. Enquanto isso, os indivíduos que não agendaram podem ficar até 775 segundos em fila.

Fig. 6. – Tempos médios em fila externa para cada faixa de horário do dia para indivíduos que agendaram ou não - Série 28/03/2019.

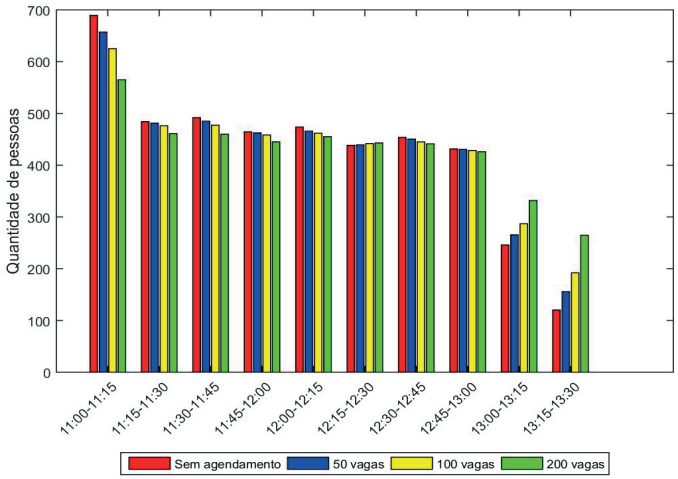


(a) Indivíduo agendado.

(b) Indivíduo não agendado.

A Fig. 7 mostra um diagrama de dispersão entre o instante de chegada do indivíduo ao restaurante e seu tempo de espera na fila externa. Nesta série histórica utilizada, nos primeiros segundos de funcionamento o tempo de espera é maior quando é possível agendar um horário, sendo que a diferença é maior quanto mais vagas são disponibilizadas em comparação quando não existe esta opção. Após um certo horário, tem-se que o tempo de espera em fila é sempre menor para os casos em que uma política de agendamento foi adotada, concordando com os resultados obtidos anteriormente.

Fig. 7. – Horário de chegada por Tempo de espera na fila externa - Série 28/03/2019.



4.3 Impacto da política de agendamento na distribuição de chegada dos indivíduos

Uma consequência direta da adoção da política de agendamento de horários é uma menor concentração de clientes em horários de pico, uma vez que uma parte dos indivíduos são agendados em horários menos procurados. A Fig. 8 ilustra a quantidade de indivíduos que chegaram ao restaurante, por intervalos de tempo, no cenário simulado baseado na série histórica de 28/03/2019. A tendência observada é que, quanto maior a quantidade de vagas disponibilizadas para agendamento, menor é a variação da quantidade de indivíduos que chegam no decorrer dos intervalos. Comparando o gráfico do caso sem agendamento e o caso com 200 vagas disponíveis, percebe-se que a quantidade de usuários nos primeiros intervalos de tempo é reduzida, enquanto nos horários finais aumenta ao considerar o agendamento.

Neste cenário, no caso de 200 vagas para agendamento, a quantidade de usuários que chegam ao RU, especialmente no intervalo entre 13:15 e 13:30, possui 267 indivíduos chegando, enquanto que o cenário sem agendamento 120 indivíduos chegam.

Fig. 8. – Quantidade de pessoas que chegam ao RU - Série 28/03/2019.

Desta forma, a implantação de uma política de agendamento reduz o tempo em fila externa ao restaurante, desde que sejam preenchidos os horários de menor demanda no almoço (a partir de 12:45), pois distribui de forma mais constante a quantidade de indivíduos que utilizam os serviços do RU. Assim, em vez de ocorrer uma concentração maior de indivíduos nas primeiras horas de funcionamento do RU e formação de filas para os processos internos, pode-se distribuir de forma a manter um fluxo constante de clientes e evitar filas, ou pelo menos reduzi-las. Nota-se que para o cenário do dia 28/03/2019 o agendamento reduziu o tempo médio de espera e ainda houve filas no exterior do restaurante.

5 Considerações Finais

Este trabalho apresentou uma simulação do funcionamento de um RU a fim de avaliar políticas para redução de filas. Apesar da simulação ser realizada em situações ideais, em que todas as vagas são preenchidas e os consumidores cumprem o agendamento, pode-se concluir que a política reduz o tempo médio em fila. Para fomentar a adesão dos usuários à política de agendamento de horários no caso do almoço, poderia ser verificado, com base no sistema da universidade, os usuários livres de atividades no período vespertino no campus, permitindo a sua ida ao RU apenas nos horários de menor demanda. Esta tática distribuiria melhor a chegada dos estudantes durante os intervalos de tempo, fazendo com que o agendamento de horários fosse mais concorrido não somente em horários de pico de demanda. Concluímos então, que a política de agendamento de horários reduz o tempo médio em fila, desde que as vagas para agendamento de todos os períodos de funcionamento sejam preenchidas. Os resultados melhoram a experiência do usuário e o fluxo de funcionamento do RU e podem ser replicada para qualquer outro tipo de problema com agendamento em casos reais, na qual a fila aumenta significativamente em determinados horários.

Resumen. El objetivo del trabajo consiste en mejorar el proceso de facturación y cobro de una organización de servicios de salud. El principal problema que presenta el Área de Finanzas se origina en el proceso de seguimiento de cobros y reclamos debido a los retrasos en el pago de los servicios prestado, generando inconvenientes de liquidez por no poder afrontar la totalidad de las obligaciones y compromisos financieros en el corto y mediano plazo. Dicha situación pone en riesgo su solvencia futura y supervivencia a largo plazo. El proceso estudiado varía en función de tres modalidades de tratamiento, del tiempo de retraso del cobro y de las diversas formas de pago. Para una mayor comprensión, se estudia la situación actual relevando las actividades que componen el proceso y sus tiempos de ejecución; se identifican las que agregan valor al cliente y la organización, de las que no. Se efectúa un análisis causa-efecto para de detectar los principales motivos que originan el problema. Se formula una propuesta de mejora, que contempla la incorporación de TIC y personal especializado, con el propósito de aumentar el valor agregado para el cliente y la organización. La implementación las mejoras reduce un 71% la cantidad actividades que no aportan valor y aumentan el 33% las que agregan valor al cliente. Disminuye un 60,79% el tiempo de actividades sin valor y aumenta el 7,94% el tiempo que generan valor al cliente. Se concluye que la metodología propuesta genera un impacto positivo para la organización y sus clientes.

Palabras clave: Agregado de Valor, Mejora de Procesos, Servicios de Salud.

Abstract. The objective of this work consists of the analysis and improvement of the billing and collection process of an organization that provides health service. The main problem that the Finance Area presents is originated in the process of monitoring charges and claims due to the delays in the payments of services, generating liquidity drawbacks due to not being able to meet all the financial obligations and commitments in the short and medium term. Such a situation puts it's future solvency at risk and, therefore, their long-term survival. The process

studied varies depending on the treatment modalities provided, the time of delay in debts and the possible forms of payment**.** For a better understanding, the current relevance of the activities that make up the process and their execution times are studied; those that add value to the client and the organization of those that do not are identified. A cause-effect analysis is carried out in order to detect the main reasons that originate the problem. A process improvement proposal was formulated, which includes the incorporation of ICT and specialized personnel, with the purpose of increasing the added value for the client and the organization. The process implementation generates a 71% reduction in the number of activities that do not add value and increases those that add value to the customer by 33%. It reduces 60.79% the time of activities without value and increases 7.94% those that generate value to customers. It is concluded that the proposed methodology has generated a positive impact for the organization and its clients.

Keywords: Added Value, Process Improvement, Health Services.

1 Introducción

La mejora de los procesos y servicios brindados a los clientes se han convertido en una tarea fundamental para las organizaciones que buscan mantenerse en el entorno competitivo actual. Para ello es necesario el desarrollo de una cultura orientada a la gestión de procesos, el trabajo en equipo, la incorporación de tecnologías, la participación del personal y la innovación.

Se toma como caso de estudio a una organización de salud de la ciudad de Mar del Plata que presta servicios especializados en la prevención, atención y reinserción social de personas que hacen un uso indebido de drogas. Frente a la necesidad de mantener la competitividad, liquidez y sostenibilidad futura de la organización y ante las falencias que posee el actual manejo de la información, se considera imperioso la incorporación de tecnologías de la información y de la comunicación (TIC) que sistematicen y faciliten el proceso de seguimiento de cobros y reclamos de la institución y permita la toma de decisiones más certeras al Área de Finanzas y la Gerencia.

El objetivo del presente trabajo es la propuesta de una mejora al proceso estudiado mediante la incorporación de TIC, con la intención de aumentar el valor agregado para el cliente y la organización. Se desarrolla un estudio de procesos para detectar los principales puntos de mejora que aumenten la eficiencia y la generación de valor. Mediante la incorporación de un software de gestión se proyecta proporcionar una herramienta sencilla y sistemática para la ejecución de las actividades del Área Financiera, como así también dotar a la organización de información confiable para la toma de decisiones.

2 Marco Teórico

2.1 Los sistemas de información y el agregado de valor
