El estudio del agregado de valor implica analizar los procesos en los niveles estratégico, táctico y operativo de las organizaciones y su cadena de valor. Entre los procesos que crean valor para el cliente se destacan aquellos relacionados con la incorporación de tecnología: por una parte se pueden identificar las que se relacionan con la incorporación intensiva y extensiva de las TIC en las decisiones sobre infraestructura, software, formación y aplicaciones que puedan requerirse en las diferentes actividades de la organización y por otra, aquellas que atañen a las tecnologías emergentes implementadas para la elaboración de productos o servicios. De esta manera, la relación entre las TIC y la generación de valor depende fundamentalmente de la mejora de los procesos de gestión de la información, permitiendo a las organizaciones satisfacer los requisitos de sus clientes y aumentar su desempeño (Albors et al., 2006)

Los sistemas de información permiten a la empresa tomar mejores decisiones, aumentar su eficiencia y brindar mejor servicio al cliente. Desde una perspectiva de negocios, un sistema de información es una importante herramienta que puede generar valor para la empresa y sus clientes. Es por ello, que los sistemas de información, particularmente los softwares de gestión empresarial, permiten que muchas más personas tengan acceso a la información y la compartan, para reemplazar los pasos secuenciales con tareas que se pueden realizar en forma simultánea y mediante la eliminación de tareas repetidas e ineficientes (Laudon y Laudon, 2012).

Para tener un sistema de información apropiado, es conveniente la participación de los usuarios en la definición de los requerimientos ya que facilita la recolección de hechos y contribuciones valiosas. Los usuarios son quienes emplearán el sistema y por ello tendrán un interés legítimo en involucrarse en su desarrollo (Cáceres, 2014)

2.2 Análisis de valor agregado de actividades

Para lograr identificar las actividades que generan un agregado de valor se puede implementar la metodología sistemática propuesta por Miles (1989) denominada Análisis de Valor Agregado de Actividades. Esta consiste en un análisis detallado de cada fase de un proceso para determinar si contribuye a las necesidades o requisitos de las partes interesadas. Persigue la eliminación de actividades que no generan valor en los procesos de la organización, la combinación de actividades que no pueden ser eliminadas y el mejoramiento de las restantes actividades que no generan valor (Hernández Oro, 2012).

En el análisis se deben identificar los distintos tipos de actividades, según se detalla a continuación:

- Actividades de valor agregado para el cliente (VAC): generan valor al cliente y está dispuesto a pagar por ellas.
- Actividades de valor agregado para la organización (VAO): generan valor a la organización y es el resultado del beneficio ofrecido al cliente.

- Actividades sin valor agregado (SVA): no contribuyen a satisfacer a los clientes internos o externos y deben eliminarse o reducirse sin afectar los productos o servicios de la organización. Estas son las actividades de inspección, revisión, espera, archivo y movimiento (Trishler, 1998).

2.3 Herramientas de análisis

Las representaciones gráficas de un proceso contribuyen a mejorar su análisis ya que permiten su desglose en actividades más específicas y detalladas. De esta manera facilita la identificación de las actividades que generan valor a los clientes y la organización de las que no lo hacen. Los diagramas de flujo se utilizan para obtener una visión global de un proceso, son una representación gráfica de la secuencia de actividades que lo conforman y facilitan la identificación de las diferentes áreas que intervienen en cada fase. Para un análisis más detallado de los procesos es necesario descomponerlo en todas las actividades que lo conforman e identificar su tipología o naturaleza. Se emplean los cursogramas analíticos que permiten determinar de forma concreta las actividades de operación, transporte, almacenamiento, demora e inspección; facilitando la identificación de las actividades que generan valor añadido de las que no. Además, estos diagramas, viabilizan comparar los procesos actuales con los desarrollados e identificar concretamente las mejoras obtenidas. Otra herramienta importante para el análisis del proceso es el Diagrama de espina de pescado que permite identificar los puntos críticos o de mejora, determinar las causas que originan los problemas detectados y establecer su relación causa-efecto (Castillo Benavides, 2015).

3 Metodología

Para el desarrollo del presente trabajo y la consecución del objetivo planteado, se adopta una metodología basada en un estudio de caso efectuado en una organización de salud de la ciudad de Mar del Plata.

Los pasos a seguir para su elaboración se enumeran a continuación:

- Paso 1: Caracterización del proceso actual de seguimiento de cobros y reclamos. Se relevan las fases del proceso y sus interacciones mediante la utilización de un diagrama de flujo.
- Paso 2: Análisis del valor agregado de las actividades del proceso actual. Se analizan en forma detallada las actividades que componen el proceso y su naturaleza, con el objetivo de poder distinguir aquellas que aportan valor de las que no. Para ello, se desarrollan cursogramas analíticos derivados del proceso relevado en el paso anterior.
- Paso 3: Identificación de problemas o puntos de mejora. En función del estudio previo, se detectan los puntos críticos del proceso mediante un análisis de causa-efecto utilizando el diagrama espina de pescado.
- Paso 4: Propuesta de mejora del proceso actual. En función de los puntos críticos detectados, se formula un conjunto de mejoras al proceso actual. El proceso con las mejoras propuestas se representa por medio de un diagrama de flujo.

- Paso 5: Análisis del valor agregado de las actividades del proceso propuesto: A partir de la implementación de las mejoras propuestas, se elaboran los nuevos cursogramas analíticos para poder determinar de forma detallada el aporte al agregado de valor del proceso perfeccionado. Se realiza un análisis comparativo del agregado de valor generado por el proceso original y el propuesto.

Para la ejecución de los pasos anteriores se efectúan visitas in situ y entrevistas programadas con los actores involucrados en el proceso analizado. Todos ellos mostraron muy buena disposición y gran interés en participar en las actividades propuestas.

4 Resultados

4.1 La estructura organizacional y las decisiones gerenciales

La organización bajo estudio es una fundación dedicada a brindar un servicio especializado de salud mental para personas que hacen uso indebido de drogas. Posee tres modalidades de tratamiento: hospital de día, de medio día turno tarde y de medio día turno vespertino, cubriendo la franja horaria de 9 a 21 horas de lunes a viernes. Actualmente está trabajando al 75% de su capacidad instalada.

El proceso de servicio varía según las tres modalidades de tratamiento y su duración oscila entre 2 a 3 años, según la evolución de cada paciente. Esta variación se debe a que es un servicio de salud altamente personalizado según las características y necesidades terapéuticas de cada uno. Los tratamientos brindados son cubiertos por obras sociales, prepagas o servicios de salud que posee cada paciente o en caso de no ser así, son abonados en forma particular. La estructura organizacional fue modificándose, desde su apertura en el año 2013, según el crecimiento del número de pacientes atendidos.

El actual organigrama de la empresa se presenta en la Figura 1. Se evidencia una estructura de tamaño pequeño con una departamentalización por funciones. Posee una dotación de 8 trabajadores distribuidos en los diferentes niveles y dos asesores externos.

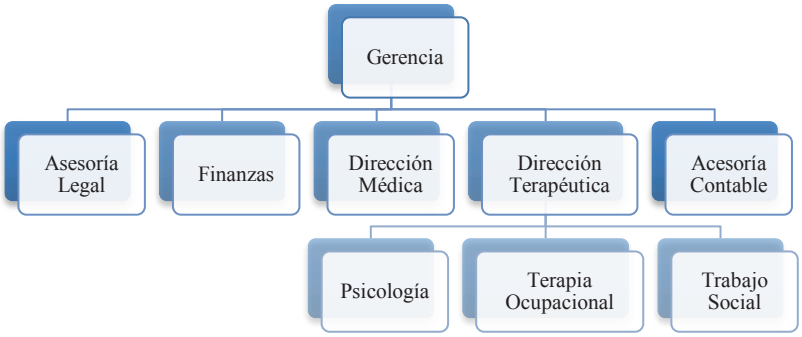

Fig. 1: Organigrama actual.

Las decisiones estratégicas son tomadas por la Gerencia, y en sus comienzos, al ser una organización pequeña esta área también se encargaba de algunas tareas y toma de decisiones de los mandos medios. Debido al incremento de pacientes atendidos estas

decisiones, en su mayoría, han sido delegadas a las áreas correspondientes. Es por ello, que la definición de los lineamientos tácticos y la toma de decisiones de cada área es crucial para el funcionamiento la organización y su sustentabilidad futura.

4.2 El proceso de seguimiento de cobros y reclamos

Actualmente el proceso de seguimiento de cobros y reclamos es realizado por el Gerente de la Fundación con una frecuencia trimestral. El encargado de Finanzas se limita a la práctica de las funciones básicas del área, ya que al desempeñarse a tiempo parcial no cuenta con el tiempo suficiente para efectuar este proceso. Según la cobertura médica de los pacientes, el tiempo de retraso del cobro y la forma de pago, el proceso presenta una serie de variantes. Para una compresión integral de las actividades que lo componen, en la Figura 2, se muestra el diagrama de flujo del mismo.

Como se puede observar, el proceso de reclamos se realiza en función del tiempo de la deuda, la cobertura que el cliente posee, ya sea mediante una Entidad de Cobertura Médica (ECM), si paga el servicio de forma particular o su ECM se lo reintegra luego de realizar el pago correspondiente. Asimismo, existen variantes según la forma de pago, puede ser por cheque o transferencia bancaria. Las actividades de espera que se identifican no dependen de la organización, ya que son tiempos que están en manos de los pacientes o ECM.

Las TIC implementadas en este proceso son escasas y poco eficientes. La documentación y las copias se emiten y archivan de forma física. El registro de los pagos se realiza mediante el uso de planillas de cálculo electrónicas y únicamente están a disposición de las áreas de finanzas y gerencial ya que no poseen un software de gestión integral.

Si bien durante el comienzo de las actividades de la organización el Gerente pudo llevar adelante en forma adecuada este proceso, con el crecimiento de la cantidad de clientes la tarea no se despliega según las necesidades de la organización. La baja frecuencia con que se realiza el seguimiento y reclamo de los cobros y la falta de disponibilidad de la información requerida para el desarrollo del proceso en tiempo y forma son los principales problemas que enfrenta la organización. Esto se traduce en significativas tardanzas en el cobro de los de los servicios prestados, el 92% de los pagos se realizan con retrasos y en el 59% de los atrasos son mayores a los 5 meses, alcanzando en los casos más desfavorables demoras que llegan a 8 meses y más. Este escenario genera inconvenientes de liquidez a la organización, debido a no poder afrontar la totalidad de las obligaciones y compromisos financieros en el corto plazo y, en consecuencia, pone en riesgo su solvencia futura y supervivencia a largo plazo.

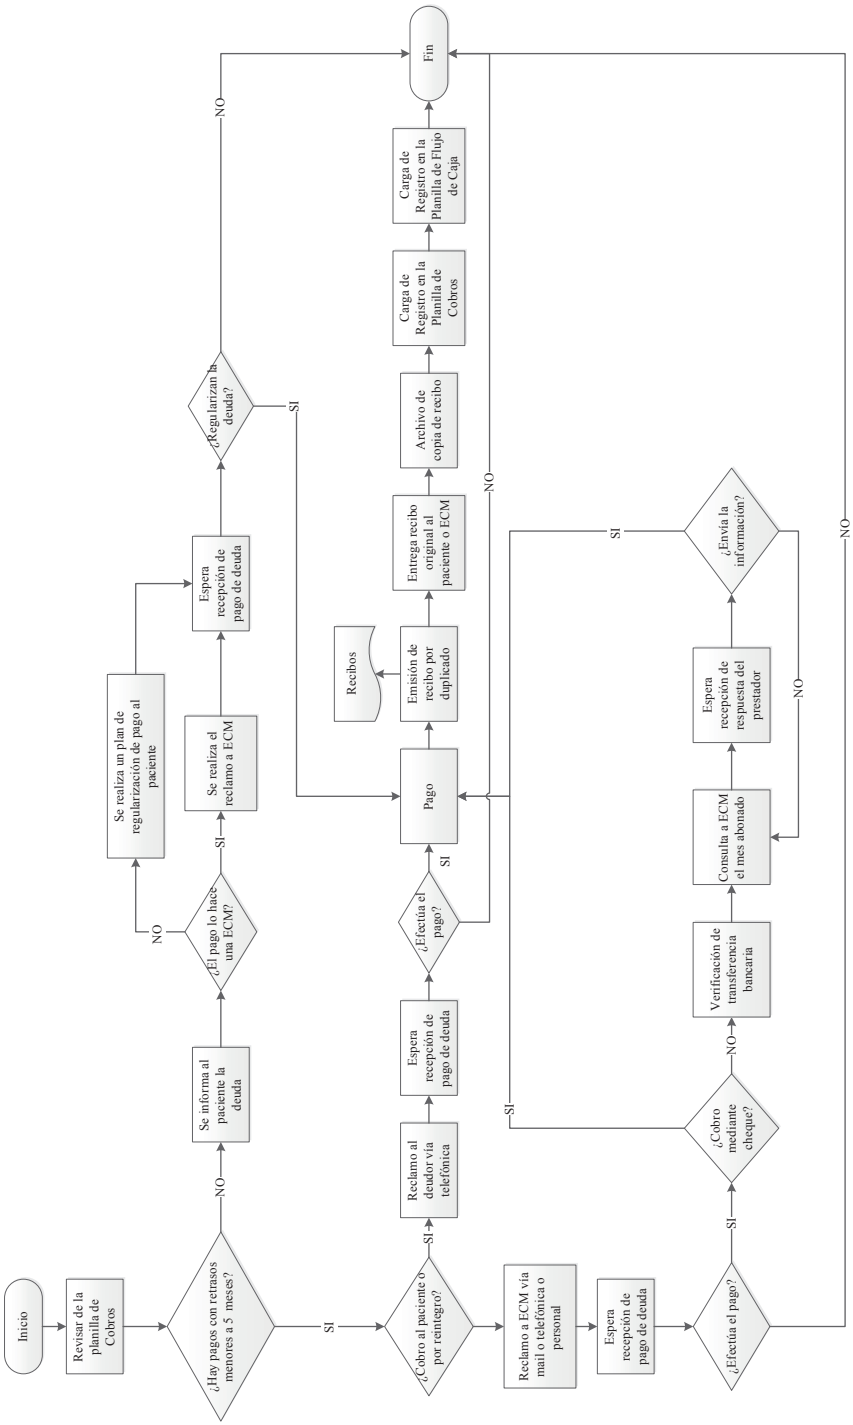

Fig. 2: Proceso actual.

4.3 Análisis del valor agregado del proceso actual

Para la realización del análisis de valor agregado, se realiza un relevamiento detallado de todas las actividades que forman parte del proceso analizado. En función de las diferentes alternativas del mismo se elaboraron cinco cursogramas analíticos con la naturaleza de cada actividad y su aporte de valor.

Se elaboran los cursogramas del:

1. Proceso seguimiento de cobros y reclamos para deudas de más de 5 meses para particulares.
2. Proceso seguimiento de cobros y reclamos para deudas de más de 5 meses para ECM.
3. Proceso seguimiento de cobros y reclamos para deudas de menos de 5 meses para particulares.
4. Proceso seguimiento de cobros y reclamos para deudas de menos de 5 meses para ECM y pago mediante cheque.
5. Proceso seguimiento de cobros y reclamos para deudas de menos de 5 meses para ECM y pago mediante trasferencia bancaria.

A modo de ejemplo, en la Figura 3 se presenta el cursograma del proceso 5. Como se puede observar, existe un importante tiempo de demora por la espera a la recepción del pago de las deudas (1,5 meses).

En la Tabla 1 se presenta el análisis de agregado de valor de los cinco procesos analizados. Respecto a la cantidad de actividades, se puede observar que todos los procesos poseen entre 17 y 46% de actividades sin valor agregado. Al analizar el tiempo de las actividades, todos los procesos reportan casi el 100% del tiempo de actividades que no generan valor.

Analizando los resultados del análisis de valor agregado del proceso total con todas sus variantes, se evidencia que el 30,435% de las actividades no generan valor al cliente ni a la organización, proporción mayor que las actividades que generan valor al cliente (19,565%). En el análisis del tiempo, se observa que solo el 0,042% de las actividades aportan valor al cliente y a la organización y el tiempo total del proceso es de 44.0852,250 minutos, significa que el tiempo de las actividades sin valor agregado representa el 99,958% % del total.

Se determina, que el porcentaje de tiempo sin agregado de valor se origina, en su mayoría, por los elevados periodos de espera para realizar el pago las deudas que varían entre 1,5 a 4,5 meses según el tipo de reclamo. La baja frecuencia con que se efectúan los reclamos y la falta de seguimiento de los mismos contribuyen al aumento de estas demoras.

4.4 Identificación de problemas

Se realizan entrevistas al encargado de Finanzas y al Gerente de la organización, en las mismas se explicita y detalla el análisis del valor agregado del proceso seguimiento de cobros y reclamos y en base a este análisis se detectan en forma conjunta una serie de problemas o puntos críticos que requieren ser solucionados para mejorar el desempeño del proceso en términos de agregado de valor.

Los principales problemas detectados son:

- El proceso no se realiza de forma sistemática.
- Falta de automatización del proceso.
- El proceso se realiza con una baja frecuencia.
- No se genera documentación digital.
- El envío de documentación en papel y presencial genera demoras.
- Existen demoras en para el cobro del servicio.
- No se efectúa un seguimiento del reclamo una vez realizado.
- El proceso de cobro por cheque o contado genera mayor complejidad y tiempo requerido.
- No existe disponibilidad de información en tiempo real para la gerencia y el área.
- El personal tiene un bajo nivel de capacitación.
- El personal posee sobrecarga de trabajo.
- Existe carga de datos duplicados.

En base a estos problemas, se elabora el diagrama de espina de pescado con la finalidad de organizar esta información en categorías (Figura 4) y facilitar la detección de las relaciones causa-efecto.

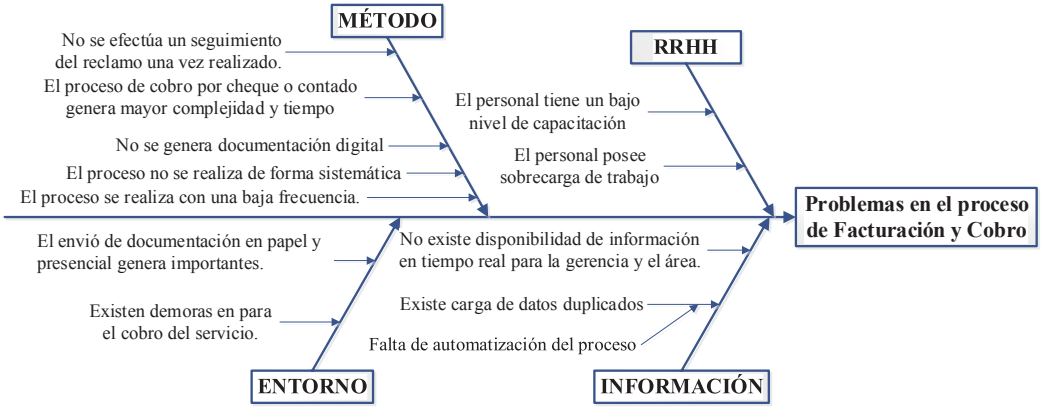

Fig. 4. Diagrama espina de pescado.

4.5 Proceso propuesto

En función del análisis de causas realizado en el paso anterior se proponen las siguientes mejoras al proceso de facturación y cobro de la organización:

- Incorporación de un software de gestión que permita automatizar y sistematizar el proceso, evitar la duplicidad de carga de datos, generar documentación digital y la disponibilidad de información en tiempo y forma para la toma de decisiones.
- Contratar un Contador Público Nacional a tiempo parcial que se dedique exclusivamente al proceso de seguimiento de los cobros y reclamos, como también al de facturación y cobro.
- Realizar la generación y envió de los recibos de manera digital.
- Aumentar la frecuencia de realización del proceso y realizar un seguimiento constante de los reclamos efectuados.
- Adoptar como única modalidad de pago la transferencia o depósito bancario con el objetivo de evitar pérdidas de tiempo y sobrecarga de trabajo al personal.
- Tercerizar el proceso de reclamos de deudas complejas al Estudio Jurídico que efectúa el asesoramiento legal a la organización.

Los problemas originados por el entorno no son posibles de modificar por parte de la organización, debido a que se producen por los métodos de trabajo de las ECM y la capacidad financiera de los pacientes particulares.

Como resultado de los cambios presentados, se presenta en la Figura 5 el proceso de seguimiento de cobro y reclamo propuesto. La incorporación del sistema permite la eliminación de la carga de datos duplicada, la generación de documentación digital y la supresión de las actividades de archivo de documentación. El envío del recibo digital desde el sistema de gestión reduce considerablemente las actividades requeridas en la última etapa del proceso. Se establece una frecuencia mensual para el desarrollo de este proceso y se adicionan actividades para el seguimiento de reclamos efectuados, con el objetivo de reducir los tiempos de espera para la regularización de las deudas. El proceso de seguimiento se realiza luego de esperar un mes a la respuesta del reclamo y posee una efectividad del 70%. Al precisar una única modalidad de cobro, se puede

observar que la supresión del pago con cheque y contado reduce dos variantes, quedando un total de cuatro alternativas del proceso.

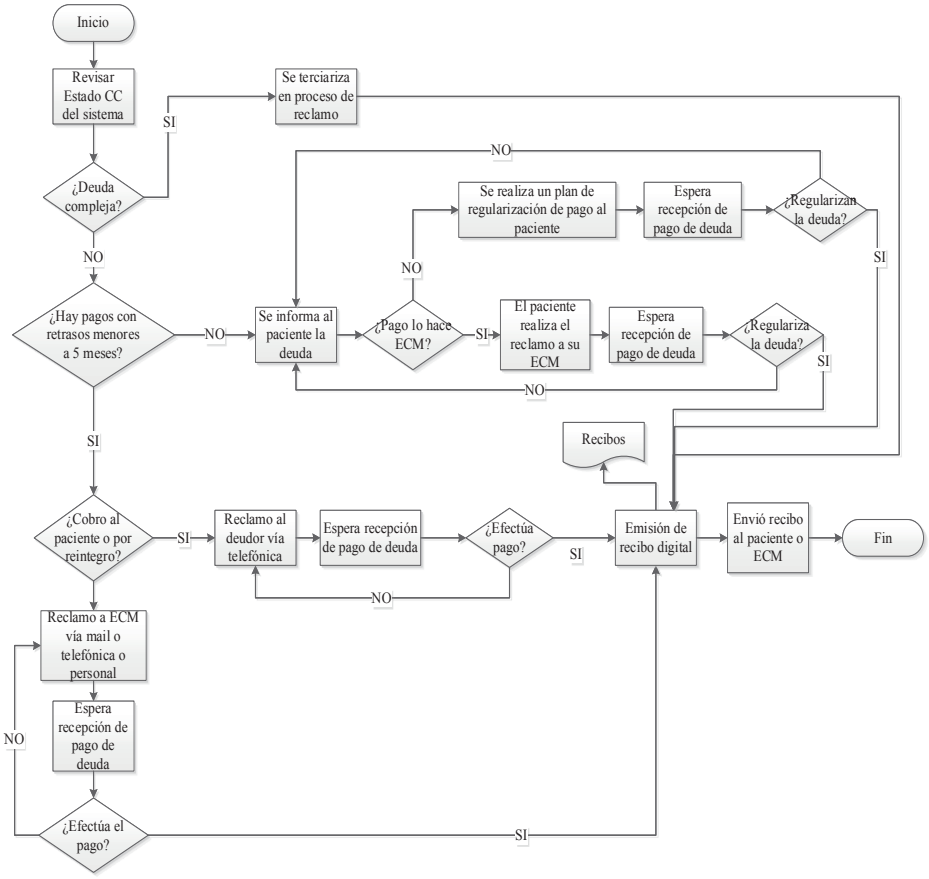

Fig. 5: Proceso propuesto.

4.6 Análisis del valor agregado del proceso propuesto

Luego de la implementación del proceso propuesto, se realiza un relevamiento detallado de todas las actividades con el objetivo de analizar el valor agregado que este genera. En función de las diferentes alternativas del proceso se elaboraron cuatro cursogramas de:

1. Proceso seguimiento de cobros y reclamos para deudas de más de 5 meses para particulares.
2. Proceso seguimiento de cobros y reclamos para deudas de más de 5 meses para ECM.
3. Proceso seguimiento de cobros y reclamos para deudas de menos de 5 meses para particulares.
4. Proceso seguimiento de cobros y reclamos para deudas de menos de 5 meses para ECM.

A modo de ejemplo, en la Figura 12 se presenta el cursograma del proceso 3. Este proceso ha logrado disminuir cinco actividades que no generan valor al cliente ni a la organización y reducir en un 37,52% el tiempo requerido para el proceso.

Cursograma Analítico Operario

Proceso: Seguimiento de cobros y reclamos para deudas de menos de 5 meses para ECM.

Método: Propuesto

Resumen

Actividad	Actual	Propuesto	Economía
Operación ○	5	3	2

Fig. 6: Cursograma analítico Proceso 4 propuesto.

En la Tabla 2 se muestran los resultados del análisis de valor agregado del proceso propuesto, con todas sus variantes. Respecto a la cantidad de actividades, se puede observar que todos los procesos poseen un porcentaje comprendido entre 12,5 y 16,667% de actividades sin valor agregado. Analizando el tiempo de las actividades, todos los procesos reportan casi el 100% del tiempo de actividades que no generan valor.

Se evidencia que el 14,815% de las actividades no generan valor al cliente ni a la organización, proporción menor que las actividades que generan valor al cliente (44,444%) y a la organización (40,741%). En el análisis del tiempo, se observa que solo el 0,069% de las actividades aportan valor al cliente y a la organización y el tiempo total del proceso es de 172.929 minutos, por lo que el tiempo de las actividades sin valor agregado representa el 99,931% % del total de este tiempo.

El porcentaje de tiempo sin agregado de valor se origina, en su mayoría, por los tiempos de espera para realizar el pago las deudas. Dicha demora es de un mes para

todas las variantes del proceso, que es la nueva frecuencia establecida para la realización del mismo.

Al comparar el proceso propuesto con el original, se observa que la implementación de las mejoras planteadas permite una reducción de un 41,30% de la cantidad de actividades que lo componen y un 60,78% del tiempo total requerido para su desarrollo. Respecto al análisis de valor agregado, se evidencia una reducción del 71,43% de la cantidad actividades que no aportan valor y un aumento del 33,33% de las actividades que agregan valor al cliente. Analizando la variable tiempo, se alcanza una reducción del 60,79% del tiempo de las actividades sin valor y 48,95% del tiempo de actividades que generan valor a la organización, mientras que el tiempo de actividades que generan valor al cliente aumenta en un 7,43%.

Tabla 2. Análisis del Valor Agregado del proceso total propuesto.

Proceso		Actividades				Tiempo (min)			
		VAC	VAO	SVA	Total	VAC	VAO	SVA	Total
Proceso 1	**Cantidad**	3	4	1	**8**	14,500	46,000	43200,000	**43260,500**

5 Conclusiones

La metodología propuesta resulta ser efectiva en la mejora del valor agregado del proceso de seguimiento de cobros y reclamos de la empresa analizada. El estudio de procesos ha permitido relevar y analizar detalladamente las actividades que lo componen y ofrece información de entrada para realizar el análisis de valor agregado. Este análisis hizo posible la detección de las actividades que agregan valor al cliente, a la organización y las que no lo hacen, permitiendo identificar los puntos críticos y posibilidades de mejoras del proceso estudiado. En función del mismo, se propone un conjunto de cambios destinados a eliminar los problemas detectados. La incorporación de las TICs al proceso, mediante el uso de un software de gestión, ha reportado un cambio significativo en el método de trabajo, reduciendo actividades innecesarias y duplicadas y permitiendo el acceso a la información necesaria para la toma de decisiones. La incorporación a la organización de una persona capacitada para realizar este proceso ha sido

un cambio fundamental ya que cuenta con los conocimientos necesarios para el desarrollo de las actividades como así también para su continuo análisis y mejora.

Se ha demostrado que la mejora propuesta ha aumentado de forma significativa la eficiencia del proceso y el valor agregado generado para el cliente y la organización. De esta manera, se concluye que la metodología presentada para la generación de valor en el proceso seguimiento de cobros y reclamos ha generado resultados con impacto positivo para la organización y sus clientes, favoreciendo su competitividad y sostenibilidad futura.

Abstract

Cluster analysis is an active area of research which is applied to a wide range of domains, spanning from physics to neuropsychology. The structure of clustering problems is shown to be hard to solve by exact methods and therefore heuristic procedures are a feasible approach. The present work develops a new hybrid metaheuristic based on the Black Hole Algorithm (BHA), a population-based and nature-inspired algorithm, which is under explored, despite its simple structure and effectiveness. Random local searches are inserted at strategic places of the algorithm and new features added. Results show improvement over the original BHA and related work, thereby rendering the new heuristic procedure competitive. Furthermore, the new approach is easy to implement and requires few parameters. Therefore, it can be used as a competitive alternative to classical algorithms. Computational experiments are run over well-known benchmark datasets as well as newly generated ones. Lastly, future potential research directions are outlined.

Keywords: Cluster Analysis, Black Hole Algorithm, Hybrid Metaheuristics

1. Introduction

Data clustering is a fundamental tool in the data analysis and pattern recognition literature. For instance, its applicability spans from studies on the formation of galaxies [1] to grouping of neuropsychological types of psychiatric patients with bipolar disorder, to assess subjective cognitive difficulties and psychosocial functioning [2]. Clustering is an unsupervised machine learning procedure that seeks to group data in such a way that the dissimilarity between clusters is maximized. Therefore, cluster analysis can be modelled as an optimization problem.

The high computational complexity of clustering problems, which are shown to be NP-hard [3,4], makes approaches that explore all states of the problem to seek for the optimal solution extremely time consuming and therefore unfit. Thus, many heuristic procedures are proposed. These procedures are often classified as hierarchical or partitional [5]. The former works by creating a hierarchy of clusters on the data and iteratively merging similar clusters. The latter, on the other hand, separates data directly into dissimilar and non-empty clusters. Heuristic approaches are especially important for large scale instances and provide good solutions at reasonable running times.

One of the most popular heuristic algorithms for cluster analysis is k-means [6], which works by grouping data points into a given number of clusters such that the sum of squared distances between each point and its nearest centroid is minimal. However, its performance greatly depends on the initial solution provided to the algorithm and convergence at local optima is often verified. To avoid these shortcomings several metaheuristic algorithms are used instead.

Metaheuristic algorithms can be roughly divided into two subgroups: single-based and population-based metaheuristics [7]. Single-based metaheuristics start with a single solution and progress iteratively toward better solutions until no further improvement can be found. Simulated annealing is a very typical example of single-based metaheuristics [8]. It operates based on the annealing process of solid materials and accepts worse solutions with certain probabilities to explore the solution space more thoroughly. On the other hand, population-based algorithms make use of several random initial solutions and optimization is performed on the entire population. A very typical example for the latter category is Genetic Algorithms (GA), which operates based on Darwinian theory of evolution and evolve an entire population until the best solution is found, i.e. the fittest individual among all [9].

Population-based metaheuristics have gained considerable attention over the last decades in cluster analysis problems and have been shown to be very competitive [5, 10, 11]. One of such kind, less explored, is the Black Hole Algorithm (BHA), which is a physics-based metaheuristic and operates according to the functioning of black holes and surrounding stars in the universe [12]. The algorithm works by generating a random population of solutions (stars) at the start, from which the best candidate is selected to be the black hole. The population is evolved by gravitating stars toward the black hole and new ones are generated each time a candidate crosses the event horizon.

In the process, if a candidate happens to be a better solution, then the black hole is replaced by this new solution.

The BHA has been applied successfully in many other optimization problems [13, 15, 16]. Since its inception, however, very few papers have replicated BHA and explored potential hybridizations of the algorithm for cluster analysis, despite its simple structure and effectiveness, which renders the algorithm very attractive from an implementation point of view.

The implementation of hybrid metaheuristics to solve optimization problems is common and successful in many applications. For example, Mageshkumar et al. [17] merges two metaheuristic algorithms, namely Ant Colony Optimization and Ant Lion Optimization, along with Cauchy's mutation operators to increase efficiency in clustering problems. Hybridizations involving population-based as well as single-based metaheuristics are abundant and provide interesting insights to further research on more efficient ways to solve optimization problems.

In this paper, we extend the BHA with random local searches at strategic places of the algorithm, hereafter referred to as BHA-LS. The new hybrid algorithm is tested on several well-known benchmark datasets. Results are compared to the original black hole algorithm [12] to test the feasibility of the algorithm presented in this work. BHA-LS is shown to be competitive in terms of stability, accuracy and running time.

The remainder of this paper is organized as follows. Section 2 describes the clustering problem and a mathematical formulation is presented. Then, in Section 3 the original BHA is discussed and the proposed algorithm is developed in detail. Section 4 describes computational experiments and results. Section 5 concludes with a discussion on future work directions.

2. Problem description

Cluster analysis aims at grouping a set of objects into disjoint clusters such that the similarity of objects within each cluster is maximum. Usually, to evaluate similarity between objects a Euclidean distance metric is used. One might therefore state the problem as follows: given a set of N objects, assign each object to one of M clusters, such that the sum of squared distance between each pair of nodes, is minimized.

Nascimento et al. [18] provides a linearized mathematical formulation to the problem based on a non-linear representation firstly proposed by Rao [19]. The formulation reads as follows:

$$minimize\ F(Y)$$

$$= \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} d_{ij} y_{ij} \qquad (1.0)$$

subject to

$$\sum_{k=1}^{M} x_{ik} = 1, \quad i \; in \; \{1, \dots, N\} \tag{1.1}$$

$$\sum_{i=1}^{N} x_{ik} \geq 1, \quad k \; in \; \{1, \dots, M\} \tag{1.2}$$

$$x_{ik} \in \{0,1\} \quad i \; in \; \{1, \dots, N\}, \; k \; in \; \{1, \dots, M\} \tag{1.3}$$

$$y_{ij} \geq x_{ik} + x_{jk} - 1, \quad i \; in \; \{1, \dots, N\}, j \; in \; \{i + 1, \dots, N\}, k \; in \; \{1, \dots, M\} \tag{1.4}$$

$$y_{ij} \geq 0, \quad i, j \; in \; \{1, \dots, N\} \tag{1.5}$$

The objective function aims at minimizing the distance d_{ij} among all objects that belong to the same cluster. Constraints (1.1) ensure that an object is placed only in one cluster. Constraints (1.2) guarantee that a cluster has at least one object, i.e. is non-empty. Constraints (1.3) state that x_{ik} is strictly binary. Constraints (1.4) and (1.5) ensure that y_{ij} is 1 if, and only if, x_{ik} and x_{jk} are 1, and 0 otherwise. The algorithm developed in this paper is adapted to solve this formulation.

3. Basic concepts and proposed algorithm

The Black Hole Algorithm is a population-based metaheuristic based on the black hole phenomenon [12]. As such, a random population of solutions, called stars, are placed in the search space at initialization. At each iteration, the fitness value of each solution is computed, and the best candidate is selected to be the black hole. Stars gravitate toward the black hole using the following formula:

$$x_i(t+1) = x_i(t) + r * (x_{BH} - x_i), \quad i = 1, \dots, P \tag{2.0}$$

where $x_i(t)$ and $x_i(t+1)$ are the location of stars at iteration t and $t+1$, respectively. x_{BH} is the current location of the black hole and r is a random number in the interval $[0,1]$. P represents the population size.

As the stars gravitate toward the black hole, some of them might achieve a fitness value better than the black hole, and thus the black hole is replaced by the new

star. Also, if a star enters the range of the black hole, i.e. its event horizon, the star is swallowed, and a new random star is generated. This guarantees that the population remains constant with respect to the number of potential candidates. The radius of the event horizon is calculated as follows:

$$R = \frac{f_{BH}}{\sum_{i=1}^{P} f_i} \tag{2.1}$$

where f_{BH} is the fitness value of the black hole, f_i is the fitness value of the i-th star and R the radius of the black hole event horizon. When the distance of a star and the black hole is less than R that star is collapsed and a new one is randomly generated. As described in Soto et al. [14], the death of a star is computed by generating a random number in the interval $[0,1]$, which if it is less than R, computed for each star individually, then a new star is randomly placed in the population.

Here we introduce the concept of relative positions so that the stochastic nature of the previous computation is erased. This allows one to control for solutions that are too close to that one provided by the black hole but with greater costs. The radius of the event horizon is computed as in (2.1) and the relative position (RP) of the i-th star in the universe is calculated as follows:

$$RP_i = \frac{f_i}{\sum_{j=1, j\neq i}^{P} f_j} \tag{3.0}$$

Then, the relative distance between the i-th star and the black hole reads:

$$d_{i,bh} = \frac{RP_i - R}{R} \tag{3.1}$$

If $d_{i,bh}$ is less than a parameter Δ, called the point of no return, then the star dies and a new one is randomly generated. Notice that the diversification of the system can be partially controlled by setting different values of Δ.

When a star is collapsed in upon itself and the formation of a stellar black hole sets off, the material of the dead star is progressively shrunk into a very dense object. Following this principle, when a candidate solution is selected as a new black hole, we introduce a very quick local search, referred to as *Densification*, which is supposed to increase the density of the star, i.e. decrease its cost. The proposed algorithm is as follows:

Algorithm 1 Densification

Input: candidate black hole solution
1: RC = select a random cluster
2: **for** i = 1 to N **do**
3: **if** i is assigned to RC **then**

```
    for j = 1 to M do
        switch object from RC to j
        compute fitness
        if fitness > candidate solution fitness then
            update configuration of candidate solution
            RC = j
        end if
    end for
  end if
end for
```
Output: optimized black hole solution

A stop criterion for the original BHA may be achieved by setting a maximum number of iterations independently of the state of the system, or a maximum number of iterations without improvement. In this paper the latter is chosen to insert a second type of local search into the algorithm.

Physicists teach us that black holes do not last forever since they emit sub-atomic particles. This process is known as Hawking's radiation and is named after the physicist Stephen Hawking. Therefore, if no source of mass is provided to black holes, they would eventually run out of rotation energy and mass, disappearing from existence. As a parallel, in our algorithm, after a certain number of iterations without improvement, i.e. the black hole gets isolated from the system, we introduce a second type of local search aimed at optimizing the black hole solution and make the system active again. This last local search is referred to as *Radiation* and the pseudo-code reads as follows:

Algorithm 2 Radiation

Input: candidate black hole solution
```
for i = 1 to ΩN do (Ω is a real number less than one)
  RN = select a random node in [1, N]
  for j = 1 to M do
    if RN is assigned to j then
      for k = 1 to M\j do
        assign RN to k
        compute fitness
        if fitness > candidate solution fitness then
          update configuration of candidate solution
        end if
      end for
```

```
    end if
  end for
end for
```
Output: optimized black hole solution

The BHA-LS algorithm consists of generating a random population of stars at initialization, set the number of iterations without improvement for operation, gravitate stars toward the black hole and generate new stars according to relative distances, as introduced before. Each time a new black hole is found the *Densification* algorithm is called. By the same token, each time the black hole gets stuck at a sub-optimal state for a certain number of iterations, the *Radiation* algorithm is called. A pseudo-code for the general algorithm is presented below.

Algorithm 3 BHA-LS

Input: random population of stars and dataset
1: δ = initialize number of iterations without improvement
2: counter = 0
3: find black hole among stars
4: **while** counter < δ **do**
5: gravitate stars toward black hole according to (2.0)
6: compute fitness of stars
7: **if** new black is found **then**
8: call *Densification*
9: update configuration of the black hole
10: **else**
11: compute relative position of stars according to (3.0)
12: **for** i to P **do**
13: compute relative distance of star i according to (3.1)
14: **if** $RP_i < \Delta$ **then**
15: generate random star in the place of i
16: **end if**
17: **end for**
18: repeat 11-17 until there are no dead stars
19: **end if**
20: **if** a multiple β of δ has been achieved **then**
21: call *Radiation*
22: **end if**
23: **end while**
Output: final solution

4. Computational experiments and results

4.1 Pre-testing and parameters setting

Pre-testing was executed over 10 small datasets, generated by placing random centroids inside a square and distributing points around each centroid according to a normal distribution. *Instances A* comprise 20 nodes and 2 centroids and *Instances B* comprise 50 nodes and 4 centroids.

The BHA-LS algorithm is made up of four parameters, namely Δ, δ, β and Ω. The point of no return, Δ, was set to 0.25. The number of iterations without improvement, δ, was set to 100. The number of iterations to trigger *Radiation*, β, was set to every 25 iterations without improvement. Lastly, Ω was set to one quarter. During pre-testing it was verified that higher values for Ω did not contribute significantly to quality of solutions and only increased CPU running times. Table 1 displays the optimal values for pre-testing datasets, according to 1.0, the average gap in percentages, the number of optimal solutions found by the algorithm and the average CPU running times in seconds.

Table 1. Results on pre-testing datasets for 100 runs of BHA-LS on each instance.

Dataset		Optimal	Average Gap (%)	Number of optima found	Average CPU Time (s)
Instances A	A.1	8348.6836	3.32	71	0.0013
	A.2	8009.9048	3.44	73	0.0014
	A.3	8201.6025	7.65	79	0.0020
	A.4	6891.7427	12.80	75	0.0016
	A.5	8410.6553	6.81	78	0.0015
Instances B	B.1	32359.9023	3.43	34	0.1675
	B.2	30562.3027	6.57	33	0.1689
	B.3	27175.5898	4.24	43	0.1688
	B.4	27483.0547	3.31	25	0.1639
	B.5	29114.4160	8.27	57	0.1525

4.2 Benchmark datasets

Experiments were run over two groups of benchmark datasets. The first group comprises the multidimensional datasets *Iris*, *Wine* and *Wisconsin Breast Cancer* (*Cancer*), which are public available in the machine learning repository http://www.ics.uci.edu/-mlearn/MLRepository.html. The second group comprises the geometric datasets *Flame*, *R15* and *Aggregation* which are public available in

http://cs.joensuu.fi/sipu/datasets/. Table 2 displays the number of clusters, number of features, number of objects and number of objects per cluster for each of the datasets.

Table 2. Characteristics of the test datasets.

Dataset	Number of clusters	Number of features	Number of objects	Objects per cluster
Iris	3	4	150	(50,50,50)
Wine	3	13	178	(59,71,48)
Cancer	2	9	683	(444,239)
Flame	2	2	240	(87,154)
R15	15	2	600	(40,40, …, 40)
Aggregation	7	2	788	(46,171,103,274,35,131,35)

The performance of the algorithm is evaluated using two metrics widely used in the cluster analysis literature. The first metric is the Error Rate, which measures the external quality of clustering by computing the number of misplaced objects. The second is the Sum of intra-cluster distances and can be seen as an internal quality measure.

The Error Rate is calculated as follows:

$$ER = \frac{number\ of\ misplaced\ objects}{total\ number\ of\ objects} \times 100 \quad (4.0)$$

The Sum of intra-cluster distances reads as:

$$Z = \sum_{i=1}^{M}\sum_{j=1}^{G}\sqrt{\sum_{k=1}^{K}(O_j^k - z_i^k)^2} \quad (4.1)$$

where Z corresponds to the Sum of intra-cluster distances, G is the number of objects assigned to centroid i, O_j^k is the kth coordinate of the jth object, and finally z_i^k is kth coordinate of the ith centroid.

The proposed clustering algorithm BHA-LS was implemented in Java language and run on a computer with an Intel Core i5-7200U CPU @2.50 GHz and 8 GB memory. Results are calculated based on 100 runs of the algorithm and are compared to those in recent literature.

Results on the first group of datasets, and average error rates achieved by the original Black Hole Algorithm [12], are displayed in Table 3. BHA-LS achieved smaller error rates for *Iris* and *Cancer* as compared to the original black hole algorithm [12], which achieved 10.02% and 3.70% for each of the datasets, respectively. Furthermore, still with respect to Error Rate, BHA-LS performed better than the recent work by Abdulwahab et al. [20], in which the authors present a hybrid metaheuristic

with the Black Hole and Levy Flight algorithms and achieved 9.40% and 3.65% error rates, for *Iris* and *Cancer*, respectively. As far as the *Wine* dataset is concerned, the average Error Rate remained roughly one standard deviation above the average Error Rate in [12] and [20]. It is important noting that in both works, the BHA and its variant performed better than well-known population and single-based metaheuristics. On the other hand, the Sum of intra-cluster differences remained slightly above those calculated by [12] and [20].

Table 3. Results on the first group of datasets for 100 runs of BHA-LS.

Dataset	Criteria	Error Rate (%)	Sum of intra-cluster distances	CPU Time (s)	Original BH Error Rate (%)
Iris	Best	6.67	97.51	0.42	-
	Average	9.11	98.19	0.64	10.02
	Worst	12.67	103.73	1.23	-
	Std	0.88	1.39	0.13	-
Wine	Best	28.08	16530.54	0.66	-
	Average	29.33	16667.21	0.98	28.47
	Worst	32.02	17592.37	1.55	-
	Std	0.57	256.3733	0.16	-
Cancer	Best	2.93	2995.55	16.51	-
	Average	3.17	3005.83	22.17	3.70
	Worst	3.95	3061.10	31.88	-
	Std	0.16	11.88	3.19	-

Results on the second groups of datasets are displayed in Table 4. To our knowledge, this is the first time a variant of the black hole algorithm is applied to solve these geometric datasets. The Error Rate averages for *Flame*, *R15* and *Aggregation* are 15.29, 0.45 and 14.46, respectively. The shape complexity of these datasets makes them harder to classify and therefore the performance of BHA-LS has been more limiting as compared to state-of-the-art algorithms [21, 22]. Fig. 1 displays the average solutions obtained to each of the geometric datasets and their corresponding optimal configurations.

Table 4. Results on the second group of datasets for 100 runs of BHA-LS.

Dataset	Criteria	Error rate (%)	Sum of intra-cluster distances	CPU Time (s)
Flame	Best	14.17	772.50	1.02
	Average	15.29	785.84	1.66
	Worst	16.67	796.57	2.68
	Std	0.63	4.40	0.34
R15	Best	0.17	7499.68	47.25
	Average	0.45	7545.55	60.96
	Worst	1.17	7593.11	98.47
	Std	0.19	17.01	7.17
Aggregation	Best	13.58	16943.73	57.30
	Average	14.46	18241.56	87.99
	Worst	15.86	19561.73	134.62
	Std	0.62	394.31	17.68

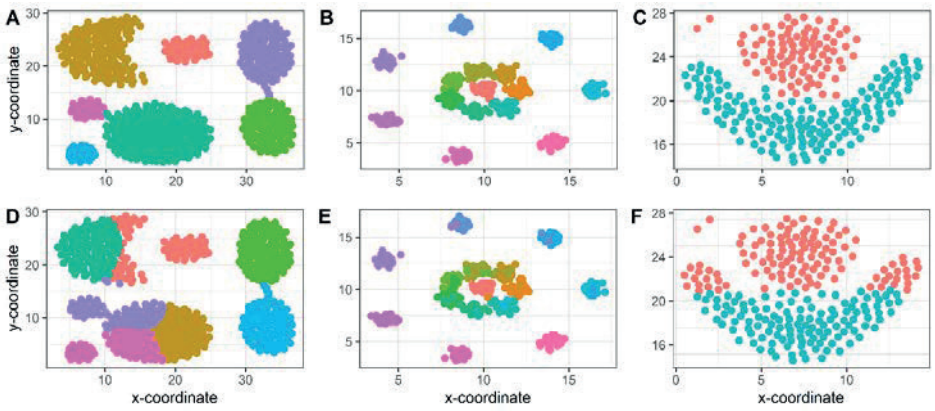

Fig. 1. Plots on the upper half of the figure (A, B and C) are the optimal configurations of datasets *Aggregation*, *R15* and *Flame*, respectively. Plots on the lower half of the figure (D, E and F) represent the average solution obtained by the BHA-LS algorithm for datasets *Aggregation*, *R15* and *Flame*, respectively. Each color inside each plot represents a cluster.

5. Conclusions

This work studied a new hybrid metaheuristic based on the black hole algorithm for clustering problems. The accuracy of the algorithm was tested on well-known benchmark datasets and provided competitive results. The simple structure of BHA-

LS along with its accuracy makes the algorithm an alternative candidate to classical procedures commonly used for cluster analysis. The local searches introduced in the present work are structurally simple, and better approaches can be incorporated into the BHA-LS framework to improve its quality and efficiency. Particularly, the insertion of 2-opt solutions is encouraged in future research, which may boost optimization and improve the structure of solutions. Lastly, the comparison of the framework presented in this paper with state-of-the-art algorithms, such as spectral clustering techniques [23].

Abstract. Accurate management of information in the links of the supply chain makes it possible to achieve the general objectives of the companies. From this perspective, the determination of demand becomes essential, since each link plans its activities based on market requirements. In the automotive industry, there is a great variety of factors that generate variability in its demand, especially for the spare parts, therefore, determining each product demand becomes complex, due to the fact that auto parts demand is not stable. The using up of methodologies and techniques to analyze the demand is an essential work in the supply chain. Therefore, this work presents a review about papers developed to forecast the demand for automotive spare parts in the supply chain. Also, the document presents alternatives to the decision-makers about the methodologies that can be applied depending on the individual characteristics and objectives of their companies. The classification of the reviewed documents is according to the link in the supply chain and their forecasting method used to solve the problem described in the link, which makes it easier to find the documents according to the interest of readers. Online databases as Elsevier, ScienceDirect, Springer, and Mendeley were consulted. Also, the paper highlights key areas for the future research field.

Keywords: Spare parts, Forecasting demand, Supply chain.

1 Introduction

The supply chain management (SCM) in the auto parts industry is characterized by being complex, due to hundreds or thousands of products with intermittent and variable demand. The demand for these products depends on their positioning in the market and to determine it is very difficult because of the diversity of products. Some factors that determine the high complexity to forecast demand of the automotive spare parts are:

i. The supply of the products, which depends on the origin and type of suppliers, lead time and delivery time, delivery amount, and purchase volumes of products;

ii. The inventory of each product according to the storage and customer service objectives of the company;
iii. The distribution of products based on company policies;
iv. The manufacture of the products, which depends on whether the products are sold directly to the customer or must be assembled within the company;
v. The production capacity;
vi. The life cycle of auto parts and the introduction of new products in the automotive market.

Then, as a conclusion, it is essential to determine the behavior of the demand, aims to obtain accurate forecasts to the needs of the market. Ravindran and Warsing Jr. (2016) consider that the success of a manufacturing supply chain depends on its ability to accurately predict customer demand and produce in time to meet their requirements. Prediction is the starting point for most decisions in supply chain management. An important characteristic of the demand is related to the fact that, whether the demand is externally driven by factors that are outside the direct control of the company, or if it is driven by internal management decisions (Ravindran, 2008).

Therefore, this document is a tool for decision-makers in the supply chain, which help to identify the research works and case studies published from 2010 to 2021, that have similar problems to their situations, which make easier to find alternative solutions in less time and with less effort, as a part of the objective in this document. The documents were classified in books, book chapters, review articles, research articles, web site, magazines, journals, and conference papers published in on-line databases as ScienceDirect, Elsevier, Springer, and Mendeley. The papers were identified under different combinations of keywords such as spare parts, automotive aftermarket, forecasting demand, method and methodologies, supply chain, and its links. From the general query results (2,572 articles), there were selected 291 review articles and research articles by ScienceDirect database, which give more specific information about the published year, journal magazine and access type, in order to give more information to the readers and find key areas for future research.

The paper is organized as follows: Section 2 provides a general literature review about the supply chain in the spare parts industry including automotive. Section 3 presents the selected articles classified according to their subject in the supply chain such as supply, inventory, distribution, transportation, manufacture, production planning and provide some documents, which describe the problems solved on each link and keywords to facilitate the search. Section 4 addressed the literature about forecasting demand in the supply chain in general and for the automotive industry and shows the documents organized according to forecast methods used to determine the demand. Section 5 contains the conclusions and highlight the key areas for future research.

2 The supply chain in the automotive spare parts

According to Lokad (2019) the automotive aftermarket industry expects to achieve in 2020 a global value of over USD $700 billion by selling approximately 80 million of automobiles, because today the customers realize the importance of the preventative maintenance and regular services of their cars to increase their lifetime. The automotive spare part is a big industry in the world and all of the links in this supply chain work together to achieve the objectives of the companies.

Sabri and Beamon (2000) define a supply chain as "a set of facilities, supplies, customers, products and methods of controlling inventory, purchasing, and distribution", where each element plays an important role from the raw material to the finished product (from supplies to customer). Mentzer et al. (2001) said the supply chain makes it possible that the customer gets auto spare parts according to their expectations; considering that the supply chain has organized its links to obtain the results planned. According to Mehdizadeh (2020), it is important to consider two kinds of spare parts: i. spare parts for automotive production and, ii. spare parts for maintenance service of the cars, which is well known as the aftermarket industry; both of them have a similar supply chain, however the behavior of their demands are different.

The first one depends on the production of the new car models and the second one depends on the cycle of life of the spare parts and the maintenance of the cards in the market. Matsumoto and Ikeda (2015) named the last one as remanufactured products or the aftermarket. This work considers the documents found on the database for both types of spare parts, which is based on selected information from on-line databases as Elsevier, ScienceDirect, Springer, and Mendeley. They classified their documents in different types of publications: web site, magazine, chapter, conference paper, books, reviews articles, article, and research articles. The keywords used, to select the articles from the databases, were "forecasting demand for spare parts", which got the maximum result 3,853 documents (books, reviews articles, and research articles) from 1997 to 2021.

The period was reduced from 2010 to 2021 in order to get the most recent documents, obtaining 191 review articles and 1358 research articles. Figure 1 shows the distribution of the articles published.

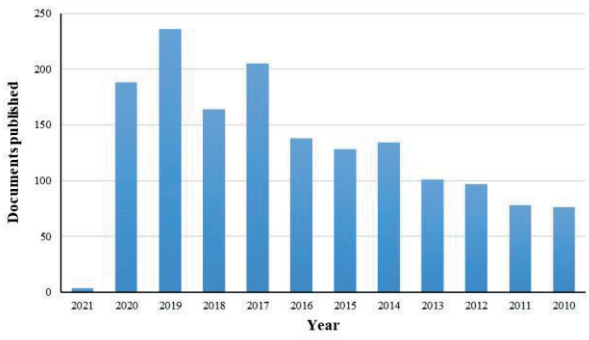

Figure1. Distribution of articles published. Source: ScienceDirect Database (2020)

The documents were accepted for its publication in the International Journal of Production Economics, Journal of Cleaner Production, Renewable and Sustainable Energy Reviews, Procedia CIRP, Energy Policy, European Journal of Operational Research, IFAC-PapersOnLine, Technological Forecasting and Social, and Computers & Industrial Engineering Energy.

3 Forecasting demand for automotive spare parts and supply chain links

As it was mentioned previously, papers were identified under different combinations of keywords such as spare parts, automotive aftermarket, forecasting demand, method and methodologies, and supply chain and its links. From the general query results (2,572 articles), there were selected 191 review articles and research articles by ScienceDirect database, which give more specific information about the published year, journal magazine and access type.

Table 1 shows the results got from the combination of the keywords considering the period from 2010 to 2020.

Table 1. Results of search on ScienceDirect database

KeyWord	Review article	Research article
Spare parts forecasting demand	191	1,358
Forecasting demand for automotive spare parts	310	277
Forecasting demand for automotive aftermarket	7	59
Methodology forecasting demand for automotive spare part	34	187
Method forecasting demand for automotive spare part	42	249
***Method forecasting demand for automotive spare part and Supply Chain**	**33**	**182**
Logistic	18	79
Inventory	27	151

Source: ScienceDirect database (2020). * The keywords were combined as: “Method forecasting demand for automotive spare part” and the link in supply chain.

Behnam (2018) said that product forecasts are a critical input into the supply chain, finance, and marketing decisions, also he wrote a literature review about judgmental demand forecasting with an approach focused in the integrating of forecasting methods. He considers the role of expert opinion and contextual information and show the application of behaviorally informed support systems. The literature is focused on the industrial practice. Stip et al. (2019) comment that it is normal that customers have services contracts, including agreements on spare parts supply for their companies.

Zhu et al. (2019) considers that spare parts demand forecasting is essential to spare parts inventory control, however, it is very difficult to determine the demand because of its feature of irregularity during the time; they propose a forecasting procedure to estimate the spare part demand behavior based on a maintenance plan, this forecast let to develop a dynamic inventory control method. Also, Rodrigues et al. (2020) consider that the quality of future demand forecasting determines the performance of any inventory control model. If the forecast demand is accurate then, the safety inventory level is low and the fill rate increases. They show an approach for a spare parts inventory control model for non-repairable items with periodic review, where the demand behavior varies over time. V. Lukinskiy et al. (2020) considers that “Inventory management is one of the most important logistics functions”, where is important to determine the optimal stock (current, safety) levels and optimal order quantity of all products in the company and determine the adequate inventory management strategies; Also, in their work, they show a characterization of papers on demand forecasting and inventory management, where they describe the methodology used to solve the problem, the aim of the document, and a general description of the document.

Mehdizadeh. (2020) and Rego et al. (2015) consider that a good part of the research is focused on to determine forecasting consumers’ demands; also Mehdizadeh (2020) said that "better forecasting of consumers’ demands helps the retailers place more accurate orders to the distributor". However, the retails consider in their warehouses the products with fast-moving and some middle-moving products trying to decrease the backorders and reduce the lost sales cost, they look for decreasing the ordering cost such as freight and insurance and inventory hold cost (Goodarzi et al., 2017). Therefore, the distribution and inventory of products depend on accurate forecasting demand in both links.

Ottosson et al. (2019) predict future demand with causal-based fore-casting methods using condition monitoring data, considering fault codes, as explanatory variable. Furthermore, an evaluation is made on what effects its implementation would result in a transport company. Similarly, Stip et al. (2019) studied the service Bill of Material (BOMs) in a large Original Equipment Manufacturer in the semiconductor industry. They developed a method to generate alerts for possible fails or errors during the operations, which generates a multiple sources of machine information for determining the demand of the spare parts.

Ansersson et al. (2018) in their work "explore and propose how product-in-use data can be used in, and improve the performance of, the demand planning process for automotive aftermarket services". They recognize the relevant product-in-use data and

divides them into categories considering different life cycle phases and demand frequencies. Also, they find relevant areas of application of product-in-use data in the demand planning process, and on their performance effects.

Table 2 shows an article classification according to the Supply Chain approach. The classification contains the articles from the original search which were published from 2017 to 2020 and their relevance in the link of the Supply Chain because some of them cover more than a link. Also, the classification has a general description of the paper and the keywords which the author considers important on the paper. The keywords are added to facilitate the new search by the readers.

Table 2. Article classification according to the Supply Chain approach

Approach	Author	Description	Keywords
Supply Chain	Zhu et al. (2020)	Simple forecasting mechanism to estimate the spare part demand distribution based on the maintenance plan, and develop a dynamic inventory control spare part demand forecasts.	Spare parts inventory control, Spare parts forecasting, Maintenance planning.
	Sharma et al. (2017)	The methodology helps to optimize the maintenance activities and forecasting the requirement of spare parts both before and during the mission.	Mission reliability, Simulation, Genetic algorithm, Army Failure simulation, Spare parts forecasting.
	Rosienkiewicz M. et al. (2017)	The hybrid spares demand forecasting method dedicated to mining companies.	Spare parts, Demand forecasting, Artificial Neural Networks (ANN), Information Criterion, Bayesian Information, Mining industry.
	Ali et al. (2017)	Strategy for evaluating a simple Downstream Demand Inference (DDI) strategy based on Simple Moving Average (SMA) for supply chains where information cannot be shared.	Supply chain management, Information sharing, Simple moving average ARIMA, Downstream demand inference.
	Mobarakeh et al. (2017)	The document presents forecasting methods, their variants, and artificial intelligence (AI) methods developed for irregular demands, which the propose is to determine the best method variant that is capable of accurately forecasting not only uncertain but unpredictable demand in a business aircraft.	Spare parts supply chains, Demand forecasting, Boot Strapping, Business Aircraft's industry.
Logistics	Dombi et al. (2018)	A methodology for modeling and forecasting spare part demand for electronic commodities in the spare parts logistics services.	Spare part logistics; electronic aftermarket, services; purchase life-cycle forecasting; knowledge discovery; clustering time series.
	Boutselis et al. (2018)	Application of Bayesian network models for forecasting the demand for spare parts in the last phase for the logistics service system.	Bayesian networks, Failure rates, Spare parts forecasting, changing demand context.

	González et al. (2017)	A comparison among classic methods of moving averages, final value and exponential smoothing, the prestigious autoregressive integrated models of moving averages (ARIMA), the rarely implemented artificial neural networks (ANNs) and the very little explored ARIMA-ANNs hybrid models.	Demand Forecasting, Supply chain management, Forecasting hybrid models, ARIMA-ANN performance comparison, Automobile spare parts logistics.
Inventory	Stip et al. (2019)	A method to generate alerts for possible errors and determine the Bill of Material (BOM) per installed machine and determine the inventory of spare parts.	Configuration management, Spare parts, Inventory management, Forecasting, Data science.
	Zhu et al. (2020)	Develop a dynamic inventory control spare part demand forecasts.	Spare parts inventory control, Spare parts forecasting, Maintenance planning.
	Rezaei et al. (2018)	Inventory optimization based on a mathematical model to minimize the total investment subject to fill rate as an inventory service measure at both part and location level.	Business aircrafts' spare parts management, Uncertain and unpredictable demand, Lead-time demand distribution, Inventory optimization, Inventory parameters estimation, simulated annealing.
	Zhu et al. (2017)	The empirical method by applying extreme value theory to model the tail of the lead time demand distribution to improve the performance of the inventory.	Forecasting Inventory, Spare parts, Extreme value theory Semi-parametric.
	Teixeira et al. (2017)	The document presents a multi-criteria classification of a spare part for integration in a computerized maintenance management system of a manufacturing company, the methodology defines groups for which a stock management policy will be associated.	Inventory management. Maintenance management, Multi-criteria classification, Spare parts, Spare parts management.
	Sharma et al. (2017)	The methodology helps to optimize the maintenance activities and forecasting the requirement of spare parts both before and during the mission. Also, it determined the requirement by having a forecasting technique for reducing the supply lead times.	Mission reliability Simulation, Genetic algorithm, Army Failure simulation, Spare parts forecasting.
	Hu et al. (2017)	Literature review of OR in spare parts management according to a framework for OR in spare parts management, established based on the product lifecycle process.	Inventory, Spare parts management, Operational research (OR).
	Costantino et al. (2017)	A model for a single site the Zero-Inflated Poisson (ZIP-METRIC)is built for Spare parts management for irregular demand items.	Inventory management, Logistic, Intermittent demand, lumpy demand, Zero-Inflated Model.
	Bergman et al. (2017)	An approach was developed for demand forecasting using Bayes' rule to improve the forecast accuracy of parts from new equipment programs.	Intermittent demand, Bayesian forecasting, Engineering estimates.

Manufacture and production planning	Stevenson et al. (2005)	A review of production planning and control and spare parts.	Production planning and control; Make-to-order; Job shop; Small and medium sized enterprises; Workload control.
	Israel et al. (2017)	A Process of predicting equipment failures and Intelligent Maintenance System.	Supply Chain, Spare Parts, Intelligent Maintenance Systems, Integrated Planning, Discrete event simulation.
	Stip et al. (2019)	A method to generate alerts for possible errors and determine the Bill Of Material (BOM) per installed machine in the field.	Configuration management, Spare parts, Inventory management, Forecasting, Data science.
	Yufune et al. (2020)	A demand forecasting model regarding the replacement as probability event for maintenance planning.	Remanufacturing, Mining machine parts, Demand forecasting, Hydraulic pump, Simulation.
	Andersson et al. (2018)	To explore and propose how product-in-use data can be used in, and improve the performance of the demand planning process for automotive aftermarket services	Forecasting, Big data, Digitalization, Aftermarket, Demand planning, Product-in-use.
	Gu et al. (2017)	A double-level combination forecasting approach for repairable spare parts based on relevant data for airplanes.	Demand forecasting, Repairable airplane spare parts, Double-level combination forecast, Genetic neural network, Exponential smoothing, Grey model.
Transport	Otosson et al. (2018)	Predict future demand with causal-based forecasting methods using condition monitoring data, specifically fault codes, as explanatory variable in a transport company.	Forecasting, Spare part logistics, Condition monitoring data, Fault codes, correlation analysis, regression analysis.
Distribution	Alfieri et al. (2017)	Two allocation policies are proposed to use a dynamic critical level to reserve on-hand inventory for high priority customers.	Dynamic critical level, Multiple demand classes, Distribution–free policy.

The results in Table 2 show that the links manufacturing, production planning, and inventories have more articles developed about demand forecasts for spare parts. On the other hand, for Distribution and Transport articles there are only few of them. This results show the importance of the accurate forecast demand on those link, also the impact on the supply chain.

4 Forecasting demand for automotive spare parts

Knowing the demand in each link of the supply chain is a fundamental part of achieving success for the companies. For the spare parts management to forecast demand is an important operational issue, and it has been a big challenge. For Israel et al. (2019) spare parts demand is sporadic and erratic, which impairs its forecasting with available statistical tools and damaging service level and potentially increasing production costs in the industrial sector.

V. Lukinskiy et al. (2020) argue that authors are skeptical about the forecasting and accuracy of the demand, because, in some situations, it is possible to identify base demand for a product which is predictable but in other cases, the demand is unpredictable and uncertain. Also, Sillanpää et al. (2018) consider that probabilistic models based on distribution forecasts help to determine the demand when there is a lack of accuracy in the planned orders of the consumer.

Petropoulos et al. (2014) in their work studied fourteen popular forecasting methods and some combinations with them, seven time-series features (seasonality, trend, cycle, randomness, number of observations, inter-demand interval, and coefficient of variation) under one strategic decision: the forecasting horizon; take into a count intermittent demand data as namely average inter-demand interval, squared coefficient of variation of the non-zero demands and number of available observations. Petropoulos et al. (2015) explored empirically the efficiency of forecast combinations in the intermittent demand context by using a combination of time series. And, Petropoulos et al. (2016) built the heuristics which predict the demand and reduce the variance in the times series by transformed time series and the inverse intermittent demand series.

Babai et al. (2019) propose a new forecasting method that is a modification of the Syntetos and Boylan approximation. The forecasting of intermittent demand is studied under the classical forecasting studies methods, but the majority of these studies do not take into account underlying demand-generating factors (Van Steenbergen et al., 2020). In addition, the application of forecasting methods is limited because the available data; also, the factors influencing spare parts demand are different because of the phases of the lifecycle of the products; in this case, Van Steenbergen et al. (2019) presented an innovative demand forecasting method with name DemandForest, which is a mix of K-means, Random Forest, and Quantile Regression Forest, based on the historical sales data of previously introduced products and product characteristics of existing and new products; the objective of the method is predict the total demand and its patterns of a new product during the introduction period. According to Turrini et al. (2019), "spare parts forecasting is divided into parametric and non-parametric approaches", where non-parametric methods normally based on bootstrapping procedures which evaluate the percentiles of the distribution from the data, also they explain that parametric forecasting considers a certain distribution of the lead-time demand which it is estimated directly from the data through an estimation method.

Hasni et al. (2019) developed a literature review about parametric and the non-parametric approaches, where they describe the bootstrapping approach and discuses some of its statistical properties. Also, they consider that bootstrapping methods show a good empirical performance in comparison with their parametric counterparts, and they confirm the accuracy of bootstrapping methods for intermittent demand forecasting should be a priority for spare parts management. Yufune et al. (2020) proposed a demand forecast model considering a Weibull distribution as a probability event of the replacement of the spare parts, and they simulated the demand obtained in the mining machinery operation. Matsumoto et al. (2016) proposed a model mix Weibull distribution and Holt-Winters model to obtain the forecast demand of automotive electric components. Also, Matsumoto and Ikeda (2015) proposed a demand forecasting model by using time analysis specifically double exponential smoothing method. Babai et al. (2020) proposed a Bayesian method based on compound Poisson distributions, in which the performance of the non-parametric method improves for longer lead-times and higher demand variability when compared to the parametric one. Geda et al. (2018) developed a similar study based on Bayesian estimation to propose a forecasting model of product returns using DLM using negative binominal function and Markov Chain Monte Carlo. Gonzalez et al. (2017) made a comparison between traditional time series methods and ARIMA-ANNs (autoregressive integrated moving average - artificial neural networks) and they conclude that, in terms of implementation, the classic methods are the easiest and fastest to start to work. Also, and the classical methods provide good results when faced with fluid behavior in demand. However, the ANN (artificial neural network) methods promise good results and presented a good fit for the sample period but began to fail in the erratic post-sample periods, as it was found the literature.

Table 3 shows the articles obtained from the original search which were published from 2017 to 2020 and they were chosen according to their objective and relevance in the link of the Supply Chain too, organized in descending order. Also, Table 3 shows the method used to analyze the demand and the objective of the paper, to make it easier to choose the document by the reader.

Table 3. Documents of forecast demand spare part from 2017 to 2020.

Author	Method (s)	Objective
Yufune et al. (2020)	Time series analysis and simulation.	To build a demand forecasting model regarding the replacement as probability event.
Otosson et al. (2018)	Regression forecast.	To predict future demand with causal-based forecasting methods using condition monitoring data.
Dombi et al. (2018)	Clustering time series.	To build a methodology, which mainly advantageous in long-term forecasting, it is useful in supporting purchase planning decisions in the ramp-up and declining phases of purchase life-cycles of product-specific spare parts.
Boutselis et al. (2018)	Bayesian network models.	To determine the demand using Bayesian network models for spare parts.

Andersson et al. (2018)	Causal-based forecasting methods.	To explore and propose how product-in-use data can be used in, and improve the performance of the demand planning process for automotive aftermarket services.
Zhu et al. (2017)	Extreme value theory.	To determine the lead time demand periods computed over overlapping intervals.
Zhijie et al. (2017)	Mathematical model.	To establishes a general model for predicting the consumption of equipment spare parts based on unit life.
Sharma et al. (2017)	Simulation and Genetic algorithms.	To use simulation for predicting failures in the army equipment.
Rosienkiewicz M. et al. (2017)	Regression modeling and ANN.	To propose a hybrid spares demand forecasting method dedicated to mining companies.
Ali et al. (2017)	Single Exponential Smoothing and Simple Moving Average (SMA) method.	Developing a strategy for evaluating a simple Downstream Demand Inference (DDI) strategy based on Simple Moving Average (SMA) for supply chains where information cannot be shared.
Mobarakeh et al. (2017)	Artificial intelligence (AI) method and Boot strapping method.	To investigate forecasting methods, their variants and artificial intelligence (AI) methods, developed for irregular demands.
Gu et al. (2017)	Genetic neural network model.	To build a double-level combination forecasting approach for repairable spare parts.
González et al. (2017)	ARIMA-ANN models.	To compare methods for determining the automobile spare parts demand.
Bergman et al. (2017)	Bayesian forecasting.	An approach was developed for demand forecasting using Bayes' rule to improve the forecast accuracy of parts from new equipment programs.

Based on the results in Table 3, the papers developed about the forecast of automotive spare parts are few, this shows an opportunity area for the research and expert in this knowledge field. Also, this is evidence that papers developed in this field involve the combination of various knowledge areas such as mathematics, statistics, management, engineering, and supply chain, just to mention some.

5 Conclusions and future research

Determining the behavior of demand in any productive sector is a fundamental job. The selection of a suitable forecasting method determines the achievement of the decision-makers' objectives. Therefore, the forecasting method selected should be as precise as possible and letting decision-makers eliminate uncertainty at any point in the supply chain. The selection of the forecasting method is a complex task, for this reason, this document shows some of the documents that have been developed until now, in order

to forecast the demand in some link of the supply chain, as well as show some methodologies developed that can be applied in any sector, providing greater tools for decision-makers in organizations.

The documents considered in the results section belong to publications made from 2017 to 2020, taking into account their relevance in some link in the supply chain and their year of publication. The database consulted for this purpose was ScienceDirect, since it was the one that provided the most detailed search for the selection of articles.

As shown in the results of Table 2, the links in the supply chain with the highest number of publications made on the topic of demand forecasts for spare parts are manufacturing, production planning, and inventories, because these links support a large part of the productivity of companies, without detracting from the work carried out in the other links of the supply chain.

From the above, we can propose new lines of research in the remaining links, guiding organizations to seek greater integration of the links in the supply chain, since the forecast of demand for each link has an integral impact on the chain. In addition, the results show that the documents developed in this area of knowledge, specifically for the automotive sector, are not very extensive, so it represents important opportunity areas for researchers and experts, considering the economic activity that this sector represents in the real world.

Atributos em modelos de maturidade para cadeias de suprimento inteligentes

Gabriella Moreira[1], Lucas Tozi de Toledo Coelho[1], Vinicius Pires Comin[1], Silvana Detro[1], Eduardo Alves Portela Santos[1]

[1] Universidade Federal do Paraná, Curitiba, Brasil

Resumo. Os modelos de maturidade auxiliam as empresas a avaliarem e classificarem o desempenho de determinada área ou processo organizacional. Dentro de cada modelo de maturidade os atributos também devem ser avaliados para direcionar a avaliação feita. Uma grande área oportuna para a aplicação é dentro da logística, nas chamadas cadeias de suprimentos. Contudo, as mudanças pelas quais as empresas estão passando internamente com o advento da Indústria 4.0 incentivam um novo estudo a partir dos modelos já existentes para atualizá-los, de acordo com as novas demandas dos mercados, que indireta e/ou diretamente afetam o desempenho dos processos de uma organização. Os modelos de maturidade também conseguem ajudar a empresa no planejamento e organização, uma vez que mapeiam seus processos atuais e fornecem uma direção para que seu objetivo seja alcançado: a melhoria contínua. Tendo isso em mente, inicialmente nesta pesquisa foi feita uma revisão bibliográfica em algumas bases de dados para que pudesse ser estudado modelos de maturidade - relacionados a *Supply Chain* e Indústria 4.0 - publicados, bem como seus eventuais *gaps*. Assim, após uma grande análise e discussão dos resultados obtidos após a revisão, ao final desta pesquisa foi desenvolvido um novo modelo de maturidade que relaciona questões e processos importantes das empresas atuais. O modelo elaborado é apresentado brevemente neste documento e ainda será testado em uma indústria do setor automotivo.

Keywords: Modelo de Maturidade, Indústria 4.0, Cadeia de Suprimentos.

1 Introdução

A Cadeia de Suprimentos (*Supply Chain*, em inglês) já era muito conhecida no século XX. Em 1991, o termo foi definido por [1] como aquele responsável por integrar "cada elemento do processo de produção e suprimento, desde as matérias primas até o cliente final". Segundo [2], a cadeia de suprimentos de uma determinada empresa pode ser definida como uma série de atividades interligadas que abrangem a coordenação, o planejamento e o controle de produtos e serviços entre fornecedores e clientes**.**

A integração da *Supply Chain* no desempenho organizacional tem papel importante e é relacionada tanto à integração interna quanto à integração de fornecedores e de

clientes [3]. A mesma ideia foi defendida por [4], ao afirmar que as atividades do processo devem ser integradas internamente e posteriormente com negócios parceiros.

De acordo com [5], a colaboração entre seus membros gera um menor custo total e melhor desempenho do serviço. Além disso, para [6], as demandas do mercado por menores custos, flexibilidade, capacidade de resposta e maior qualidade devem ser atendidas pela cadeia de suprimentos.

Para que saibam lidar com o aumento dos desafios de gerenciamento, as empresas devem tornar-se mais inteligentes [7]. Ferramentas que conseguem auxiliar as previsões dentro da *Supply Chain* mesmo com os riscos inerentes, como incertezas de demanda e informações disruptivas, são extremamente importantes para a logística pois conseguem torná-las mais flexíveis e inteligentes nas operações feitas [8]. Uma das formas de se tornarem mais espertas, com maior habilidade de gerenciamento, consiste na adoção das novas tecnologias digitais provindas da Indústria 4.0.

Dentro do gerenciamento da cadeia de suprimentos (*Supply Chain Management*, em inglês, ou SCM, abreviado) é possível fazer a adoção de algumas técnicas que auxiliam no gerenciamento como *Big Data Analytics*, RFID e manufatura aditiva [9]. As empresas capazes de adquirirem essas habilidades, criadas pelo uso das tecnologias digitais, terão vantagens em relação aos seus competidores e concorrentes que não aproveitarem [10]. Como as disrupções de mensagens e tecnologias digitais influenciam no SCM, os pesquisadores estão voltando os olhos para os temas nas últimas duas décadas, pois como ambas influenciam na SCM é coerente esperar integrações entre os dois assuntos [9].

Quando falamos de Indústria 4.0, termos como *Digital Supply Chain* (DSC), *Smart Factory* e *Smart Supply Chain* (SSC) podem ser utilizados para caracterizar esse cenário quando trata-se de um entendimento comum. O que pode se afirmar é que as tecnologias digitais já estão presentes e todos estes termos tentam explicar como elas irão transformar os atuais modelos de negócios [11].

Pelo fato das tecnologias já estarem ingressando os chãos de fábrica, os benefícios são evidenciados quando uma companhia planeja-se para integrar o mundo físico com o das informações, reduzindo lead times, flows de produção mais definidos a partir de uma demanda prevista de acordo com flutuações do mercado e aumentando as relações entre fornecedores e clientes [12].

Os principais destaques da Indústria 4.0 podem ser apontados como *Big Data*, *Cloud Computing, Internet of Things* (IoT) e customização em massa [13]. A aplicação da Indústria 4.0, com suas respectivas tecnologias, dentro da cadeia de suprimentos de uma empresa pode ser feita de forma variável. Ela consegue ser sistematizada de forma pontual, como no uso por RFID, de forma local, quando utiliza-se do IoT ou de forma global, quando fala-se da interconectividade entre as cadeias de suprimento de uma mesma empresa [10].

Visto isso, ressalta-se a necessidade de utilização de métodos avaliativos que ofereçam um diagnóstico dos elementos e processos da cadeia moderna. Como exemplo, a empresa Basis melhorou seus processos e atingiu o nível 5 de maturidade do modelo CMMI [14], que se refere à melhoria contínua dos processos das organizações por meio de inovações e melhorias tecnológicas [15].

Dessa forma, notando-se os diversos benefícios advindos dos modelos de maturidade e o impacto das tecnologias disruptivas, este artigo objetiva fazer uma análise da revisão bibliográfica, a fim de identificar os modelos de maturidade utilizados e encontrar possíveis *gaps* ou necessidades que precisam ser atendidas no contexto de *Supply Chain* e Indústria 4.0. Além disso, no final deste documento é apresentado um novo modelo de maturidade que ainda será testado e aplicado em uma empresa do setor automotivo.

Metodologia

Primeiramente foi feita uma busca na literatura por artigos e estudos relacionados ao tema de Modelos de Maturidade e Cadeia de Suprimentos. Para isso foi necessário definir quais bases de dados seriam utilizadas para tal. Foram definidas: *Web of Science*, *Scholar*, *Science Direct* e *Scielo*.

Em seguida, foram definidas as palavras-chave que seriam utilizadas para realizar a busca dos artigos nas bases de dados. Nessa etapa, as palavras foram testadas e verificou-se se o resultado obtido com a busca estava de acordo com o tema da pesquisa. Por fim, as palavras-chave definidas foram: *maturity model AND supply chain*; mat*urity model AND indust* 4.0*; *maturity model*; *maturity level**; *technolog* AND maturity model*.

Após a definição das bases e das palavras-chave, os artigos encontrados foram filtrados para que fossem excluídos artigos repetidos. Além disso, a pesquisa teve como foco maior os artigos com data de publicação mais recente, porém isso não excluiu artigos anteriores muitos relevantes a esta pesquisa. Dessa forma, para a revisão buscaram-se artigos publicados desde 2015, sobre o tema proposto.

Após concluída essa primeira etapa de busca, foi feito uma leitura mais aprofundada dos artigos, e foi possível refinar os resultados obtidos, verificando se o título e o resumo de cada artigo estavam condizentes com o tema proposto. Os artigos que não seguiam a linha da pesquisa foram descartados.

Os artigos restantes foram lidos integralmente. Os que estavam de acordo com o tema foram mantidos e selecionados para formar o portfólio final, e os que não estavam seguindo o tema foram descartados. A metodología apresentada está representada de forma visual na Figura 1.

Fig. 1. Fluxograma da metodologia seguida neste estudo

Os artigos relevantes foram selecionados e compilados em uma planilha para melhor visualização. Nessa planilha também foram destacados os pontos-chave de cada artigo, tais como: título, ano de publicação, autores, palavra-chave utilizada na busca e objetivo do artigo.

Com essa base organizada, foi possível partir para a próxima etapa, mapear os atributos e níveis utilizados por cada autor em cada modelo de maturidade apresentado. Vale ressaltar que os atributos e níveis observados nos modelos em questão, foram analisados e dez modelos de maturidade principais foram selecionados, os quais são o foco central deste estudo. Por fim, baseado nos modelos selecionados, foram feitos três quadros, o primeiro com a nomenclatura de cada modelo de maturidade, o segundo com a relação dos níveis utilizados nesses modelos e o terceiro, que apresenta os atributos utilizados pelos autores desses modelos e a frequência com que eles aparecem em cada modelo selecionado.

2 Revisão da Literatura

2.1 Modelo de Maturidade

Com base em dados coletados em sua pesquisa, [16] mostraram que existe uma relação significativa entre a cadeia de suprimentos de uma empresa e as vantagens competitivas que podem advir dela. Além disso, pode-se perceber o quanto é crucial o papel dos diferenciais competitivos no mercado atual [16]. Nesse cenário, é necessário que as organizações evoluam dentro de suas cadeias o conceito de maturidade dos processos para gestão [17].

Modelos de maturidade ganharam destaque nos últimos anos e são responsáveis por proporcionar a melhoria sistemática e contínua de desempenho do aspecto analisado [18]. Evidências mostram que as empresas podem melhorar o desempenho da sua cadeia de suprimentos por meio da criação e desenvolvimento de um modelo de maturidade [19]. Embora, inicialmente, os modelos de maturidade não estejam ligados diretamente aos processos da cadeia de suprimentos, nos últimos anos ocorreram diversas pesquisas sobre o tema, em que era representado o uso dos modelos tomando como base os KPIs (*Key Performance Indicators*) para analisar e medir o desempenho das operações da cadeia [20].

Percebeu-se que, apesar de existirem tipos variados de modelos de maturidade, apresentados no Quadro 1, inclusive alguns bem recentes, que baseiam sua abordagem especificamente numa cadeia de suprimentos, apenas um autor, [21], aborda diretamente as tecnologias da Indústria 4.0 como medida de avaliação para nível de maturidade, com foco nas tecnologias. O modelo de maturidade considerando as tecnologias 4.0 foi publicado em 2016. Porém, como o mundo sempre passou por transformações que exigiram o progresso, e até hoje o reflexo dessas mudanças influenciam nosso dia a dia [22], faz-se necessário identificar como as novas tecnologias podem influenciar a maturidade da cadeia de suprimentos no momento atual.

Quadro 1. Principais modelos de maturidade encontrados por meio da revisão da literatura feita

Número de Referência	Nome do Modelo de Maturidade
[17]	Supply Chain Management Maturity Model (SCM³)
[36]	Supply Chain Capability Maturity Model - S(CM)²
[37]	Quality Management Maturity Grid (QMMG)
[38]	Demand management maturity model
[21]	Industry 4.0 Maturity Model
[39]	Supply Chain Maturity Model - SCM²
[35]	Maturity Model for Supply Chain Flexibility
[40]	Fuzzy analytical hierarchy process (FAHP)
[41]	Classification tree for supply chain maturity model
[20]	Business Process Orientation Maturity Model (BPOMM)

O termo maturidade pressupõe a evolução de um estado inicial até um estado final, em que existe um desenvolvimento dos processos, através de estados intermediários da maturidade [23]. Ademais, a maturidade pode ser definida como o momento em que uma empresa alcança a condição ideal para atingir suas metas. Essa condição é atingida por meio do desenvolvimento das operações, passando por vários estágios intermediários [24]. Os modelos de maturidade também definem que o progresso em direção ao sucesso e à realização dos objetivos definidos ocorre em etapas [17].

A estrutura de um modelo de maturidade tem como principais objetos: níveis, dimensões e atributos. Dimensões são "áreas específicas que descrevem diferentes aspectos do objeto de avaliação de maturidade" enquanto os níveis são "arquétipos da maturidade do objeto que é avaliado" [25]. Os níveis variam de acordo com o modelo de maturidade e respectivos autores. O Quadro 2 mostra uma relação da quantidade e nomenclatura dos níveis encontrados nos modelos de maturidade selecionados pelos autores deste artigo.

Quadro 2. Níveis dos modelos de maturidade destacados na revisão da literatura

Número de Referência	Quantidade de níveis no modelo	Descrição do nível mínimo	Descrição do nível máximo
[17]	5	1. Ad Hoc	5. Estendido
[36]	5	1. Indefinido	5. Conduzindo
[37]	5	1. Incerteza	5. Certeza
[38]	4	1. Transacional	4. Avançado
[21]	5	1. Incompleto	5. Exemplar
[39]	5	1. Nunca ou não existe	5. Sempre ou existe
[35]	5	1. Sem flexibilidade; Paradigmático	5. Flexibilidade
[40]	5	1. Não estruturado	5. Otimizado
[41]	4	0. Sem gerenciamento da cadeia de suprimentos	3. Liderança, trabalho em equipe, entre outros
[20]	5	1. Ad Hoc	5. Estendido

O Quadro 2 mostra que os modelos analisados apresentam entre 4 e 5 níveis e, que a maturidade da cadeia de suprimentos pode ser analisada considerando diferentes aspectos. Os processos dentro de uma Cadeia de Suprimentos necessitam de modelos de gerenciamento e avaliação que, orientados ao desenvolvimento, resultam em melhores níveis e melhores formas de medir o progresso. Transformar em números os níveis de maturidade de uma empresa por meio de um modelo representa uma oportunidade dessa empresa de solidificar seus indicadores e seus processos de melhoria e tornar sua estratégia mais competitiva [20].

Assim sendo, pode-se dizer que um modelo de maturidade visa proporcionar o entendimento acerca do nível em que uma empresa se encontra, dentro das dimensões e atributos definidos. Cada avanço de nível de maturidade representa um desenvolvimento na capacidade de previsão, no controle dos processos, na efetividade e na eficiência [20]. O entendimento de seus níveis de maturidade, permite à organização avaliar quais são suas forças e fraquezas, priorizando oportunidades de melhoria e melhor gerenciamento de planos de desenvolvimento [26].

As empresas mais orientadas ao desenvolvimento dos seus processos atingem níveis melhores de desempenho organizacional e conseguem criar um melhor ambiente de trabalho, baseado na cooperação e com menor número de conflitos [27]. Além de trazer benefícios internos, quanto maior é o nível de maturidade alcançado

por uma entidade, mais diversificada pode ser a sua base de clientes, tornando sua cadeia de suprimentos mais especializada [28].

Atributos

O modelo de maturidade é dividido em dimensões a serem analisadas. Dentro dessas dimensões, analisa-se individualmente alguns atributos, que possuem características e definições próprias [29] e são divididos nos níveis determinados pelo modelo de maturidade. Em um estudo que se referia ao CMM, citou-se que "se espera que os atributos [essenciais] caracterizem uma organização em um nível de maturidade específico" [30].

Os atributos detalham o modelo de maturidade, de forma a decompor certos aspectos de seu domínio [31] e, além disso, os atributos são utilizados para classificar um objeto de competência de uma das áreas empregadas no modelo de maturidade e podem ser atributos genéricos e atributos específicos. Os genéricos são aqueles comuns a todas as dimensões selecionadas no modelo (ELENA), enquanto os específicos são parte de apenas uma dimensão [32].

Em seu estudo acerca do desenvolvimento de um modelo de maturidade para implementação das tecnologias da Indústria 4.0, [33] definiram 7 dimensões e 38 atributos. Um exemplo de dimensão utilizada foi "Base tecnológica da Indústria 4.0", a qual avaliou mais especificamente 8 propriedades, dentre as quais tem-se Internet das Coisas e Internet de Serviços. Essas propriedades que são estudadas mais detalhadamente são conhecidas como atributos.

No que se trata do quesito dimensões de maturidade da cadeia de suprimentos, tanto a literatura quanto a prática sugerem que as principais categorias são planejamento, abastecimento, produção, entrega de resultados, desenvolvimento de novos produtos e itens que retornam à produção [19]. Do mesmo modo em que as dimensões evoluem ao longo do tempo, o nível de integração e desempenho de gestão da cadeia de suprimentos aumenta. Existem também algumas dimensões que se repetem em diferentes modelos, às vezes apenas com uma outra nomenclatura, mas com o mesmo significado [34].

Assim, os atributos mais frequentes presentes nos modelos selecionados na literatura foram: Flexibilidade; Tecnologia da Informação; Performance; Relação com o cliente; Inventário e Sistemas de Produção, conforme pode ser visto no Quadro 3.

Quadro 3. Relação dos atributos estudados nos modelos de maturidade selecionados na literatura

Atributos avaliados	Número de referência dos artigos selecionados										Σ
	[17]	[36]	[37]	[38]	[21]	[39]	[35]	[40]	[41]	[20]	
Relacionamento com o consumidor		x		x	x	x				x	5
Economia / custos			x						x		2
Flexibilidade	x		x		x	x	x			x	6
Recursos humanos		x			x	x					3
Busca pelo progresso								x	x	x	3
Tecnologia da informação		x		x	x	x	x	x			6
Estoque / inventário	x	x			x	x					4
Tempo de espera	x										1
Liderança					x			x	x		3
Gestão e Logística		x					x		x		3
Cultura da Organização					x		x				2
Performance	x	x		x		x	x			x	6
Planejamento e Estratégia				x	x		x				3
Sistemas de Produção		x				x		x		x	4
Produtos					x						1
Qualidade			x								1
Fornecedores				x		x					2
Trabalho em equipe								x			1

Após análise do Quadro 3, conclui-se que são poucos os autores que avaliam a tecnologia da informação ou algum outro aspecto ligado às tecnologias da Indústria 4.0, o que corrobora o desenvolvimento de um modelo que tenha seu foco voltado a esse aspecto.

A respeito da flexibilidade, em muitos periódicos esse é um atributo considerado importante na área de gestão operacional da cadeia. Por esse motivo, seu conceito já foi utilizado para diferentes objetivos, tais como medir a flexibilidade de produtos, de mix, volume e entregas. Neste caso, considerando as características das tecnologias 4.0, bem como as características dos consumidores atuais, é importante focar em um

outro conceito, que é a flexibilidade como medida da habilidade ou facilidade com que a cadeia pode mudar ou reagir à mudanças [35].

Sobre tecnologia da informação, busca-se medir a existência de ferramentas, métodos e dados que possam dar suporte aos sistemas da cadeia de suprimentos, por exemplo, dados estatísticos para previsão de demanda. A performance está voltada para a existência e a extensão de indicadores e medidores de desempenho da cadeia de suprimentos. Em termos de relação com o cliente, o que se avalia é o foco dado ao cliente como parte do processo de gestão da cadeia, além do nível de satisfação do cliente [34].

A dimensão relacionada ao gerenciamento do armazém ou inventário inclui todas as operações ligadas ao controle e gerenciamento de estoque, tais como matéria-prima utilizada, produtos acabados, peças de reposição, produção parada, etc. Por fim, os sistemas de produção representam todas as funções, processos e atividades que atuam diretamente na transformação de um produto ou serviço, ou seja, são as ações que agregam valor ao produto, como redução de defeitos, logística de problemas dentro da linha, planejamento de produção, bem como o desenvolvimento de projetos para redução de custo e tempo [36].

3 Modelo de Maturidade com foco na Indústria 4.0

Para o desenvolvimento do modelo de maturidade, primeiramente foram estudados os atributos mais frequentes na literatura. Conforme Quadro 3, apresentado anteriormente, os atributos de maior frequência foram: Flexibilidade; Tecnologia da Informação; Performance; Relação com o cliente; Inventário e Sistemas de Produção. Assim, pode-se considerar que estes atributos são os mais relevantes para a cadeia de suprimentos. A partir dessa relação, decidiu-se que uma das dimensões que iríamos adotar seria a Flexibilidade, justamente por ela ter sido considerada relevante por grande parte dos autores pesquisados. Em seguida, em função da alta frequência nos artigos e também por ser um dos focos deste estudo, decidiu-se que Produção seria nossa segunda dimensão analisada.

Além disso, ao longo da pesquisa percebeu-se que muitos autores consideravam a logística como ponto importante para estudo da cadeia de suprimentos. Sendo assim, e pelo fato de nosso foco ser também a Indústria 4.0, decidiu-se que uma das dimensões do modelo deveria incluir a logística, porém ligada a Indústria 4.0, resultando na dimensão de Logística 4.0. Por fim, é importante considerar que, apesar de não estar presente nos modelos de maturidade analisados, a sustentabilidade é um aspecto importante a ser considerado, pois possui uma força considerável para o gerenciamento das cadeias de suprimentos por parte dos líderes das empresas [42]. Portanto, o modelo proposto é composto pelos seguintes aspectos: Flexibilidade, Produção, Logística 4.0 e Sustentabilidade como dimensões principais. Em seguida, nos aprofundamos em cada uma dessas dimensões, dividindo-as em três atributos cada.

Por fim, baseando-se na relação de nome e número dos níveis de maturidade encontrados na literatura, apesar de a maioria dos autores adotarem uma divisão em 5

níveis, optou-se por utilizar quatro níveis, a fim de facilitar a compreensão da evolução da maturidade, por parte dos respondentes. Por fim, um questionário foi desenvolvido para avaliar e indicar o nível de maturidade da organização respondente, considerando os quatro níveis estabelecidos, e assim, indicar onde seus recursos deveriam ser investidos, a fim de otimizar o desempenho de sua cadeia em geral.

4 Considerações Finais

Como visto, a literatura já possui trabalhos feitos dentro da área nos quais apresentam alguns modelos que permitem a avaliação das cadeias de suprimentos. A partir dos atributos considerados mais relevantes e que aparecem em maior quantidade nos estudos realizados, é possível realizar a criação de um modelo de maturidade cada vez mais efetivo, de acordo com as mudanças no cenário logístico e industrial que contribuem para a evolução e melhoria das dimensões de cada cadeia de suprimentos. Com o aumento dos desafios na cadeia de suprimentos, as empresas devem tornar-se mais inteligentes para que saibam lidar com os novos problemas de gerenciamento [7].

Contudo, ainda há um déficit na construção de modelos que avaliem, de fato, o grau de maturidade inserido dentro do contexto da Indústria 4.0. Devido à recente implementação do termo, os estudos dentro da área ainda são muito básicos, o que impede um aprofundamento dos modelos de maturidade com enfoque neste tema.

Como há uma escassez de modelos que conectem os modelos de maturidade com a Indústria 4.0, paralelamente à esse estudo está sendo desenvolvido outro artigo, em que no modelo de maturidade desenvolvido serão adicionadas as tecnologias da Indústria 4.0, para avaliar a possibilidade de sugerir à empresa ou indústria uma ferramenta ou metodologia que possa auxiliar no desenvolvimento e na otimização dos processos que foram classificados com níveis mais baixos anteriormente. Além disso, o modelo de maturidade será testado pela primeira vez em uma indústria do setor automotivo, assim sendo possível avaliar tanto a efetividade do modelo quanto sua aplicação.

Como o conhecimento acerca das tecnologias digitais encontra-se cada vez mais difundido dentro das organizações, para trabalhos futuros vê-se a necessidade em de maior estudo dentro da correlação entre a Indústria 4.0 e os modelos de maturidade.

dornesflorencia@gmail.com

Abstract. En este trabajo se aborda un caso de estudio de la industria manufacturera del calzado. Particularmente, se analiza el caso de una PyME de calzado de cuero de Argentina. El estudio se focaliza en la variabilidad de rendimiento que implica trabajar con materias primas de origen animal, y su consiguiente impacto en la capacidad de producción. Para ello se modeló el proceso de producción respetando todos los factores que incorporaban incertidumbre al problema. Se generaron simulaciones de eventos discretos para analizar el sistema, y se detectó el cuello de botella. Al analizar las potenciales alternativas para salvar la limitación en la capacidad, se optó por la incorporación de un nuevo trabajador. Los resultados de la propuesta de solución permitieron mostrar que incorporar un trabajador aumentaba la productividad más que proporcionalmente al incremento directo de mano de obra.

Keywords: Plant Simulation, planificación estocástica de la producción, producción de calzado, simulación, cuello de botella.

1 Introducción

La fabricación de calzado es una de las actividades productivas más importantes de Coronel Suárez, localidad de la Provincia de Buenos Aires, Argentina. Consiste en un proceso productivo de elevada complejidad, que involucra diversas máquinas específicas y una gran cantidad de operarios especializados. La diversidad de productos que se pueden obtener conlleva la necesidad de planificación de distintos procedimientos particulares, con operaciones adecuadas para cada modelo. Asimismo, en términos generales, la fabricación involucra las siguientes etapas: recepción de materia prima y cortado, aparado, armado y empaque.

El caso a trabajar es un problema de producción de calzado de seguridad de una empresa argentina, cuyos principales clientes son las fuerzas de seguridad. La problemática primordial radica en la necesidad de trabajar con cuero natural. Este material de origen animal se considera el insumo crítico del proceso puesto que interviene en mayor proporción en la fabricación del producto y, por sus características naturales, los rendimientos de su utilización no son constantes a causa de la variabilidad del tamaño de la pieza de cuero y a la elevada probabilidad de presencia de agujeros en la misma. Por lo tanto, las operaciones iniciales de todo el proceso de fabricación, es decir, el proceso

de cortado y preparado del cuero, tienen un rendimiento variable dependiente de las condiciones del cuero que ingrese. Además, dadas las características mecánicas del cuero, la operación de costura se vuelve realmente crítica. Por lo tanto, la probabilidad de ocurrencia de fallas (ej., rotura de agujas) u operaciones defectuosas (ej., costura deficiente) es significativa. La ocurrencia de dichos eventos (cueros no estándares y fallas operativas) impacta de forma negativa en la planificación de la producción.

En la literatura se encuentran numerosos antecedentes de trabajos que se basan en la simulación de eventos discretos para el estudio de casos similares de manufactura. Entre ellos, Malega et al. [1], Yang et al. [2], Zhang et al. [3] y Wang et al. [4]. Respecto a la industria del calzado, su estudio ha sido abordado por Dang & Pham [5], donde se realiza el diseño de una línea de montaje con 62 tareas, tiempos de operación inciertos y estaciones de trabajo paralelas, con el objetivo de maximizar el desempeño de la línea determinando un ajuste optimizado de los parámetros operativos y una asignación óptima de tareas. Por otra parte, Sadegui et al. [6] realiza la optimización de la línea de producción, haciendo foco en el área de costura, identificada como el cuello de botella del proceso. El objetivo es equilibrar la línea de montaje, minimizando el número de estaciones de trabajo requeridas y suavizando la carga de trabajo en los operadores.

Por otra parte, existen diversos casos donde se aborda la simulación de las fallas de equipos. Ahmadi et al. [7] evalúa las averías de máquina en un entorno estocástico mediante simulación, considerando que tiempo medio entre fallas y la reparación siguen una distribución exponencial. Las mismas consideraciones de distribución son utilizadas por Zandieh & Gholami [8].

En este trabajo se plantea el abordaje de un caso de estudio de una planta de producción de calzado de cuero. El proceso productivo está sujeto a distintas fuentes de incertidumbre que afectan la capacidad de producción, tanto por el rendimiento del cuero como por la probabilidad de rotura de las máquinas. Es por eso que, para aumentar la capacidad de producción, es necesario un abordaje que permita analizar la producción considerando las incertidumbres propias del proceso. Dada la cantidad de operaciones, la complejidad del proceso y la naturaleza propia del mismo (influencia significativa de factores aleatorios), resulta adecuado un enfoque basado en simulación de eventos discretos [9]. Se plantea como alternativa para el aumento de la capacidad de producción la incorporación de un nuevo trabajador. Los resultados avalan la alternativa propuesta mejorando la productividad más que proporcionalmente.

El resto del trabajo se organiza de la siguiente manera. En la Sección 2 se presenta el problema junto con el proceso productivo. En la Sección 3, se analiza la propuesta de mejora y se introduce la herramienta a utilizar. Mientras que en la Sección 4, se define el tipo de experimento a realizar junto con sus parametrizaciones, y se presentan los resultados obtenidos. En la Sección 5, se presentan las conclusiones del trabajo.

2 Descripción del problema

En esta sección, en primer lugar, se describe el proceso de fabricación completo del producto, desde la recepción de la materia prima hasta el acordonado y empaque del mismo. Posteriormente, se identifica y detalla el problema a resolver en este trabajo.

2.1 Descripción del proceso de manufactura

El borcego de seguridad es un producto hecho a base de cuero natural, forrado internamente y reforzado adecuadamente, provisto con suelas con propiedades dieléctricas, resistentes a óleos e hidrocarburos, cementada y pegada con costura de seguridad en Scátola.

El proceso de fabricación del producto en análisis se representa en el diagrama de flujo de la Fig. 1. Si bien el proceso real consiste en múltiples etapas específicas, para los fines del problema que se pretende estudiar en este trabajo se condensó dicha información. Esta condensación consistió en el agrupamiento de operaciones por centro de trabajo, manteniendo el suficiente nivel de detalle como para representar fielmente el problema de capacidad a trabajar. A su vez, esta condensación también respetó la naturaleza estocástica del problema, permitiendo modelar la variabilidad propia de trabajar con materias primas naturales (el rendimiento del cuero es variable) y su procesamiento exigente (rotura de máquinas). Por lo tanto, el problema modelado permite modelar el sistema real de producción validando el modelo.

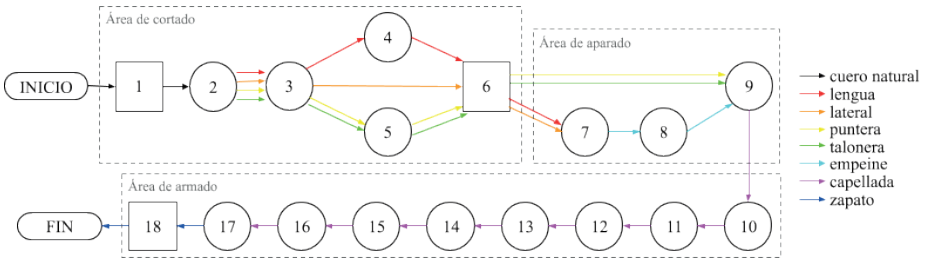

Fig. 1. Diagrama de flujo del proceso productivo de los borcegos de seguridad. Referencias: 1-Recepción de materia prima; 2-Cortado; 3-Rebajado; 4-Bordado de logo; 5-Pegado de refuerzos; 6-Control de calidad intermedio; 7-Cosido de lengua y laterales; 8-Ojalillado; 9-Cosido de la capellada; 10-Costura Strobel; 11-Humectado; 12-Calzado de horma y marcado; 13-Raspado, halogenado y cementado de suela y cortes; 14-Horno; 15-Pegado de suela; 16-Prensado de suela; 17-Costura de seguridad Scátola; 18-Control final, limpieza y empaque.

Su elaboración se inicia con la recepción de materia prima (1), a la cual se procede a realizarle la inspección táctil y visual del cuero, y el control y calibración de espesores. Los materiales se transportan al área de corte, donde se obtienen las diez piezas requeridas para la producción de un par de zapatos: 4 laterales, 2 lenguas, 2 punteras y 2 taloneras. Esto se realiza en un balancín pluma (2), junto con troqueles o sacabocados especiales para cada parte y a la medida de la horma del pie, con cuidado de descartar las secciones del cuero agujereado, arrugado o de espesor variable. Es importante que

se le realice un rebajado de cuero (3) de forma tal que disminuya el espesor en el perímetro de las piezas cortadas para que, al momento de realizar la costura entre piezas, se obtenga un espesor constante y se evite, además, la rotura excesiva de las agujas de las máquinas de coser. Posteriormente, se procede al bordado de la marca de los borcegos (4) en la lengua de éstos, el pegado de refuerzos (5) en las punteras y taloneras, y el control de calidad intermedio (6) de todos los componentes.

En el área de aparado se pegan, doblan y arman las distintas piezas del zapato. Los operarios se encargan de culminar la realización de la capellada realizando el ensamble de las piezas mediante su costura, utilizando máquinas de coser de una (9) y dos agujas (7). Adicionalmente, se realizan los ojales (8) requerido para el acordonado del zapato.

Luego, en el área de armado, se procede a la finalización del zapato. Esto requiere, en primer lugar, del proceso de montado, donde se cose la plantilla de armado mediante la máquina Strobel (10) y se trata el cuero con vapor (11) para ablandarlo en la máquina de humectar cortes. Posteriormente, se realiza el ensuelado por proceso de pegado tradicional, que consiste en el calzado de la horma y marcado de la suela (12), junto con su raspado, se incorpora el adhesivo y se pega (13). Para ello se incrementa la temperatura en un horno (14) y se pega a presión la suela durante 30 segundos (15 y 16). Por último, se desmonta la horma. Adicionalmente se realiza una costura de seguridad en Scátola (17).

Finalmente, el producto se limpia y se realiza el control final del mismo, procediendo a su acordonado y empaque (18).

En la Tabla 1 se muestra la cantidad de trabajadores que actualmente trabajan en la fábrica y el detalle de actividades que realiza cada uno. El número de operación coincide con las operaciones del diagrama de flujo presentado en la Fig. 1.

Tabla 1. Asignación de las operaciones productivas de los trabajadores. Las operaciones se definen a partir de las referencias del diagrama de flujo. Los trabajadores que realizan transporte manual de piezas se indican con una X en la última columna.

Trabajador	Cantidad	Operaciones	Transporte manual de piezas
Worker:1	1	(2)	
Worker:2	1	(3); (4)	X
Worker:3	1	(5); (6)	
Worker:4	1	(7); (8)	
Worker:5	1	(9); (10); (11)	X
Worker:6	1	(12)	
Worker:7	1	(13)	
Worker:8	1	(14); (15)	
Worker:9	1	(16)	
Worker:10	1	(17); (18)	X

2.2 Detalle del problema a resolver

La problemática principal de este proceso es que, al trabajar con materias primas naturales, su acondicionamiento exige un procesamiento intensivo, el cual termina limitando la capacidad de producción real de la planta. Esta limitación se da en el proceso de fabricación por la gran variabilidad del rendimiento de la principal materia prima que es el cuero natural. Al tratarse de un insumo de origen animal, no solo el tamaño de las piezas recibidas resulta variable, sino que también puede presentar agujeros, o algunas secciones quemadas (por el proceso de curtiembre) y con gran frecuencia el espesor es variable. Para minimizar el impacto de estas condiciones en el proceso de producción, la elección del proveedor de materia prima es fundamental, al igual que las habilidades del cortador (operación 2, Fig. 1), quien debe posicionar los troqueles de tal forma que se minimice el descarte de piezas cortadas no aptas para lograr el nivel de calidad deseado del producto final.

Sin embargo, una vez logradas las piezas cortadas, la mayor exigencia se encuentra en el área de aparado (operaciones 7,8 y 9, Fig. 1), donde los operarios deben calibrar las máquinas de coser según el espesor del cuero, ya que, si no se ajusta la máquina al espesor del cuero, entonces la probabilidad de rotura de las agujas crece considerablemente. Es por eso que el desempeño del área de aparado tiene una vinculación directa con el cuero. La criticidad del ajuste de máquina al espesor del cuero es tal que, en una jornada estándar de trabajo, se pueden llegar a romper 10 agujas por día (realizando todos los ajustes necesarios) y, en caso de saltear algún ajuste, la cantidad de roturas de agujas aumenta. Por lo tanto, es un área que demanda mucho tiempo de setup (no es tiempo productivo), e incluso el tiempo de reparación por rotura también es considerable.

Por otro lado, las operaciones de costura allí realizadas inciden directamente en la calidad y estética de los borcegos terminados, por lo que un mal desempeño genera una obtención mayor de zapatos de segunda calidad, lo cual tiene un impacto económico para la empresa. Por lo tanto, se trata de una operación que debe realizarse con el máximo de los recaudos, lo que en términos operativos implica tiempos de operación no reducidos. Es por eso que, para aumentar la capacidad de producción, debe analizarse detenidamente el área de aparado. Para ello se realizaron una serie de simulaciones en condiciones estándares para evaluar, en términos relativos, como se desempeñaba dicha área. En la Fig. 2 se presenta una gráfica que muestra la utilización del tiempo de la jornada laboral por parte de cada trabajador (del inglés, "*worker*"). A simple vista se observa que el único trabajador sin tiempo ocioso es el trabajador 4 (la parte verde implica modo "operación" y la parte gris "esperando"), que resulta ser el trabajador asignado a las operaciones (7) y (8) (Tabla 1). Por lo tanto, se identifica que la limitante de capacidad o el cuello de botella se encuentra en las operaciones (7) y (8) asignadas al trabajador 4.

Fig. 2. Gráfico de barra de las proporciones de los tiempos de las distintas actividades realizadas por cada operario en función del tiempo total de trabajo normalizado, bajo condiciones iniciales.

3 Propuesta de solución

En esta sección se parte del proceso de producción presentado, junto con sus características estocásticas, para analizar una potencial alternativa que permita aumentar la capacidad de producción. Para ello primero se describe la propuesta de solución en términos del proceso productivo y, luego, se proponen los medios para evaluar la solución propuesta.

3.1 Propuesta de solución

El problema de capacidad se evidencia en las operaciones (7) y (8) que son las que realiza el trabajador 4. Esas limitaciones de capacidad se deben a que es una operación muy demandante de mano de obra debido al permanente ajuste que debe realizarse en la máquina para procesar el cuero de espesor variable. Por lo tanto, para aumentar la capacidad de producción del sistema, bastaría con aumentar la capacidad del cuello de botella [10]. Ahora bien, una forma de aumentar la capacidad de producción de esas operaciones sería reduciendo la cantidad de tiempos de ajustes que requiere esa máquina, ya que éstos no son tiempos productivos en el sentido estricto. Sin embargo, la necesidad de los ajustes de máquina se debe a la variabilidad del espesor del cuero, que, tal como se comentó en la sección anterior, es una característica propia de la materia prima que se utiliza para el proceso. Por lo tanto, para reducir el tiempo destinado a los ajustes, sería necesario reducir la variabilidad del espesor del cuero, algo que no es posible.

Por lo tanto, la posibilidad de aumentar la capacidad de esas operaciones radica en aumentar los recursos productivos disponibles en esa operación, ya sea aumentando la cantidad de máquinas, o aumentando la cantidad de operarios. En este trabajo optamos por esta última opción. Lo que se propone como solución para el aumento de la capacidad de producción es la incorporación de un nuevo trabajador asignado a las mismas operaciones que el operario 4 de la Tabla 1.

3.2 Enfoque de implementación de la solución

Para la verificación de la efectividad de la alternativa elegida para el aumento de la capacidad, se utiliza el software Tecnomatix Plant Simulation 15 [11]. Se trata de un

software de simulación del flujo de material en un sistema de eventos discretos. El software permite evaluar procesos complejos y dinámicos brindando el soporte a la toma de decisiones relacionadas con la producción. Para ello, el simulador permite la ejecución de distintos experimentos representando distintas alternativas y configuraciones, sin requerir la experimentación con el ambiente real de producción.

Para el modelado del proceso productivo se tomó en consideración el layout real de la empresa, con tiempos estimados a partir de la producción diaria promedio. Ese Layout se presenta en la Fig. 3., los números asociados a cada una de las estaciones de trabajo condice con los números presentados en las etapas del proceso de la Fig. 1.

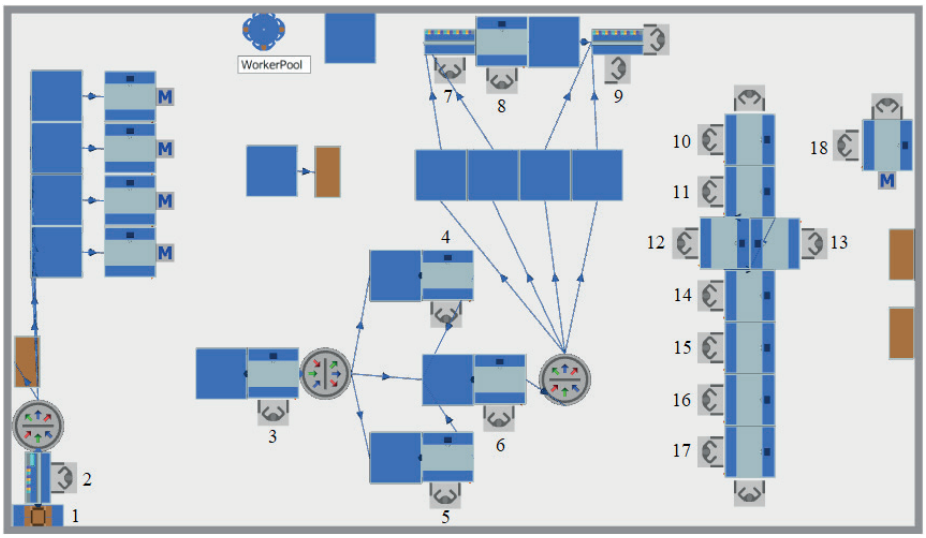

Fig. 3. Vista en planta del modelo 3D del proceso productivo real de calzado, utilizando Plant Simulation. Las referencias corresponden a las operaciones del diagrama de flujo de la Fig.1.

4 Experimentos y resultados

4.1 Diseño experimental

La realización de los experimentos requiere un modelado previo del sistema productivo. Se introdujeron diversos puntos de variabilidad asociados al rendimiento de la materia prima, los tiempos de operación, las fallas operativas por rotura de agujas en el área de aparado y la calidad del producto terminado.

En el caso del rendimiento del cuero natural, se definió considerando un proveedor de materia prima de calidad media-alta, donde las piezas descartadas debido a las deficiencias del material varían de 0 a 4%, con una distribución uniforme.

Respecto a los tiempos operativos, éstos fueron estimados a partir de la información del caso real provista por la PyME, tomando en consideración la producción diaria de

100 zapatos/día. Dado que las actividades son realizadas con la intervención de los trabajadores, los tiempos pueden discrepar debido a factores inherentes del sistema. Dicha variabilidad se modela a partir de una distribución triangular de los tiempos operativos, considerando a los valores mínimos y máximos como una proporción equivalente al 95% y 115% del valor de la moda, respectivamente.

Las fallas por rotura de agujas de las máquinas de coser del área de aparado se determinan a partir de la rotura histórica de agujas en la totalidad de la fábrica, que dependen del material que se procesa. Para el caso particular del cuero, debido a sus características, la rotura es de aproximadamente 10 agujas/día y, se definió para ambas máquinas con un intervalo entre roturas caracterizado por una distribución exponencial negativa. Por su parte, la duración se define a partir de una distribución normal, con un valor esperado de 4 minutos y una desviación estándar de 15 segundos.

Finalmente, se modeló la variabilidad del control de calidad final (operación 18 de la Fig. 1) de manera análoga al rendimiento del cuero. En este caso, los zapatos catalogados como de segunda calidad son de 0% a 2% de la producción total, con una distribución uniforme.

Por último, se establece para la jornada laboral la realización de un único turno, de lunes a viernes, desde las 6:00 hasta las 15:30 hs., con un descanso de 1 hora. Las condiciones hasta aquí detalladas se mantienen durante la realización de los experimentos. Como se describió previamente, la alternativa que se evalúa es incrementar la capacidad del sistema actuando sobre el cuello de botella, lo cual implica la incorporación de un nuevo operario con condiciones idénticas al trabajador 4. Por lo que los experimentos analizados consistieron en:

- Experimento 1: configuración estándar y cantidad de trabajadores estándar
- Experimento 2: configuración estándar y cantidad de trabajadores +1.

4.2 Resultados

Para comparar los dos experimentos se consideró como métrica de comparación la productividad promedio diaria. Se realizaron 50 corridas de cada experimento, con una extensión de 30 días. Los resultados obtenidos se muestran en la Fig. 4 a través de los intervalos de confianza. En la Fig. 4 se observan mejoras sustanciales en la productividad al incorporar un operario más (Experimento 2). El mayor impacto se da en las salidas de borcegos terminados. Bajo las condiciones iniciales (Experimento 1), la producción media es de 2786,73 pares/mes, con un desvío estándar de 286,04 pares. Al implementar la segunda estrategia, incorporando únicamente un nuevo operario en el cuello de botella, la producción es de 3562,47 pares/mes, con un desvío estándar de 340,63 pares. Es decir, la productividad se ve incrementada en un 27,84%. Este incremento porcentual si se lo compara con el incremento porcentual de la fuerza de trabajo (1 trabajador sobre 10 trabajadores, 10%) implica un aumento más que proporcional.

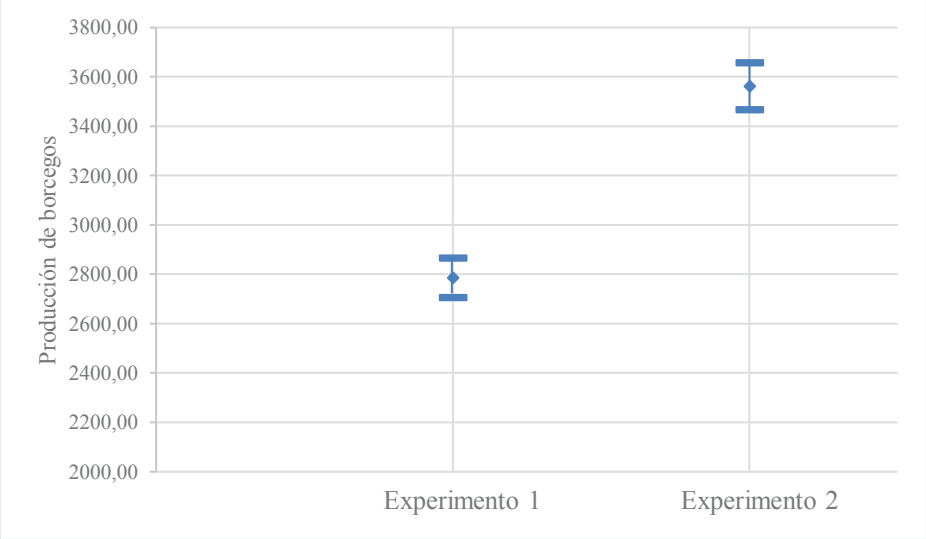

Fig. 4. Intervalo de confianza de la producción de borcegos para el experimento 1, con las conficiones iniciales, y el experimento 2, con la capacidad del cuello de botella incrementada.

Por otra parte, al observar la distribución de la proporción del tiempo trabajado por cada operario (Fig. 5), se observa un incremento general y una disminución en los tiempos de espera, comparado con la Fig. 2. Es de interés consignar que el nuevo trabajador incorporado es denominado como "Worker 5" en la Fig. 5, por lo que los Worker 6 a 11 de la Fig. 5, corresponden a los Worker 5 al 10 de la Fig. 2. Por otro lado, se observa en la Fig. 5, que la carga de trabajo se encuentra más balanceada entre los distintos trabajadores del proceso (las barras verdes tienden a ser más equilibradas que en la Fig. 2).

Fig. 5. Gráfico de barra de las proporciones de los tiempos de las distintas actividades realizadas por cada operario en función del tiempo total de trabajo normalizado, para el Experimento 2. El trabajador adicional se encuentra referenciado como Worker:5, por lo cual los demás trabajadores se ubican desfasados de su designación previa de la Fig. 2.

5 Conclusiones

El trabajo abordó la resolución de la problemática de capacidad de un caso real de una línea de producción de calzado. Para esto, se realizó un modelo de simulación del proceso productivo utilizando el software Plant Simulation, que permitió detectar la principal restricción del sistema, a saber, el área de calzado, en particular el trabajador 4. En consecuencia, se planteó una solución alternativa para incrementar la capacidad del cuello de botella añadiendo un operario extra, y se llevaron a cabo experimentos para evaluar el impacto de la solución propuesta.

Los resultados obtenidos a partir de la comparación de la situación inicial y la alternativa reflejan un impacto positivo significativo en la producción mensual de borcegos de la fábrica. Es decir, la solución propuesta potencia el sistema en conjunto, de forma más que proporcional al incremento de la capacidad.

ufprppgem@gmail.com

Resumo: A indústria 4.0 vem mudando a forma de produzir, oferecendo tecnologias inteligentes aos sistemas de manufatura para a transformação tecnológica das plantas fabris. Esta mudança depende de aplicações e combinações de tecnologias digitais como a (IoT) para o monitoramento *online* para a realização da coleta, do armazenamento e da transformação dos dados do processo em informações valiosas para auxiliar nas tomadas de decisões. Neste contexto, constatou-se, que as pequenas e médias indústrias apresentam dificuldades na utilização dos dados de processo e são apontadas como um elo fraco, tornando-se as maiores vítimas na transição para a indústria 4.0. A pesquisa apresenta como objetivo a avaliação de como estão sendo tratada a medição de desempenho baseada em dados para máquinas, no contexto da indústria 4.0. A abordagem metodológica segue por meio da aplicação do método (*Knowledge Development Process-Constructivist*) Proknow-C, para a construção do Portifólio Bibliográfico e da Análise Bibliométrica de forma estruturada alinhando ao tema de pesquisa. O resultado apresentou o método de seleção do Portfólio Bibliográfico e a Análise Bibliométrica para mensurar de forma qualitativa e quantitativa o grau de relevância e reconhecimento científico da seleção do Portfólio Bibliográfico, o qual possibilitou a análise dos dados para construção de um modelo de medição de desempenho com base nas fontes dos artigos pesquisados.

Palavras-chaves: Manufatura Conectada, Data Analytics, Medição de Desempenho, Manufatura Inteligente.

1. Introdução

As descobertas no campo da ciência e tecnologia vêm ocorrendo e progredindo através das revoluções industriais gerando inovações na computação e automação no processo produtivo [1]. Nestas evoluções, muitos dos dados, os quais podem ser utilizados para a medição do desempenho de máquina permanecem retidos nas máquinas e precisam ser extraídos e compilados manualmente para obter a informação de desempenho [2]. Recentemente a indústria de manufatura foi promovida para *Smart Manufacturing* (SM) e os processos advindos da indústria 4.0 vêm sendo altamente flexíveis, dependendo do desenvolvimento de inovações baseada em dados, para alcançar altos níveis de autonomia e otimização da manufatura [3, 4]. Um entendimento notável e comum, é que os sistemas de

manufatura evoluam para acomodar algumas características, tais como: A inteligência para a fabricação de objetos constituídos por homens, máquina e material (3M); A conexão para a configuração de objetos de fabricação, utilizando conexões com outros objetos do sistema para colaboração, conhecimento e serviços disponíveis na *internet;* e a capacidade de resposta por meio da fabricação (personalizada) lidando com mudanças internas e externas [4, 5].

Os conceitos trazidos pela indústria 4.0 são as principais prioridades para muitas organizações, entretanto o termo indústria 4.0, ainda não está claro para muita delas, segundo [6], algumas empresas enfrentam dificuldades para entender estes fenômenos e não obtém o conhecimento para identificar as etapas necessárias para uma transição saudável para alcançar a indústria 4.0. A IoT criado por Ashton, no Auto-ID Center do MIT em 1999, foca na formação de uma "*Internet*" composta por grandes números de "Coisas" interconectadas por uma infra-estrutura global de inter-rede que usa o protocolo TCP/IP para conectar e controlar remotamente as "Coisas" [3, 5]. Com a crescente demanda de IoT e dispositivos de sensores espera-se, que os dados gerados a partir de um processo de fabricação cresçam exponencialmente gerando os chamados "*big data analytics*" foco da *smart manufacturing,* oportunizando o desenvolvimento de um sistema para o monitoramento *online*, gerando informações para auxiliar os gestores nas tomadas de decisões [7, 6]. A *big data analytics* é um dos recentes avanços tecnológicos com forte aplicabilidade na manufatura [8]. A coleta, o armazenamento e a transformação de uma grande quantidade de dados são um dos principais elementos da manufatura inteligente industrial [7].

Para manter o alto desempenho dos sistemas de manufatura exige-se das indústrias, o emprego de métodos e ferramentas para gerenciar a medição do desempenho ao longo do ciclo de vida do sistema, os quais são introduzidos para garantir o desempenho planejado por meio do monitoramento *online*, avaliação do desempenho e resposta para adequação dos desvios do desempenho. A medição é seguida pela análise do desempenho por meio de indicadores, para que as decisões sejam tomadas. Nos níveis mais altos da fábrica, as medições de desempenho são agrupadas nos principais indicadores de desempenho *key performance indicators* (KPIs). O KPI é um parâmetro e fornece informações sobre um fenômeno com significado e relevância para os objetivos de desempenho, como um fator crítico para o sucesso atual e futuro da organização e devem ser numericamente e precisamente quantificáveis [9].

Para [9], a coleta e a análise otimizada destes dados, os quais auxiliam a gestão nas tomadas de decisões são, no entanto, um processo complexo e dinâmico. Isto é, ainda mais verdadeiro, nas pequenas e médias indústrias, as quais apresentam dificuldades em utilizar os dados do processo e foram classificadas como um elo fraco, sendo as maiores vítimas na transição para a indústria 4.0 [10]. A realidade descrita, sobre as dificuldades das pequenas e médias indústrias em adaptarem seus processos e recursos, para uma transição saudável para a indústria 4.0, revela uma problemática, a qual apresenta como fator determinante à baixa adoção de tecnologias para a medição de desempenho baseada em dados para máquinas. Diante desta problemática, qual

alternativa poderia ser proposta para a medição do desempenho para máquinas e equipamentos de forma *online*, e desta forma contribuir para mitigar os impactos na transição para a indústria 4.0? Para tanto, o objetivo geral da pesquisa foca na avaliação de como estão sendo tratada a questão da medição de desempenho baseada em dados para máquinas no contexto da indústria 4.0.

2. Procedimentos metodológicos

Para o desenvolvimento desta pesquisa, foram aplicadas duas, das 4 etapas da metodologia *Proknow-C*, sendo a seleção de um portfólio e a análise bibliométrica do portfólio. Desta forma, será construída apenas parte do conhecimento, os quais são suficientes para identificar o modelo de avaliação acerca do tema da pesquisa conforme (Fig.1)

2.1 Metodologia de pesquisa: Proknow-C

O *Knowledge Development Process-Constructivist (Proknow-C)* é um método de revisão sistemática proposto por [11, 12], similar aos demais e destaca-se no propósito da geração do conhecimento [32]. O método *Proknow-C* é utilizado tanto para a seleção de Portfólio Bibliográfico, quanto para Análise Bibliométrica de forma estruturada e gradual alinhado ao tema de pesquisa. Partindo do pesquisador, o interesse para delimitar e definir as premissas, no que tange as bases de pesquisas, aos eixos de buscas, aos cortes temporais, aos filtros e aos critérios para inclusão ou exclusão de publicações [13, 14, 15, 16, 17, 32]. Permitindo a construção do conhecimento, dando suporte à realização das pesquisas na seleção de publicações considerando o fator de impacto relevante na comunidade científica [18, 19]. O método é composto por quatro etapas (Fig.1): (a) seleção de um portfólio bibliográfico; (b) análise bibliométrica do portfólio; (c) análise sistêmica; e, (d) definição da pergunta de pesquisa e objetivo de pesquisa [15, 16, 17, 20].

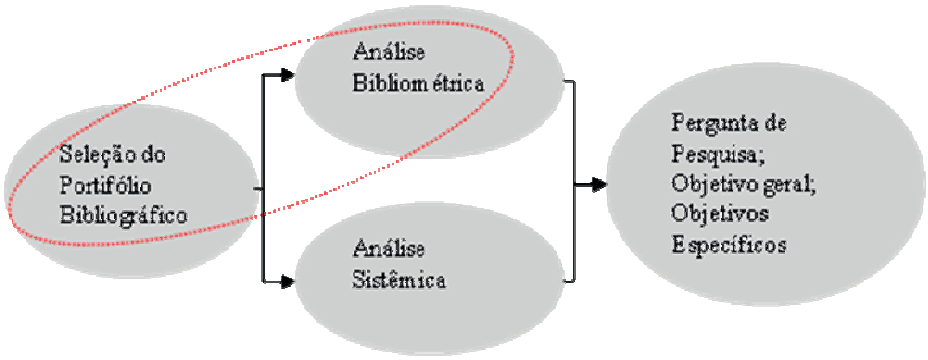

Fig.1. Etapas do processo Proknow-C. Adaptado de [12]

2.2 Seleção do Portfólio Bibliográfico

A busca pelas publicações científicas foram realizadas, nas bases de dados de forma sistemática, seguindo a metodologia *Proknow-C*. O processo de seleção de portifólio de artigo contribuiu para a seleção de Portfólio Bibliográfico, considerando como relevante na comunidade científica [21; 14]. De acordo com [15; 21] o subprocesso de seleção do portfólio são desenvolvidos através de duas etapas: a) a seleção dos artigos nas bases de dados (Banco de Artigos Brutos); e b) a filtragem dos artigos selecionados alinhado ao tema da pesquisa.

Etapa (a) iniciou-se com as definições de três eixos de pesquisa representadas pelos termos de buscas em língua inglesa: *manufacturing, data analytics and Performance measurement.* As buscam foram realizadas nas bases de pesquisa *(Scopus, ScienceDirect e Web of Science,* em Agosto de 2019, seguindo o critério de artigos publicados nos últimos seis anos (2013 a 2019) e validando-os com o teste de aderência dos termos de buscas. **Etapa (b)** em seguida foram aplicados os filtros, tais como: a exclusão de artigos com acesso restrito e em duplicidades, artigos com títulos e *abstracts* não alinhados ao tema de pesquisa. Resultando na construção de um Portfólio Bibliográfico, alinhados ao tema e reconhecidos na comunidade cientifica.

2.3 Análise Bibliométrica do Portfólio Bibliográfico

A fase de Análise Bibliométrica denominada por [15], caracteriza pela aplicação da análise dos artigos, para o gerenciamento da informação e do conhecimento científico para o pesquisador, sobre o tema pesquisado [13]. O objetivo desta análise foca na quantificação e apresentação destas informações, através de ferramentas de análises e construção deste conhecimento [14, 21]. Os resultados destas análises da fase de bibliometria foram desenvolvidos em quatro etapas, de acordo com [18, 19, 21, 22, 23, 24, 25]: (a) Estimar o grau de relevância dos periódicos; (b) Estimar o reconhecimento científico dos artigos; (c) Estimar o grau de relevância dos autores; (d) Estimar as palavras-chave mais utilizadas.

3. Análise de Resultados

3.1 Seleção do Portfólio Bibliográfico

O processo de seleção de portfólio consiste em selecionar publicações, consideradas relevantes na área de conhecimento e alinhadas com percepção do pesquisador ao tema de pesquisa. No entanto, o processo de seleção [21], segue em duas etapas: O item 3.1.1 refere-se à construção da base de seleção de artigos brutos e o item 3.1.2 consiste na filtragem da base bruta de artigos, com base no alinhamento do tema de pesquisa.

3.1.1 Seleção do banco de artigo brutos

a) Termo de busca: Inicialmente foram necessárias identificar os eixos da pesquisa, para posteriormente indexar em cada eixo, aos termos de buscas relacionadas com o tema de pesquisa. As combinações dos eixos com as palavras chaves seguem conforme Tabela 1, todas descritas no idioma inglês.

Tabela 1. Termo de buscas

Eixo I: *Manufacturing*	**Eixo II: *Data Analytics***	**Eixo III: *Performance measurement***
Smart production	*Internet of Things*	*Key performance Indicator (KPI)*
Industry 4.0	*Machine learning*	*Machine performance*
Smart manufacturing	*Real-time process*	*Productive efficiency monitoring*

b) Definição do banco de dados: Para a pesquisa foram selecionadas 3 bases de publicação cientifica, sendo elas: *Scopus, ScienceDirect e Web of Science*.

c) **Busca de artigos no banco de dados foram** realizadas nas bases dos periódicos definidas no item (b) em agosto de 2019, com filtro de datas para os artigos publicados entre os anos de 2013 a 2019, sendo selecionado para o banco de artigos brutos um total de 880 títulos relacionado ao tema de pesquisa, sendo 277 artigos pela *Scopus*, 378 pela *ScienceDirect* e 225 pela *Web of Science*.

d) Testes de aderência dos termos de buscam verificaram, se os termos inicialmente determinados na busca das publicações do Portfólio Bibliográfico, se alinham com o tema de pesquisa. O resultado evidenciou, que, dos 13 termos de buscas pertencentes aos dois artigos, sete deles *(smart manufacturing, manufacturing performance methods, manufacturing performance challenges, performance measurement, manufacturing, big data, real-time processing)* encontravam-se listados entre os termos de buscas definido nos eixos da pesquisa.

3.1.2 Filtragem do banco de dados

Esta etapa consiste na seleção dos artigos disponíveis com maior relação ao tema e o fator de impacto na comunidade científica. Para esta análise, a base de dados foi exportada para o *Software Mendeley* e as informações contidas como (título, *abstract*, palavras-chaves, autores, DOI entre outros, o arquivo em PDF da publicação). Na sequência, foram realizados os filtros, por meio de leitura, dos 880 artigos do banco de artigos brutos (BAB) para dar origem à base do Portfólio Bibliográfico.

a) Filtros dos artigos quanto à (repetição e redundância): Esta fase analisou por meio do *Software Mendeley,* o banco de artigos brutos, com 880 obras

selecionadas. Assim foi possível verificar a redundância dos artigos, sendo que, 21% (168) dos artigos foram removidos por apresentar duplicidade e acesso restrito, restando 698 artigos no banco de artigos brutos;

b) Filtros dos títulos dos artigos estão alinhados com o tema da pesquisa: Nesta fase foram realizadas as leituras integrais dos títulos dos 698 artigos da base de artigos brutos. Destes 82,5% (576) artigos foram excluídos, pois não estavam alinhados com o tema de pesquisa. No final desta etapa restaram na base de artigos brutos, apenas 11,6% (81) das obras selecionadas;

c) Filtros dos resumos dos artigos estão alinhados com o tema da pesquisa: Realizado mais um corte, desta vez, no que tange ao alinhamento do *abstract* com o tema de pesquisa. Dos 81 artigos filtrados na fase anterior, 72,8% (59) artigos foram removidos do portifólio, em função do *abstract* não estar alinhando com o tema de pesquisa. Restaram nesta fase 22 artigos.

d) Filtro de reconhecimento científico: Para verificação do reconhecimento científico dos 22 artigos, foram realizadas duas pesquisas: uma na base do *Google Scholar* para consultar os números de citações obtidas por cada artigo. Outra na base *Journal Citation Reports (JCR)*, para verificar, qual o fator de impacto científico dos periódicos indexados na Web of Science. Nesta fase, em relação às citações dos artigos na plataforma Google Scholar, apenas 4,5% (1) artigo não obteve nenhuma citação, mas foi considerado no portifólio por dois motivos: O primeiro por ser uma publicação de maio de 2019, e o segundo, por estar publicado no periódico com maior fator de impacto dentre as bases que compões o portifólio. Quanto o fator de impacto dos periódicos indexados na Web of Science, 27,2% (6) artigos foram eliminados por não obter o índice JCR, sendo 18% (4) foram publicados em congressos internacionais e 9% (2) foram publicados em revistas científicas internacionais. Restando 72,7% (16) para análise de alinhamento textual.

e) Filtro de alinhamento do texto integral com o tema de pesquisa: Ao final da seleção de portifólio 13 artigos foram relevantes e estão alinhados ao tema de pesquisa reconhecido cientificamente, tanto por citações das publicações, quanto pelo fator de impacto dos periódicos.

3.2 Análise Bibliométrica do Portfólio Bibliográfico

O processo de Análise Bibliográfica consiste na aplicação de métodos matemáticos e estatísticos [21]. Para [20], a análise bibliográfica foca em gerar conhecimento ao pesquisador sobre as características da pesquisa. Nesta etapa, [20] o pesquisador pode alcançar dados complementares sobre o tema de pesquisa e construir inferências para sustentar as suas escolhas. Sendo assim, [21] sugere o desenvolvimento da bibliometria em quatro etapas: 3.2.1 Estimar o grau de relevância dos periódicos;

3.2.2 Estimar o reconhecimento científico dos artigos; 3.2.3 Estimar o grau de relevância dos autores; 3.2.4 Estimar os termos de buscas mais utilizados.

3.2.1 Estimar o grau de relevância dos periódicos

Para estimar o grau de relevância do periódico foram consideradas duas análises: A **primeira** refere-se à identificação do periódico, que obteve o maior número de publicação. A análise evidenciou que os artigos do portifólio bibliográfico foram publicados em 12 periódicos. Deste portifólio, o "*International Journal of Production Research*" foi o que apresentou o maior grau de relevância, com duas publicações, os demais, apenas um cada. A **segunda análise** buscou-se avaliar o fator de impacto científico dos periódicos, onde os artigos do Portfólio Bibliográfico foram publicados. Esta análise seguiu por meio do JCR, uma ferramenta da Clarivate Analytics usada para avaliar e comparar periódicos. Para tanto, de acordo com a (Fig.2), segue, o *ranking* dos periódicos que compõe o Portfólio Bibliográfico. O *ranking* geral do JCR é composto por 12.515 posições e todos os 13 artigos do Portfólio Bibliográfico possuem relevância com impacto científico relevante indexado pelo (JCR). "A melhor classificação obtida foi pelo Periódico *"Technological Forecasting and Social Change"* na posição no *ranking* em 1784 com a publicação do artigo intitulado "*Influence of big data adoption on manufacturing companies' performance: An integrated DEMATEL-ANFIS approach"*. As demais classificações seguem na ordem de menor para maior posição do *ranking*.

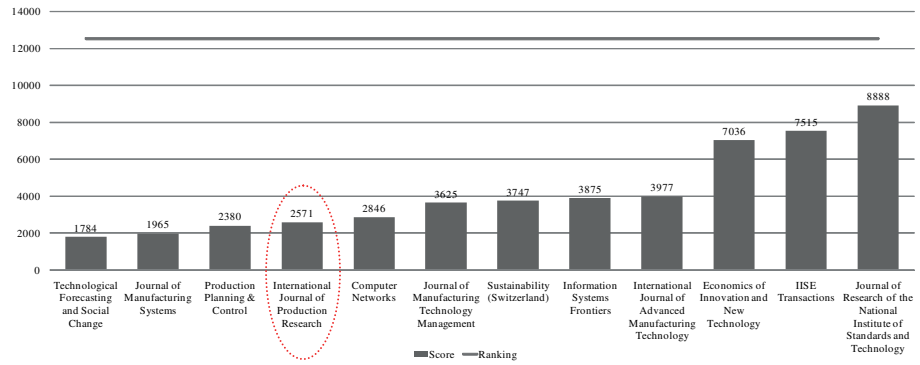

Fig.2. *Ranking* do Portfólio Bibliográfico. Adaptado de Journal Citation Reports (2019)

3.2.2 Estimar o reconhecimento científico dos artigos

O reconhecimento científico dos artigos do Portfólio Bibliográfico consiste em pesquisar a quantidade de vezes que o artigo foi citado, para isto utilizou-se como base de consulta, a plataforma *Google Scholar*. No contexto ilustrado pela (Fig.3), seguem os resultados. Todos os artigos apresentaram ao menos uma citação no indexador do Google Scholar. O artigo, que obteve o maior número de citação (127), está intitulado como "*Deep learning for smart manufacturing: Methods and*

applications publicado em (2018)". Vale considerar, que a data de publicação, no caso, publicações recentes apresentam menos citações, mas este fator, não reduz o grau de relevância do artigo, na pesquisa.

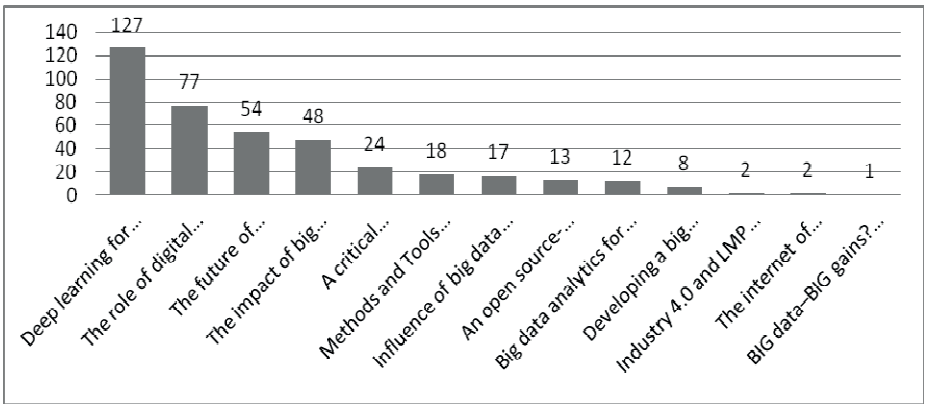

Fig.3. Citações dos artigos do Portfólio Bibliográfico. Adaptado de Google scholar (2019)

3.2.3 Estimar o grau de relevância dos autores

Nesta fase analisou-se por meio da plataforma Google Scholar o numero de vezes, que os autores foram citados em outras pesquisas. No total de 50 autores, 35 tiveram citações formalizadas e outros 15 não foram localizados na plataforma. A (Fig.4) apresenta os dez primeiros colocados citados em outras. As análises referem-se a somente a esta pesquisa.

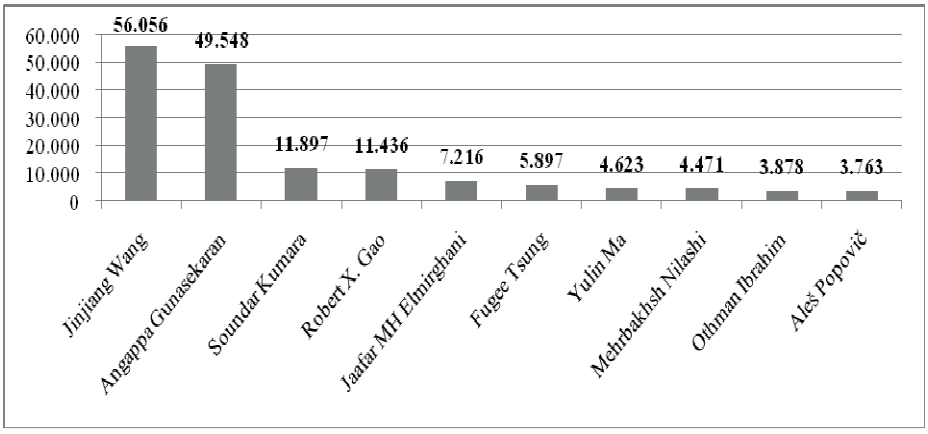

Fig.4. Citações dos 10 autores mais citadas em outras pesquisas. Adaptado de Google scholar (2019)

3.2.4 Estimar os termos de buscas mais utilizados

Neste caso, é interessante observar, através da (Fig.5), entre todos os 62 termos de buscas identificadas no Portfólio Bibliográfico, os 10 primeiros, correspondem a 55% dos que foram utilizadas nos eixos de busca da pesquisa.

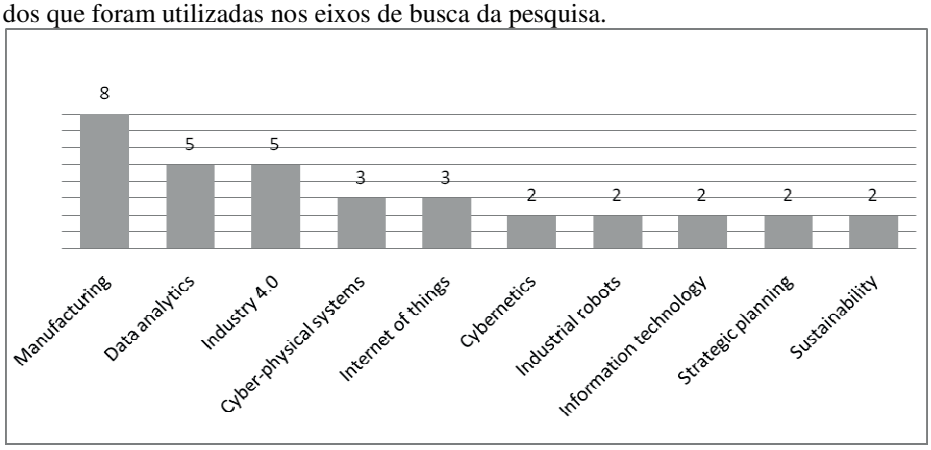

Fig.5. Relevância dos termos de buscas

3.3 Contribuições para o avanço da área

Sobre a avaliação de como esta sendo tratada a questão da medição de desempenho baseada em dados para máquinas, no contexto da indústria 4.0 percebeu-se, que o tema abordado, enfrenta grandes desafios, os quais vão desde a aplicação da pesquisa para o desenvolvimento para oferecer um roteiro estratégico, como guia para o processo de transição para a indústria 4.0 [6], até a avaliação de sucesso para a transformação das indústrias em fabricas inteligentes [26]. Evidenciou-se, nas literaturas pesquisadas dos últimos anos, que o tema incorpora outras dimensões sustentáveis na transformação digital [20]. Para [7, 9] estas dimensões podem auxiliar nas tomadas de decisões, no que tange a falta de conhecimento arquitetônico centrada na IoT, relacionada à grande quantidade de dados, com a dificuldade de coleta, armazenamento e análise deste volume de dados. A crescente ênfase na transformação digital está relacionada em apresentar um caminho para reduzir às limitações de recursos na revolução industrial 4.0, auxiliando a gestão das pequenas e médias indústrias, no processo de transformação digital [6]. Os resultados deste estudo podem ajudar a gestão destas pequenas e médias indústrias de manufatura, a focar com precisão nos fatores relevantes, para contribuir com os modelos de medição de máquinas baseada em dados para máquina, com as inovações tecnológicas, a fim de melhorar desempenho e competitividade futura de seus processos e estratégias [8]. A Tabela 2 apresenta uma lista de sugestões de pesquisas futuras inspiradas pelos autores, para o avanço e evolução da área identificada no Portfólio Bibliográfico.

Tabela 2. Relação das oportunidades identificada no Portfólio Bibliográfico

Aspectos de Avaliação	**Autores**	**Pesquisas Futuras**
Realização de pesquisas para a construção de um modelo	[6]	Identifica o melhor roteiro estratégico para a transição da indústria 4.0, na gestão das pequenas e médias empresas.
	[3]	Concentrar na aplicação de outras teorias para analisar a geração de conhecimento a partir dos dados gerados pelo monitoramento *online*; o retorno do investimento sobre as inovações tecnológicas em organizações, que estão muito longe da perspectiva operacional da indústria 4.0; realizar a aplicação e a implementação da estrutura proposta para analisar a integração do *Cyber Physical*.
	[7]	Investigar o *design* ideal da estrutura da arquitetura baseado em código aberto no processamento de dados *online* e melhorar o algoritmo de mineração de dados usando dados históricos de sensores para garantia do desempenho do processamento.
Desenvolvimento de modelos de medição	[27]	Desenvolver pesquisas em computação em nuvem e pesquisa sobre a inteligência computacional, incluindo aprendizado profundo.
	[28]	Desenvolver tecnologias para coletar, armazenar e processar dados, bem como aplicar a *big data* na transformação digital associada de inovação e novos modelos de negócios.
	[8]	Desenvolvimento de modelos teóricos de pesquisa em estudos exploratórios futuros e amplos usando análise estatística para a modelagem de equações estruturais; Aplicação de outras técnicas de *decision making*, como preferência por similaridade com a solução ideal e *Analytic Network Process,* combinados com técnicas sofisticadas de computação para produzir resultados mais interessantes; Realizar a comparação entre as perspectivas de diferentes de clientes, funcionários e fornecedores; e Mensusrar o impacto da adoção de *big data* investigando desempenho financeiro e não financeiro das empresas de manufatura.
Implementação e aperfeiçoamento	[4]	Avançar em um ambiente de *cyber-physical* production systems CPPS de forma *online,* onde o controle em tempo real será mais desafiador.
	[29]	Empregar a computação quântica para fins de aprendizado de máquina e poder ajudar a destronar “lei de Moor”, fornecendo mais espaço de processamento por unidade de tempo.
	[30]	Aperfeiçoar a exploração dos dados com a utilização do *Big Data Analytics* (BDA) para contribuir com a melhoria das operações e destacar seu desempenho.

Tabela 2. Continuação: Relação das oportunidades identificada no Portfólio Bibliográfico

Aspectos de Avaliação	Autores	Pesquisas Futuras
Medição dos dados	[9]	A realização da medição de desempenho para *smart manufacturing systems* (SMS).
	[5]	Estimular a abordagem sobre o desenvolvimento de novas Tecnologias *internet of manufacturing things* (IoMT) e metodologias analíticas para melhorar serviços de manufatura e otimizar os sistemas de manufatura.
Replicação	[31]	Replicar as descobertas sobre papel das tecnologias digitais para o serviço na transformação de empresas industriais.
Avaliação do sucesso	[26]	Desenvolver pesquisa utilizando uma rede bayesiana para expressar as dependências causais entre os constructos usando probabilidades condicionais, considerando o tipo de *tecnologia para a indústria 4.0* como o variável moderada para estudar o efeito da pratica *lean manufacturing* na *sustentabilidade organisational performance*; Desenvolvimento de um sistema de apoio à decisão que possa ser usado para prever a *sustentabilidade organisational performance para* completar os estudos longitudinais e entender, como implantação das tecnologias da indústria 4.0 influenciam nas conclusões do presente estudo no futuro.

4.4 Modelo para medição do desempenho de equipamento

De acordo com as oportunidades identificadas no Portfólio Bibliográfico, relatado pela Tabela 2 construída com base nas sugestões de pesquisas futuras inspiradas pelos autores [3, 4, 5, 6, 7, 8, 9, 26, 27, 28, 29, 30, 31] apresenta-se uma proposta de um modelo para medição de desempenho baseada em dados para máquinas**,** ilustradas pela (Fig.6), contemplando a integração deste modelo por três camadas, sendo elas:

***Manufatura* (*Entradas*)**: Este módulo acomoda diferentes tipos de atividades e consiste na entrada de informações e recursos para a produção da manufatura e a coleta de dados aplicada por meio do monitoramento *online*, onde: **A máquina**: informações da capacidade produtiva e parâmetros de produção, tais como: tipo de produtos, produção/hora entre outros; **Processo:** Determinar o processo de acordo com o tipo de produto. Por exemplo: produto 1- linha a, b, c; Produto 2 – linha b, c, d; **Informação:** Toda a informação do processo será enviada para ser processada; **Pessoas:** o recurso mais importante da operação será responsável por lançar dados no sistema e interpretar os dados monitorados para serem analisados e decisões serem tomadas;

Análise de dados* (*Transformação de Processos*)**: Este módulo consiste em duas funções: ***Armazenamento: utilizado para o armazenamento dos dados coletados e

Processamento de dados: dados coletados serão processados para gerar informações relevantes do processo;

Medição do desempenho (Saídas): O módulo permite a gestão visual das informações dos dados coletados e processados de forma *online* para auxiliar as tomadas de decisões para o gerenciamento da produção. Os dados podem ser apresentados por indicadores chaves do desempenho, no qual possibilita não só a gestão da produção, como também a operação da produção, a enxergar de forma clara, o desempenho monitorado do equipamento.

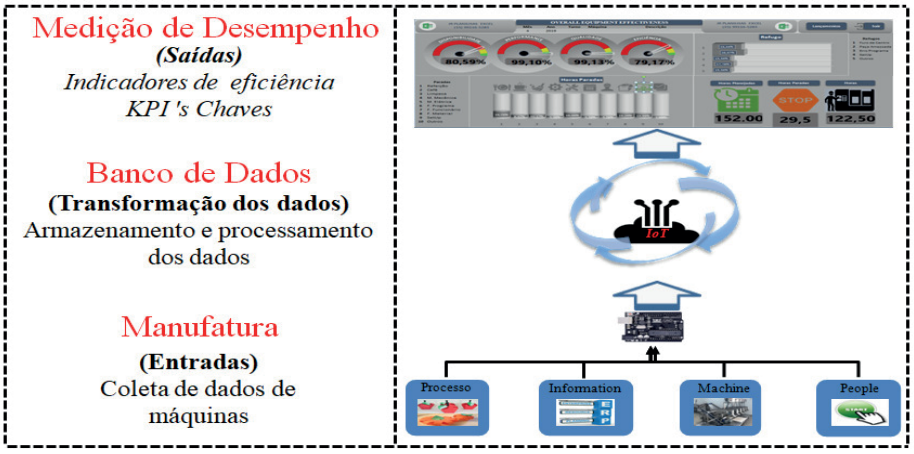

Fig.6. Manufatura Conectada

4. Conclusão

A **Análise Bibliométrica** composto por 13 artigos selecionados apresentou como resultado os seguintes dados: Os artigos foram selecionados em 12 periódicos indexados no JCR, sendo que a melhor classificação obtida foi pelo Periódico, "Technological Forecasting and Social Change" com posição no ranking de n° 1.784. O periódico com o maior grau de relevância foi o "*International Journal of Production Research*", o qual apresentou dentre os demais, duas publicações selecionada para o Portifólio Bibliográfico. No que tange o reconhecimento científico dos artigos do Portfólio Bibliográfico publicados entre o anos de (2013 e 2019), todos obtiveram índice de citação no Google Scholar, sendo o artigo com o maior número de citação (127) está intitulado como "*Deep learning for smart manufacturing: Methods and applications* publicado em (2018)".

Para o grau de reconhecimento dos 50 autores identificados no Portfólio Bibliográfico considerou-se o fator de impacto cientifico dos artigos publicados em nas bases medidas pelo (JCR) e as citações dos autores em outras publicações medidas por meio da plataforma Google Scholar, neste quesito, 15 autores não foram localizados na

plataforma, os demais apresentaram reconhecimento científico relevante. Quanto às análises dos termos de buscas foram identificados 62 termos, destes 55% também compõe os termos de buscas que foram utilizadas nos eixos da pesquisa e estão classificados entre os 10 primeiros mais citados nos artigos do Portfólio Bibliográfico.

A revisão sistemática possibilitou buscar na literatura, alguns dos principais artigos reconhecidos cientificamente, para tomar conhecimento sobre quais temas estão sendo tratados pelos pesquisadores na atualidade, sobre a medição de desempenho. Desta forma, possibilitou conhecer, quais periódicos são os mais relevantes sobre o tema de pesquisa, quais termos de buscas está sendo utilizados nas publicações e identificar neste portifólio, quais contribuições podem ser relevantes para serem aplicadas em pesquisas futuras. Neste contexto, o objetivo da pesquisa sobre a avaliação de como esta sendo tratada, a medição de desempenho baseada em dados para máquinas, no contexto da indústria 4.0 foi alcançado, pois com base nas propostas de contribuições inspiradas em pesquisas futuras para avanço da área, foi proposto um modelo medição do desempenho com base em dados de máquinas, compondo-se de três módulos (*manufatura, banco de dados e medição do desempenho*) para coletar, armazenar e transformar os dados em informações a ser gerenciadas por meio de indicadores. Com este resultado da-se por concluída a pesquisa, tendo como o objetivo proposto sendo alcançado e os resultados como satisfatórios.

Para futuras pesquisas, mesmo considerando que já existe algo pronto como (ferramentas/algoritmos e outras tecnologias de dados maduras) cabem a implementação e a avaliação dos resultados desta proposta.

Resumen.
Un laboratorio de análisis de materiales para obras de ingeniería civil proporciona servicios a la población, sin embargo, actualmente el tiempo requerido para realizar cada prueba no está documentado, simplemente se deja al conocimiento del personal técnico; es decir, cuando llega un cliente y solicita algún servicio, la persona que los atiende, de acuerdo con su experiencia, le proporciona el tiempo aproximado de entrega. El proceso inicia llenando una solicitud y finaliza entregando el informe de resultados, previo al llenado de una encuesta de calidad. El objetivo de este artículo se enfoca en dos aspectos relevantes para la evaluación y análisis de un servicio, primero, se definen indicadores de desempeño y después se modela e implementa el modelo de simulación para estimar valores resultantes para el proceso en estudio, con base en ambos, será posible evaluar y analizar el sistema a desarrollar para seleccionar las propuestas de mejora. El trabajo sigue una metodología de 5 pasos, siendo: (1) análisis de datos, (2) descripción de elementos de soporte, (3) establecimiento de KPIs, (4) definición de procesos operativos del laboratorio y (5) implementación de un modelo de simulación. Con la ejecución de esta metodología fue posible estimar el nivel de servicio del proceso, y es posible simular los valores esperados para futuras operaciones del laboratorio con la finalidad de evaluar los KPIs y a partir de estos mejorar el nivel de servicio de los clientes.

Palabras clave: Laboratorio de materiales, órdenes de trabajo, desempeño, KPI's, simulación

1. Introducción

La medición del desempeño en los procesos u operaciones que realiza una empresa, permiten conocer si están siendo realizados conforme al nivel esperado, los indicadores claves de desempeño (KPIs) son métricas muy utilizadas para determinar el cumplimiento de las actividades en una empresa Toor & Ogunlana (2009) consideran que los KPIs son útiles, ya que permiten comparar el desempeño actual contra el esperado en términos de efectividad, eficiencia y calidad; así mismo los KPIs permiten evaluar el desempeño de todas las partes involucradas en la cadena Sellitto et al. (2015) a través de los Operadores de Referencia de la Cadena de Suministro (SCOR) que consisten en procesos estandarizados de la cadena de abastecimiento, métricas y atributos de desempeño normalizados, prácticas y habilidades laborales tipificadas; consideran que el SCOR permite evaluar la confiabilidad, la capacidad de respuesta, la agilidad, y los costos.

Los KPIs deben representar las necesidades y objetivos de la empresa, y al mismo tiempo deben estar orientados a la misión y visión, tal como Shahin y Mahbod (2006) indican que los KPIs reflejan y se derivan a partir de los objetivos de la organización, así mismo, cada indicador debe estar basado en criterios que permitan su posterior análisis, Palma (2014) considera que las métricas utilizadas en el nivel uno de los modelos SCOR son KPIs y la función de estos es medir y expresar el rendimiento general de una característica en específico, Gunasekaran et al. (2004) consideran que la medición del desempeño de las cadenas de suministro se puede realizar en tres niveles: estratégico, operacional y táctico, así mismo, las métricas utilizadas para medir el desempeño y el mejoramiento en cada nivel deben capturar verdaderamente la esencia del desempeño organizacional.

Al momento de realizar algún proyecto es de gran importancia evaluar el desempeño logrado durante el avance del mismo, por lo que es necesario establecer indicadores que determinen si el desempeño se encuentra en el nivel deseado, Ogunsanmi (2013) menciona que los KPIs pueden ser utilizados para identificar las fortalezas y debilidades en proyectos compartidos entre el sector público y privado, además de ser herramientas útiles para la gestión del desempeño de los proyectos, Ugwu y Haupt (2005) hacen referencia que al momento de desarrollar estrategias efectivas para entornos sustentables en la construcción, es necesario considerar 3 elementos claves: 1) una formulación clara y establecimientos de objetivos, 2) identificar y evaluar alternativas en términos cuantitativos y/o cualitativos y 3) una implementación efectiva de la alternativa seleccionada; por lo que, para desarrollar el segundo punto es necesario establecer KPIs que permitan evaluar aquellas alternativas que sean establecidas en ambos términos.

Cuando es requerido establecer KPIs se debe considerar que no todos los indicadores son aplicables a los mismos proyectos o empresas, estos no deben ser vistos de manera general, dependiendo de las necesidades del proyecto o de la industria, y en conjunto con la misión, visión y objetivos establecidos, los KPIs determinan diferentes aspectos. Kang et al. (2016) realizan una descripción detallada de los KPIs utilizados en su investigación, consideran elementos de soporte como tiempo, cantidad y mantenimiento, luego se establecen las relaciones entre cada elemento que servirán para medir aspectos específicos dentro del sistema.

Al tratar de replicar o imitar el comportamiento de algún sistema o las operaciones que realiza una empresa, es necesario apoyarse en técnicas de simulación de procesos. Gómez et al. (2015) hacen referencia que la simulación puede ser utilizada con la finalidad de dar solución a problemas reales, mediante el análisis y descripción del comportamiento del sistema, así mismo Rouzafzoon (2016) recreó los servicios ofrecidos en un hospital, considerando que para medir el desempeño de los resultados en el modelo de simulación es necesario establecer KPIs, el autor considera el nivel de servicio como un aspecto crítico en la administración de los hospitales.

Para reproducir la forma en que una empresa está operando, es necesario describir todos los procedimientos que son realizados, desde la solicitud de algún servicio o bien la contratación para elaborar algún producto, Sánchez et al. (2015) consideran que para desarrollar el proceso de simulación se debe tomar en cuenta como insumo la estructura real del proceso productivo, de esta manera, se deben detallar todos aquellos procedimientos involucrados para cumplir los requerimientos de los clientes.

Por lo anterior mencionado, y en referencia a lo que se hizo, se tienen que considerar todas las entradas al sistema como la cantidad de presupuestos a elaborar, la cantidad de órdenes de trabajo (OT) a cumplir, así mismo, todos aquellos insumos que son necesarios para atender los requerimientos de la demanda de los seis tipos de servicios.

Para todo esto se requiere poseer un amplio conocimiento de los procesos de transformación, por ejemplo, qué proceso es necesario realizar para transformar un presupuesto en el resultado de una prueba solicitada, así como los tiempos que tarda la elaboración de la prueba, y finalmente conocer las salidas del sistema real (porcentaje de OT, el ingreso neto obtenido, entre otras). Así mismo, es importante caracterizar correctamente todas estas variables, ya que permitirán establecer las bases para desarrollar el modelo de simulación con el uso de algún software y establecer escenarios, para identificar la manera más eficiente de gestionar los recursos del laboratorio frente a diferentes condiciones de demanda, decisiones que se tomarían a partir de la generación de los KPIs en cada escenario evaluado.

El artículo está estructurado de la siguiente manera: en la sección 2, se describe la metodología aplicada para atender el caso de estudio; en la Sección 3 se explica el caso de estudio, así como los elementos necesarios para establecer los KPIs y el modelo de simulación; en la Sección 4 se muestran los resultados obtenidos, y en la última sección se discuten los principales hallazgos y las conclusiones del presente trabajo.

2. Descripción del Método

Las herramientas de simulación permiten recrear el comportamiento de las actividades que realiza una empresa. Gómez et al. (2015) consideran que mediante la simulación se pueden desarrollar escenarios de sistemas complejos con el objetivo de comprender su comportamiento. Los modelos de simulación de acuerdo con Morales et al. (2013) están compuestos por un conjunto de representaciones, expresadas como relaciones matemáticas, lógicas o simbólicas, entre las entidades que interactúan en el sistema, pues a través de la simulación es posible conocer aspectos fundamentales en la opera-

ción de las empresas. Sánchez et al. (2015) consideran que la aplicación de esta herramienta ofrece una alternativa para conocer de forma correcta los puntos críticos que pueden tener los procesos de producción y plantear soluciones que aumenten la eficiencia y disminuyan el tiempo de ejecución de diferentes actividades.

Para establecer las bases necesarias para el desarrollo de un modelo de simulación Andrés et al. (2016) consideran necesario diferenciar 3 tipos de variables dentro del sistema. En la tabla 1 se muestran los tipos de variables:

Tabla 1. Clasificación de Variables

Tipo de variable	Descripción
De Nivel	Representan acumulaciones del sistema, normalmente son las variables más importantes y muestran cada instante la situación del modelo, cada variable de nivel está asociada a una o varias variables de flujo.
De Flujo	Determinan la variación de los niveles, recogen las acciones resultantes de las decisiones tomadas en el sistema, determinando las variaciones de los niveles.
Auxiliares	Son parámetros que permiten una mejor visualización de los aspectos que condicionan el comportamiento de los flujos.

Fuente: Modificada a partir de Campuzano et al. (2010), Andrés et al. (2016)

La metodología que se propone se presenta en la figura 1:

Figura 1. Diagrama de la metodología para abordar el caso de estudio
Fuente: Elaboración propia

En el primer paso se realiza la recolección de todos los datos iniciales relacionados a la atención de órdenes de trabajo del laboratorio del caso de estudio, posteriormente en la descripción de los elementos de soporte se detallan los elementos que son susceptibles a contabilizar como el número de presupuestos, los presupuestos confirmados (OT), tiempo de confirmación, etc. Para el establecimiento de KPIs, es necesario describir la relación que guardan los elementos de soporte y con base en ello, establecer los indicadores que permiten conocer la situación actual del laboratorio del caso de estudio.

Luego, para el desarrollo de los procesos operativos se menciona de manera general los procesos que son realizados, así como el tiempo que tardan en completar las órdenes de trabajo. Finalmente, para el desarrollo del modelo de simulación es necesario contar con las bases anteriormente mencionadas, para así establecer los parámetros que permitan estimar el nivel requerido de los KPIs. Cabe mencionar que la administración de laboratorio del caso de estudio, no está a cargo de los autores.

3. Aplicación de la metodología al caso de estudio

Este laboratorio se encarga de realizar análisis de materiales para la construcción, las pruebas están orientadas a acero, concreto hidráulico, concreto asfaltico, elementos prefabricados, geotecnia y topografía, que mediante el análisis de estas pruebas es posible conocer las propiedades físicas de los materiales en cuestión, la forma en que se atiende una OT se muestra en la figura 2

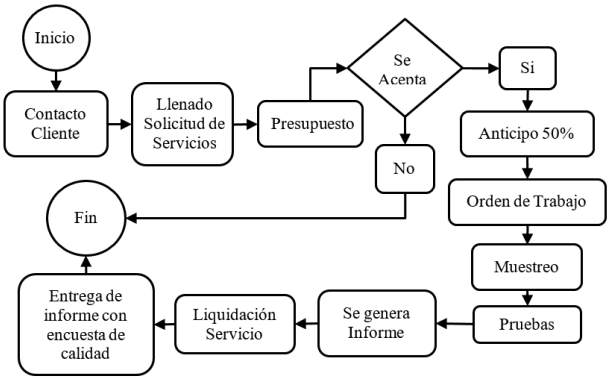

Figura 2. Procesamiento de órdenes de trabajo
Fuente: Elaboración propia

Según la figura 2, se inicia con el llenado de solicitud de un servicio para realizar un presupuesto de alguna de las pruebas ya mencionadas, cuando los clientes aceptan el presupuesto, se considera confirmado y se convierte en una OT, por lo tanto, a partir de este momento el tiempo de servicio inicia y una vez que la última prueba ha sido realizada se detiene el tiempo que tarda una OT en ser completada. Debido a la naturaleza del laboratorio, no se considera el tiempo en que se genera el informe, ya que este es elaborado una vez que las pruebas son terminadas y se entrega al momento de la liquidación de los servicios.

En la figura 3 se observa de manera general la operación del laboratorio.

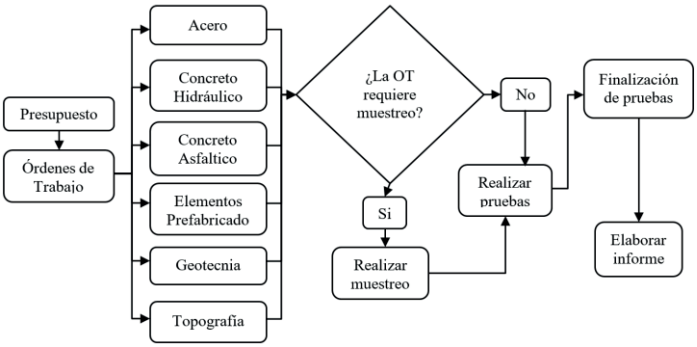

Figura 3. Operación general del laboratorio
Fuente: Elaboración propia

La figura 3 indica que los presupuestos que son recibidos, sin embargo, solo un porcentaje de los presupuestos solicitados se convierten en una OT, dependiendo de la preferencia de los clientes puede ser cualquiera de los 6 servicios previamente mencionados, así mismo, conforme al tipo de servicio de la OT ésta requerirá un muestreo y diferentes pruebas serán realizadas.

Las cifras reales obtenidas a cerca de los prepuestos y órdenes de trabajo que solicitaron los clientes de manera mensual durante el año 2019, se presentan en la tabla 2 y en la tabla 3, en la cual las abreviaturas corresponden de la siguiente manera:

- PRE = Presupuesto
- AC = Acero
- CAS = Concretos Asfalticos
- CHA = Concretos Hidráulicos
- EP = Elementos Prefabricados
- GA = Geotecnia
- MULTI = Múltiple
- CONF = Confirmación

Tabla 2. Porcentajes de confirmación de OT del año 2019

Mes	PRE AC	OT AC	PRE CAS	OT CAS	PRE CHA	OT CHA	PRE EP	OT EP	PRE GA	OT GA	PRE MULTI	Total PRE	Total OT	% CONF

Total	22	17	7	2	51	39	2	1	106	30	9	197	90	45.66

Tabla 3. Porcentajes de confirmación y preferencia de servicio del año 2019

Porcentajes	AC	CAS	CHA	EP	GEO	MULTI	Confirmación General
% Confirmación por servicio	77.27	28.57	76.47	50.00	28.30	0.0	45.69
% Preferencia por servicio	11.17	3.55	25.89	1.02	53.81	4.57	100%

La figura 4 muestra la preferencia de los clientes para el año 2019.

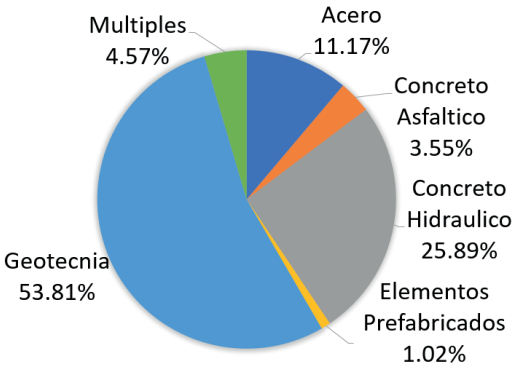

Figura 4. Preferencia de los servicios del año 2019 para los 6 tipos de servicios
Fuente: Elaboración propia

Existe una preferencia muy marcada para los servicios de geotecnia y concreto, así mismo, estos porcentajes servirán como base para establecer la distribución del tipo de servicio solicitado en los presupuestos.

En la tabla 2 se puede observar que existe una mayor carga de trabajo en los meses de febrero, abril, agosto, septiembre y noviembre, debido a que más del 50% de los presupuestos fueron confirmados, así mismo casi todos estos meses se confirmaron más de 10 órdenes de trabajo, estos datos serán utilizados para realizar la simulación, por ejemplo, para el mes de abril de un total de 26 presupuestos recibidos solamente se confirmaron aproximadamente el 61.54%, por lo que, 16 órdenes de trabajo deberán ser atendidas.

La categorización de los datos se realizó de la siguiente manera:

1) Fecha de solicitud de presupuesto
2) Tipo de servicio
3) Fecha de orden de trabajo
4) Descripción del servicio solicitado
5) Fecha de entrega de la orden de trabajo

De esta manera es posible conocer la fecha en que un presupuesto fue solicitado y el tiempo que tarda en confirmar el cliente (fecha de OT), los tipos de órdenes y la descripción de los servicios que solicitan los clientes permiten tener una estimación del tiempo necesario para atender la OT; en resumen, se pueden conocer todas las entradas del sistema.

3.1 Establecimiento de los KPIs

Para determinar si el nivel de servicio está siendo alcanzado a la meta fijada, en la tabla 4 se puede observar los KPIs establecidos:

Tabla 4. Indicadores claves de desempeño a considerar de forma general.

KPI	Cálculo
% de confirmación por servicio (1)	%CS = PRE Confirmados / PRE Recibidos
% de confirmación Total (2)	%CT = PRE Totales Confirmados / PRE Totales Recibidos
Órdenes atendidas (3)	OA = Total de órdenes atendidas
Órdenes en atención (4)	OEA = Total de órdenes en proceso
% de atención de órdenes (5)	%AO = Órdenes atendidas / Órdenes en el sistema

3.2 Desarrollo de los procesos operativos

Para desarrollar el modelo de simulación primeramente es necesario describir el proceso real que sigue el laboratorio, en la figura 5 y 6 se muestra el proceso:

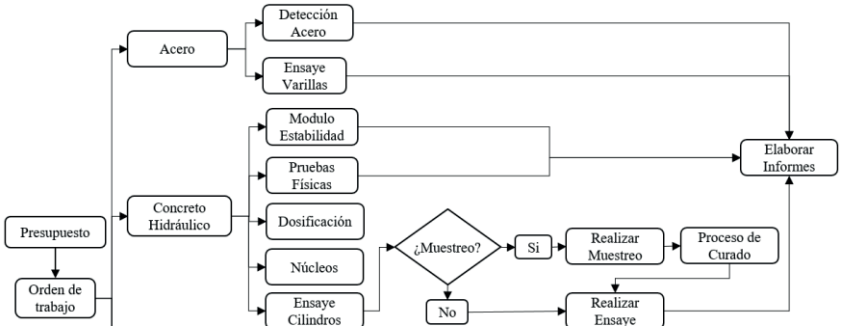

Figura 5. Procedimientos para los servicios de AC y CHA
Fuente: Elaboración propia

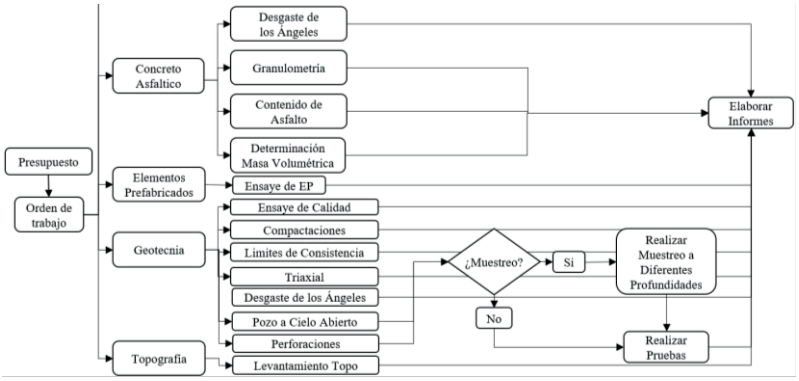

Figura 6. Procedimientos para los servicios de CAS, EP, GEO y Topografía
Fuente: Elaboración propia

De la figura 5, se inicia el proceso recibiendo la solicitud de presupuestos, la cual no necesariamente es la misma de manera diaria, así mismo, se asigna un número de presupuesto que permite realizar procesos de trazabilidad; un porcentaje de estos presupuestos es confirmado lo cual procede a convertirse en una OT, por ejemplo, en la tabla

2 para el mes de abril existe una probabilidad de casi el 62% de que un presupuesto se confirme (OT) y de nuevo se establece un número de OT dependiendo del tipo de servicio contratado, el número de OT está ligado con el número de presupuesto.

La forma en que se procede a atender las OT es considerando la disciplina de líneas de espera FIFO; es decir, las primeras OT que ingresan al laboratorio deben ser las primeras en salir, sin embargo, el tiempo de ejecución de las pruebas es variable y esto provoca que, para las salidas (entrega del informe) no se observe ese comportamiento.

De los seis tipos de servicio, en cuatro de ellos, se requiere el traslado del personal al sitio donde se realiza la obra de construcción para extraer muestras de material; en otros casos, los clientes llevan sus muestras, por lo que este tiempo es considerado en la duración de ejecución de las pruebas.

Una vez que todas las pruebas han sido ejecutadas los resultados son reportados en los libros correspondientes, estos sirven como base para elaborar los informes de los clientes, por último, se le solicita al cliente la liquidación de los servicios, que al término de esta se le entrega el informe y se finaliza el proceso con aplicación de la encuesta de calidad de servicio.

3.3 Desarrollo del modelo de simulación

Para replicar el comportamiento del laboratorio a través de un modelo de simulación, fue necesario determinar las propiedades del sistema real, las cuales son establecidas de me manera previa, y que a su vez debe permitir que varíen durante el proceso de la simulación (Chase, & Aquilano, N. J., 2009).

Para el desarrollo del modelo de simulación fue necesario el uso de herramientas computacionales que permitieron recrear la manera en la cual el laboratorio procesa las OT, eligiéndose el software Arena® ya que en su versión estudiantil ofrece los recursos necesarios para la implementación del modelo y para realizar la simulación se utilizó una computadora personal con un procesador Intel Core i3, con una memoria RAM 4.0 GB y con un sistema operativo de 64 bits.

3.3.1 Definición de parámetros

Para la ejecución del proceso de simulación serán considerados los meses en los cuales hubo 10 o más OT confirmadas (febrero, abril, agosto y septiembre), los parámetros bajo los cuales el modelo de simulación se regirá se muestran en las tablas 5 y 6 en las cuales PRO = Probabilidad

Tabla 5. Parámetro de probabilidad de pruebas y confirmación por mes

Tipo de Servicio	% PRO PRE Mes 2	% PRO CONF Mes 2	% PRO PRE Mes 4	% PRO CONF Mes 4	% PRO PRE Mes 8	% PRO CONF Mes 8	% PRO PRE Mes 9	% PRO CONF Mes 9
AC	17	100	31	100	11	50	0	0
CAS	0	0	0	0	11	0	5	0

CHA	33	50	19	100	36	71	40	88
EP	0	0	4	0	0	0	0	0
GA	44	38	46	25	42	50	55	28
MULTI	6	-	0	-	0	-	0	-

En la tabla 5 no se consideran los presupuestos múltiples, debido a que este en tipo de solicitudes, los clientes sólo preguntan para conocer el costo de los servicios.

Tabla 6. Parámetro de probabilidad de pruebas por tipo de servicio por cada mes

Tipo de prueba	% PRO prueba Mes 2	% PRO prueba Mes 4	% PRO prueba Mes 8	% PRO prueba Mes 9
Acero				
Detección de Acero	25	0	0	0
Ensaye de Varillas	75	100	100	0

3.3.2 Definición de variables

Variables de nivel
Estas variables permiten acumular las OT y solo varían de acuerdo al comportamiento de las variables de flujo, dentro del modelo se consideran las siguientes:

Llegadas de presupuestos: representa la cantidad de presupuestos que llegan de manera diaria

OT sin confirmar: indican la cantidad de presupuestos que no fueron confirmados

OT atendidas: son todas las OT que fueron completadas

Variables de flujo
Este tipo de variables determinan la variación de los niveles, así mismo recolectan la información que resulta a partir de las acciones tomadas dentro del sistema, para el desarrollo del modelo se considera el tiempo necesario para realizar las pruebas de los servicios correspondientes, el tiempo de ejecución está considerado en días, en la tabla 7 se muestra las distribuciones que fueron establecidas para la ejecución del modelo de simulación.

Variables auxiliares
Para el caso de estudio, no fue necesario recurrir a este tipo de variables.

Tabla 7. Distribuciones para las variables de flujo

Proceso	Distribución
Llega presupuestos febrero	Triangular (1,1,4)
Llega presupuestos abril	Triangular (1,2,10)

4. Resultados

La ejecución del modelo de simulación se realizó considerando los meses que contaron con 10 o más OT confirmadas, las cuales representan también un mayor nivel de confirmación (50% o más), la duración de la simulación fue 30 días. En la tabla 8 se muestran los resultados, en la tabla 9 se observan los KPIs resultantes del proceso de simulación y en la tabla 10 se muestran los KPIs obtenidos a partir de los datos del año 2019

Tabla 8. Resultados del modelo se simulación

OT	Mes 2	Mes 4	Mes 8	Mes 9
Presupuestos recibidos	18	8	12	13
OT confirmadas	4	5	3	6
OT rechazadas	14	3	11	7
OT atendidas	3	5	3	6
OT en proceso	1	0	0	0

Tabla 9. KPIs obtenidos, según el modelo de simulación

KPI	Mes 2						Mes 4					Mes 8					Mes 9

%AO				66.67						100.00					100.00					100.00	

Tabla 10. KPIs obtenidos de acuerdo a los datos del año 2019

KPI	Mes 2						Mes 4					Mes 8					Mes 9				
	AC	CAS	CHA	EP	GA	MUTI	AC	CAS	CHA	EP	GA	AC	CAS	CHA	EP	GA	AC	CAS	CHA	EP	GA
PRE	3	0	6	0	8	1	8	0	5	1	12	2	2	7	0	8	0	1	8	0	11
OT	3	0	2	0	3	0	8	0	5	0	3	1	0	5	0	4	0	0	7	0	3
%CS	100	0	33.33	0	37.5	0	100	0	100	0	25	50	0	71.42	0	50	0	0	87.5	0	27.27
%CT				44.44						61.53					52.63					50	
OA	3	0	2	0	3	0	8	0	4	0	2	1	0	5	0	4	0	0	7	0	3
OEA	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0
%AO				100						87.5					100					100	

Para el mes 2, logró una atención en las OT del 66.67%; es decir, una de las tres órdenes se quedó en proceso, esto se debe a que una de las OT fue de CHA y fue de la prueba de muestreo y ensaye de cilindros, la cual tiene una durabilidad de 28 días, conforme a la norma NMX-C-159-ONNCCE-16, considera que para pruebas de concreto hidráulico, es necesario 28 de curado para su análisis de resistencia a la compresión. En el mes 4, se tuvo una orden de atención del 100%; es decir, se atendieron las cinco órdenes que llegaron, lo cual demuestra que atendiendo esa cantidad de OT es posible cumplir los requerimientos de los clientes, del mismo modo para el mes 8 y 9, se obtuvo el 100% de atención de las órdenes que ingresaron, siendo estas 3 y 6 respectivamente.

5. Conclusiones

A través del establecimiento de los parámetros para los 4 meses con mayor cantidad de OT confirmadas, es posible conocer el comportamiento del laboratorio. Así mismo, considerando este nivel de trabajo, el laboratorio es capaz de atender la demanda de los meses restantes, tomando en cuenta los parámetros establecidos. En la tabla 9 se puede observar que la preferencia sobre los servicios de GA y CHA siguen manteniéndose comparado con la tabla 3, sin embargo, los porcentajes de confirmación por cada mes fueron menores.

Mediante la aplicación de herramientas de simulación, fue posible determinar si el laboratorio está atendiendo las OT con el nivel de atención esperado, como se puede observar en la tabla 9 el laboratorio puede atender correctamente las OT que ingresan a él, para los 4 meses establecidos.

Comparando las tablas 9 y 10 es posible observar que el indicador %AO tiene un rendimiento similar considerando la propuesta del modelo de simulación, sin embargo, esto se debe a que la mayoría de las pruebas entrantes tienen un corto tiempo de duración, así mismo, se debe considerar que aquellas órdenes que llegan a final de mes no podrán ser completadas durante el mismo mes, lo que a primera vista podría ser indicativo de un bajo rendimiento, en cambio, una forma de considerar el nivel de atención sería contemplarla para el mismo mes, de esta forma no afectaría los meses consecuentes.

A partir de los resultados obtenidos, se puede concluir que actualmente el laboratorio se encuentra operando con un nivel de servicio cercano al 100%, mediante el establecimiento de los KPIs fue posible determinar el nivel de servicio que el laboratorio está ofreciendo hacia los clientes, de la misma forma, con las métricas establecidas se puede detectar alguna alteración en la atención de las OT para cada tipo de servicio, o bien, reforzar los procedimientos para seguir garantizando el nivel de servicio esperado por los clientes.

Despacho óptimo de buses eléctricos bajo incertidumbre en los tiempos de viaje

Karam A. Kharrat, Víctor M. Albornoz and Linco J. Ñanco

Universidad Técnica Federico Santa María,
Departamento de Industrias, Santiago, Chile.
karam.kharrat.14@sansano.usm.cl

Resumen. Actualmente, Santiago de Chile es la segunda ciudad del mundo con más buses eléctricos y uno de los problemas importantes que debe abordar el sistema de transporte público es el despacho óptimo de estos, teniendo en cuenta una programación de salidas dada y tiempos de viajes que son considerados estocásticos. En este trabajo se contempla planificar los despachos de dos almacenes de buses en un día completo de operación, dividido en ciertas franjas horarias, en las cuales se tiene determinados comportamientos de los tiempos de viaje y disponibilidad de buses. Se formula un modelo de optimización estocástica con recurso de múltiples etapas y se resuelve una instancia en particular para así determinar la respectiva secuencia de salidas e instantes en que se cargará la batería de cada bus con el propósito de atender el plan de salidas propuesto inicialmente.

Keywords: Ciudades inteligentes, buses eléctricos, programación estocástica multietapa, problema de programación de vehículos con múltiples almacenes.

1. Introducción

Aspectos tan importantes como la sustentabilidad y la reducción en las emisiones de gases con efecto invernadero están presentes en el diseño y funcionamiento de los actuales sistemas de transporte público. En este sentido, tanto en Europa como en Asia ya operan buses eléctricos desde hace algunos años, y, en el caso específico de Santiago de Chile, esto ocurre desde marzo de 2019 [1]. Es más, a finales del año 2019, Santiago se consolidó como la segunda ciudad del mundo con más buses eléctricos, con un total de 386 buses [2]. Asimismo, en junio del presente año, el Ministerio de Transporte y Telecomunicaciones de Chile anunció que se espera duplicar prontamente la flota actual, llegando a disponer en un breve plazo de 776 vehículos eléctricos [3]. Con estos buses no solo se busca disminuir las emisiones de CO_2 del sistema, sino también mejorar la calidad del servicio, pues estos poseen aire acondicionado, espacios para cargar dispositivos eléctricos, etc. Sin embargo, su empleo también plantea desafíos operacionales al momento de satisfacer el cumplimiento de salidas programadas, ya que su despacho debe tomar en cuenta el nivel de la batería y programar sus respectivas

cargas frecuentemente. Lo anterior, sumado a la incertidumbre de las condiciones de tráfico durante el día, generan antecedentes a tomar en cuenta en el despacho de los buses eléctricos.

En [4] se detalla el problema de la programación de vehículos convencionales (VSP por sus siglas en inglés), en donde se presentan los distintos antecedentes asociados a este problema, tipos de programación de vehículos y sus variaciones. Sin embargo, no se tratan buses eléctricos, ni aspectos estocásticos en los modelos presentados, a diferencia del problema que aborda el presente trabajo.

Con respecto a las variaciones en el modelo base en vehículos convencionales, [5] estudia el problema en ciudades grandes que poseen múltiples almacenes de buses. Para abordar este problema generalmente se tiende a descomponerlo en problemas de programación (scheduling) para cada uno de estos almacenes tratados individualmente. El modelo propuesto es utilizado en un día completo de operación subdividido en mañana, tarde y noche y resuelto a través de una heurística ad–hoc.

En [6] se aborda el despacho de buses eléctricos sin considerar cambio de batería, contemplando una discretización de los niveles de batería para decidir cuántos viajes hará el bus antes de tener que volver al terminal a realizar una carga. Los autores resuelven cuatro instancias de su modelo, donde las primeras dos son de pequeño y mediano tamaño y fueron resueltas a través de un modelo de programación lineal entera. Las otras dos fueron resueltas mediante generación de columnas. Cabe mencionar que estos autores no consideran comportamientos estocásticos en su modelo.

Por otra parte, en [7] se considera una flota con buses eléctricos e híbridos, en donde dada una programación inicial de salidas, se busca el despacho óptimo de buses, logrando con esta mezcla de flota reducir los problemas de carga de batería. Cabe mencionar que en este problema se atienden varias líneas de servicio, pero todos los buses comienzan su recorrido desde un almacén en común. El modelo presentado corresponde a un MIP y no se consideran aspectos bajo incertidumbre.

En [8] se propone un modelo dinámico con estrategias robustas que considera aleatoriedad en las condiciones de viajes para la programación de despacho de buses eléctricos. En particular, la representación de la red, tanto en el modelo determinista como en su versión estocástica, se realiza a través de nodos *time span*, es decir, cada viaje, estación de carga y almacén de bus es representado por su respectivo nodo y tiene asignado un intervalo de tiempo. Cabe mencionar que el problema estudiado se formula considerando un solo almacén de buses, y tanto un modelo determinista como uno estocástico que son lineales en variables entera–mixta y que se resuelven a través de estrategias tales como: path–based formulation, Branch–and–price y initial path set generation.

En el presente artículo se aborda un problema con múltiples almacenes de buses eléctricos y condiciones de tráfico estocásticas, en el cual la representación de la red es *time–expanded* (a través de nodos *time span*) y se formula un modelo de optimización estocástica con recurso de múltiples etapas. Por lo que sabemos hasta el momento, no existen trabajos que abarquen estos temas en conjunto.

En lo que sigue del artículo, la sección 2 describe los principales antecedentes del problema y el modelo de optimización estocástica propuesto. La sección 3 describe antecedentes del caso de estudio abordado y los resultado preliminares alcanzados. Por último, la sección 4 da cuenta de las conclusiones alcanzadas y el trabajo futuro a desarrollar.

2. Metodología

El problema abordado consiste en la programación de despachos de buses eléctricos bajo condiciones de tráfico estocásticas y considera la programación detallada de la salidas y de la carga de batería de cada bus en cada almacén. Un aspecto importante del problema comprende entonces la variabilidad observada en los tiempos de viaje, haciendo necesaria la incorporación explícita de este antecedente bajo incertidumbre en un modelo de toma de decisiones para el problema. Bajo el nombre de Programación Estocástica se reúne una parte importante de la literatura de modelos de optimización bajo incertidumbre, que a través de los modelos con recurso permite considerar la inclusión de diversos escenarios posibles para un antecedente como el señalado. Estos modelos con recurso extienden los modelos deterministas de Programación Matemática al incluir explícitamente variables aleatorias en los parámetros del modelo. En particular, un modelo con recurso en Dos Etapas provee una solución óptima en la cual hay variables de decisión, llamadas here–and–now, cuyo valor es previo e independiente a la realización del parámetro aleatorio y variables de decisión llamadas de recurso (por escenario), cuyo valor se adopta en respuesta a la decisión de la variable here–and–now y de una realización específica de la variable aleatoria (escenario), lo cual permite dar la flexibilidad necesaria al modelo propuesto. En este trabajo, como en muchos otros, las decisiones se toman sobre múltiples intervalos de tiempo y el valor de los parámetros aleatorios cambia con una dependencia intertemporal, dando origen a un modelo con recurso de Múltiples Etapas que extienden el anterior, ver por ejemplo [9].

Así, el modelo propuesto en este trabajo abordará la operación de un intervalo de tiempo, el cual será subdividido a su vez en múltiples etapas (de tiempo) según el comportamiento de los tiempos de viaje estocásticos. Para entender mejor el modelo estocástico con recursos de múltiples etapas propuesto, definimos previamente lo que entendemos por etapa, estado y escenario.

a) **Etapas**. Se tomará una franja horaria de un día de operación, y esta franja se subdividirá en distintos intervalos de tiempo que definen las etapas del modelo, en cada una de las cuales se deberá tomar la decisión de qué bus realizará la salida programada, tomando en cuenta la información de las etapas anteriores y la definición del parámetro asociado al tiempo de viaje en esa etapa.
b) **Estados**. Como ya se ha señalado, en este modelo, el parámetro bajo incertidumbre es en el tiempo de viaje de los buses eléctricos, y para ello este parámetro es modelado como un número finito y discreto de estados, en

donde cada uno tiene asociado una probabilidad condicional de ocurrencia definida para cada etapa en que se ha subdivido el horizonte de planificación.

c) **Escenarios**: Un escenario corresponde a la defínción de una serie de estados desde la primera hasta la última etapa. Para entenderlo mejor, esto puede ser representado como un "árbol", en donde cada estado es la ramificación de un nodo, y un escenario correspondería a algún camino desde el primer nodo en el "árbol" hasta un nodo en la última etapa. La probabilidad de ocurrencia de cada escenario corresponde a la probabilidad condicional de que ocurran todos los estados pertenecientes a dicho escenario.

Para ejemplificar lo anterior, se presenta un árbol de escenario en la Figura 1, en donde existen tres etapas. Utilizando este ejemplo para el problema en cuestión, a cada etapa puede pertenecer un número finito de viajes. En el primer nodo los buses que atenderán las salidas programadas se deben adoptar independientemente de los tiempos de viaje, mientras que las decisiones pertenecientes a la segunda etapa presentan dos tipos de estados (podría ser uno pesimista y otro optimista) en los tiempos de viaje resultante de los buses disponibles para el despacho, y a su vez, estos se vuelven a ramificar en dos estados, dando origen así a la tercera etapa. Cada una de estas ramificaciones tiene asignada una probabilidad, en donde en cada etapa, la suma de las probabilidades de ocurrencia de todos los estados en dicha etapa debe sumar 1. Respecto a los escenarios, en este ejemplo se pueden apreciar cuatro escenarios, los cuales corresponden a los cuatro posibles caminos desde el nodo 1 hasta los nodos 4, 5, 6 y 7. Cabe mencionar que, la suma de la probabilidad de ocurrencia de todos los escenarios debe ser igual a 1.

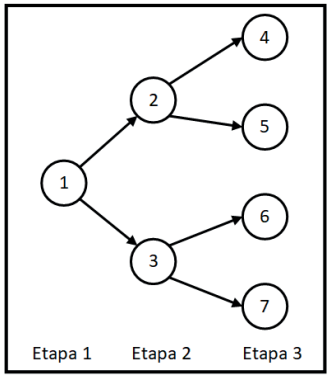

Figura 1: Árbol de escenarios con 3 etapas.

Motivado por el problema que enfrenta una empresa del transporte público de la ciudad de Santiago de Chile, los principales supuestos considerados en la formulación del modelo son los siguientes:

- Viajes tipo *deadhead trip* (viajes sin pasajeros) no están permitidos.

- Existe un solo tipo de cargadores.
- No está permitido el cambio de batería.
- La flota está conformada solo por buses eléctricos.
- Si un bus visita una estación de carga, este estará ahí un tiempo fijo cargando su batería independiente del nivel de carga.

El problema a su vez es representado mediante un grafo $G = (N, A)$, donde N representa el conjunto de nodos y A el conjunto de arcos. N está conformado por el nodo de "origen" o_k; el nodo de "término"d_k de cada almacén de buses eléctrico k (estos dos nodos se encuentran en el mismo lugar físico, es decir, ambos hacen referencia al almacén k); el conjunto de viajes I, en el cual están considerados todos los viajes de los k almacenes, cada uno de estos con un horario de salida ya programado y tiempos de viaje estocásticos que deben ser atendidos una sola vez y por un solo bus; y el conjunto de nodos virtuales V^k, los cuales se encuentran en los almacenes, pero se distinguen de o_k y d_k en el sentido de facilitar el modelamiento. Estos nodos virtuales se dividen a su vez en V_1^k y V_2^k, donde el primero permite representar un bus eléctrico que se dirige al almacén de buses, carga su batería y luego continúa con la secuencia de viajes, mientras que el segundo permite representar cuando un bus eléctrico va al almacén de buses, no carga su batería y espera simplemente para luego continuar con la secuencia de viajes. Cabe mencionar que estos nodos son denominados nodos *time span*, es decir, no solamente se encuentran en un punto espacial, sino que también temporal, por lo que cada nodo tiene asignado un intervalo de tiempo y así la red completa resulta ser una red *time–expanded*.

Los conjuntos, parámetros y variables de decisión del modelo se describen a continuación:

Conjuntos
S : Conjunto de escenarios.
K : Conjunto de almacenes de buses eléctricos.
A_s^k : Conjunto de arcos del almacén k bajo el escenario s.
N^k : Conjunto de nodos del almacén k.
I : Conjunto de viajes que hay que atender.
V^k : Conjunto de nodos virtuales del terminal k, los cuales se dividen en V_1^k y V_2^k .
V_1^k : Buses que llegan al almacén k, cargan batería, y luego salen a seguir atendiendo la secuencia de viajes.
V_2^k : Buses que llegan al almacén k, no cargan batería, y luego en algún momento vuelven a seguir atendiendo la secuencia de viajes.
W_j : Conjunto de nodos que si al finalizar un viaje deciden cargar su batería (V_1^k), coinciden con parte del tiempo de carga del bus que luego de realizar el viaje j decidió cargar su batería.

El primer conjunto corresponde a los escenarios posibles del modelo estocástico multi–etapa. El segundo está vinculado con todos los almacenes de buses eléctricos. El tercer conjunto hace referencia a los arcos admisibles que se logran desde cada terminal, bajo un cierto escenario, es decir, la conexión entre un viaje

y otro o entre un viaje y un almacén de bus (ya sea parar iniciar su viaje, cargar batería, esperar o retornar al almacén una vez terminada la secuencia de viajes). El siguiente conjunto corresponde a los nodos de la red, es decir, los viajes, el nodo de origen y nodo destino final de cada almacén y nodos virtuales. El quinto conjunto son todos los viajes que se deben atender. Luego, vienen los conjuntos de nodos virtuales, los cuales hacen referencia a un viaje al almacén para seguir atendiendo futuros viajes de su secuencia. Por último, está el conjunto de nodos que deciden cargar su batería y coinciden con parte del tiempo de carga de batería del bus que realizó anteriormente el viaje j.

Parámetros

$e_{i,j}$: Consumo de batería desde el nodo i al nodo j.
W : Porcentaje de batería que se carga en una estación.
r^k : Cantidad de vehículos en el almacén k.
E_{max} : Máximo nivel de batería permitido.
E_{min} : Mínimo nivel de batería permitido.
Cr^k : Cantidad de estaciones de carga disponibles en el almacén k.
M : Penalización por no atender un viaje.
p_s : Probabilidad de que ocurra el escenario s.
c_{ij} : Costos operacionales por realizar el recorrido por el arco (i, j).

Cabe mencionar que los costos operacionales consideran el tiempo ocioso del bus eléctrico cuando espera en el terminal (V_2^k), el costo de cargar batería en el terminal (V_1^k) y un costo fijo por uso de vehículo, es decir, por sacar un bus eléctrico del almacén para que sea utilizado en atender los viajes requeridos.

Variables de decisión

$x^k_{i,j,s}$: Variable binaria que vale 1 si el bus del almacén k, bajo el escenario s, realiza el viaje al nodo j luego de haber realizado el viaje al nodo i y 0 si no.
$z^k_{i,j,s}$: Variable binaria que vale 1 si el bus del almacén k, bajo el escenario s, **no** realiza el viaje al nodo j luego de haber realizado el viaje al nodo i y 0 si no.
$g_{j,s}$: Variable real que indica el consumo de batería acumulado del bus al terminar el viaje al nodo j bajo el escenario s.
$Aux1^k_{i,j,s}$: Variable auxiliar real.
$Aux2^k_{i,j,s}$: Variable auxiliar real.

La primera variable de decisión mostrada tiene como finalidad escoger la secuencia de viajes que realizará cada bus eléctrico. La segunda variable de decisión corresponde a si se decide no atender un viaje en particular debido a que no es posible. Cabe mencionar que esta última permitiría saber qué viajes necesitarán el apoyo de otro bus adicional para así lograr atender todos los viajes. La variable $g_{j,s}$ sirve para llevar un recuento de la batería consumida por cada bus mientras realiza su secuencia de viajes. Por último, las dos variables auxiliares serán utilizadas para tener una representación lineal de las restricciones

relacionadas con el consumo acumulado de batería.

$$\text{mín} \quad \sum_{s\in S} p_s \left[\sum_{k\in K} \sum_{(i,j)\in A_s^k} c_{i,j} x_{i,j,s}^k + \sum_{k\in K} \sum_{(i,j)\in A_s^k} M z_{i,j,s}^k \right] \tag{1}$$

s.a

$$\sum_{i:(i,j)\in A_s^k} (x_{i,j,s}^k + z_{i,j,s}^k) = 1, \quad \forall j \in I, \forall k \in K, \forall s \in S \tag{2}$$

$$\sum_{j:(o_k,j)\in A_s^k} x_{o_k,j,s}^k \leq r^k, \quad \forall k \in K, \forall s \in S \tag{3}$$

$$\sum_{i:(i,j)\in A_s^k} x_{i,j,s}^k - \sum_{p:(j,p)\in A_s^k} x_{j,p,s}^k = 0, \quad \forall j \in I \cup V_1^k \cup V_2^k, \forall k \in K, \forall s \in S \tag{4}$$

$$g_{j,s} = \sum_{i:(i,j)\in A_s^k} (Aux1_{i,j,s}^k + e_{i,j} \cdot x_{i,j,s}^k), \quad \forall j \in I \cup V_2^k, \forall k \in K, \forall s \in S \tag{5}$$

$$Aux1_{i,j,s}^k \leq E_{max} \cdot x_{i,j,s}^k, \quad \forall i \in N^k, \forall j \in N^k, \forall k \in K, \forall s \in S \tag{6}$$

$$Aux1_{i,j,s}^k \leq g_{i,s}, \quad \forall i \in N^k, \forall j \in N^k, \forall k \in K, \forall s \in S \tag{7}$$

$$Aux1_{i,j,s}^k \geq g_{i,s} - (1 - x_{i,j,s}^k) \cdot E_{max}, \forall i \in N^k, \forall j \in N^k, \forall k \in K, \forall s \in S \tag{8}$$

$$g_{j,s} = \sum_{i:(i,j)\in A_s^k} (Aux2_{i,j,s}^k - W \cdot x_{i,j,s}^k), \quad \forall j \in V_1^k, \forall k \in K, \forall s \in S \tag{9}$$

$$Aux2_{i,j,s}^k \leq E_{max} \cdot x_{i,j,s}^k, \quad \forall i \in N^k, \forall j \in N^k, \forall k \in K, \forall s \in S \tag{10}$$

$$Aux2_{i,j,s}^k \geq 0, \quad \forall i \in N^k, \forall j \in N^k, \forall k \in K, \forall s \in S \tag{18}$$

$$g_{j,s} \geq 0, \quad j \in I \cup V_1^1 \cup V_1^2, \forall s \in S \tag{19}$$

$$\textit{Restricciones de no anticipatividad} \tag{20}$$

La función objetivo (1) minimiza los costos totales de la programación realizada en el uso de vehículos y carga de batería, incluyendo un término que penaliza los viajes no atendidos. Respecto a las restricciones del modelo, la restricción (2) asegura que cada viaje debe ser atendido una vez, ya sea por la

flota de buses disponible o por algún bus de apoyo en la práctica ($z^k_{i,j,s}$). La restricción (3) asegura que no se pueden utilizar más buses eléctricos de los disponibles en cada almacén de buses. La restricción (4) asegura la conservación de flota de buses. La restricción (5) permite calcular el consumo acumulado de energía del bus al realizar un viaje del nodo i al nodo j bajo el escenario s. Las restricciones (6)–(8) representan una linealización de la ecuación no–lineal $g_{j,s} = \sum_{i:(i,j)\in A^k_s} (g_i + e_{i,j}) \cdot x^k_{i,j,s}$, cuya representación lineal es la ecuación anterior. De igual manera la restricción (9) actualiza el consumo acumulado de energía del bus eléctrico cuando este carga su batería, y al igual que la restricción (5), esta restricción se debe linealizar y para ello se utilizan las restricciones (10)–(12) conjuntamente con una variable auxiliar ($Aux2^k_{i,j,s}$). La restricción (13) no permite que un bus eléctrico atienda un viaje si su porcentaje de batería es menor al porcentaje mínimo necesario para abandonar el almacén de buses. La restricción (14) asegura que la cantidad de buses que visiten la estación de carga del almacén k no exceda su capacidad. Las restricciones (15)-(19) muestran la naturaleza de las variables de decisión. Por último, las restricciones (20) son esenciales para los modelos estocásticos con escenarios, ya que aseguran que las decisiones en un nodo deben ser iguales, es decir, si tomamos como ejemplo la Figura 1, correspondería a un caso de 4 escenarios y 3 etapas, entonces, si uno tomara todos los viajes correspondientes al nodo 1, se tendría las mismas decisiones de ese nodo en todos los escenarios. Del mismo modo, si tomamos el nodo 2 de la segunda etapa, las decisiones tomadas en ese nodo deben ser las mismas para el escenario 1-2-4 y para el escenario 1-2-5. En el contexto del problema, las decisiones corresponden al arco (i, j) a recorrer por el bus eléctrico.

El modelo resultante corresponde a un modelo lineal de optimización estocástica de múltiples etapas en variables entera–mixta. En la siguiente sección se describe un caso de estudio preliminar a partir de la problemática que define el despacho de un recorrido de buses eléctricos de una empresa del transporte público de Santiago.

3. Caso de estudio

3.1. Análisis estadístico

En esta sección se estudia una instancia utilizando información real de la operación durante meses normales del año 2019 de una línea de recorrido de bus eléctrico del transporte público de la ciudad de Santiago de Chile. En primer lugar, se realizaron diferentes test de ajuste de distribución de probabilidades de Kolmogórov-Smirnov a los tiempos de viajes de todo un día y para intervalos de tiempo, obteniendo por ejemplo que la mejor distribución es una distribución normal con datos de todo un día, ver Figura 2.
Luego, se agruparon los días de la semana de acuerdo a comportamientos similares. De esta forma, la semana se dividió en 3 grupos: lunes–martes–miércoles, jueves–viernes y sábado–domingo.

Ante la variabilidad observada, la Tabla 1 permite apreciar los tiempos esperados y la desviación estándar de distintas zonas horarias de los días sábados y

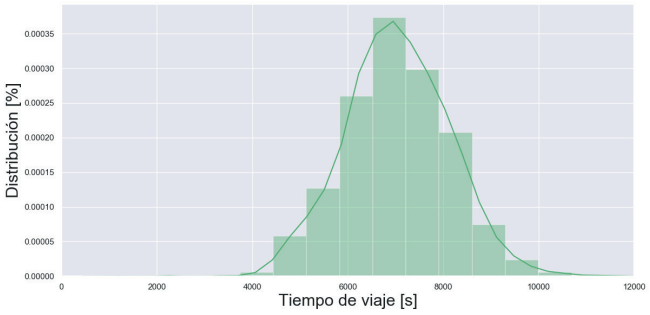

Figura 2: Ajuste de distribución a los tiempos de viajes.

domingos. Cabe mencionar que en el fin de semana no hay registro entre las 00:01 y las 08:00 debido a que en ese horario la empresa utiliza buses convencionales.

Tabla 1: Tiempos medios y desviación estándar de distintas zonas horarias.

Zona horaria	Media $[HH:MM:SS]$	Desv Estándar $[HH:MM:SS]$
8:00 - 12:00	1:46:33	0:14:37
12:00 - 17:15	1:53:41	0:14:25
17:15 - 22:15	1:44:08	0:10:58
22:15 - 00:00	1:27:21	0:17:43

Del mismo modo, el caso de estudio se realiza en un día sábado, específicamente en la zona horaria $12:00-17:15$, en la cual se vuelven a calcular los tiempos medios y desviaciones estándar dentro de la misma zona horaria con intervalos de tiempos cada 15 minutos, para así poder separar, dentro de esta zona horaria, el problema en múltiples etapas.

En esta instancia preliminar se utilizan 2 almacenes de buses, en donde cada uno de ellos debe atender 22 viajes (44 viajes en total), los cuales tienen una frecuencia de salida cada 15 minutos. Además, se cuenta con 11 buses y 7 estaciones de carga en cada almacén. Se considera como supuesto que todos los buses a utilizar comienzan con 100 % de su batería cargada y que no es posible que el bus atienda un viaje si su nivel de batería es menor al 30 %. El problema es dividido en 3 etapas, en donde los primeros 3 viajes de cada almacén pertenecen a la primera etapa, los siguientes 6 viajes a la segunda etapa y el resto a la tercera etapa. Se consideró, para cada etapa, un estado optimista y otro pesimista de acuerdo a la desviación estándar de cada etapa, generando así 4 escenarios que forman un árbol de escenarios como el mostrado en la Figura 1.

La probabilidad de ocurrencia de cada estado es del 50 %, y los viajes que se encuentran en la primera etapa tienen tiempos de viajes deterministas.

3.2. Resultados Computacionales

La información de la cantidad de viajes y las respectivas salidas de estos, para cada uno de los almacenes de buses eléctricos, se encuentran en un archivo Excel. Luego, a través de Python 3.7 se realiza el procesamiento de datos para formar la red *time-expanded* y entregar toda esta información al modelo formulado en Pyomo. El modelo fue resuelto con el solver Gurobi 9.0.2 en un computador con un procesador Intel Core i5 de 1.60[GHz] y 8[Gb] de RAM. El tiempo de ejecución de la instancia resuelta fue de 15,3 segundos.

El modelo resuelto entrega, para cada escenario, la secuencia que debe seguir cada bus, y los viajes que no se pueden atender por falta de flota, en donde la penalidad de esta último asciende a un valor del orden de $\$10^6$. Por otra parte, los costos operacionales son del orden de $\$10^3$.

El valor de la función objetivo en este modelo (conocido como *Recourse Problem* en la literatura) resulta ser de $17.620.764, y para medir la calidad e importancia de esta, es necesario analizar ciertos indicadores que son comunes en problemas estocásticos, tales como:

- EVPI (*Expected value of perfect information*): Representa la máxima cantidad que el tomador de decisiones está dispuesto a pagar por contar con toda la información acerca del futuro, y se calcula como la diferencia entre el *Recourse Problem* (RP por sus siglas en ingles) y el promedio del óptimo de cada escenario resuelto por separado (conocido como *Wait-and-see*).
- VSS (*Value of stochastic solution*): Muestra el verdadero aporte del modelo estocástico comparado con la calidad de la solución resultante de un modelo determinista subyacente. Para este indicador es necesario calcular previamente el *Expected result of using the EV solution*, el cual corresponde a resolver el modelo determinista usando como instancia el promedio de los parámetros con incertidumbre de los escenarios (EV), y luego tomar las decisiones de primera etapa realizadas y fijarlas en el modelo estocástico con recursos. Este resultado se conoce como EEV, y la diferencia del RP con el EEV corresponde al VSS, el cual permite cuantificar el valor que tiene el modelo estocástico.

Para este caso de estudio, el valor del *Wait-and-see* resultó ser $12.916.522, mientras que el EV de $12.126.022 y el EEV de $20.620.764. Asimismo, se tiene que la cota inferior y superior del RP es el *Wait-and-see* y el EEV, respectivamente.

En la Tabla 2 se muestran los valores de los indicadores mencionados anteriormente.

Tabla 2: Valores de indicadores.

Indicador	**Valor**
EVPI	$ 4.704.242
VSS	$ 3.000.000

Se puede apreciar, en primer lugar, que ambos indicadores representan un valor cercano al 30 % y al 20 % del valor del modelo con recurso, respectivamente. Ahora bien, el resultado del EVPI, quiere decir que el tomador de decisiones está dispuesto a pagar como máximo $ 4.704.242 por contar con información sobre el futuro, mientras que el VSS muestra que existe una gran ganancia al usar el modelo estocástico frente al determinista para el escenarios promedio, lo cual da relevancia al uso de la metodología propuesta.

4. Conclusiones y trabajos futuros

En este trabajo se formula un modelo de optimización estocástica multi–etapa para la programación de salidas de flotas de buses eléctricos con múltiples almacenes de buses, donde se considera como parámetro bajo incertidumbre el tiempo de viaje ante las condiciones de tráfico. Asimismo, el modelo emplea una representación de la red a través de nodos *time–expanded*, lo cual no es muy común en la literatura para este tipo de problema. Hasta donde sabemos, no hay evidencia de trabajos que abarquen todos los aspectos considerados. Adicionalmente, analizamos la información de operación en meses normales del año 2019 de una línea de buses eléctricos del transporte público de la ciudad de Santiago de Chile, y se determinó que la distribución que mejor se ajustaba a los tiempos de viajes es la distribución normal. Luego, se dividieron los días de la semana en tres grupos que compartían comportamientos similares dentro de ciertas franjas horarias, por lo que así se pudo dividir el día completo de operación, de los días pertenecientes a estos grupos, en varias franjas horarias.

Se resolvió una instancia utilizando la información de operación de un día sábado. Esta instancia fue resuelta para una de esas franjas con un modelo de optimización estocástica con recurso de tres etapas con 4 escenarios. El solver seleccionado logra resolver esta instancia en alrededor de 15 segundos. Para poder medir la calidad de la solución estocástica (RP), se calculó los valores *Wait-and-see*, EEV y EV, los cuales fueron usados para calcular los indicadores EVPI y VSS. El primer indicador muestra la máxima disposición a pagar por el tomador de decisión por contar con información sobre el futuro, mientras que el VSS muestra que existe una gran ganancia al usar el modelo estocástico frente al determinista en escenarios con incertidumbre. Ambos indicadores alcanzaron valores altos en términos relativos, por lo que se concluye que este modelo de optimización estocástico tendría un gran impacto al ser utilizado en este problema.

Como trabajo futuro, se espera agregar al modelo cierta flexibilidad en el despacho lo que permitirá eventuales retrasos en las salidas, con su correspondiente penalización por minuto de retraso. Del mismo modo, agregar más de un recorrido de bus eléctrico, y realizar este modelamiento de múltiples etapas con más de una zona horaria. Respecto a los tiempos de resolución, hasta el momento no parecen ser muy elevados, pero si al agregar estos nuevos aspectos los tiempos de resolución aumentan considerablemente, será necesario evaluar un método de resolución algorítmico.

Agradecimientos

Esta investigación cuenta con el apoyo de la Dirección de Postgrados y Programas (Beca Magíster USM) de la Universidad Técnica Federico Santa María.

Resumo. Apesar do seu surgimento ter ocorrido no meio industrial, atualmente, a filosofia *Lean* pode ser encontrada em diversas áreas da sociedade. Inicialmente, *Lean* Manufacturing, era visto como uma iniciativa que buscava eliminar desperdícios. Com a sua disseminação em outras áreas como serviços, engenharia, militar e saúde, percebe-se que essa filosofia possui um potencial relevante, podendo ser utilizada em qualquer tipo de atividade ou organização. O objetivo deste estudo foi aplicar os conceitos *Lean* em organizações escolares. Os passos metodológicos utilizados podem ser descritos pela capacitação da equipe, identificação dos principais desperdícios encontrados através da análise dos processos, elaboração e implementação de uma proposta de melhorias. O estudo caracteriza-se como um estudo de caso, que ocorreu em uma organização de nível técnico privado entre os meses de outubro de 2019 e março de 2020. Como resultados destacam-se a redução no volume de material impresso, redução no consumo de insumos em exercícios práticos, redução no tempo de atendimento e de feedback e engajamento da equipe de trabalho nos processos de melhoria. Os resultados do estudo demonstram a aceitação e potencialidade do *Lean* como uma ferramenta de melhoria apresentando sua contribuição em diversas áreas. Como destaque, elenca-se a redução com energia elétrica, água e insumos diretamente ligados as atividades educacionais realizadas em laboratório.

Palavras-chave: *Lean*, Educação, Aplicabilidade, Ensino Básico, Ensino técnico.

1 Introdução

A educação é vista como um fator importante na evolução da sociedade. Nos últimos anos começou a mostrar sinais de estagnação, e observou-se um declínio no apoio financeiro do governo à educação [1].

A atenção às análises de custo-efetividade e custo-benefício aumentou, aos países está sendo solicitado realizar mais com os mesmos recursos, ou ainda menos, devido às tendências econômicas descendentes da última década [1,2]. As instituições educacionais, consequentemente, concentraram-se na redução de custos e no aumento da eficiência e, ao mesmo tempo, trabalharam para atender ou mesmo superar as expectativas [1,3].

Os princípios e práticas *Lean* foram incorporados em todo o mundo em organizações do setor público e privado, sendo desenvolvidas ao longo de várias décadas, objetivando estabelecer a excelência operacional como estratégia. *Lean* é um termo utilizado para denominar uma filosofia de negócios fundamentada nos princípios iniciais do Sistema Toyota de Produção. Busca a melhoria contínua visando a eliminação de desperdícios que não agregam valor ao produto final [4]. É importante entender que os conceitos e técnicas do *Lean* devem ser adequados aos ambientes de ensino.

Os primeiros registros de implementação *Lean* em ambientes educacionais surgiram no início dos anos 2000 [5], e nos últimos anos demonstram uma tendência de crescimento [6].

Danese *et al*.[7] destaca que embora a implementação dos conceitos *Lean* estejam sendo cada vez mais aplicados, e os registros de casos bem sucedidos apareçam a todo momento, a literatura sobre *Lean* implementado em instituições educacionais ainda dá seus primeiros passos. Grande parte das pesquisas publicadas destacam a aplicação do pensamento enxuto no ensino superior, classificado como *Lean Higher Education* (LHE) [8]. Sendo assim, encontra-se na literatura uma lacuna quanto a sua aplicação em instituições de nível básico e técnico.

O objetivo deste estudo foi aplicar os conceitos *Lean* em uma organização escolar de nível técnico, através de um estudo de caso, identificando os principais desperdícios por meio da avalição dos processos, elaboração e implementação de uma proposta de melhoria subdividida em 6 etapas, com o propósito de reduzi-los, visto que, a eliminação de desperdícios é a prioridade da filosofia *Lean*, em busca de altos padrões de eficiência.

2 Referencial Teórico

Lean é um termo utilizado para denominar uma filosofia de gestão fundamentada no Sistema Toyota de Produção, que busca olhar atentamente as atividades básicas de um negócio e identificar o que é desperdício e o que é o valor a partir da ótica dos clientes usuários.

O Sistema Toyota de Produção surgiu logo após a Primeira Guerra Mundial, mudando o sistema de produção artesanal para a produção em massa [9]. A produção em massa tradicional era composta pelo sistema de Taylor, agrupado a inovações de manufatura desenvolvidas por Ford e de técnicas de administração e *marketing* de Sloan, onde grupos organizados de trabalhadores que controlavam tarefas e funções no trabalho, sendo este sistema, vitorioso por décadas [10].

Logo após a Segunda Guerra Mundial, Eiji Toyoda e Taichi Ohno, da Toyota japonesa aproveitaram o momento de dificuldades na indústria automobilística, para desenvolver o modelo de produção enxuta, sendo que este conceito emprega as vantagens de produção de ambos os modelos (artesanal e em massa), mas, evita os altos custos do primeiro modelo bem como a rigidez do segundo modelo [11]

Sistema *Lean* é descrito como a integração de princípios, técnicas operacionais e ferramentas que levam a incessante busca pela perfeição para a criação de valor ao cliente, tornando as empresas mais eficientes, competitivas, reduzindo custos, melhorando a qualidade e aumentando a satisfação do cliente [12].

O *Lean* busca a eliminação de desperdícios nas organizações, seja nas operações, tarefas, tempo, energia, dinheiro ou de materiais, diretamente vinculada a qualidade total e requer um grande envolvimento dos funcionários em todos os níveis de decisão. Os trabalhadores multifuncionais e com autonomia na tomada de decisões são na produção enxuta peças fundamentais [13,14].

O *Lean* é baseado em cinco princípios fundamentais, na premissa de que as organizações são compostas de processos [15]. Esses são:

I. Especificação de valor do ponto de vista do cliente;

II. Identificação do fluxo de valor para cada produto e eliminação das etapas que não criam valor;

III. Fluidez do produto de forma suave e contínua pelo fluxo de valor;

IV. Onde o fluxo contínuo não é possível, é necessário permitir que os clientes obtenham o valor entre todas as etapas;

V. Apontar para um estado de perfeição, reduzindo o número de etapas e o tempo necessário para atender o cliente [11].

Ainda, Arboleda [16], define *Lean* como uma filosofia de gestão que melhora os processos produtivos pela eliminação de todos os tipos de desperdícios, obtendo como resultados a efetividade e a agilidade, propiciando que a empresa se torne competitiva no mercado. De acordo com os proponentes dos princípios *Lean*, embora essas definições possam variar por setor, todas elas são encontradas de alguma forma em todos os tipos de organização.

Nesse sentido, surge o denominado *Lean Higher Education* (LHE), diante da necessidade de se adotar práticas e conceitos da produção *Lean* aos serviços administrativos, especificamente no que se refere aos serviços administrativos de instituições de ensino. Seu objetivo consiste na eliminação de passos e atividades desnecessárias que

sobrecarregam funcionários e não adicionam valor nos processos que devem beneficiar os estudantes, escolas e demais participantes [17].

Embora ainda haja um equívoco geral de que o *Lean* fornece ferramentas puramente de manufatura [18], os princípios *Lean* estão sendo cada vez mais usados em outros ambientes, como nas instituições de ensino superior para melhorar o processo [19]. Mesmo que se reconheça que exista diferença entre os resultados de um processo de fabricação e um serviço educacional, há uma sobreposição considerável em termos de sistemas de entrega [5].

Alguns fatores críticos podem ser identificados na implementação do *Lean* em instituições escolares de nível superior, o que tem se tornado um desafio para uma implementação de sucesso. Antony *et. al* [18] listou alguns desses desafios encontrados no momento de implementação:

- Problemas com terminologias vindas da indústria de fabricação para o setor de ensino;

- Desconforto no uso de ferramentas e técnicas que se mostraram eficazes nos setores de manufatura e serviços;

- Processos isolados e não em perspectiva de sistemas;

- Falta de consciência dos benefícios do *Lean* na indústria não-manufatureira;

- Falta de aceitação, apoio e comprometimento da equipe de gestão desde o início da iniciativa *Lean*, sem este envolvimento todo o esforço será absolutamente inútil;

- Visão de que a iniciativa *Lean* é uma solução rápida de corte de custos para atender *déficits* orçamentários, não alcançando os benefícios reais;

- Falta de pensamento do processo e propriedade do processo. Tudo é tratado como uma atividade ou tarefa ou procedimento, mas não como processo. O pensamento de processo não é prevalente em muitas instituições escolares e o estabelecimento de processos no local de trabalho requer uma mudança de mentalidade;

- Necessidade de definir e comunicar uma visão clara da cultura desejada no estabelecimento na busca de obter maior comprometimento organizacional;

- Falta de compreensão sobre os diversos tipos de clientes, dificultando o desenvolvimento de estratégias para atender as necessidades dos clientes;

- Pouco esforço no envolvimento da estratégia e aplicação do *Lean* por parte dos funcionários. É necessário conscientizar a real importância do esforço de cada um no momento de implementação;

- Falta de diversos recursos (tempo, orçamento, etc);

- Fraca ligação entre os projetos de melhoria contínua e os objetivos estratégicos das instituições.

A aplicação apropriada desta filosofia às instituições de ensino superior implica, assim, a busca de oportunidades para melhorar os processos, usando os princípios nas práticas diárias de gestão. Balzer [20] argumenta que o pensamento *Lean* pode auxiliar

as universidades na melhora contínua dos processos, fornecendo aos beneficiários o que eles esperam, ou seja, processos que respeitem a temporalidade, livres de erros, e que esteja disponível conforme a necessidade do beneficiário.

Portanto, para fornecer um fluxo contínuo baseado em altos padrões e eficiência, é importante definir claramente quais são os desperdícios e entender as relações entre eles para determinar as causas e, depois, encontrar métodos para eliminá-los. Os principais tipos de resíduos foram definidos como superprodução, espera, transporte, processos inadequados, inventário, movimentação, defeitos e comportamento. Precisa-se compreender que, os oito desperdícios citados anteriormente podem ser encontrados e definidos em qualquer tipo de organização, assim como nas organizações escolares.

No Tabela 1 são apresentados de forma comparativa dos oito desperdícios entre o *Lean manifaturing* e o *Lean Higher Education*.

Tabela 1: Comparativo desperdícios *Lean* (Fonte: autoria própria)

Desperdício	**Autor**	***Lean manufaturing***	**Autor**	***Lean Higher Education***
Superprodução	[21]	Produzir excessivamente ou cedo demais, resultando em um fluxo pobre de peças e informações, ou excesso de inventário;	[23,24]	Desenvolvimento de mais cursos do que o necessário; Produzindo mais do que o necessário para uso imediato. Carga de trabalho desequilibrada através semestres e programação irregular.
Espera	[21]	Longos períodos de ociosidade de pessoas, peças e informação, resultando em um fluxo pobre, bem como em lead times longos;	[23,24]	Atrasos na marcação do trabalho dos alunos; Fila para nada, à espera de documentos a serem aprovados, os sistemas de TI o tempo de inatividade, procurando arquivos, livros e documentos. Tempo necessário para responder a consultas de estudantes.
Transporte excessivo	[21]	Movimento excessivo de pessoas, informação ou peças resultando em dispêndio desnecessário de capital, tempo e energia;	[24]	O movimento de materiais tal como papel, múltiplos aprovações, múltiplas transferências. E-mail excessivo anexos.
Processos Inadequados	[21]	Utilização do jogo errado de ferramentas, sistemas ou procedimentos, ge-	[24]	Os funcionários não atuam em sua área de formação/ especialização.

		ralmente quando um processo mais simples pode ser mais efetivo;		
Inventário desnecessário	[21]	Armazenamento excessivo e falta de informação ou produtos, resultando em custos excessivos e baixa performance do serviço prestado ao cliente;	[24]	Mais suprimentos ou itens do que o necessário. Registros e documentos mantidos por mais tempo do que útil necessário.
Movimentação desnecessária	[21]	Desorganização do ambiente de trabalho, resultando baixa performance dos aspectos ergonômicos e perda frequente de itens.	[24]	O movimento desnecessário de funcionários e alunos. Departamentos espalhados por vários sites / campus.
Produtos Defeituosos	[21]	Problemas frequentes nas cartas de processo, problemas de qualidade do produto, ou baixa performance na entrega;	[23,24]	Observações evitáveis das atribuições; Erros na introdução de dados, salas de aula subutilizadas, erros de calendários.
Criatividade não utilizada dos funcionários	[22]	Indivíduos de alta capacidade realizando atividades de baixa capacidade.	[24]	Não usar habilidades completos das pessoas. Não dar às pessoas o direito de trabalhar

Sendo assim, o *Lean* é amplamente considerado em vários setores como a melhor prática para melhoria contínua, gerando interesse na educação sendo considerado um sistema de gestão organizacional muito útil [20]. O Sucesso de qualquer esforço organizacional, incluindo a aplicação do *Lean*, dependerá se a instituição está adequadamente preparada para implementar mudanças em todo o sistema.

3 Metodologia

3.1 Enquadramento metodológico da pesquisa

Este estudo, quanto a sua natureza é classificado como uma investigação aplicada que, de acordo com Prodanov & Freitas [25] tem por objetivo gerar conhecimentos para aplicação prática voltada a solução de problemas específicos, envolvendo verdades e interesses locais; sendo descritiva, pois seu objetivo é caracterizar os processos educacionais e expor como as tarefas são efetuadas, de acordo com o exposto por Gil [26] de que "as pesquisas descritivas têm como objetivo primordial a descrição das características de determinada população ou fenômeno".

Foi conduzido seguindo parâmetros de um estudo de caso simples, observando os processos da unidade em estudo e aplicando os conceitos do *Lean* para a observação

dos resultados. O estudo de caso, para Gil [27] trata de uma investigação empírica e compreende um método abrangente, utilizando-se da lógica do planejamento, coleta e análise de dados, visando uma investigação de um caso específico, delimitado e contextualizado em tempo e lugar.

Ainda Ventura [28] ressalta algumas das vantagens do estudo de caso como o estimulo a novas descobertas, em função da flexibilidade do planejamento, enfatizando a multiplicidade de dimensões de um problema, ainda apresenta geralmente simplicidade nos procedimentos, permitindo uma análise em profundidade dos processos e as relações entre eles.

Quanto a abordagem do problema, o processo da pesquisa caracteriza-se como quali-quantitativo [29]. Qualitativo, no que diz respeito a análise percepção dia/usuários em relação aos benefícios, bem como na elaboração e aplicação dos conceitos *Lean* e, quantitativo, quanto a mensuração dos resultados.

3.2 O estudo de caso

Com o propósito de avaliar as contribuições efetivas do *Lean Education*, os princípios e ferramentas de melhoria foram aplicadas em uma unidade educacional de ensino médio e técnico privado. A unidade em estudo funciona das 7:00 as 23:00 de segunda a sexta. Ao todo, cerca de 421 alunos estão matriculados de forma regular. Os cursos ofertados possuem carga horária mínima de 2 horas nas modalidades de aperfeiçoamento, os cursos de média ou longa duração possuem carga horária de 60 horas até 1600 horas.

Apesar da jovialidade das instalações, cerca de 3 anos, existem aspectos relatados pelos alunos passíveis de melhoria como: Demora no atendimento; ineficiência nos processos de organizações educacionais; excesso de burocracia; superprodução de materiais didáticos desatualizados; desorganização de ambientes e falta de informação e relação a programação das atividades.

Com o propósito de melhora na avaliação da instituição pelos discentes, foi iniciado o projeto de melhoria em outubro de 2019. A condução e aplicação do projeto foi dividido em etapas envolvendo cerca de 70% da equipe de profissionais da unidade educacional. A equipe inicial do projeto foi formada por técnicos de ensino, coordenadores pedagógicos, secretários, colaboradores do setor administrativo e colaboradores dos setores de limpeza e organização.

O projeto foi desenvolvido em seis etapas, conforme apresentado na Figura 1:

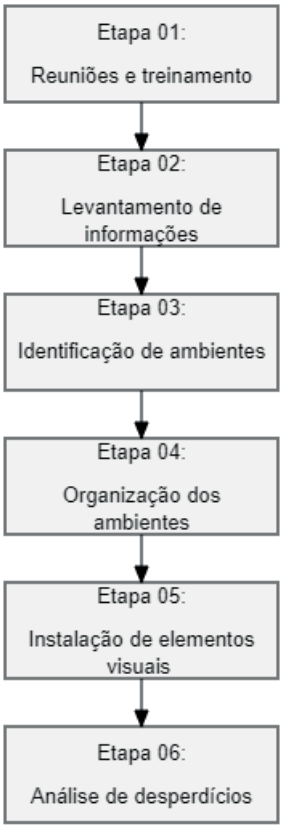

Figura 1: Etapas do estudo de caso (Fonte: Autoria própria)

A realização do estudo, utilizou como embasamento teórico da Tabela 1 com referência aos 8 desperdícios. A etapa 1 foi realizada por meio de reuniões e treinamentos da junto a equipe da unidade educacional. A etapa 2 foi realizada por meio do levantamento de informações. A etapa 3 correspondeu a identificação dos ambientes. A organização dos ambientes correspondeu a etapa 4. A etapa 5 foi realizada por meio da instalação de elementos de identificação visual. A etapa 6 correspondeu a identificação dos desperdícios.

4 Descrição do estudo de caso

Inicialmente, houve uma preocupação com a assimilação dos princípios e métodos utilizados pela filosofia *Lean* pelos colaboradores. Essa afirmação vai de encontro com a afirmação de Marvel e Standridge [30] quando os autores comentam que a implantação tradicional do *Lean* pode negligenciar a interação, variabilidade e dependências

peculiares ao ambiente em estudo. Frente a esta situação, as etapas iniciais propuseram a capacitação da equipe e análise dos ambientes em estudo.

A primeira etapa foi realizada por meio de reuniões e treinamento com os profissionais da unidade. Nessa etapa, o principal objetivo foi promover a conscientização e engajamento no projeto. Apesar do termo *Lean* ser novo para quase todos os integrantes a aceitação foi positiva. Um aspecto negativo dessa fase foi a ausência de alguns integrantes da alta administração. Cabe ressaltar que, apesar da provável contribuição, organizar momentos nos quais todos participantes pudessem participar, foi um grande desafio. Ao todo foram realizadas 6 reuniões com duração de 45 minutos. A Figura 2 apresenta as atividades desenvolvidas em cada uma das reuniões.

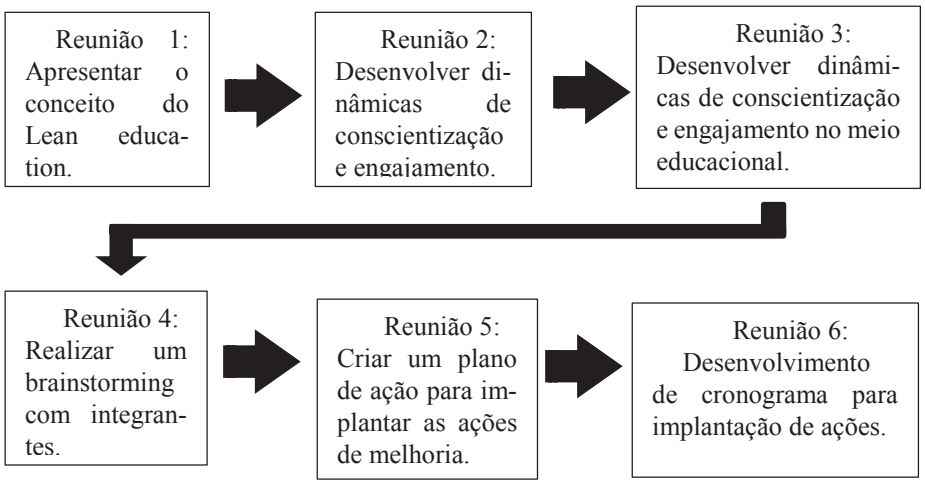

Figura 2: Assuntos tratados em cada reunião da Etapa 1 (Fonte: Autoria própria)

Ao final da primeira fase os princípios e contribuições do *Lean* já eram de domínio dos participantes. O cronograma inicial previu 3 meses de atividades encadeadas e dependentes nos laboratórios de práticas mecânicas e de modelagem computacional.

A segunda etapa foi realizada por meio da divisão dos integrantes em equipes para realização do levantamento de informações nos ambientes da unidade educacional. Cada equipe foi formada por um capitão e três outros colaboradores. Durante 15 dias as equipes analisaram os ambientes por meio de observações in loco e gravações de vídeo. Essa etapa evidenciou os potenciais da filosofia *Lean* em relação aos pontos de melhoria. Com o propósito aumentar a visão holística dos integrantes, as equipes foram, propositalmente responsabilizadas por ambientes que não faziam parte do seu dia-a-dia. Os principais pontos analisados nessa etapa foram: Espera; superprodução; Transporte excessivo; processos inadequados; Produtos ou serviços defeituosos; movimentação desnecessária e talentos não utilizados.

Ao final da segunda etapa, os problemas identificados foram compartilhados em uma sétima reunião. Os principais pontos elencados foram a movimentação excessiva

de técnicos em busca de materiais que estavam armazenados em outros ambientes; movimentação excessiva de alunos nos laboratórios ao longo do processo educativo em virtude da necessidade de ferramentas ou insumos; indisponibilidade de dados relacionados as atividades a serem desenvolvidas, necessidade de busca ou assinatura de documentos ou informações de posse da secretaria; desperdícios de água, luz e insumos pedagógicos; necessidade de organização diária ou a cada turno dos ambientes de aulas teóricas; falta de informações quanto ao respectivo ambiente de aula e a movimentação constante de profissionais na logística de materiais.

A terceira etapa teve como foco a identificação de pontos adequados para a instalação de placas ou murais. Complementando a terceira etapa, deu-se início a quarta etapa com a realização da organização das atividades para a promoção da organização dos ambientes. A quinta etapa do projeto foi desenvolvida com a criação de *tags* para instalação nas portas e marcação da posição do mobiliário no piso.

A sexta etapa foi realizada com o propósito de analisar desperdícios relacionados ao atendimento do público e solicitações de documentos. Para melhoria desse processo, foram instalados no hall de entrada, quadros informatizados com o ensalamento e o mapa de toda a unidade educacional. Outras ações foram desenvolvidas como a análise do sistema de iluminação e a sua adequação em relação ao horário de funcionamento. O desenvolvimento das etapas metodológicas promoveram melhorias e ganhos substanciais apresentadas na seção Discussão.

5 Resultados e discussões

Percebeu-se que a primeira etapa foi de extrema valia, pois possibilitou de forma organizada e clara, que todos os participantes tivessem o conhecimento necessário sobre a identificação e aplicabilidade da filosofia *Lean,* tendo interferência direta nos resultados da segunda etapa. A Tabela 2 apresenta os desperdícios identificados nos ambientes da unidade educacional utilizando como referência os oito desperdícios apresentados na Tabela 1.

Tabela 2: Identificação dos desperdícios (Fonte: Autoria própria)

Desperdício	Desperdício encontrado na organização
Superprodução	1 – Iluminação excessiva, 2 – Impressão de materiais, 3 – Ambientes demasiadamente grandes frente as turmas alocadas, 4 – Carga horária incompatível com o conteúdo ministrado, 5 – Repetição de itens em diferentes períodos no plano de curso
Espera	1 – Retorno por feedback do professor, 2 – retorno por disponibilidade de vagas, 3 retorno de informações da secretaria, 4 – agendamento com coordenadores e responsáveis.
Transporte excessivo	1 – Movimentação de equipamentos entre laboratórios e salas de aula, 2 – Estoque de materiais nos andares superiores

Processos Inadequados	1 – Processo de compras demasiadamente longo e repetitivo; 2 – Solicitação de cadastros; 3 – Solicitações e protocolos de documentos;
Inventário desnecessário	1 – Excesso de livros; 2 – Excesso de apostilas; 3 – Materiais sem aplicabilidade na área elétrica, 4 – Material na área mecânica sem aplicabilidade; 5 – Materiais na área moveleira desatualizados ou vencidos e 6 – Materiais sem aplicabilidade na área vestuário.
Movimentação desnecessária	1 – Adequação das salas de aula para desenvolvimento de oficinas; 2 – movimentação de alunos entre salas ou laboratórios, 3 – Buscar materiais na biblioteca, coordenação ou outro ambiente.
Produtos Defeituosos	1 – Apostilas defeituosas ou desatualizadas, 2 – livros desatualizados, 3 – materiais com prazo de validade ultrapassado;
Criatividade não utilizada dos funcionários	1 – Alocação de colaboradores em funções desalinhadas com sua formação ou expertises.

Todos os desperdícios identificados foram alvo de estudo, dessa forma, sendo alvo de melhoria. As ações foram coordenadas pelos pesquisadores conjuntamente com os profissionais da unidade educacional.

Comparando o material estimado pelo docente para a realização das aulas práticas, percebeu-se que o consumo era, em média, 18,75% maior que o previsto. Após a realização do controle visual pelos próprios alunos, esse percentual foi reduzido e o material utilizado em aula passou a ser equivalente a 94,12% do estimado, inferior a estimativa. De forma complementar, foi instalado um quadro kanban para controle dos insumos da área metalmecânica. Antes da instalação do Kanban em média, 1 vez a cada mês havia a falta de algum insumo, após a implatação esse número foi zerado.

A organização dos ambientes interferiu no tempo médio necessário para a localização de ferramentas, no primeiro momento, em média eram necessários 44 minutos em um período de 4 horas de aula. Após a instalação dos quadros esse tempo reduziu para 8 minutos em média. Com a realocação de equipamentos e móveis o deslocamento médio dos alunos, que era de 657 metros no período de 4 horas de aula foi reduzido para 49 metros em média.

A identificação dos ambientes educacionais foi realizada por meio da instalação de placas, demarcações no piso, local para depósito de refugos e a instalação de quadros de gestão visual. Ainda nessa etapa, realizado o dia do descarte, a identificação dos equipamentos e os procedimentos de limpeza e desligamento, a demarcação dos corredores, a realocação de móveis e a criação de kits de ferramentas e utensílios por setor. Nos laboratórios de práticas foram instalados quadros para a organização das ferramentas.

Com a instalação dos Tags, a frequência com a qual o ar condicionado ou as luzes dos ambinetes ficam indevidamente ligados foi reduzida em 94%. O tempo médio de organização das salas para o próximo período de aula que era de 16 minutos foi

reduzido para 4 minutos. Esses ganhos foram obtidos em virtude da instalação de POKA YOKE nas mesas dos professores de ambientes como as salas de aula, desenho técnico, robótica e informática.

A solicitação de documentos e demais itens da secretaria passaram a ser registrados em um quadro de recados instalado no ambiente. Um ponto de destaque desse setor foi a redução no tempo de emissão e entreda de certificados reduzindo de 42 dias em média para 5 dias.

Um ganho parelelo e não previsto inicialemnte foi identificado no volume de materiais descartados por desuso, insumos de impressão e tempo disponibilizado para essas atividades. A prática de impressão de materiais didáticos sempre foi realizada pela equipe da biblioteca considerando o número de alunos matriculados nos cursos. Como alternativa, foi proposto a impressão dos materiais frente a solicitação dos docentes, uma prática que poderia ser considerada um Kanban informal. Após a aplicação dessa nova rotina o volume de mateiriais impressos foi reduzido em cerca de 7%.

Em relação a infraestrutura foram realizados ajustes nas torneiras nos banheiros coletivos e a instalação de placas indicativas referente a organização dos ambientes de alimentação. Essas mudanças impactaram diretamente nos custos fixos da unidade gerando uma redução de 31,12% em média no total de energia elétrica consumidos ao longo de um mês.

6 Considerações finais

Objetivou-se com este estudo a verificação da aplicabilidade dos conceitos *Lean* em uma organização escolar de nível técnico, utilizando-se de um estudo de caso. Sendo assim, identificou-se os principais desperdícios por meio da avaliação dos processos, sendo elaborado um projeto de melhoria constituído por seis etapas, reuniões e treinamento, levantamento de informações, identificação de ambientes, organização dos ambientes, instalação de ambientes visuais, análise de desperdícios.

O método apresentado demonstrou ganhos substanciais relacionados ao tempo de uso dos equipamentos e no custo relativo aos cursos, essa condição foi obtida devido ao maior controle e conscientização dos discentes, redução nos gastos com energia elétrica, água e materiais.

Dessa forma, o método pode ser visto como um instrumento simples porém adequado para superar os desafios encontrados na implantação do *Lean* em instituições de ensino técnico inicialmente caracterizada pela resistência ou indiferença da alta gerência.

Entre os principais desafios superados, pode-se destacar a identificação clara em relação aos ganhos obtidos, no estudo de caso, destaca-se os ganhos financeiros por meio da economia de insumos e serviços destinados as atividades educacionais práticas, essas atividades referem-se a atividades realizadas em laboratório como usinagem ou fresagem.

Outro aspecto de destaque é a clareza na descrição das etapas de implantação, apesar de largamente utilizada, a filosofia *Lean,* padece de instrumentos de implantação e

manutenção, em específico, desenvolvidos especificamente para unidades educacionais de ensino técnico.

Sugere-se como continuidade da pesquisa, manter as atividades e ampliar o número de ações e de seus impactos para outros setores da unidade educacional. Um ponto negativo foi a falta de interesse dos gestores regionais frente aos possíveis ganhos a serem obtidos com o projeto. Dessa forma, a falta mobilização e organização de horários, gerou obstáculos que poderiam ser evitados com o apoio da alta gerência.

Abstract. In this paper, we introduce the problem of minimizing total implementation cost of a 2-D indoor localization system for underground mine tunnels, guaranteeing a constant accuracy. To address this problem, we propose a system based on Cell-ID technique and visible light communication (VLC) technology with square panels of light-emitting diode (LED) lights, which fixes the maximum position error in each cell by considering the distribution of overlapping and non-overlapping cells. Formally, our system is mainly defined by an easy-to-implement algorithm based on a simple order rule. In order to illustrate the usefulness of the proposal, an example is provided. Finally, potential applications in the industrial environments are discussed and future research is proposed.

Keywords: Visible light communication, Indoor localization system, Accuracy, Cost minimization.

1 Introduction

In the last decade, visible light communication (VLC) systems for positioning has gained the attention of researchers due to its merits in terms of accuracy, cost, safety, and reliability for indoor environments [13]. Several works are related to channel design models [10, 8], while others researches assessed signal propagation and interference mitigation [11]. Most of researches related to the physical design of VLC [15, 5, 12] seeks to improve the system accuracy, considering accuracy as a result of the optimized location of the LED lights. Nevertheless, the research carried out by [6] seeks to determine the distribution of circular light-emitting diode (LED) lamps, mounted on the ceiling, in order to provide a 1-D linear positioning system with a constant accuracy along the tunnel. This perspective has large advantages in order to improve safety in mining operations.

Complementary to the previous works in this field, our research integrates the cost and 2-D positioning systems with overlapping and non-overlapping cells,

which allows to explore Cell-ID technique and VLC applications with square panels of LED light in larger mining tunnels.

2 Description of the indoor positioning system

2.1 General overview

We introduce the problem of minimizing total implementation cost of a 2-D indoor localization system with a constant accuracy. Consider underground mine tunnels, where the location is determined into the two coordinate axis (along the tunnel). In this scenario, we assume a 2-D indoor localization system based on Cell-ID technique and VLC technology. A practical implementation of Cell-ID and VLC technology is detailed in [6]. An unique code is assigned to each cell, in order to identify the lamp location. Each LED device is identical and produces a square illumination pattern subject to the used beam angle, which constraints on the minimum and maximum lighting area at the floor level and the position defined by it. Considering that the calculation of the accuracy depends on the amount of error present in the localization [16], several areas could be not necessary covered with a specific and constant error at minimal cost by using the same size of squares LED device.

To face this situation, a solution alternative emerges from the distribution of overlapping and non-overlapping cells. Some similarities with other problems in the family of *packing* are found. Considering the overlapping condition, our problem is close to the *three-dimensional bin packing problem* [9] and the *container loading problem* [3]. However, the most of these problems on 2D do not allow the overlapping elements to be positioned [7]. In addition, these problems consider the number of elements (or boxes) and their dimensions as parameters, no decision variables, with the goal of minimizing the free space [4]. Therefore, the results do not necessarily have to completely cover the surface.

To address our problem, without loss of generality we consider a rectangular area of sides a and b, $a \leq b$.

In the case of non-overlapping cells, a LED device produces a square illumination pattern of side ℓ with a maximum distance error δ between the real and estimated positions. This above value is expressed by $\delta = \frac{\ell\sqrt{2}}{2}$. Then, the projection of nine LED lamps has a coverage area of $(3\ell)^2$. Without loss of generality, we fix the maximum distance error $\delta = \frac{\sqrt{2}}{2}$, with $\ell = 1$. A VLC positioning system projection of nine square LED lamps in a rectangular area with $b = a$ with non-overlapping cells is illustrated in Fig. 1.

To consider the case of overlapping cells, we introduce the concept of *complete cell* as follows:

Definition 1. *A complete cell is a set of equal overlapping cells that defines a maximum distance error $\delta = \frac{\sqrt{2}}{2}$ independent of the number of cell identification codes received.*

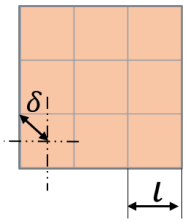

Fig. 1: VLC positioning system projection of nine square LED lamps with non-overlapping cells.

Fig. 2 illustrates a scenario with a complete cell with four overlapping cells of side $\ell = 2$, assuming equal distance between LEDs and identical beam angles. In this case, the mobile node estimated position will depend on the number of identification binary codes received from each cell and the maximum distance error δ between the real and estimated positions still remain the same, as it is depicted in Fig. 1.

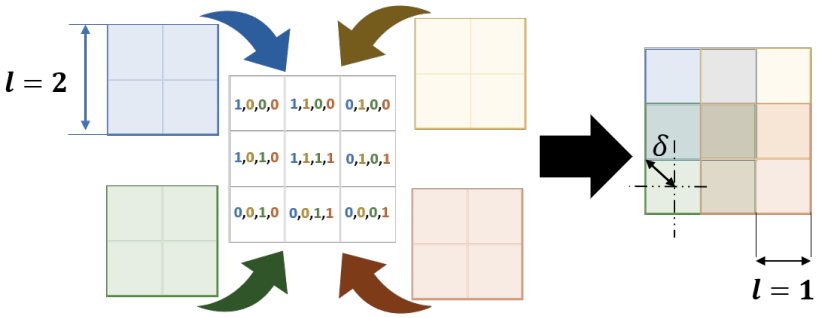

Fig. 2: VLC positioning system with a complete cell defined by four overlapping cells. The binary number with colors represents the possible cell identification codes received.

Theorem 1. *Consider a positive integer number ℓ. A complete cell the side $2 \cdot \ell - 1$, requires a set of ℓ^2 equal overlapping cells of side ℓ.*

The proof is based on geometric Euclidean analysis. The detail is omitted by space constraint.

From these above results, we propose a easy-to-implement algorithm in the next section.

2.2 Algorithm

Let α_ℓ be the cost of a unit cell of side ℓ, $\ell \geq 1$. First, we obtain a feasible solution for the rectangular area $a \cdot b$ by a number $a \cdot b$ of non-overlapping cells of side $\ell = 1$ with a total implementation cost equal to $a \cdot b \cdot c_1$. The previous value represents an upper bound for the objective value of the problem. Second, we compute the complete cell of maximum side $\ell_{\max}$ and the maximum number of each feasible complete cell β_ℓ defined by cells of side $\ell \leq \ell_{\max}$, comparing the implementation cost of a complete cell defined by cells of side ℓ and the non-overlapping cells of side $\ell = 1$ subject to the same coverage area. Finally, the algorithm considers a simple rule defined by the decreasing cost order $(2 \cdot \ell - 1)^2 / \left(\ell^2 \cdot \alpha_\ell\right)$, locating the cells configuration according to it when possible, and completing the remaining area with non-overlapping cells of side $\ell = 1$.

3 An illustrative example

Table 1 shows the parameters considered for an illustrative example, considering a rectangular area.

Table 1: Illustrative example parameters.

Rectangular area	sides	a=10	b=20		
	area	200			

Unit cell side (ℓ)	1	2	3	4	5
Unit cell cost (α_ℓ)	3.00	5.63	8.85	6.13	12.96
Complete cell side $(2 \cdot \ell - 1)$	1	3	5	7	9
Complete cell cost $(\ell^2 \cdot \alpha_\ell)$	3.0	22.5	79.7	98.1	324.0

The initial feasible solution is given by 200 unit cells of side $\ell = 1$ with a total implementation cost equal to 600. Finally, Figure 3 represents the solution obtained by the easy-to-implement algorithm, where the gray squares corresponds to unit cells that define the complete cells. This solution is optimal.

4 Conclusions

This article introduced the problem to minimize the total implementation cost of a 2-D indoor localization system based on Cell-ID technique and VLC technology for underground mine tunnels, guaranteeing a constant accuracy. The system is based on easy-to-implement algorithm based on simple order rule. The usefulness of the proposal is illustrated by an example.

From the obtain results, the benefits of our proposal for transmitting positional information about elements within indoor scenario could be extended

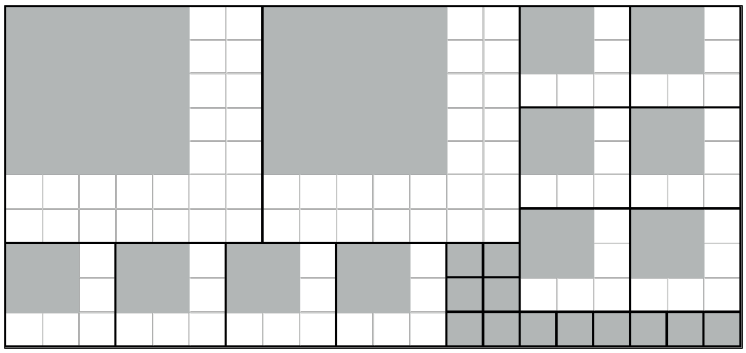

Fig. 3: Optimal VLC positioning system with overlapping and non-overlapping cells for the illustration example. The total implementation cost is equal to 457.3. The number of the considered complete cells defined by the overlapped unit cells of side ℓ equal to 5 and 2; are 2 and 11 respectively. The remaining space is completed with 12 unit cells of side $\ell = 1$.

to the industrial environment, in particular to conceive and design warehouse management systems (WMS), one of the central links in any supply chain [14]. In these systems, the part traceability control is based on detection by RFID systems or manual picking performed by operators with barcode reading devices [1]. However, it can lead to somewhat limited information on the real-time positioning of parts or inventory items. That is, once an item has been removed from its shelf (or rack) and is moved to another location, we only have information about the item being removed, and not about the evolution or path of that item. If there is movement control, it is on the carrier of the element [2]. Thus, our proposal would greatly improve the availability of information, with an easier implementation since it is directly linked to the lighting system.

Finally, future research work could be focused on the formulation of mathematical models and algorithms in order to obtain optimal or approximate solutions for the problem.

slpessa@utfr.edu.br

Abstract: O presente estudo apresentou a utilização do método PDCA como instrumento de padronização de processos e eliminação de falhas, voltado ao departamento logístico de um centro de distribuição de alimentos do sudoeste do Paraná. No que tange os procedimentos metodológicos, a pesquisa se caracteriza como um estudo de caso aplicado, com abordagem quali-quantitativa, descritiva e exploratória. Os resultados obtidos elucidam que a aplicação da metodologia se mostrou eficiente na identificação dos pontos falhos do processo, e na elaboração de planos de ação com o intuito de mitigar erros no processo de envio de mercadorias aos clientes finais, bem como na diminuição de gastos extras decorrentes de entregas não planejadas e combustível gasto pela frota de veículos. De maneira geral, pode-se observar que, de acordo com as expectativas a empresa alcançou seus objetivos com redução do gasto em combustível com os veículos da frota, melhoria no departamento estudado e desempenho operacional, em cerca de 60%.

Keywords: Método PDCA, Melhoria de Processos, Centro de Distribuição.

1 Introdução

O desempenho de qualquer empreendimento, depende de como é planejada e executada a atividade que se pretende explorar, usando os recursos naturais, materiais e humanos para alcançar os objetivos a que se propõe, considerando a inserção no contexto sócio-econômico e politico [1].

No setor industrial, a constante mudança em busca de aperfeiçoamento e a alta competitividade, fazem com que as empresas se esforcem para a competitividade de classe mundial. Isso também faz com que a manutenção esteja sob pressão crescente, objetivando melhorias, por exemplo, confiabilidade e disponibilidade das instalações de produção, assim como a redução de custos e resíduos. Com a implementação da manutenção centrada na confiabilidade, manutenção produtiva total e manutenção centrada nos negócios, tal conceito evoluiu muito nas últimas décadas [2]. Estes fatores exigem que as indústrias se comportem de maneira diferente adequando-se a esta realidade [3].

Da mesma forma, em um centro de distribuição (CD), os processos devem ser planejados e organizados, a fim de alcançar padronização sem desperdício de tempo. Um centro de distribuição traz como propósito possibilitar maior flexibilidade e dinamismo nas

entregas, no corte de custos de transporte e na armazenagem dos produtos [4]. Os principais objetivos de um centro de distribuicão são: receber, separar, armazenar e expedir os produtos para seus destinos finais.

O estabelecimento de uma rotina, planejamento, controles e melhorias para a manutenção possibilitam alcançar eficiência em termos de disponibilidade dos ativos, com custos competitivos e qualidade elevada [4]. Para tanto, se torna necessário traçar uma estratégia de manutenção adequada para as necessidades específicas da empresa [5].

A prática da melhoria contínua aplicada aos processos possibilita a eliminação da causa do problema em questão, partindo de sua identificação através de mecanismos de controle de processos, isso faz com que a qualidade deixe de ser uma opção e passe a ser vista como sinônimo de sobrevivência, tornando-se assim a satisfação total das expectativas e das necessidades dos clientes, passando a fazer parte da prestação de serviço, assim como do produto, assumindo a melhoria contínua como uma filosofia a ser seguida pelas organizações [6].

Para que a melhoria contínua seja implementada, existem diversas metodologias e suas respectivas ferramentas, capazes de auxiliar em processos de gestão. Uma das metodologias de destaque é o Método PDCA (Plan, Do Check, Action) que é um método capaz de gerenciar tomadas de decisão, com o objetivo de melhorar as atividades de uma organização, sendo também explorado na busca de melhoria de performance, o que torna este método capaz de contribuir significativamente para a obtenção de melhores resultados [7].

Considerando os conceitos apresentados, este estudo objetiva, de modo geral, apresentar a utilização do método PDCA como instrumento de eliminação de falhas em um centro de distribuição de alimentos localizado no sudoeste do Paraná.

Para tanto, foram traçados como objetivos específicos: verificar as causas de problemas operacionais do CD através da análise de processos; aplicar a metodologia PDCA para propor um plano de melhoria.

Este estudo se enquadra, em sua essência, como pesquisa aplicada, pois a finalidade do conhecimento produzido é de aplicação prática, utilizado na solução de demandas reais e específicas.

2 Referencial Teórico

2.1 Gestão da qualidade, gestão de processos e Ciclo PDCA

No meio industrial, tem sido feitos grandes investimentos para promover processos de melhoria contínua e redução sistemática de desperdícios, com a finalidade de se manter elevados índices de competitividade e qualidade dos produtos [1].

Um sistema de gestão da qualidade compreende todos os procedimentos utilizados por uma organização, para gerenciamento de suas atividades [8].

No entanto, na literatura vigente e qualificada, pode-se encontrar versões diferentes para qualidade, sendo a definição de qualidade pautada em atender as exigências do consumidor [9,10].

Os sistemas de gestão da qualidade são um importante meio para a introdução e sistematização da filosofia e dos procedimentos da qualidade nas organizações [11]. Esses modelos de gerenciamento de sistemas são oriundos da crescente complexidade dos processos produtivos, o que possibilita tratar de maneia simplificada problemas de cunho complexo [12].

No entanto, processo é o meio de transformação de inputs em outputs, no chamado processo de agregação de valor [13]. Processo é a produção onde efetivamente ocorre a transição dos inputs em outputs [14].

afirma que os processos devem ser mapeados e inseridos em um fluxograma que discrimina a sequência das atividades a serem realizadas, bem como seu grau de importância, pois na gestão de processos é essencial que cada colaborados tenha consciência do que seu trabalho representa, para que todos os envolvidos no processo possam contribuir para a eficácia do método, assim como deve ser na gestão da qualidade [15].

O Ciclo PDCA, sendo um método de gerenciamento de tomada de decisões, pode garantir o alcance das metas necessárias para a sobrevivência de uma organização [16].

O PDCA é uma ferramenta utilizada para a aplicação das ações de controle dos processos, diretrizes de controle, planejamento da qualidade, manutenção de padrões e alteração da diretriz de controle, com o intuito de realizar melhorias [17]. Dentro do PDCA podemos encontrar outras ferramentas coadjuvantes, como o Diagrama de Pareto, que consiste na apresentação de um gráfico de colunas, que permite a priorização de problemas, entre outras ferramentais. O Diagrama de Ishikawa, ou Diagrama de Causa e Efeito, como é também conhecido, é outra ferramenta da qualidade que fundamenta o PDCA. Sua função é organizar o raciocínio das discussões do problema em questão. O P (plan), D (do), C (check) e A (action), traduzindo do inglês para português significa: plan - planejar; do - fazer; check - verificar; action – agir (olhar Fig.1)

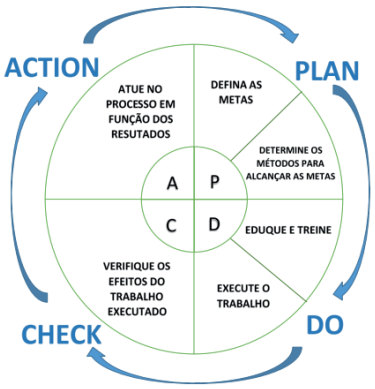

Fig. 1. O Ciclo PDCA

Na primeira fase do ciclo é realizado o estudo prévio de onde há problemas internos na empresa que estão gerando resultados diferentes dos esperados. Uma vez estabelecidos os pontos a serem melhorados, são elaboradas as metas para correção e o que

espera que aquela atividade ou processo desempenhe e alcance. Para esta fase, ferramentas coadjuvantes podem se utilizadas a fim de auxiliar na identificação dos problemas, como por exemplo o Diagrama de Pareto e Diagrama de Ishikawa [15].

O Diagrama de Pareto é representado através de um gráfico de barras verticais que dispõe a informação de forma visual e evidente, o que permite o estabelecimento das metas a serem atingidas [16].

O Diagrama de Ishikawa, por outro lado, possibilita estruturar de maneira hierárquica as causas do problema em questão, além de que foi projetado para ilustrar, de maneira cara, as várias causas que afetam um processo, através de classificação e relação de causas, permitindo estruturar sistemas que necessitem de resposta de forma gráfica e sintética, disponibilizando uma visão detalhada sobre o assunto estudado [18].

A segunda etapa é o "DO", termo originário do inglês que significa: fazer. Nesta etapa será dada ênfase à execução do trabalho onde é importante cumprir os padrões e métodos estabelecidos [3].

A terceira fase trata da verificação das metas e se as falhas foram verdadeiramente eliminadas, para tanto, se os resultados forem positivos, as metas forem atingidas e os objetivos alcançados, o processo pode passar para a quarta fase, no entanto se houver a verificação de que as metas não foram atingidas e as expectativas não foram sanadas, o planejamento precisa ser refeito e as etapas iniciadas novamente.

Na quarta e última fase do ciclo, ocorrerá a tomada de ações corretivas, caso seja necessário ou a padronização do processos adotados, para casos onde os objetivos foram alcançados. Nota-se que esse método é amplamente utilizado pro organizações par gerenciar seus processos internos, de forma a garantir alcance de metas estabelecidas, tendo as informações como fator de direcionamento das decisões [19].

O PDCA padroniza as informações do controle da qualidade, evita erros lógicos nas análises, e torna as informações mais fáceis de serem entendidas. Pode também ser usado para facilitar a transição para o estilo de administração direcionada à melhoria continua [17].

2.2 Cadeia de Suprimentos

A gestão da cadeia de suprimentos é um processo estratégico. Lida com a previsão da demanda, seleção dos fornecedores, fluxo de materiais, contratos, estuda informações e movimentações financeiras, cria novas instalações como fábricas, armazéns, centros de distribuição; se relaciona com clientes, e trata também de questões mais amplas como a economia, a sociedade, o meio ambiente [20].

De maneira geral, a cadeia de suprimentos é uma abordagem sistêmica, a qual demanda alta interação entre os participantes, necessitando de cooperação simultânea de diversos *trade-offs* [21].

Dentre os benefícios do estudo da cadeia de suprimentos de forma integrada destaca-se melhor gestão do fluxo da demanda, a qual pode melhor sinalizar a necessidade de compra e venda de produtos, diminuindo os desperdícios e prejuízos [3].

2.3 Centro de Distribuição

O Centro de Distribuição é uma configuração regional de armazém onde são recebidas cargas consolidadas de diversos fornecedores. Essas cargas são fracionadas a fim de agrupar os produtos em quantidade e sortimento corretos e, então, encaminhadas para os pontos de venda, mais próximos [22].

O CD é um ponto de intermédio entre os fornecedores e o cliente final [23]. Nas empresas sentiram necessidade de utilizar os centros de distribuição, dada a alta demanda de pedidos e a necessidade de melhor gerenciá-los [17,23].

Os centros de distribuição propiciam redução no custo de transporte e, com isso, a maximização dos lucros e da agregação de valor ao produto. Um centro de distribuição que é utilizado por vários fornecedores garante que os mesmos trabalhem com cargas consolidadas. Para consumidores, por outro lado, além da diminuição no custo de transporte, existe a economia de duração de operação gerada, graça ao recebimento de uma única carga, por exemplo, com todos os materiais necessários, ao invés de receber carregamentos divididos e de vários fornecedores [24].

Ao reduzir custos logísticos e aumentar a eficiência na movimentação de mercadorias, o CD acaba contribuindo para a melhora nos níveis de serviço, colocando a empresa tomadora de serviço em um novo patamar de competitividade. Através desse nível de serviço, a empresa pode aumentar sua participação no mercado [3].

3 Metodologia

Para que o conhecimento gerado seja aceito como científico, é necessário que o processo de construção considere regras e procedimentos, além de atentar para o formato, o método e os instrumentos do "conhecer" [25]. A determinação do método científico é relevante para a efetivação do estudo e seus resultados, visto que pretende nortear e delinear os meios utilizados para a sua validação [11].

A pesquisa caracteriza-se como um estudo de caso com abordagem quali-quantitativa, descritiva e exploratória. O estudo de caso é uma pesquisa que busca analisar fenômenos atuais em uma situação real, dentre os maiores benefícios, destaca-se a possibilidade de desenvolver uma nova teoria, e de aumentar o entendimento sobre eventos reais contemporâneos [26]

Ainda, em relação à abordagem do problema, em situações em que há questionamentos subjetivos de indutivos, explana-se como um estudo qualitativo, e nas circunstâncias em que os dados podem ser mensurados considera-se como pesquisa quantitativa [27].

Com o intuito de preservar a identidade da empresa pesquisada, o codinome CDD será adotado para representar a empresa. O processo estudado foi o desenvolvido pelo setor da expedição, com enfoque principal a entrega das mercadorias aos clientes, ou seja, a expedição e a logística. A pesquisa não se retringiu apenas a esse setor, de forma isolada, o setor de faturamento, de maneira específica a Nota Fiscal eletrônica, também presente no processo da expedição foi observado.

Os setores da expedição e faturamento pertencem a departamentos distintos, sendo a expedição parte do departamento de logística e o faturamento parte do departamento financeiro.

O processo do CDD se inicia com o recebimento das cargas consolidadas, sendo as mercadorias conferidas e alocadas de acordo com suas respectivas famílias de produtos; independente da marca do produto, quando recebido pelo CDD é alocado com seus similares (olhar Fig. 2). A organização do local de armazenagem é responsabilidade do setor de expedição.

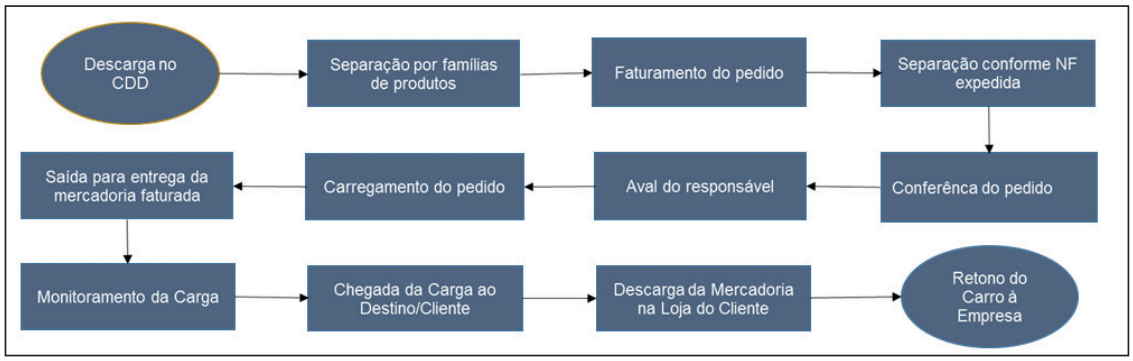

Fig. 2. Descrição do processo de recebimento de cargas consolidadas

Sempre que um cliente efetua um pedido na plataforma on-line, este é recebido pelo setor de faturamento, o qual expede a Nota Fiscal eletrônica (NFe) e a envia ao setor da expedição para que o pedido possa ser separado e, posteriormente, entregue a seu destino final. Esse processo se inicia com a separação da mercadoria constante no pedido, a qual, após separada, é conferida pelo colaborador responsável pelo setor da expedição, o qual assina o pedido, liberando-o para que possa ser alocado no veículo que realizará a entrega.

Como os pedidos dos clientes são entregues em datas específicas, o veículo que realizará a entrega é demandado pelo tamanho e quantidade de pedidos a serem entregues.

Após todos os procedimentos de conferência da carga, a mesma é alocada no veículo de entrega, de modo a minimizar possíveis avarias.

Cada veículo é designado para uma rota específica, estipulada a partir da localização das lojas dos clientes. Todos os veículos que compões a frota responsável pela entrega dos pedidos, carrega um dispositivo GPS, o qual é acompanhado pelo responsável pelo setor da expedição, de dentro da empresa sempre que os veículos saem da empresa para realizar as entregas.

Os dados foram coletados através de observações in loco dos setores estudados e da análise de documentos disponibilizados pela empresa. Após a coleta de dados, as informações coletadas foram tabuladas em questionários eletrônicos e analisadas de

forma qualitativa e quantitativa, pautadas na bibliografia vigente e qualificada. Os resultados obtidos se encontram na seção subsequente deste estudo.

4 Resultados

Esta seção apresenta a aplicação do método PDCA no setor de expedição do CDD, considerando que é o setor que mais gera custos à empresa. A seguinte ordem foi obedecida para a aplicação do método: identificação do problema, observação do problema, análise, planejamento/plano de ação, ação, checagem, padronização e conclusão (olhar Fig. 3). Além da ferramenta PDCA, utilizou-se como ferramenta coadjuvante o Diagrama de Ishikawa e o Diagrama de Pareto.

Fig. 3. Cronograma simplificado da aplicação do método PDCA

O estudo ocorreu entre os meses de janeiro e julho, no ano de 2019 e, por meio da observação dos processos desenvolvidos pela empresa, pode-se constatar que haviam alguns gargalos no processo estudado, de maneira específica, na entrega das mercadorias aos clientes. Foi possível identificar a necessidade de realizar melhorias entre a comunicação dos setores envolvidos, considerando que havia demora excessiva entre o faturamento do pedido e a expedição da NFe, acarretando no atraso de alguns veículos, bem como entregas não programadas, desenvolvidas em regime de urgência, dada a necessidade de um cliente por determinada mercadoria, gerando custos extras com frota de veículos de entrega, para tanto, foi realizado um Braisntorming com os responsáveis pelos setores estudados, juntamente com a equipe gestora da empresa, (olhar Fig. 4), para que as possíveis causas de problemas pudessem ser levantadas e , posteriormente, corrigidas.

8

Causas	Possíveis Soluções
Entregas Imediatas	Reorganizar faturamento dos pedidos. Entregas a cada 14 dias
Movimentação desnecessária dos carros e colaboradores	Efetuar entregas somente quando necessário/Cada colaborador deve desempenhar uma função e ser responsável por ela
Excesso de manutenção corretiva nos carros/perda de tempo com conserto que origina gastos com outro carro para efetuar a entrega do pedido	Políticas de incentivo e pré agendamento para as manutenções preventivas.
Carros da frota que apresentam problemas	Propor a checagem e cuidados com os carros
Falta de organização na hora de carregar a mercadoria nos carros	Delegar a função a um colaborador que deverá conferir a mercadoria e organizar o carregamento das mercadorias dentro dos carros, sendo responsável pelo processo.
Falta de comunicação entre os setores, em específico, a direção e o setor logístico	Abrir espaço nas reuniões para sugestões e reclamações, levando em conta as ideias dos colaboradores.

Fig. 4. Causas latentes de problemas no CDD

Após levantamento, medidas iniciais estudo de ações corretivas e planejamento foram analisadas, para que se pudesse aplicar o método PDCA. O Diagrama de Pareto (olhar Fig. 5) foi aplicado como ferramenta coadjuvante de identificação.

Fig. 5. Diagrama de Pareto relacionado aos problemas do CDD

Com a elaboração do Diagrama de Causa e Efeito, o departamento logístico pode compreender de forma mais os possíveis erros identificados, podendo agir de maneira a adequar seus processos e reorganizar suas entregas.

As respostas para as sete perguntas foram obtidas juntamente com a diretoria da empresa, pautadas em estudos analíticos e sugestões dos colaboradores visto a necessidade de respaldo para cada ação que seja tomada dentro da empresa.

Após a implementação da ferramenta da qualidade PDCA, a equipe do setor logístico, como um todo, passou a enxergar o processo por eles desenvolvido de uma maneira mais crítica e técnica. Os colaboradores desse setor passaram a ter mais disciplina e cuidado ao desempenhar qualquer atividade envolvendo a logística e a organização do depósito, a partir disso pode-se notar que os resultados obtidos com a implementação de todos os passos do PDCA foram positivas do ponto de vista financeiro e das relações entre os setores da empresa, pois as mudanças proporcionaram organização e melhor sintonia entre os setores, departamento e os colaboradores da empresa.

O PDCA continua sendo aplicado, principalmente onde ainda existem falhas, não somente no setor da logística, mas na empresa como um todo, ou seja, o ciclo é reiniciado passando por todas as etapas citadas; o PDCA "gira", assim garantindo a melhoria contínua.

Em um comparativo entre o mesmo período dos anos de 2018 (olhar Fig. 6), onde a melhoria ainda não havia sido aplicada, e de 2019, já com a implementação da melhoria, pode-se observar valore significativos relacionados a adequação das falhas identificadas.

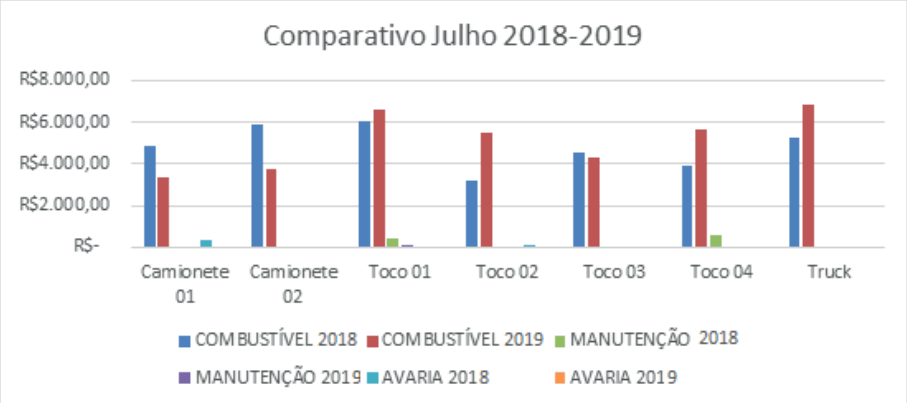

Fig. 6. Comparativo das despesas com a frota, entre o mesmo período dos anos 2018 e 2019.

O gráfico acima foi estruturado com valores obtidos através do levantamento e controle de custos, cujo o departamento da logística é responsável. Tais valores correspondem ao gasto mensal (mês de julho), dos anos de 2018 e 2019, bem como as incidências dessas causas também contadas mensalmente.

Ao observar o gráfico, pode-se notar que os custos com combustível e manutenção dos carros, no mesmo período dos anos de 2018 e 2019, diminuíram significativamente, visto que as entregas passaram a acontecer apenas a cada quatorze dias, dada à necessidade de mudança no plano de entregas.

O foco do estudo teve como base as entregas feitas logo após o faturamento das mercadorias, ou seja, assim que um pedido é faturado, o caminhão sai para entregar.
Em média, um caminhão roda 3,45 Km com um litro de óleo diesel, então, para uma cidade cuja distância é de aproximadamente 280 Km, partindo da sede da empresa, considerando a ida e a volta e admitindo que o valor de um litro de óleo diesel seja em torno de R$ 2,88, o gasto com combustível seria de aproximadamente R$ 467,00.

A descarga nessa cidade, por exemplo, antes da implementação da melhoria e reformulação do plano logístico, era feita sempre após o faturamento do pedido do cliente, o que girava em torno de cinco vezes por mês, então, o gasto de combustível, somente com essa cidade, seria de aproximadamente R$ 2335,00 mensais.

A partir da efetivação das melhorias, o caminhão passou a descarregar apenas duas vezes por mês nessa rota, totalizando um gasto de R$ 934,00, que comparado ao valor anterior, significa uma redução de aproximadamente 60 % do valor gasto apenas com combustível.

Ao final de doze meses, para um único caminhão, o valor poupado será de R$ 16.800, 00, aproximadamente, em combustível, salvos eventuais contratempos como quebra do caminhão ou possíveis acidentes.

5 Considerações finais

Com a aplicação do método PDCA, foi possível sugerir um plano de ação, bem como ações corretivas, quando necessário, com o objetivo de mitigar erros ou torná-los inexistentes. De acordo com a perspectiva e projeção, a empresa conseguiu alcançar seus objetivos, com melhoria no nível de serviço e desempenho operacional de, aproximadamente, 60%. A metodologia utilizada foi eficaz, demonstrando ser uma medida viável e que pode alcançar resultados esperados e, de certa forma, essenciais à empresa.

Como toda empresa, negócio ou ramo de atividade, a empresa pesquisada apresentava a necessidade de aperfeiçoamento, o qual foi planejado e demonstrado a partir de mudanças feitas por um grupo de pessoas que receberam instruções e aperfeiçoamento quanto à técnica de melhoria empregada.

No caso da empresa em questão, onde sua essência é a logística, os resultados tardaram a aparecer pois a mudança não ocorreu de forma imediata, porém, através de comparações entre as planilhas de entrega, que constavam as quilometragens dos carros, de antes e depois da implementação da melhoria, pode-se observar um melhor aproveitamento do tempo de trabalho disponível, o qual antes, os motoristas passavam apenas na estrada e agora podem usar o tempo em que não estão fazendo entregas para

organizar e limpar o CDD, bem como para fazer a manutenção preventiva e limpeza nos carros.

Através de relatórios semanais elaborados pelos colaboradores responsáveis pelos departamento de logística e faturamento, pode-se observar diminuição nos custos com manutenção corretiva e com avaria de carga e, consideravelmente, a redução com custos de combustível e pedágios, por exemplo, um caminhão toco que antes das melhorias custava cerca de R$ 7000,00 mensais à empresa, após a efetivação das melhorias passa a custar em média R$ 3500,00. Nesse caso houve redução de 50% do valor gasto inicialmente.

Os resultados obtidos, apesar do curto período de tempo, são satisfatórios, pois as mudanças proporcionaram uma melhor organização nos processos desenvolvidos pela empresa, principalmente nos que apresentavam mais falhas, como era o caso do plano logístico.

Juntamente com as melhorias no plano logístico da empresa e treinamentos de pessoal, o que tem papel fundamental para o constante aperfeiçoamento da empresa são as pesquisas de satisfação aplicadas aos associados por meio de e-mails, onde o cliente tem liberdade para opinar sobre o serviço que é oferecido pela empresa, bem como reclamar de algo ou sugerir alguma mudança. Tudo isso é levado em consideração dentro das reuniões mensais da presidência e diretoria e, o que for pertinente, é repassado aos envolvidos de cada setor.

As melhorias foram recentemente implementadas, porém, até o final do segundo semestre de 2019, a empresa espera obter resultados ainda melhores com os valores poupados que poderão ser redirecionados para o aumento da frota e expansão da empresa.

Abstract. To maximize the use of waste from rice production and the strengthening of the ceramic industry sector in Norte de Santander, the use of rice husk (Oryza sativa) generated as a by-product of waste in the rice industry was evaluated, as raw material for the production of a material agglomerated with clay (brick), for the housing construction sector. According to Suryana (2018) [8], the silica-rich composition of the rice husk is an advantage in the manufacture of ceramics; Portillo (2013) [10] evaluated the use of rice husk in its natural state, ground or ash for the manufacture of elements intended for construction; Díaz (2013) [11], found that composite materials for masonry use clay or cement as a matrix and as reinforcement, agricultural residues such as rice husk due to its low density, resistance to stress and low thermal conductivity. The rice husk process was carried out by 3 stages: the characterization of raw materials, (rice husk and clay); the realization of two formulations varying the amounts of rice husk and clay, (10% husk 90% clay) and (20% husk 80% clay); and the quantitative evaluation of the properties of the agglomerated material. The formulation of 10% rice husk and 90% clay, complied with the Colombian Technical Standard 4205, which establishes the mechanical strength parameters for the compression of vertical drilling masonry units such as blocks and bricks which makes it optimal for housing construction.

Keywords: 1.Husk 2.Clay 3. Agglomerated 4.Rice 5. Construction

1 Introduction

According to the Development Plan for Norte de Santander, Colombia 2016-2019, "Un Norte Productivo para todos", the rice chain represents an important economic line of the department according to the Governorate of Norte de Santander (2016) [1]; however, according to Sierra (2009) [2]; 20% of rice production is a by-product called husk, which due to its physical-chemical constitution, is a waste of very difficult biodegradation, its use is limited and it represents a considerable problem when it is incinerated in the open, generating a negative impact on the environment.

According to Sierra (2009) [2], in Colombia, although the use of rice husk is limited, different alternatives for the use of this raw material have been studied; at an international level, the characteristics of rice husk related to combustion have been studied, according to Wang (2018) [3], by increasing the proportion of rice husk, both the combustion temperature and the amount of nitrogen oxides decrease and the effect is gradually reduced. Rice husk has also been used in the construction sector, according to Ferrão (2017) [4], rice husk has been proposed as a substitute for traditional asphalt pavement fillings; In a study conducted by Widiarini (2018) [9] the porosity of a material composed of silica from rice husks was analyzed

On the other hand, the quality of the clays of the Department of Norte de Santander for the elaboration of materials destined to the construction, have also been evaluated, Rozo (2013) [12], determined the physical and mechanical properties of H10 blocks manufactured in the metropolitan area of Cúcuta.

To maximize the use of waste from rice production, the strengthening of the ceramics industry sector in Norte de Santander and thinking about the need that the construction sector has for constant innovation through environmentally friendly projects, the use of rice husk (Oryza sativa) generated as a by-product of waste in the rice industry was evaluated, as raw material for the elaboration of a material agglomerated with clay, intended for the housing construction sector; this process was carried out through 3 stages: the first consisted in the characterization of the raw materials, (rice husk and clay); the second stage consisted in the realization of two formulations varying the amounts of rice husk and clay, (10% husk 90% clay) and (20% husk 80% clay), however, it was only possible to work with the first formulation and the third stage consisted in the quantitative evaluation of the properties of the agglomerated material, the methodology used to determine the physical and mechanical properties of bricks of agglomerated material was taken from Colombian Technical Standard NTC 4017 [5], methods for sampling and testing of masonry units and other clay products; the analysis that was made to each of the samples was the determination of the mechanical resistance to compression.

2. Materials and methods

2.1. Characterization of rice husk and clay. To characterize the rice husk, the humidity percentage tests were carried out, chemical analysis of ashes, lignin and cellulose; for carrying out these tests, the particle size of the rice husk was not reduced.

To perform the characterization of the clay, an extruded ceramic physical analysis was used, in which parameters such as: dry conditions (length and mass), firing conditions (length and mass), dry shrinkage, shrinkage in cooked, dry mass losses, cooked mass losses, percentage of water absorption, percentage of initial moisture and retained on sieve 230; 10 clay samples were used to carry out this analysis.

The tests that were applied to characterize the clay are governed by the Colombian Technical Standard (NTC 4017) [5] , which establishes the methods for sampling and testing of masonry units and other clay products which allowed to identify the chemical, physical and ceramic characteristics of clay.

For the physical-ceramic characterization, the extrusion shaping method was used, the mixing water was calculated based on the plasticity of the sample, a rectangular nozzle was used and 10 cm long test tubes were made. The analysis of content retained on a sieve was carried out taking into account the procedure established in the ASTM C325 standard. Likewise, linear shrinkage in drying and cooking was measured; the drying shrinkage was made with specimens of known dimensions, which were subjected to drying at 105 ° C for 24 hours, and the firing shrinkage was carried out with the initial dimensions of the dry specimens and the final dimensions of the fired specimens.

The calculation of the contraction was made by measuring the difference in dimensions and thus determining the percentage of contraction of the specimens, and with the data of the difference in dry mass and in firing, the losses due to calcination were determined. Water absorption was determined following the methodology set forth in the NTC 4321-3 standard [10].

2.2. Design of the formulations. Two formulations were designed varying the amounts of rice husk and clay, (10% rice husk and 90% clay) and (20% rice husk and 80% clay), the first formulation allowed the extruded process, of which five samples were made, which were prepared according to the Colombian Technical Standard NTC 4017 [5].

2.3. Quantitative evaluation of the properties of the agglomerated material. The methodology used to determine the physical and mechanical properties of bricks of agglomerated material, is based on the Colombian Technical Standard NTC 4205 [6], the quality of the requirements that must be met by cooked clay bricks. The analysis performed on the five specimens was the determination of the mechanical resistance to compression.

The technique used to determine the physical and mechanical properties of agglomerated material bricks was taken from NTC 4017, methods for sampling and testing of masonry units and other clay products, where the procedures for selection and preparation of the sample. The analysis that was carried out on each of the ten bricks (five for each formulation), was the determination of the mechanical resistance to compression.

According to Rozo (2013) [12], the resistance to compression of clay brick, f'cu, is used as a quality control in the elaboration (dosage of the materials, temperature and time per burning), to know the quality of the materials and the raw material used in the manufacture of brick and to find the compressive strength of the masonry, f´m, from formulas that relate the properties of the unit and the mortars. The dimensions of each

of the bricks (length and width) and the weight were taken. The results were compared with the data established in the NTC 4205[6], standard which sets the requirements that ceramic bricks and blocks must meet, used as masonry units and establishes the parameters with which the different types of stone are determined.

3. Results and discussion

3.1. Results of the physical chemical characterization of rice husk. The results obtained from the analysis on dry basis of the rice husk used as sample for the elaboration of the agglomerated material, are observed in table 1.

Table 1. Results of the physico-chemical analysis of rice husk

Essay name	Result	Method
Ash	16.99%	AOAC 942.05
Acid Detergent Fiber (FDA)	52.46%	AOAC 973.18
Humidity	7.56%	AOAC 925.10

(Test result, 2018)

The results of the ash test are detailed in table 2 and compared with those obtained by Baller (2016) [7].

Table 2. Result of percentage of ash of rice husk present in 2 investigations

Sample	Analysis # 1 Baller (2016)	Analysis # 2 Authors (2018)
M1	17.32	16.91
M2	15.61	16.89
M3	17.07	16.92
Average	16.75	16.99

Fuente: (Justein Baller ., Alejandro Ríos, 2016)

Unlike the study by Baller (2016) [7] in which the determination of the percentage of ash is made in a time of 2.5 hours obtaining an average of 16.75% of ash, in the present investigation, 5 were required hours, obtaining a 16.99% ash.

Once the FDA test was done and comparing the results with the Baller (2016) [7] it is evident that the FDA percentage obtained was 52.46%, result lower than that obtained by Baller (2016) [7] in which a 64.39% FDA was obtained. It is evident that the fibrous amount of the plant tissue corresponding to cellulose and lignin is lower.

Comparing the percentage of humidity obtained with 7.56%, with the results of the study carried out by Baller (2016) [7] 8 to 15%, it is observed that the rice husk used in

this research has a lower amount of water, which favors the elaboration of the agglomerated material.

3.2. Results of the physical-chemical characterization of the clay:

To know the state and the physical and chemical composition of the clay used in this investigation, two tests were carried out, one physical (physico-ceramic) and one chemical (x-ray fluorescence), through which it was possible to observe the conditions that the clay has tomake the agglomerated material and check its mechanical resistance to compression.

3.2.1 X-ray fluorescence results

The X-ray fluorescence results were provided by the Sigma brickyard, where the following chemical composition of the clays is established: high contents of silicon 64.3%, aluminum 19.3%, iron 5.48%. And when comparing it with the analysis carried out by Cáceres, Sánchez & Chaparro., (2017) I was verified that the region has a high quality of clays since both studies reflect a high content of these elements, 5.48% of Aluminum represents the characteristic color of clay used in this research higher than the 4.73% present in the previous author's test. The 64.3% of silicon content is higher than the 28.96% obtained by Cáceres et al., (2017) which shows that the clays of our region have faster cooking speed. Likewise, the difference in the proportion of other elements found in the sample used for this research, but at the same time, as in the research of Cáceres et al., (2017) they present a low content of organic material, which is favorable, since the lower amount of organic matter avoids that in the cooking process there are empty spaces due to the consumption of this material [13].

3.2.2 Results of the ceramic physical characterization of clay. Table 3 shows the results obtained when performing the physical extruded ceramic analysis, to the formulation of 10% rice husk and 90% clay.

Table 3. Physical analysis by extruded ceramic

Sample.	Temp °C	Dry Condition		Cooked Condition		Contraction		Lost of mass		Water Absorption (%)
		Length (mm)	Mass	Length (mm)	Mass	Dry (%)	Cooked (%)	Dry (%)	Cooked (%)	
1		90.00	88.51	83.89	58.97					
2		90.00	85.88	84.39	57.16					
3		90.00	87.30	84.14	58.04					
4		90.00	85.72	84.45	57.12					
5	980	90.00	86.15	84.41	57.19	3.01	3.53	23.19	13.41	23.12

(Test result, 2018)

At the beginning of this extrusion process, the homogeneous mass consisting of rice husk and clay in the proportions mentioned above, an initial humidity of 1.05% was presented and an extruded pressure of 35 mmHg. There was a low level of material change in length with a contraction of 3.01% in dry material. On the other hand, these results show a contraction of 3.53% and a mass loss of 13.41%.

3.3. Results of the design of the formulations. From the characterized raw materials, two formulations were made, one with 10% rice husk and 90% clay and another with 20% rice husk and 80% clay; the elaboration of agglomerated material, was carried out according to the Colombian Technical Norm NTC 4017 [5], through the processes of mixing, forming, drying and firing of the samples, Figure 1, shows the process: mixed, extruded, drying, and cooking.

A B C D

Fig 1. A. Mixed, B. Extruded, C. Drying, D. Cooking

3.4. Result of the quantitative evaluation of the properties of the agglomerated material. The test of mechanical resistance to compression, was carried out in the treatment of 10% rice husk and 90% clay, an average breaking load of 205.79 N. was applied to each muestra. The ten test pieces evaluated from the formulation to 10% of rice husk had rectangular shape and average dimensions of 113.64 millimeters long and 36.60 millimeters wide.

It was found that the samples comply with the compressive mecanic strength properties of vertical drilling masonry units such as blocks and bricks, established in the Colombian Technical Standard NTC 4205 [6], whose parameters are between 100 kgf/cm2 to 140kgf/cm2.

4. Conclusions

The Colombian technical standard (NTC 4205) used for testing masonry units and other clays and to evaluate the chemical, physical, and ceramic characteristics of the clay establish a mechanical resistance range of 100 kgf / cm2 - 140 kgf / cm2, the agglomerated material produced in this research has a mechanical resistance of 99.5 kgf /

cm2, which reflects that the percentage of rice husk used to make a more resistant solid brick must be less than 10%.

The absorption of water that the Colombian Technical Standard 4205 stable must be in a range of 17 - 20%, once the material has been carried out in this investigation has an absorption higher than the established range, yielding a percentage of 23.12%. What would facilitate the risk of mold appearance in the long term, this characteristic is presented by the amount of rice husk used in the manufacture of the agglomerated material, since when the material is baked, pores are generated due to the presence of rice husk, which facilitates the entry of moisture to the solid brick.

From the physical analysis by extruded ceramic it was found that the material in its drying process after cooking obtained small loss of length, went from 90mm to 83.56 mm, which shows that the mixture of 10% rice husk and 90% clay is suitable for making this type of agglomerated material.

RESUMEN

Las empresas cuentan con distintos tipos de procesos en su cadena logística. De esta manera, el valor añadido que se entrega a cada eslabón genera un arma competitiva fundamental, tales como excelencia y diferenciación en el servicio de entrega, acoplarse a la tecnología y adelantarse a lo que necesitan o esperan los clientes, lo que trae como consecuencia que las empresas deben tener una eficiente gestión de inventario y recursos. Por lo que en este trabajo se estudia el caso de una Pyme, empresas que necesitan gestión de inventario para no perder clientes. En este caso se modela y simula el proceso de inventario y ventas utilizando Bizagi Modeler, con lo cual se lograron obtener los quiebres. Se modeló y simuló la situación actual y propuesta dando como resultado en la situación propuesta a un valor entre 0 y 0,5%

Keywords: Gestión de Inventarios, Simulación, BPM

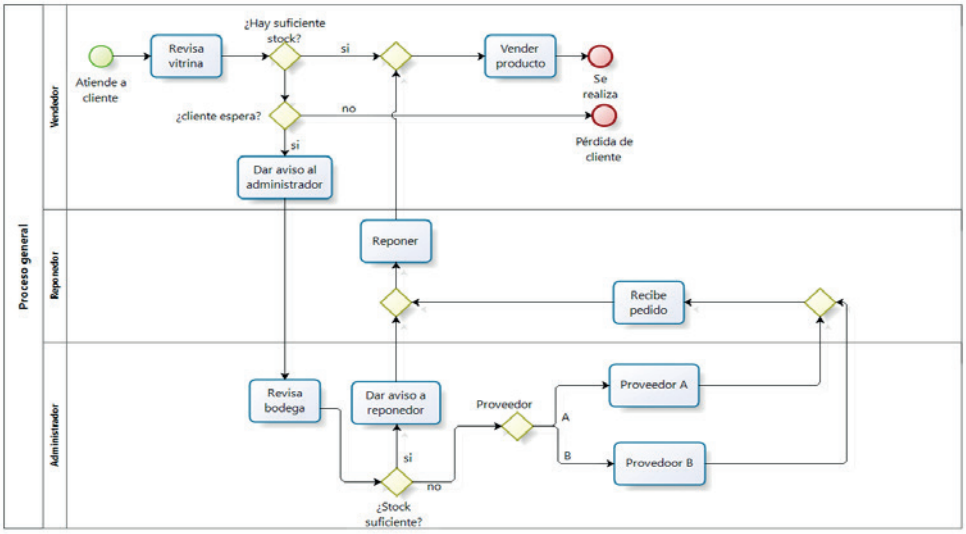
1. Introducción

Las empresas necesitan aprovisionarse de bienes y servicios para el desarrollo de sus actividades. Estos aprovisionamientos se acumulan en las empresas y deben ser gestionados para su correcta manipulación y conservación. Las pequeñas empresas deben contar con las competencias y habilidades suficientes para mejorar en forma permanente la gestión de sus recursos y así permanecer insertos en el mercado.

Para que las empresas tengan un impacto positivo en la satisfacción del cliente, es importante contar con una adecuada gestión de inventario para hacer frente a la demanda que se presente, evitando quiebres de stock que dificulten el proceso de ventas. Además de brindar una excelente atención al cliente diferenciándose de la competencia desde que se llega a la tienda hasta un servicio post venta.

Actualmente por efecto de la pandemia la empresa en estudio, empezó a trabajar online, comercio electrónico, por lo que cada vez la gestión de inventario sea hace necesaria para un mejoramiento de atención a los clientes, dado que en varios casos, los clientes, cuando no existe un producto este se pierde, si los clientes deben esperar el producto, estos esperan y vuelven el día que esta el producto en tienda.
Por las razones anteriores, el objetivo de este trabajo es proponer mejoras a la gestión de inventario, con la herramienta de simulación de Business Process Management (BPM), Bizagi Modeler para una pequeña empresa (Pyme) de Joyería, la cual se especializa en comercializar artículos de lujo como, joyas de oro de 18k y 24k tanto en tienda física como online. Se destaca que según el Ministerio de Economía las Pymes en Chile son un 48,7% de las empresas.

2. Revisión Bibliográfica



Según Christopher (1994), Prida y Gutiérrez (1996), Gómez y Acevedo (2000) el valor añadido que incorpora la logística en cada uno de las partes del sistema logístico constituye un arma competitiva importante. Tal es el caso de la excelencia en el servicio de entrega, el liderazgo en la diferenciación del producto, la gestión con un mínimo de costo o el servicio logístico al cliente sobre la base de una eficiente gestión de los inventarios.
Según Putra, Santoso (2020), las PYMES identifican las esferas contextuales que pueden orientarlas para utilizar con éxito el comercio electrónico y hacer realidad sus posibles beneficios. Por otra parte se dice que el comercio electrónico tiene un impacto positivo en el rendimiento y el impacto a nivel estratégico es indirecto, mediando a través de los niveles operacionales y de gestión.
En Nemtajela, Mbohwab (2017) la gestión de inventario debe recibir la atención que merece para que la empresa siga siendo competitiva, flexible para la demanda y a bajo costo. Los inventarios son difíciles de gestionar y controlar, y a los administradores de inventarios les resulta difícil saber cuándo pedir y cuánto pedir.
En Silva (2018), también se utiliza , la metodología BPM que le permitió simular los tiempos y el costo de cada uno de los procesos de gestión de inventarios, de una empresa Pyme en Guayaquil , Ecuador, lo que le permitió documentar todos los procesos del centro de distribución de la empresa logrando la optimización de sus recursos.
Por otra parte Morocho 2019 dice que los flujogramas se han utilizado a nivel mundial como una herramienta gráfica para describir la secuencia de actividades que corresponden a los procesos, además traen beneficios como

minimización de errores, relacionados con los protocolos de ejecución de actividades en las empresas. Además modelan los procesos para mejorar la gestión de inventarios con Bizagi Modeler.

3. Metodología

Primeramente se recopilan los datos de las ventas históricas de la empresa, y se clasifican con la metodología ABC para ordenar los artículos según los que más generan ingresos, para agrupar y trabajar de mejor manera los datos.
Una vez obtenidos los productos que generan mayores ingresos, los cuales son: tipos de aros 1, y 2 , collares, y pulseras, todo los artículos de oro de 18kilates.
El proceso de venta e inventario se diseña en Bizagi Modeler donde se obtienen los quiebres, para mejorarlos.
El diseño del proceso actual se muestra en **Figura 1.**

Figura 1: Proceso de ventas y stock

En la Figura 1, se visualiza que el proceso cuenta con tres participantes vendedor, reponedor y administrador. Cada uno de estos actores tiene actividades específicas a desempeñar. El proceso empieza cuando el vendedor atiende a un cliente y finaliza cuando el cliente compra un producto disponible o se retira por falta de stock.

El proceso cuenta con un quiebre, como se muestra en el diseño, cuando el cliente no quiere esperar porque no existe stock del artículo que desea, por lo que se pierde el cliente.
Una vez diseñado el proceso, se simula con Bizagi Modeler, para obtener los resultados de la situación actual, y la situación propuesta.

4. Proceso de simulación

Para realizar el proceso de simulación, se supone que la entrada de clientes se distribuye según una distribución Normal, con una media de 12 min., es decir cada 12 min. entra un cliente, esto con una desviación standar de 2, el proceso se simula para un mes, con un horario de 8 hrs. los 7 días de la semana. Otro supuesto es que los clientes pueden solicitar comprar más de un artículo a la vez, y hasta 100 artículos a la vez, los datos obtenidos son de la situación actual.

El proceso de la situación actual, con datos históricos parte solicitando stock para un mes, donde el lead time es de 1 semana y se solicitan pedidos de 400 productos, en el mes.

La simulación se llevó a cabo solo a los productos que dejan mayor margen, como se explicó en el capítulo 3 que son anillos de dos modelos distintos, pulseras de, cadenas, todos los productos el oro solo es de 18 kilates.

5. Resultados de la simulación.

Para simular el proceso actual, se realizaron alrededor de 10 simulaciones, hasta llegar a la mejor solución que es:

- para aros tipo 1 se tiene que solicitando 400 pedidos al proveedor al mes, el 89% de los productos solicitados son atendidos, en cambio un 11% no son atendidos por lo que se pierden los clientes.
- para aros tipo 2 se solita 100 pares al proveedor al mes, el 89% de los productos solicitados son atendidos, en cambio un 11% no son atendidos por lo que se pierden los clientes.
- para pulseras se solicitan 720 pulseras al proveedor al mes, el 82% de los productos solicitados son atendidos, en cambio un 18% no son atendidos por lo que se pierden los clientes.
- Para cadenas se solicitan 260 unidades al proveedor al mes, el 82% de los productos solicitados son atendidos en cambio un 18% no son atendidos por lo que se pierden los clientes.
-

Para la situación propuesta, donde se realizan varias simulaciones para obtener el mínimo de productos solicitados no atendidos se tiene;

- para aros tipo 1 se tiene que solicitando 2000 pedidos al proveedor al mes, el 99,5% de los productos solicitados son atendidos en cambio, un 0,05% no son atendidos por lo que casi no se pierden los clientes.
- para aros tipo 2 se solita 1000 pares al proveedor al mes, el 99,5% de los productos solicitados son atendidos en cambio un 0,05% no son atendidos por lo que casi no se pierden clientes.
- para pulseras se solicitan 2400 pulseras al proveedor al mes el 100% de los productos solicitados son atendidos en cambio un 0% no son atendidos por lo que no se pierden los clientes.
- Para cadenas se solicitan 1100 unidades al proveedor al mes, el 100% de los productos solicitados son atendidos en cambio un 0% no son atendidos por lo que no se pierden los clientes.

Se tiene que al aumentar el stock al mes, con lo cual se disminuye prácticamente a 0 los clientes que se pierden,

6. Conclusiones

En el presente trabajo se ha presentado un problema real de gestión de inventario en una Pyme. Para la cual se utiliza el Bizagi Modeler, logrando resultados deseados.

Por otra parte le el modelo propuesto ayudara a la empresa, a mantener un stock mensual de manera de no perder clientes, con lo que se produce un aumentos en las ventas, y así la disminución de pérdidas de clientes.

Como conclusión se tiene que en la situación propuesta es posible disminuir al mínimo a los clientes insatisfechos de un 11% a un 0,5 % para los aros tipo 1 y2, y de un 18% a un 0% para pulseras y collares, en estos dos últimos casos no se pierden clientes.

Se espera en el futuro simular otros procesos de la empresa, así como también para otros artículos y evaluar económicamente el proceso.

Abstract. The manufacturing industry is undergoing a major transformation based on the emerging industry 4.0 technologies, such as cloud computing, big data, internet of things and cyber-physical systems. These novelty technologies aim at providing central management for the user's flexible manufacturing requirements and information. Also, the advent of these technologies has transformed the process planning and became crucial for the building of knowledge-based process planning environments. However, current praxis cannot deal with all semantic issues within this new paradigm, as requirements must be clear, consistent, measurable, stand-alone, testable, unambiguous, unique and verifiable. In this context, multicriteria decision analysis models have gained focus of the scientific and industrial communities as a support tool for the decision-making process in the product development and advanced manufacturing as these processes excel in environments with numerous and conflicting alternatives, providing the optimal alternative. Therefore, the main objective of this research is to highlight the current issues and research tendencies regarding ontology-based interoperability systems, multicriteria decision analysis and their integration. To achieve this goal, it will be applied a literature review on the targeted technologies, discussing the current tendencies of the field and the main issues regarding their implementation and integration. Finally, the paper points themes for further research and indicates viable concepts that can compose a solution for the gaps in a systematic manner.

Keywords: Advanced Manufacturing Systems, Semantic Interoperability, Multicriteria Decision Analysis, Flexible Manufacturing Systems Process Reconfiguration.

1 Introduction

The manufacturing industry is undergoing a major transformation based on the emerging industry 4.0 technologies, such as cloud computing, big data, internet of things and cyber-physical systems. These novelty technologies aim at providing central management for the user's manufacturing requirements and information. Also, the advent of these technologies has transformed the process planning and became crucial for the building of knowledge-based process planning environments.

Furthermore, over the last two decades, the manufacturing industry has compacted their product lifecycles through the capture and integration of lifecycle knowledge in product development. This resulted in an almost simultaneous processes, which provided efficiency and flexibility while also increasing the product's final quality [1]. This is accentuated by the interconnection of the product development with trends on integrated manufacturing systems, smart factories, and concept and technologies of Industry 4.0 [2] However, current praxis cannot deal with all semantic issues within this new paradigm, as requirements must be clear, consistent, measurable, stand-alone, testable, unambiguous, unique and verifiable [2] [3].

Flexible manufacturing systems are considered the future of manufacturing because of their adaptable nature. In these systems basic modules, such as, the working machines, the material handling system or the manufacturing control system can be rearranged, interchanged or modified adapting the production system according to the enterprise's requirements. In this context, the performance of these systems is related to the system's capability and the planning and scheduling data in agreement with the market demands. Yet, as the market demands change in time the system's capabilities need to adapt to these changes. Thus, these changes can cause problems such as increase in the production time, cost and can decrease the final product's quality.
As the product's design and its manufacturing capabilities are closely related, the manufacturing system is desired to be reconfigurable in order to easily adjust for design changes that can occur in the product.

Currently, multicriteria decision analysis models have gained focus of the scientific and industrial communities as a support tool for the decision-making process in the product development and manufacturing as these processes excel in environments with numerous and conflicting alternatives, providing the optimal alternative. In this context, the multicriteria decision analysis makes for more consistent decision making as subjectivity and possible trade-offs can be contextualized and incorporated into these models. With these characteristics the multicriteria decision analysis can be incorporated and integrated with ontological approaches in order to make the decision-making process more accurate and efficient.

2 Material and Methods

The research is considered to have an applied nature, with a qualitative approach. Its scientific objectives are exploratory, using as a technical procedure a literature review and qualitative analysis (Fig. 1).

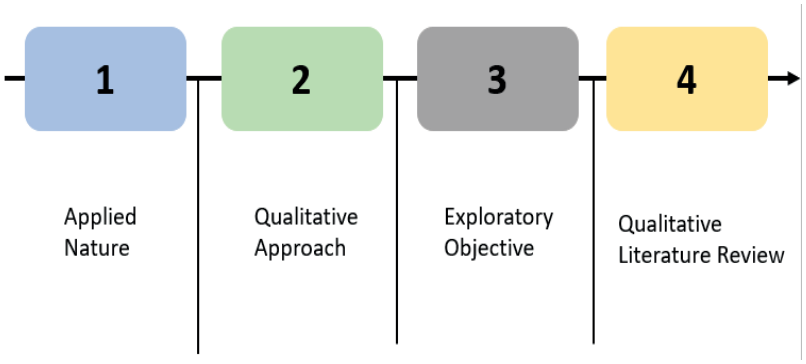

Fig. 1. Research Methodology.

The research has as its starting point a literature review on issues on the context of Reconfigurable Manufacturing Systems, such as, agility in the reconfiguration process, Semantic Interoperability such as Requirement Interpretation and knowledge representation, and Multicriteria Decision models. The goal is to establish a conceptual link between the studied areas as well as to improve understanding of the tools used in each theme and their intricate relations (Fig 2). The result of this process is a discussion on the themes, represented through a schema, which serves as the starting point to expose the current issues regarding the continuous development and flexibilization of reconfigurable manufacturing models, and their impacts in Industry 4.0.

3.1 Ontology Based Interoperability

Semantic interoperability is the ability of heterogeneous computer systems to share data with clear meaning. Therefore, it is concerned with the simultaneous transmission of the meaning of the data alongside it. This is accomplished though the addition of data about the data, which links each data element to a controlled, shared vocabulary. The meaning of the data is transmitted with the data itself, in one "information package" that is independent of any information system.

Since the introduction of the Semantic Web concept by [4] there has been numerous researches and applications of the W3C (World Wide Web Consortium, W3C) standards to provide web-scale semantic data exchange, federation, and inferencing capacities. Nowadays ontologies are one of the most popular tools for representing and sharing knowledge across different systems and domains [5].

The construction of ontologies is a viable solution on the formalization of these common information models and on the sharing of the formal information throughout the stages of the product development process, which, consequently, provides increased knowledge in the domains of application [6][7].

An Ontology is defined as "a lexicon of specialized terminology along with some specification of the meaning of terms on the lexicon" [7] [8] where the lexicon is the vocabulary of a knowledge domain. In this way, a significant differentiation can be made between ontologies by their degree of expressiveness. In this differentiation, simple ontologies, which formalizes only a taxonomy of concepts and basic relations between them are referred to as lightweight ontologies. When a lightweight ontology is enriched through the insertion of axioms in the form of constraints, they are classified as a heavyweight ontology. Nevertheless, the use of ontologies is restricted to the purpose of its application, that is, the knowledge structure formalized in an ontology has little reusability outside the scope of its application [8].

Given two different classification systems, a simple query finds all the data corresponding to a term in both information sources; however, this query can only be efficiently answered if both systems have their semantics well understood. If these systems are conceptualized in two different ontologies, the comparison of terms is a challenge due to the high variation of the detail level and logic between these ontologies [8][9]. To solve this limitation a shared ontology approach can be adopted, which enables terminological reasoning over the definition of classes in the descriptive logic ontologies by considering the axioms, set of relations and set of class definitions defined in the shared ontology [8][9].

Also, according to [10] and created digital links between virtual models improving the information sharing in the operation management. Similarly, [11] created a interoperable environment through the integration of different ontologies which resulted in dynamic collaborations between partners in heterogeneous and multi sited projects.
[11] affirms that with the rapid advanced and development of semantic technologies based on ontologies, there has been a shift towards more complex and better semantic modeling of manufacturing processes. This process culminates in the insertion of machining features in the semantic technologies in order to retrieve the considerable machining knowledge and shape semantics presented in these features.

[12], in the other hand, identifies that ontology based systems can be used for the optimization of machine fault diagnostics as this is a multi-disciplinary problem and the use of semantic mapping techniques and knowledge reasoning technologies can efficiently represent and organize fault knowledge with explicit and consistent semantic support. According to [12] these types of systems have the ability of supporting, sharing and scaling the fault knowledge presented in the system. [13] asserts that the ontology technology has great advantages in improving semantic consistency of multi-source heterogeneous data. However, for complex dynamic decision-making problems, there

are some limitations in the mining of ontology relations and the establishment of inference rules.

3.2 Multi-Criteria Decision Analysis

As globalization, collaboration, and cooperation contribute to a more connected and integrated competitive environment for the manufacturing industries, they have also made the decision-making process more complex whilst reducing the time for the decision made to be relevant.

In this context, the Multi-Criteria Decision Making (MCDM) methods are gaining importance as potential tools for analyzing complex real problems. This happens due to the inherent ability of these methods to judge different alternatives through several criteria (attributes) in order to provide the most suitable alternative. These alternatives may be further explored in-depth for their final implementation (Chung & Ng,2016). A MCDM problem can be concisely expressed in a decision matrix as shown in Fig 3.

		Criteria			
Alternatives		C_1	C_2	.....	C_n
	A_1	X_{11}	X_{12}	.....	X_{1n}
	A_2	X_{21}	X_{22}	.....	X_{2n}
	.....	.....	.....	.....	.....
	A_m	X_{m1}	X_{m2}	.....	X_{mn}

Fig. 3. Multi-Criteria Decision Analysis Generic Decision Matrix.

In this matrix each element (xij) represent the performance rating of "**m**th" alternative in respect to "**n**th" criteria, while considering also the significance of nth criteria [14]. This acquirement of the importance of each attribute, also called as weight of the attribute, is what boosted the introduction of numerous MCDM methods during the last decades.

Over the last decades, several MCDM methods have been proposed, the most popular of which are AHP (Analytic Hierarchy Process) [14-16], ANP (Analytic Network Process) [5], TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) [17–20], ELECTRE (ELimination and Choice Expressing REality) [21–23], and PROMETHEE (Preference Ranking Organization METHod for Enrichment Evaluations) [24–26].

These methods have been used to aid the decision making in several fields of knowledge, such as medicine, management and logistics, among others. This can be seen with the research of [26] which creates a systematic literature review on the use of MCDM in the optimization of supply chains and concludes that there are various combined approaches for supplier selection. However, integrated AHP approaches are more prevalent. The popularity of this type of approach is due to its simplicity, ease of use,

and great flexibility. [26] creates a novel multi criteria model for the optimization of flexible manufacturing systems.

The MCDM methods' task is to support a decision-maker in choosing the most preferable variant from many possible options, taking into account a multitude of criteria characterizing acceptability of individual decision variants [43]. MCDM problems can be divided into 2 main categories: i) continuous problems and ii) discrete problems. The second type of MCDM problems can be solved either through utility functions or outranking methods [44]. Also, according to [44] the utility approach determines a relationship between the alternatives which can be indifferent and preference of one alternative over another, this has the consequence of the methods in this group leaving out the non-comparability of the decision criteria and assume transitivity and completeness of preference [29].

On the other hand, outranking methods expand the basic set of preferential situations with the relationships they create which can be: i) indifferent; ii) weak preference; iii) strict preference and iv) incomparability. In this method the preferential situations are combined in an outranking relation [45].

Furthermore, MCDM methods can vary according to their operational approaches: : i) aggregation to a single criterion (American school); ii) aggregation by using the outranking relationship (European school) [46]. However, the mixed approach which combine elements of American and European decision-making schools have gained highlight in the scientific and industrial environments [47]. According to [47] an example of this mixed approach is the Pairwise Criterion Comparison Approach methods. Lastly MCDM methods can be differentiated according to the nature and characteristics of the used data, which will immensely affect the measurement scale. Data can be quantitative or qualitative and can be expressed in the cardinal (quantitative) or ordinal (qualitative) scale [48].

3.3 Flexible Manufacturing

The introduction of a new technology in a company's operations changes the organizational structures, processes and resources, factors that present themselves as obstacles in the decision phase and in the implementation of these new technologies. Currently, the choice of advanced manufacturing technologies is made through operational criteria such as productivity and performance, which can offer a competitive advantage and, therefore, must be chosen according to strategic criteria. [27]. The main characteristic of advanced manufacturing technologies is their flexibility (to produce a wide variety of products on a small scale without having extra costs or penalties) is pointed out by several authors [3][27][28][29].

Advanced manufacturing systems are systems that use mechanical, electronic and computational subsystems to operate and control production, encompassing a large set of machines that execute, monitor and connect the production processes [30]. The same author emphasizes that the adoption of advanced manufacturing technologies is a key condition for maintaining the company's competitiveness in the long term. Nevertheless, many advanced manufacturing implementation projects fail to be more significant in small and medium-sized companies, as the managers of these companies are the ones

who most want to implement these technologies, but they do so from instinct or information from similar companies.

Yet, [3], states in his research that small and medium-sized companies do not wish to implement, or do not understand how these technologies could assist them in improving customer satisfaction and market results. The author also states that these companies have limited financial and human resources, preventing these companies from implementing complex technological systems.

Over the past two decades, there have been reports of improvements in flexibility, quality and productivity in industries caused by the use of advanced manufacturing technologies [31][32]. [33] claim that advanced manufacturing technologies can effectively assist the length of manufacturing objectives and simultaneously consider competitive objectives and manufacturing decision areas, being considered resources mobilized for the construction of competencies. [3] stated that with the growing emphasis on flexibility to ensure a company's long-term competitiveness, the relationship between advanced manufacturing technologies has taken on an important place for decision making. In addition, the higher the level of advanced manufacturing technologies and enterprise control technologies, the greater the level of flexibility in manufacturing.

From the many flexible manufacturing technologies additive manufacturing has been prominent in both industry and academia, as it has benefits compared to traditional manufacturing models, such as geometric flexibility as well as a potential to reduce the time and cost of manufacturing products [34].

Reconfigurable manufacturing systems (RMSs) was first proposed by the Engineering Research Center of the University of Michigan in1999[29]. Though the use of these systems manufacturers could make multiple variations of customized products at the price of standardized mass products [29][35]. [29][36] analyzed the characteristics of RMS in detail and found out that the most used approaches are biological manufacturing systems (BMSs) and holonic manufacturing systems (HMSs). The reconfiguration methods could be classified into two categories: i) knowledge-based reasoning methods; ii) artificial intelligence-based optimization methods [29]. The knowledge automation technologies of RMS have attracted considerable interest. [29][37] proposed an ontology-based agent approach with the goal of fast reconfiguration of modular manufacturing systems. Furthermore, [29] [37–39] proposed the combination of knowledge-based reasoning methods with periodic inspection for the dynamic and automatic reconfiguration of systems.

For the second kind, optimal reconfiguration of manufacturing systems needs the use of advanced artificial intelligence techniques, such as deep learning and big data [40]. However, these conventional optimization methods for RMS suffers from substantial computation complexity, which hinders rapid and online reconfiguration of the manufacturing system.

There are three significant problems in current RMS. Firstly, essential measurement factors, including the scalability and reconfigurability of the current systems, which needs to be considered during the design process of the RMSs [41][42]. Secondly, current RMS realizes control logic validation with software testing after the mechanical structure reconfiguration is assembled, which will take a significant amount of time to do and is susceptible to reconfiguration mistakes. Thirdly, dealing with the rapid

reconfiguration of the manufacturing system, requires not only a digital twin architecture as a foundation but also an optimization method. These issues mean that the complex balancing and coupling relationship between the system productivity and reconfiguration cost is difficult to model in the environment of the frequent change.

4 Discussion

This research works towards finding evidence that demonstrates the current issues regarding semantic interoperability and Multi-Criteria Decision-Making methods in an advanced manufacturing environment. These issues provide sustenance to the proposal of an ontology and MCDM integration model that aims to aid the real time reconfiguration and decision making in flexible manufacturing processes in order to ensure higher quality products and increase agility of the manufacturing process.

The mapping of the current issues revealed the limitations of a ontology driven interoperability system when it is used in a highly mutable environment, and, also, how the sharing of ambiguous information in such an environment can reduce the competitiveness of an enterprise as it will difficult the decision making process, raising costs and diminishing the products quality.

The MCDM models can be associated with ontological approaches as aids for the reasoning presented in them. The application of MCDM algorithms in these approaches create case-based reasoning techniques, which can aid in the flexibilization of the ontological structure and consequently promote a more accurate and efficient decision-making process. These concepts may be used integrated with ontology-based interoperability models in order to create a flexible decision-making environment that can aid in the reconfiguration of an advanced manufacturing system allowing for a more agile process and ensuring the product`s quality. Fig. 4 highlights the relationship of the concepts that this research approached. From the figure can be seen the decision making in a flexible manufacturing environment can be divided into three main layers. The outmost layer regards the multi-criteria analysis, while the second involves the main systems in a flexible manufacturing system and finally the decision-making layer.

The multicriteria analysis layer consists in the analysis of the many heterogeneous requirements that come from the consumer and from the enterprise. These requirements range from desired finishing qualities from the consumer to material handling and stock logistics from the enterprise. As these requirements come from various sources, they may present semantic homogeneity issues which can lead to a wrongfully interpreted information that consequently will prejudice the decision-making process and the reconfiguration of the manufacturing system.

The flexible manufacturing layer encompasses the flexible manufacturing system, from the material handling system to the working machines and the main control system. This layer consists in the capability and restrictions presented in the subsystems of the manufacturing process. These restrictions combined with the requirements of the multicriteria analysis layer make the information form that will guide the decision-making process.

However, the restrictions presented by the flexible manufacturing layer can cause misunderstanding or may present semantic conflicts with one another or even with the requirements from the multicriteria analysis layer. These misunderstandings and conflicts may hinder the decision-making process that consequently impoverishes the manufacturing quality and thwarts the flexibility of the overall production process.

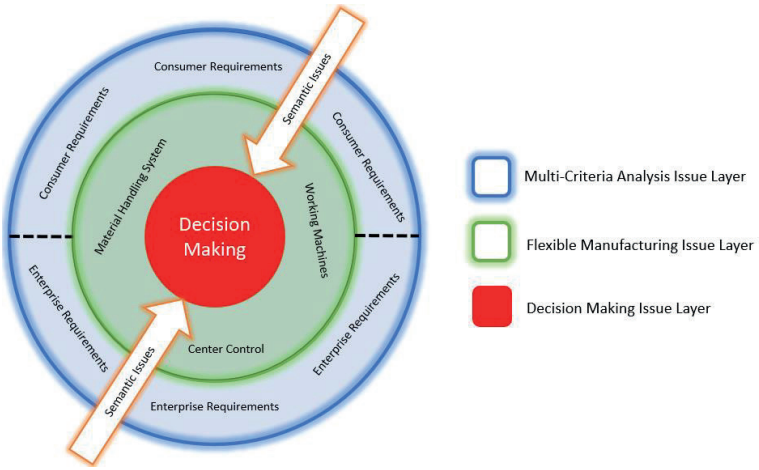

Fig. 4. Representation of Current Issues.

Finally, the decision making layer defines the decision making process, with the interpretation of the requirements and restrictions of the outwards layers and reconfiguring the manufacturing systems and processes in order to attend the requirements and generate the most value possible to the consumer and the enterprise. This process can be hindered with semantic heterogeneity issues from the other layer, while being susceptible to semantic errors in the decision making process which can compromise the timely reconfiguration of the manufacturing system that will in turn compromise the value generation and the attendance of the requirements and restrictions.

5 Conclusion

This paper presented a research that lead to the development of a model which shows some of the critical issues that hinder the development of a real time process reconfiguration environment. These areas are essential to ensure a competitive position for an enterprise in the global competitive environment it is inserted.

The standardized and formalized knowledge that is captured by an ontology driven system allows it to be retrieved, shared and reused in different stages of the reconfiguration process and, also, through the process of relating concepts, the information can be captured in its entirety as well as extended as the need arises.

Multicriteria decision analysis models have gained focus of the scientific and industrial communities as a support tool for the decision-making process in the product development and manufacturing as these processes excel in environments with numerous and conflicting alternatives, providing the optimal alternative. In this context, the multicriteria decision analysis makes for more consistent decision making as subjectivity and possible trade-offs can be contextualized and incorporated into these models. With these characteristics the multicriteria decision analysis can be incorporated and integrated with ontological approaches in order to make the decision-making process more accurate and efficient.

In order to continue this research several subjects are proposed for future works. The integration of MCDM methods with ontological applications and map the decision criteria needed for an advanced manufacturing reconfiguration process in order to develop an application ontology to aid in the reconfiguration process are some research perspectives.

Resumen. Esta investigación evaluó el nivel de cumplimiento de los principios de gestión de la calidad percibidos por los empleados de dos empresas cafeteras: una de ellas certificada y la otra sin certificar, ubicadas en la ciudad de Pasto en Nariño, Colombia. La evaluación se fundamentó en los principios definidos en la norma ISO 9001 versión 2008 y comparó los resultados con la versión 2015. Además de analizar si existían variaciones en la percepción de los principios de gestión de la calidad, se evaluó si al actualizarse la versión de la norma ISO 9001, la percepción sobre los principios de calidad cambió e incidió en la implementación, debido a que son la base para el funcionamiento eficiente y eficaz de un sistema de gestión de la calidad. Para realizar el comparativo entre las empresas se usó un estudio cuantitativo con diseño no experimental, exploratorio, descriptivo, observacional, transversal, sobre unidades independientes de investigación, correspondiendo, por tanto, a un estudio de casos en relación con la selección intencionada de la unidad de análisis. Para evaluar la percepción, se aplicó un instrumento de medición de tipo encuesta validado y aplicado previamente. Para la revisión de la norma ISO 9001, se hizo un análisis comparativo entre las versiones 2008 y 2015. Los resultados obtenidos mostraron diferencias en la percepción de los principios de la gestión de la calidad, principalmente los denominados: enfoque en procesos, liderazgo, participación del personal y enfoque al cliente por parte de los empleados de cada empresa.

Palabras clave: Certificación, ISO 9001:2015, ISO 9001:2008.

1 Introducción

Los cambios introducidos por la Norma ISO 9001:2015 pueden afectar la percepción de los principios de calidad para aquellos usuarios previamente certificados con la Norma ISO 9001:2008, la cual identificaba ocho principios para mejorar continuamente el desempeño. La actual versión de ISO 9001:2015 eliminó el principio de "Enfoque de Sistemas", aunque éste sigue implícito en la norma. Los principios de la norma son la base para desarrollar un Sistema de Gestión de la Calidad adecuado a las necesidades del cliente y para la mejora interna constante de los procesos de una organización [22]. De igual forma, los estudios comparativos entre empresas certificadas y no certificadas son escasas, no encontrándose publicaciones en el sector cafetero en bases de datos WoS, Scopus y ScIELO revisadas, pero sí en otros sectores (Brito et al, 2020; Dellana et al 2020; Heras-Saizarbitoria et al, 2015; Tamayo-Torres et al, 2014, Caro Et al, 2009; Martinez Costa y Martinez Lorente, 2003), o entre empresas no certificadas (Ghose y Roy, 2020).

El presente estudio utilizó como variables de medición, los principios de la ISO 9001:2008, que son: enfoque al cliente, liderazgo, participación del personal, enfoque basado en procesos, enfoque en sistemas, mejora continua, relación con los proveedores, enfoque en hechos. Estas variables fueron utilizadas para evaluar el nivel de cumplimiento de los principios de gestión de la calidad percibidos por los empleados de dos empresas cafeteras colombianas, una certificada y una no certificada, y posteriormente, para comparar dichos resultados con la ISO 9001:2015.

El objetivo de la implementación de sistemas de gestión de la calidad es la mejora continua de los procesos, productos y servicios lo que permite la satisfacción de los clientes y el fortalecimiento de la responsabilidad de la organización [1. Por otro lado, las organizaciones implementan los sistemas de gestión de la calidad para demostrar la capacidad de proporcionar productos y servicios acordes a los requisitos del cliente [46]. Los beneficios obtenidos por las empresas posterior a la certificación ISO 9001, pueden verse mejorados o disminuidos de acuerdo con algunos factores tales como: a) motivación de la empresa por adoptar el modelo; b) la formación y educación continua de las personas permite sostener y mejorar el sistema; c) el permanente cumplimiento de los principios de gestión de calidad, que son el fundamento del sistema[5]. Es importante incluir el mantenimiento de los sistemas de gestión de la calidad dentro de los aspectos que generan efectos positivos en la productividad y la mejora de la calidad de los procesos. El marco de gestión de mantenimiento basado en siete cualidades de los principios de gestión puede ayudar a una organización a: aumentar la producción con los mismos activos, reducir la necesidad de reemplazo de capital y mejorar el rendimiento, costo y productividad, [28].

En este contexto, es de esperar que las empresas que se han certificado presenten un mayor grado de cumplimiento para todos los principios de gestión de la calidad que las empresas no certificadas; a partir de ésta fundamentación teórica, surge la necesidad de establecer la hipótesis: Los empleados de una empresa certificada según ISO 9001, perciben un mayor nivel de cumplimiento de los principios de gestión de la calidad que los de una empresa no certificada, lo que permite determinar si con el

proceso de certificación, se han incrementado los beneficios intrínsecos a la misma. Dicha hipótesis puede ser evaluada con la versión 9001:2008 o 9001:2015.

Para esta investigación se optó por un estudio de tipo mixto, cualitativo y cuantitativo con diseño no experimental con el fin de realizar una comparación de la percepción de los principios de gestión de la calidad entre los dos tipos de empresas y su interrelación por niveles jerárquicos; además, se buscaba que el instrumento diseñado midiera los principios o dimensiones de gestión de la calidad de forma relacionada para tres grupos: personas externas a la organización, liderazgo y funcionamiento interno de la organización. En este contexto, se requería el uso de métodos exploratorios y descriptivos. Para esto se realizó una recolección de datos mediante la elaboración y aplicación de instrumentos en un contexto claramente definido [30].

Se utilizó un estudio de caso, al ser una investigación de tipo cualitativa que observa de forma detallada a sujetos de estudio [42]. El uso de la investigación cualitativa tiene la ventaja de recoger y recopilar información de una muestra para aumentar la comprensión particular de un fenómeno.

2 Metodología

2.1 Material

Debido a que el estudio comenzó a finales del año 2014, cuando la última versión de la norma ISO 9001:2015 aún no estaba vigente, inicialmente se aplicó un enfoque de estudio de caso, seleccionando una empresa cafetera certificada según la norma ISO 9001:2008 y una empresa cafetera sin certificar, ambas localizadas en la Región de Nariño, Colombia; se realizó un censo en cada una de ellas, aplicando la encuesta a todos los trabajadores de las empresas. Posteriormente con la adaptación de la empresa certificada a la versión 2015, se evaluaron los cambios relacionados con los principios de calidad, entre la versión 2008 y 2015 en la empresa certificada, aplicándose un nuevo instrumento. Se aplicaron 38 encuestas en la empresa certificada y 29 encuestas en la empresa no certificada, los niveles jerárquicos a los que se aplicó la encuesta fueron directivos, constituidos por gerentes y administradores y operarios constituidos por el personal encargado del proceso, el área de empaque y almacenamiento de producto terminado.

Método

En primer lugar, se identificaron tres objetivos específicos para el estudio. Posteriormente, se realizó una caracterización de los empleados y la relación entre las variables. El estudio corresponde a una investigación de tipo cuantitativa con diseño no experimental, exploratorio, descriptivo, observacional, transversal sobre unidades independientes de investigación, correspondiendo a un estudio de casos [48] en relación con la selección intencionada de la unidad de análisis correspondientes a los empleados de ambas empresas.

Para evaluar la percepción de los niveles de cumplimiento de los principios de gestión de calidad, entre los niveles jerárquicos de la empresa cafetera certificada y no

certificada según ISO 9001:2008, se usó un análisis cuantitativo, exploratorio, descriptivo de tipo observacional.

Para evaluar la percepción de los niveles de cumplimiento de los principios de gestión de la calidad de los empleados de la empresa certificada según ISO 9001:2015, con la percepción de los empleados de la empresa no certificada, se usó un análisis cuantitativo, asociativo observacional.

Finalmente, para analizar las diferencias entre las versiones 2008 y 2015 de la norma ISO 9001, respecto a los principios de gestión de la calidad y su aplicación a nivel empresarial, se usó un análisis cualitativo, asociativo observacional.

2.2 Instrumento

El instrumento empleado registra la percepción de las dimensiones asociadas al cumplimiento de los Principios de Gestión de la Calidad; fue diseñado y validado cualitativamente en la investigación realizada por Pérez y Pérez-Luco (2010) [39] relacionado con la ISO 9001:2008; como complemento a este instrumento, se utilizó la norma ISO 9001:2015. De un universo de 12 empresas cafeteras de Nariño Colombia invitadas para la aplicación del instrumento, acudieron dos, una de ellas certificada y la otra sin certificar; la encuesta se aplicó mediante censo a un total de 67 empleados; los resultados se evaluaron mediante un análisis porcentual que permitió determinar cuantitativamente la percepción de los principios de gestión de la calidad en cada una de las organizaciones [11].

El instrumento aplicado contó con 40 preguntas en total, 5 preguntas para cada uno de los ocho principios de los sistemas de gestión de la calidad, como se muestra en la Tabla 1.

A partir de los ocho principios de la gestión de la calidad, se obtuvieron puntajes máximos y porcentajes de cumplimiento en cada principio por empresa y por nivel jerárquico. Para analizar los resultados obtenidos de la aplicación de la encuesta, se codificó la escala de tipo Likert de la siguiente manera: 0 nunca, 1 casi nunca, 2 regularmente, 3 casi siempre, 4 siempre. Teniendo en cuanta que por cada principio hay 5 preguntas y que la valoración máxima en la escala de Likert para cada pregunta es de 4, el puntaje máximo a obtener para cada uno de los ocho principios es de 20 puntos, lo que representa el 100% de cumplimiento del principio. A partir de este análisis se realizaron los cálculos de porcentaje de cumplimiento en cada empresa y en cada nivel jerárquico.

En los resultados se presentan los promedios de puntaje total por tipo de empresa y nivel jerárquico y su expresión en porcentaje en relación con el puntaje máximo posible a partir de la codificación de la escala de Likert.

A continuación se representa el instrumento empleado para recolectar la información.

3 Resultados y Discusión

La implementación de ISO 9001 en sus diferentes versiones en empresas cafeteras no es común en Latinoamérica, aunque algunos estudios en otros países se han enfocado en implementar la norma para mejorar la calidad de los procesos [38]. En Colombia, se ha estudiado el efecto de implementar sistemas de gestión en empresas procesadoras de café [11] y del desempeño de algunas empresas [4].

Para realizar este estudio de caso, se analizó en forma censal una población objetivo de 67 empleados, de los cuales 38 pertenecen a la empresa certificada y 29 a la empresa no certificada. Se logró encuestar al 100% de la población objetivo, donde el 32.84% corresponde al nivel jerárquico directivo, de los cuales el 81.82% cuentan con educación superior. En la población total bajo estudio, el 44.44% de los operarios cuenta con educación superior.

Al comparar los instrumentos de medición en el modelo para la versión 2015 de la norma ISO 9001, se encontró que la mayoría de preguntas era aplicable para los principios actuales debido a su similitud, diferenciándose principalmente en el principio "enfoque basado en procesos", que actualmente engloba lo que en la versión 2008 estaba contenido en dos principios, "enfoque basado en procesos" y "enfoque de sistema para la gestión"; además, se encuentra presente en el principio de la versión actual de "Gestión de las relaciones", que aunque comparte aspectos con el principio de la versión 2008 "Relaciones mutuamente beneficiosas con el proveedor", la versión actual amplía su aplicación a otras partes interesadas de la empresa, como por ejemplo los accionistas u otros grupos de interés (ISO, 2015). Se comprueba con este estudio que la organización debe familiarizarse con los principios de gestión de la calidad, y comprender sus cambios en la versión vigente, para evitar malinterpretar el nuevo requisito y cometer fallas en la implementación o ajuste del sistema de gestión [32]. Una comparación de los resultados obtenidos al aplicar el instrumento se detalla en la Tabla 1 y la Tabla 2 para directivos y operarios, respectivamente.

Tabla 1. Porcentajes de cumplimiento de los principios de gestión de la calidad según directivos, ISO 9001: 2008.

Principio	Directivos empresa certificada (%)	Directivos empresa no certificada (%)
Enfoque al cliente	77.50	70.50
Liderazgo	82.42	57
Participación del personal	84.17	58.5
Enfoque en procesos	92.50	74.5
Enfoque en sistemas	87.08	64
Mejora continua	86.25	63
Relación con los proveedores	81.67	64.5
Enfoque en hechos	87.08	64

Fuente: Autor, a partir de las encuestas realizadas.

Tabla 2. Porcentajes de cumplimiento de los principios de gestión de la calidad según operarios, ISO 9001: 2008.

Principio	Operarios empresa certificada (%)	Operarios empresa no certificada (%)
Enfoque al cliente	77.5	70
Liderazgo	87.8	57.63
Participación del personal	85.96	67.10
Enfoque en procesos	89.61	80.79
Enfoque en sistemas	84.23	75.53
Mejora continua	86.33	75
Relación con los proveedores	85.96	69.74
Enfoque en hechos	88.8	67.1

Fuente: Autor, a partir de las encuestas realizadas.

En la empresa certificada, los directivos y los operarios obtuvieron un puntaje máximo de cumplimiento en el principio "enfoque en procesos" y un puntaje mínimo en los principios "enfoque al cliente" coincidiendo con el estudio realizado por Pérez & Pérez-Luco (2010) [39], quienes señalan que los trabajadores de la empresa certificada de su estudio, percibe un mayor cumplimiento en los principios de gestión de la calidad relacionados con sistemas, procesos y productos, mientras que la menor percepción del cumplimiento se encontró en los principios relacionados con clientes, personas y liderazgo. Sin embargo, es importante notar que, debido a que el primer principio de la gestión de la calidad es el enfoque al cliente, el cual establece que las organizaciones dependen de sus clientes y por lo tanto deben comprender sus necesidades, satisfaciendo sus requisitos y esforzándose por exceder sus expectativas [33], este aspecto debería arrojar resultados altos en la empresa certificada. Una percepción baja del principio enfoque al cliente se relaciona con la imagen corporativa y la satisfacción del cliente, [17] en su análisis de la percepción de los clientes respecto a la calidad del servicio recibido, quien analizó los factores que determinan la satisfacción o insatisfacción de clientes y encontró que "… el servicio que presta el personal encargado de la atención al cliente es un aspecto crítico en la evaluación de la calidad del servicio".

Una discriminación gráfica de los resultados relacionados con la percepción evaluada se encuentra en la Figura 1, donde se observa mayor puntaje para los directivos que para los operarios, como era esperado.

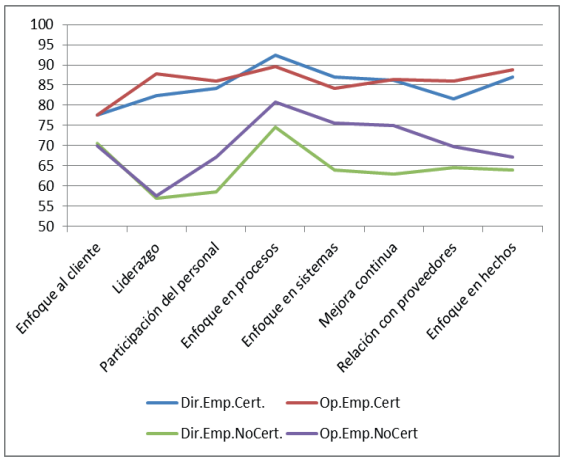

Fig 1. Empresa Certificada y No Certificada. Gráfico de percepción de cumplimiento (%) ISO 9001:2008.
Fuente: Autor

En la empresa no certificada, los directivos y operarios obtuvieron un puntaje máximo de cumplimiento en el principio "enfoque en procesos" y un puntaje mínimo en el principio "liderazgo", seguido por el principio "participación del personal"; se infiere que esto se debe a que en las empresas certificadas el personal de todos los niveles de la empresa debe involucrarse totalmente en el logro de los objetivos de la organización mediante una cadena de participación y comunicación.

Respecto a la participación del personal, en la empresa no certificada se observó un nivel bajo, relacionado principalmente con dos factores: inexistencia de un plan de incentivos y falta de reconocimientos para motivar al personal hacia la participación y el liderazgo. Los resultados se pueden observar en la Tabla 3.

Tabla 3. Comparación de los puntajes de cumplimiento de los principios de gestión de la calidad entre la empresa certificada y no certificada.ISO 9001:2008.

Total puntaje por empresa

Empleados	Puntaje	Porcentaje %
Directivos certificada	136.33	85.2%
Directivos no certificada	103.2	64.5 %
Diferencia directivos certificada y no certificada	33.13	20.7%
Operarios certificada	137.27	85.8 %

Operarios empresa **no certificada**	112.59	70.4%
Diferencia operarios certificada y no certificada	24.68	15.43 %

Fuente: Autor a partir de las encuestas realizadas.

Tanto en la empresa certificada como en la empresa no certificada, los directivos y los operarios obtuvieron un puntaje máximo de cumplimiento en el principio de gestión de la calidad denominado "enfoque en procesos"; sin embargo, en la empresa certificada los porcentajes de cumplimiento en este principio fueron mayores que en la empresa no certificada, lo que indica que en la empresa certificada existe un mayor entendimiento y gestión de las actividades como procesos interrelacionados y coherentes, lo que posibilita la optimización del rendimiento de la organización.

En la empresa certificada y en la empresa no certificada los puntajes mínimos se obtuvieron en los principios relacionados con personas. En este contexto, en la empresa certificada los menores puntajes se obtuvieron en los principios relacionados con personas externas a la organización (enfoque al cliente y gestión de las relaciones). Por otra parte, en la empresa no certificada los puntajes mínimos se obtuvieron en los principios relacionados con personas internas a la organización (liderazgo y participación del personal).

A continuación, en las tablas 4, 5, 6 y 7, se analiza cada uno de los principios de calidad de acuerdo a las versiones 2008 y 2015 de la norma ISO 9001, relacionando las preguntas realizadas y validadas previamente. Como se podrá observar, en la versión de 2015, no hubo cambios grandes en los principios de "Liderazgo" y "Enfoque en procesos". Hubo cambios intermedios en los principios "Participación del personal" y "Enfoque basado en hechos". Sin embargo se realizaron cambios relevantes en los principios de "Enfoque al cliente", "Mejora Continua" y "Relación mutuamente beneficiosa con el proveedor", principalmente debido a que el nuevo enfoque, busca que la empresa involucre de forma mas distintiva, además de los clientes receptores del producto a otros grupos de interés, que la empresa debe identificar como relevantes para lograr sus objetivos de calidad, adicionalmente la ISO 9001:2015 se orienta mas a un contexto estratégico que contempla un análisis externo mas profundo, que abarca no solo mejoras internas, sino estrategias que involucran el entorno empresarial, la identificación y prevención de riesgos.

El principio de "Enfoque en Sistemas" se eliminó debido a que se consideró inmerso en las interacciones de los elementos del sistema.

Tabla 4. Relación principios de las versiones 2008 y 2015 de la norma ISO 9001.

Principio de Gestión de Calidad ISO 9001:2008	Pregunta del instrumento relacinada con la norma ISO 9001:2008	Principio de Gestión de Calidad ISO 9001:2015	Pregunta relacinada con la norma ISO ISO 9001:2015 / Cambio
1.Enfoque al cliente	P.1 Existen reclamos de los clientes hacia la empresa P.13 Me interesa mucho satisfacer los requerimientos de los clientes P.21 Los clientes tienen una buena percepción de la empresa P.29 La Empresa tiene buena comunicación con sus clientes P.33 Yo sé lo que los clientes requieren de esta empresa	Enfoque al cliente	Preguntas: Igual que en la versión 2008, las preguntas: P.1, P.13,P.21, P.29, P.33 Cambio: Se incluye el concepto de partes interesadas, que además de los clientes, son grupos capaces de impulsar o frenar la satisfacción del cliente, se destaca mayormente en las sesiones 4.3, 5.2.2 , 8.3.2 , 9.3.2 de la norma ISO 9001:2015.
2.Liderazgo	P.2 La Gerencia entrega directrices claras respecto al quehacer rutinario de la empresa P.12 La Gerencia se esfuerza mucho en enseñarnos sobre cómo llegar a cumplir los objetivos de calidad propuestos P.20 La Gerencia nos motiva fuertemente a comprometernos con la calidad P.28 La Política de Calidad de la empresa orienta nuestros esfuerzos hacia un mismo objetivo P.34 Los objetivos de la calidad de la empresa son bien conocidos por todos	Liderazgo	Preguntas: Igual que en la versión 2008, las preguntas: P.2, P.12,P.20, P.28, P.34 Cambio: No hubo cambios importantes.

Tabla 5. Continuación 1, relación principios de las versiones 2008 y 2015 de la norma ISO 9001.

Principio de Gestión de Calidad ISO 9001:2008	Pregunta relacinada con la norma ISO 9001:2008	Principio de Gestión de Calidad ISO 9001:2015	Pregunta relacinada con la norma ISO ISO 9001:2015 / Cambio
3.Participación del personal	P.3 En esta empresa se reconoce y estimula la iniciativa y el trabajo bien hecho P.11 Todo el personal se siente muy comprometido con la empresa. P.19 Esta empresa entrega los conocimientos para que las personas desarrollen en buena forma su trabajo P.27 En esta empresa todos nos sentimos partícipes de sus logros y beneficios P.35 La empresa invierte permanentemente en la formación y perfeccionamiento de sus empleados	Participación del personal.	Preguntas: Igual que en la versión 2008, las preguntas: P.3, P.11,P.19, P.27, P.35. Cambio: En la nueva versión es similar, aunque da mayor relevancia a la competencia y toma de conciencia, además incluye de forma mas clara a las personas externas que realizan trabajos que pueden afectar la conformidad del producto.
4. Enfoque en procesos	P.4 Conozco los insumos de entrada para mi proceso P.10 Sé cuál debe ser el resultado de mi proceso P.18 En caso de desviaciones en mi proceso sé lo que tengo que hacer P.26 Sé cuál es la secuencia de las actividades de mi proceso P.36 Sé muy bien cuáles son los aspectos que debo controlar de mi proceso	Enfoque en procesos	Preguntas: Igual que en la versión 2008, las preguntas: P.4, P.10,P.18, P.26, P.36. Cambio: No hubo cambios importantes.

Tabla 6. Continuación 2, relación principios de las versiones 2008 y 2015 de la norma ISO

Principio de Gestión de Calidad ISO 9001:2008	Pregunta relacinada con la norma ISO 9001:2008	Principio de Gestión de Calidad ISO 9001:2015	Pregunta relacinada con la norma ISO ISO 9001:2015 / Cambio
5. Enfoque en Sistemas	P.5 En esta empresa siempre se cumple con lo planificado P.9 Conozco cómo influye la calidad de mi proceso en los demás procesos que se realizan dentro de la empresa. P.17 La estructura organizacional de esta empresa es difundida para el conocimiento del personal P.25 La relación entre las distintas áreas de la empresa es fluida. P.37 Los recursos están disponibles oportunamente para el desarrollo de mi proceso	Enfoque en Sistemas	Se eliminó, ya que según la nueva versión, éste principio sería un poco redundante, ya que el concepto estaría inmerso en todos los elementos que interactuan en el sistema de gestión.
6. Mejora Continua	P.6 En esta empresa los problemas y/o errores se usan para mejorar los procesos P.16 En esta empresa se evita la repetición de un problema o error P.24 Es muy importante para mi colaborar en la mejora de la actividad en que participo P.32 En esta empresa se mejoran los métodos de trabajo para prevenir problemas futuros P.38 Los aportes de los empleados ha ayudado a mejorar la calidad de los productos y servicios de la empresa	Mejora	Preguntas: Igual que en la versión 2008, las preguntas: P.6, P.16,P.24, P.32, P.38, es necesario profundizar en elementos estratégicos. Cambio: Reemplaza el concepto de "mejora continua" por el de "mejora", ya que el primero hace énfasis en optimizar el rendimiento al interior de la organización, pero el segundo involucra además de lo interno, un análisis estratégico total, que se relaciona también con el concepto de prevención de riesgo.

Tabla 7. Continuación 3, relación principios de las versiones 2008 y 2015 de la norma ISO

Principio de Gestión de Calidad ISO 9001:2008	Pregunta relacinada con la norma ISO 9001:2008	Principio de Gestión de Calidad ISO 9001:2015	Pregunta relacinada con la norma ISO ISO 9001:2015 / Cambio
7.Relación mutuamente beneficiosa con el proveedor	P.8 La empresa evalúa periódicamente a sus proveedores P.14 La empresa explica claramente a los proveedores qué necesita de ellos P.22 La empresa siempre informa a sus proveedores de las calificaciones obtenidas por ellos P.30 La empresa mantiene buenas relaciones con sus proveedores P.40 Los proveedores siempre cumplen con la calidad requerida	Gestión de las relaciones	Preguntas: Aplican las preguntas de proveedores, igual que en la versión 2008, las preguntas: P.8, P.14,P.22, P.30, P.40, es necesario abarcar otras partes interesadas, de acuerdo a la definición que la empresa haga específicamente, de los grupos que pueden afectar el cumplimiento de objetivos estratégicos. Cambio: Reemplaza el concepto de "Relación mutuamente beneficiosa con el proveedor" por el de "Gestión de las relaciones", ampliando el concepto para dar mayor relevancia a otras partes interesadas como por ejemplo: organismos gubernamentales, comunidad, etc.
8. Enfoque basado en hechos.	P.15 La empresa tiene indicadores de gestión para controlar los procesos P.23 La Gerencia maneja la información adecuada para tomar decisiones P.31 La empresa usa los resultados de los indicadores para mejorar la calidad de los procesos y del producto P.39 La Gerencia toma las decisiones importantes con base en la información generada en las diferentes áreas de trabajo P.7 Conozco el cumplimiento de metas de mi área de trabajo	Toma de decisiones basada en evidencia	Preguntas: Igual que en la versión 2008, las preguntas: P.15, P.23,P.31, P.39, P.7 Cambio: Reemplaza el nombre "Enfoque basado en hechos" por "Toma de decisiones basada en evidencia", aunque internamente no hubo cambios grandes, la nueva versión ayuda a entender mejor la relevancia de basar las decisiones en evidencia, teniendo en cuenta las fuentes, documentación e interpretación.

Fuente: Análisis a partir de encuentas, norma ISO 9001 versiónes 2008 y 2015 [24, 25]

4. Conclusiones

El presente estudio además de realizar un comparativo entre empresas certificadas y no certificadas, también permitió equiparar las dos últimas versiones de la norma ISO 9001 año 2008 y año 2015, concluyendo que, aunque en el contenido de la norma actual existen algunos cambios sustanciales, respecto a los principios de calidad las diferencias de percepción son mínimas.

Los principios de calidad que más cambios tuvieron entre las versiones 9001:2008 y la 9001:20015son: el enfoque basado en procesos y la gestión de las relaciones, convirtiéndose en una visión más amplia de sistema y grupos de interés para la empresa.

Los directivos de la empresa certificada presentan un 20.71% más, de cumplimiento en todos los principios de gestión de la calidad que los directivos de la empresa no certificada y los operarios de la empresa certificada presentan un 15.42% más, de cumplimiento que los empleados de la empresa no certificada, lo que confirma la hipótesis formulada: "los empleados de la empresa certificada con ISO 9001, perciben un mayor nivel de cumplimiento de los principios de gestión de la calidad".

En general, se observa que la implementación de un Sistema de Gestión de la Calidad con base en la Norma ISO 9001 en la empresa certificada permitió obtener mayores puntajes en la medición de la percepción de los principios de gestión de la calidad.

Esto permite afirmar que, a partir de la certificación, se incrementaron algunos beneficios internos tales como: el análisis y evaluación de los datos y la información para la toma de decisiones y el entendimiento de los procesos interrelacionados como un sistema.

Mediante la utilización del método de comparación de promedios ponderados a partir de la medición de los principios de gestión de la calidad de la investigación, es posible que una organización evalúe de manera sencilla si los beneficios intrínsecos a la certificación se incrementan o disminuyen. Para esto, pueden utilizar una metodología similar a la propuesta en este trabajo, ya que es adaptable a otro tipo de empresa u organización.

En la empresa certificada, los directivos y los operarios obtuvieron un puntaje máximo de cumplimiento en el principio de gestión de la calidad denominado enfoque en procesos y un puntaje mínimo en los principios enfoque al cliente y relación con proveedores; estos resultados coinciden con el estudio realizado por Pérez y Pérez-Luco (2010) [39]en Chile.

Comparando la investigación con otros estudios, se encontró que la certificación ISO mejora las percepciones de los clientes respecto a aspectos como: calidad, satisfacción e imagen corporativa y también permite obtener otros beneficios relacionados con marketing [34].

En la empresa certificada el puntaje mínimo se presentó en los principios relacionados con personas externas a la organización como clientes y proveedores, mientras que en la empresa no certificada los menores puntajes se presentaron en principios orientados hacia el interior de la organización como son participación del personal y liderazgo.

Sistema Innovador De Producción De Agua Segura: Análisis Económico Y Comparación Con Otras Alternativas

Jorge Emilio Almazán[1], Miguel Cervantes-Schamun[1], Dolores Gutiérrez-Cacciabue[1] y Verónica Beatriz Rajal[1]

[1] INIQUI-CONICET, Facultad de Ingeniería (Universidad Nacional de Salta), Avda. Bolivia 5150- 4400 Salta, Argentina
emilioalmazan8787@gmail.com

Abstract. Estudios recientes demostraron que en la provincia de Salta hay zonas donde diferentes poblaciones no tienen acceso a agua segura para el consumo y se abastecen de agua de fuentes superficiales sin ningún tratamiento previo (aguas turbias en la estación húmeda). Esto se traduce en los datos alarmantes que muestran la cantidad de enfermedades relacionadas con el consumo de agua contaminada, lo que afecta principalmente a los niños. Frente a este gran desafío se diseñó un sistema modular de obtención de agua segura que involucra un proceso de clarificación (usando un clarificante natural autóctono) y una desinfección por medio de ultrafiltración. En este trabajo se buscó evaluar la rentabilidad del sistema propuesto, mediante un análisis económico que incluyó los costos asociados al mismo y los ahorros en salud pública que se obtendrían. Además, se comparó el precio del litro de agua segura obtenido con otras opciones presentes en el mercado local. Así, se pudo concluir que esta alternativa tecnológica para la provisión de agua segura es rentable y competitiva.

Keywords: Agua Segura, Evaluación Económica, Tecnología Alternativa

1 Introducción

Ante la dificultad (económica, social y política) de disponer de agua potable para consumo humano aparece el concepto de agua segura. Se define como un agua libre de bacterias peligrosas, metales tóxicos disueltos, o productos químicos dañinos a la salud, y es considerada segura para beber. En Salta (provincia del noroeste argentino), el crecimiento acelerado de la población provocó que un gran número de personas se asienten en lugares donde no se encuentran disponibles los servicios básicos de agua potable y saneamiento, incrementando los problemas de salud pública con la aparición de enfermedades de origen hídrico que afectan a ancianos y niños principalmente [1]. Estas enfermedades son la segunda causa de muerte en menores de 5 años [2].

Como una solución a esta problemática se diseñó un sistema de producción de agua segura, el cual incluyó un sedimentador que utiliza un clarificante natural autóctono (mucílago de penca de tuna, *Opuntia ficus-indica miller*) y un módulo de ultrafil-

tración (UF) para desinfectar el agua [3]. El agregado de la etapa de clarificación hizo que el equipo sea más versátil y pueda ser alimentado a partir de cualquier fuente de agua superficial (turbia o no), además la UF es reconocida por su eficacia en la producción de agua segura [4,5]. Además, se realizaron ensayos microbiológicos y fisicoquímicos que verificaron la eficiencia de este proceso mediante estudios [6].

El objetivo de este trabajo fue evaluar la rentabilidad económica de este sistema de producción de agua a partir de los costos involucrados y compararlo con otras alternativas de potabilización que existen actualmente en el mercado.

2 Materiales y métodos

Se valorizó el mercado subexplotado de la penca de tuna, de donde se extrae el mucílago utilizado para clarificar el agua. Se estimó su costo tomando como base la clarificación de 100 L de agua. Se fijó un rendimiento del 78% de cada penca (extracción y utilización del mucílago húmedo), el precio de la fruta que se comercializa se estimó en $ 40 el kg, se calculó el costo de mantenimiento de las plantaciones (el 15% del costo de la fruta) y se seleccionó la dosis óptima del clarificante natural determinada previamente (0,4 g/L de agua turbia) [7]. La ventaja de utilizar un clarificante natural reside en que es un producto inocuo que no compromete la salud humana, a diferencia de las sales inorgánicas usadas convencionalmente [8], también que las poblaciones rurales tendrían un fácil acceso al mismo, por ser una planta autóctona que crece en toda la provincia de Salta [9], y que el costo del mismo sea bajo.

Luego, con el diseño del sistema de producción de agua segura [3], se determinaron los costos unitarios de cada equipo como así también los de los insumos involucrados (válvulas, bomba centrífuga, mangueras, manómetros, cartuchos de ultrafiltración, estructura metálica y accesorios varios), previendo una vida útil de 10 años. Luego de la producción diaria (200 L/d) se realiza una limpieza del sistema, por lo que fue necesario estimar también los costos de los desinfectantes involucrados (hidróxido de sodio, ácido cítrico e hipoclorito de sodio). De este modo se obtuvieron los costos anuales de producción incluyendo también los costos de limpieza. Es importante mencionar que el recambio de cartuchos de ultrafiltración se realiza cada 30 días. Se tomaron valores de boletas de facturación de Energía Eléctrica brindadas por EDESA (Empresa Distribuidora de Electricidad de Salta) para la estimación de los cargos de este tipo, de acuerdo a la potencia necesaria para la bomba funcione en el sistema. Finalmente, se calculó el costo del litro de agua segura producido por el equipo propuesto y se lo comparó con otras alternativas de provisión del recurso.

Al realizar el flujo de caja económico, al ser un proyecto de carácter social, en la inversión se consideró que se usarían los ahorros inherentes al gasto de salud pública provocados por el consumo de agua no potable. Para esto se tomó el 40% de los casos tratados de diarrea en niños de Salta Capital menores de 5 años durante el año 2018 en el Hospital Materno Infantil de Salta en Consultas, Salas de Internación Abreviada (SIA), Clínica Pediátrica y Unidades de Terapia Intensiva, arrojando un valor promedio de 267896 U$D/año. Se calcularon los indicadores económicos VAN (valor actual

neto), TIR (Tasa interna de retorno) y el período de recuperación de la inversión para evaluar la rentabilidad del proceso.

3 Resultados y discusión

El costo estimado del clarificante natural fue de 0,013 U$D/100 L de agua clarificada. Su costo es competitivo en comparación a los usados en la actualidad como clarificantes tradicionales. Particularmente el sulfato de aluminio (uno de los clarificantes más utilizados en el mercado), tiene un costo aproximado de 0,014 U$D/100 L de agua clarificada con una dosis óptima de 50 mg/L [10].

Luego de solicitar cotizaciones a diferentes proveedores, se estimó el costo unitario del equipo diseñado en 726 U$D, con una vida útil de 10 años. El valor de cada limpieza fue estimado en 16,15 U$D y al cartucho de UF (Hidrolit Abland Home Small) se le asignó un costo de $99,34 U$D, provisto por el fabricante.

El precio del litro de agua potable producido con el sistema de producción fue de 0,098 U$D/L, que convertido a pesos argentinos (con una cotización de 1U$D=45,3$, válida para abril de 2019) equivalen a 4,44 $/L. Cuando se comparó este precio con los existentes en el mercado local (Tabla 1), el mismo era aproximadamente un 41% menor, sin tener en cuenta los gastos de transporte desde las fábricas de agua potable hasta las comunidades rurales y la compra de un dispensador necesario para el cómodo abastecimiento de este recurso.

Tabla 1. Diferentes alternativas para la compra de agua segura para consumo humano.

Marca/ Empresa	Volumen (L)	Costo ($)	Precio del litro de agua ($/L)	Dispensador ($)
Ideal	20	220	11	380
Soda Mónica	20	220	11	310
3 Cerritos	20	210	10,5	300
Ivess	20	240	12	350

Cuando se realizó el flujo de caja económico para calcular los indicadores económicos, se tomó un riesgo país 900 y una inflación interanual del 51,3%. El Valor Actual Neto (VAN), la Tasa Interna de Retorno (TIR), el Retorno de Inversión (RI) y el Rendimiento del proyecto en un horizonte de 10 años (REND) fueron: VAN= U$D 300641, TIR = 63,7%, RI = 2 años y 7 días y REND = 128,33%. Como se pudo comprobar el proyecto es rentable con un óptimo rendimiento. Cabe destacar que esta propuesta no pudo ser evaluada como un proyecto de inversión económico netamente, debido a que tiene involucrado un factor social relacionado con el mejoramiento de la calidad de vida de las personas. Por esta razón se tomó como inversión el gasto de salud pública evitado que es aquel que se obtendría si las familias de Salta Capital y alrededores tuvieran acceso a agua segura. Con la inversión se podría construir en el primer año del proyecto 300 equipos de obtención de agua potable, y con la recuperación de la inversión y en el año 5, 300 equipos más, haciendo un total de 600 equipos. Estos equipos serían distribuidos en viviendas y escuelas rurales.

4 Conclusiones

Se pudo determinar la rentabilidad de la implementación del sistema de producción de agua potable y el costo del litro de agua, el cual resulta competitivo con los existentes en el mercado. También se determinaron los montos que se ahorrarían en la salud pública por la ejecución del proyecto. Sin embargo hay que tener en cuenta otros beneficios asociados al mismo que son: la disminución en morbilidad en niños por deshidratación, el aumento de productividad de las personas beneficiarias, ya que se evita la detención de la actividad laboral por motivos de salud, el impacto en contra de la desnutrición infantil, ya que el agua potable es un elemento esencial para la asimilación correcta de nutrientes y un buen desarrollo cognitivo, y otros beneficios sociales que requieren de un análisis extenso para ser medidos.

Abstract. With the increasing demand for investments in innovation and digital transformation, there is a need for more detailed analysis from the practical initiatives being carried out. Government benefits have served as an incentive for companies, with governments seeking industry development and improvements in aspects that are of society's interest. The objective of this study is to verify how companies in the Brazilian automotive industry have been funding the formulation of new products and solutions in this scenario. Questions were sent to specialists from the industry and local institutions that finance and support research and development, who pointed out the following funding options: own resources; government benefits; partnerships; loans and grants; venture capital and private equity. Analyzing the options made by the industries consulted, it was possible to notice a clear difference between them. One of the companies prioritized the use of its own resources, while the other had no restrictions on the use of different options. Another difference observed is the way in which companies deal with the use of tax benefits: while one counts on the services of a consultancy company to analyze projects with the potential to recover the investment made, another company consulted does not use this type of service. Results of the study also highlight that both management guidelines and organizational culture have the potential to impact the way companies make their investments. This paper, hence, discusses these differences to provide insights related to the funding of digital transformation initiatives both for academics and practitioners.

Keywords: Innovation, Digital Transformation, Investment, Expert Consult, Automotive Industry.

1 Introduction

With the increasing demand for investments in innovative projects, which help companies to develop skills that lead to digital transformation [1], there is a need for more detailed analysis of how these initiatives have been taking place in a practical context. To carry out these investments, organizations need resources to fund the necessary initiatives, which include hiring labor and purchasing equipment and supplies, focusing on leveraging performance [2].

In relation to the automotive industry, some of these means of financing are more notorious. Large companies have a structure that makes it possible to develop new projects using their own resources, whether tangible or intangible. This investment capacity can be verified in the results presented by the organizations, which in some cases are public. Government benefits have also served as an incentive and financial complement to these initiatives, with the governments using these actions to develop the industry in certain areas, while seeking improvements in aspects that are of interest to the whole society [3]. Around the world, it is possible to verify the realization of this type of initiative in countries like Thailand [4], China [5] and Mexico [6].

2 Objectives

The main objective of this study is to carry out a listing of the methods that automotive manufacturers can use to finance investments in their projects for the creation and development of innovative projects, that meet the needs of a market that increasingly turns to the use of technology. The definition of innovation used is that of the Oslo Manual [7], which defines it as the implementation of new products, processes, marketing methods and organizational models.

To this end, a consultation was first carried out with industry specialists, which was followed by contact with professionals from other organizations that are related to the activity of resources, aiming at the identification of possible means that have not been mentioned by the industries. This turns the responses to become more comprehensive, bringing options that can be considered by other organizations in the same industry that have different characteristics from those found in the larger organizations. Another objective of this study is to perform the analysis of the responses obtained, so that patterns or discrepancies can be identified. This makes it possible to ask questions about improvements that could be made in processes such as the choice of means of financing by companies, as well as in the creation of laws that establish government incentives.

3 Method

The method chosen for the collection of information was a consultation with specialists, who, according to [8], are professionals who represent different perspectives on a given subject. The use of this method is justified by the need to obtain different points of view, not only from industries, but from other organizations that can provide support to automotive companies that may come to seek more information on project financing.

The research was divided into two stages, as described below. In the first phase, the same questions were sent by electronic correspondence to professionals from two large automotive manufacturers, with facilities in the Brazilian city of Curitiba. In order to increase the variety of responses, contact was also made with a funding agency and an industrial federation that support research and development in the same region. The consultation with professionals from the region cited is due to the fact that several companies in the automotive industry have factories in the area, which justifies the need for certain common contextual characteristics among them, and the diversity of

organizations of which the people consulted are part of allows a greater variety of possible different results, which may be more suitable for other industries in the automotive sector that are not large industries. This branch includes companies with different activities, which can vary between the supply of parts and the creation of solutions that meet the process of development, creation, and sale of vehicles.

In the second stage, the responses were then detailed and analyzed under different aspects, as follows:

• Description of each fundind method mentioned;

• Based on the data generated in the previous step, analysis of possible critical points in relation to each investment method.

4 Results

According to the responses obtained, with the five specialists consulted, it was possible to verify the existence of the following options for investments funding, as described in Table 1.

Table 1. Funding methods cited by each expert.

Origin	Expert	Funding means used/cited
Industry 1	Project manager	Partnerships with research organizations, tax benefits, use of own resources.
Industry 2	Innovation projects coordinator	Partnerships with research organizations, tax benefits, use of own resources, financing.
Government funding agency	Operations Coordinator for the Private Sector	Specific loan and financing lines, grants, investment funds.
Local industrial federation	Marketing manager	Partnerships with research organizations.
	Industrial funding coordinator	Specific financing lines.

4.1 Use of own resources

The definition of resources used in this research is based on the work of [9], who classifies them as tangible and intangible assets linked to the company, and which can vary from the employees and the physical structure of the organization, to the technology and capital used.

One of the possible options for industrial organizations is the use of these resources, which can take place in different ways. In projects for innovative products and services development, companies use this means in the expenditure of financial resources for the acquisition of items and contracting of services directed to R&D activities [10].

4.2 Tax benefits

Tax benefits are incentives provided by governments for companies to carry out certain activities, usually meeting some predetermined objective. This is one of the most used financing methods by Brazilian companies, which can be seen by the increase in its use in the last two decades [3].
An example of a benefit by the Brazilian government is the extinct Inovar-Auto, a program that granted tax credits to companies in exchange for vehicles manufacturing with the use of technology that would enable greater safety and energy efficiency, something that has become a concern of several countries [11].

4.3 Partnerships with research organizations

One type of initiative that was mentioned by several professionals was the establishment of partnerships with research organizations, for the development of processes and the creation of products and solutions. This activity can take place in two ways: these organizations can provide support through the provision of specific labor, so that projects are developed internally by companies, or else in the joint development of certain products or processes.

4.4 Loans and financing

Companies can obtain loans and financing from public and private banks, which often have specific lines for specific purposes. Data from the National Bank for Economic and Social Development [12] are public, for transparency reasons, which enabled the verification of data on loans made by the consulted automotive industries.

4.5 Grants

According to the Financier of Studies and Projects (FINEP), a Brazilian agency for the promotion of technology, grants are non-reimbursable public resources directed to the development of certain innovative products that are of public interest, but that are not receiving investments from the private sector [13]. The activities funded are research and technological development.

4.6 Venture capital and private equity

Venture Capital and Private Equity are two types of investment funds that can also be used by companies, the first of which is aimed at disruptive companies in the beginning of activity and with growth potential, while the second can be used by established companies [14]. Venture Capital fund investors seek to offer not only financial resources, but certain skills they have, which may be useful to the investee company [15].

5 Discussion

With the listing of the funding means used or cited by the organizations consulted, it was possible to perceive that some are seen as viable by a greater number of specialists, such as the use of loans and financing and partnerships with research agencies, which fund both the equipment used and manpower to carry out the projects. One of the possible justifications for this is the variety of organizations that make it possible to obtain these resources, as well as the fact that funding and research support agencies are generally specialized in meeting certain demands, such as equipment financing and new technologies development, respectively.

In relation to the differences between the automakers, the specialist from Industry 1 showed a preference for the use of its own resources, avoiding loans, while the specialist from Industry 2 showed no restrictions on the use of extern resources, like financing. Another difference observed is the way in which companies deal with the use of tax benefits: while Industry 1 has a consultancy company analyzing projects with the potential to recover the investment made, the other industry consulted does not use this type of service, carrying out the process internally. Knowledge management mechanisms could assist companies in fulfilling all necessary obligations.

In relation to the use of government incentives, the specialist at Industry 2 reported that the company was unable to use a certain benefit because it did not present profit. This fact demonstrates the need for verifying whether the benefits offered are aligned with the needs and characteristics of companies.

6 Conclusion and recommendations

The presented work focused on conducting an empirical study on the available funding means for investments in projects aimed at innovation and digital transformation, with a focus on the automotive industry. By sending questions to professionals from companies related to the research scope, it was possible to identify not only the current funding sources, but the different usage profiles of them among the companies consulted.

The differences found between the two industries can be justified by organizational and cultural aspects. Future research may turn to more specific analyzes of these differences, with the identification of the elements that influence decision making by managers.

Another topic that can be evaluated in greater detail is the process of creation of the laws related to the granting of tax benefits, so that it can be verified if there is an alignment between the requirements and procedures mentioned in the laws, and the reality of the companies that are its target audience.

Resumo. Com o crescente desenvolvimento econômico e tecnológico, as empresas estão cada vez mais descobrindo possibilidades de mercados, mas também estão encontrando mais concorrência e uma exigência maior na qualidade de seus produtos. Com o advento do *Lean Manufacturing*, muitas melhorias podem ser aplicadas no chão de fábrica, mas uma das mais efetivas é a simulação de eventos discretos. Com a simulação é possível representar com facilidade todas as etapas de estocagem, logística, fabricação e inspeção de uma entidade (matéria prima, produto semiacabado e produto final). Com a representação dos fenômenos no modelo de simulação se torna possível a identificação de qual melhor *layout*, aonde estão os gargalos, as perdas, quais estações de trabalho não estão trabalhando como deveriam, quais produtos possuem maior valor agregado. Este trabalho tem como objetivo desenvolver um modelo de simulação que represente da melhor maneira possível o setor de preparação de madeira em uma indústria moveleira. Por meio da análise dos processos produtivos que envolvem este setor, desenvolver ferramentas que possibilitem a coleta de dados do chão de fábrica, integração destes dados com o *software* de simulação e validação do modelo comparando os resultados com o histórico de produção. Posteriormente, é realizada a análise crítica do modelo, desenvolvimento das possíveis melhorias e aplicação destas no chão de fábrica. Por meio da metodologia utilizada, espera-se que o modelo atinja um elevado índice de similaridade com a realidade, proporcionando a fácil identificação dos gargalos e dando subsídios para a tomada de decisão da empresa.

Keywords: Indústria Moveleira, *Lean Manufacturing*, Simulação.

1 Introdução

A indústria mundial moveleira foi e continua sendo constituída, predominantemente, por pequenas empresas, que até os anos 50, visavam atender quase que exclusivamente ao mercado interno dos seus respectivos países. Somente a partir da década de 50 teve início o comércio internacional de móveis, consolidando-se na década de 70 [1]. Até o final do século passado, o mercado era altamente concentrado em produtores e cliente de países desenvolvidos. Já no início do século XXI, esse cenário começou a mudar

com uma notória entrada de países emergentes, como por exemplo, o Brasil, que em 2015 ocupou a 5° posição com 3,2% da produção mundial [2].

No Brasil, a indústria moveleira teve a sua evolução atrelada às mudanças que ocorreram na economia nacional. A partir de 1990, com a abertura comercial promovida pelo governo, houve grandes investimentos na compra de novos equipamentos de alta tecnologia, o que renovou o parque de máquinas do setor [3]. A partir dos anos 2000, o setor começou a apresentar um bom crescimento, principalmente voltado para as exportações. Porém o setor moveleiro brasileiro ainda se caracteriza como opção de terceirização de mão de obra e venda de matéria-prima para países desenvolvidos.

Atualmente, o setor vem investindo em melhorias tanto nos processos produtivos, quanto na qualidade de seus produtos [2]. O investimento no *design* é um dos principais objetivos hoje da indústria moveleira nacional, visando agregar valor aos seus produtos e uma participação mais atuante e independente no mercado internacional [3]. Mas, junto com ele, também são necessárias mudanças na forma de pensar e organizar o chão de fábrica [5].

O pensamento *lean*, vem de encontro com esses desafios enfrentados pela indústria moveleira. A filosofia *lean* tem como objetivo agregar maior valor ao produto, reduzindo os desperdícios. Uma organização enxuta entende o valor agregado ao cliente e foca seus processos-chave para continuamente ampliar este valor. A meta final é fornecer um valor perfeito para o cliente, por meio de um processo de criação de valor que tem como alvo "atingir zero resíduos" ou buscar o "defeito zero" [4].

Uma das principais ferramentas que dão suporte à implementação do pensamento *lean* é a simulação [5]. Por meio da simulação, é possível reproduzir todo o processo produtivo do começo ao fim. Os *softwares* de simulação utilizam conceitos desenvolvidos na metodologia enxuta, associados a modelos matemáticos e uma interface de "conversa" com o usuário. Assim, tais *softwares* permitem a identificação e análise de problemas, além de testar propostas de solução, alternativas e até realizar previsões, tornando-se um forte aliado na tomada de decisão [5].

Neste contexto, o presente trabalho tem como objetivo desenvolver um modelo de simulação que represente as atividades exercidas no setor de preparação da madeira numa fábrica moveleira, integrando, em tempo real, dados do chão de fábrica com o *software* de simulação. O *software* escolhido foi o Arena®. As informações de entrada serão coletadas, de forma *online*, a partir do banco de dados da fábrica por meio de relatórios no formato MS Excel.

2 Revisão Bibliográfica

Nesta seção, tópicos relevantes para o desenvolvimento da pesquisa são revisados. Em primeiro lugar, o conceito de *Lean Manufacturing* é abordado, visto que a filosofia enxuta se encontra como um dos principais fatores de contexto do trabalho. Em segundo lugar, conceitos de base do estudo das filas são apresentados no sentido de contextualizar a problemática abordada neste trabalho, bem como possibilitar a interpretação do comportamento das entidades submetidas à simulação. Em terceiro lugar, o conceito da

simulação de eventos discretos é explorado. Por fim, o *software* de simulação Arena® - escolhido para o desenvolvimento do trabalho - é apresentado.

2.1 O Sistema *Lean Manufacturing*

Um sistema de manufatura é constituído por máquinas, pessoas e outros recursos com o objetivo de produzir um determinado produto ou serviço. O sistema *Lean Manufacturing* tem como fundamento principal conduzir os sistemas convencionais de produção para um sistema de produção enxuto com foco na melhoria dos processos e redução das perdas. [6]

A ideia de produção enxuta tem como objetivo identificar os processos que agregam valor ao produto, alinhá-los da melhor maneira possível, aproveitando a melhor qualidade no menor tempo, sem que haja interrupções no sistema. Utilizando os insumos de maneira mais eficaz, com menos perdas, visando eliminar ou reduzir os processos que não agregam valor. Tornando o trabalho mais satisfatório, dando ênfase na qualidade, atingindo apenas a quantidade necessária no tempo adequado [7].

Um método de análise ou diagnóstico principal para atingir os objetivos da filosofia é por meio da identificação do fluxo de informação de todas as etapas do produto ou serviço. Nesse sentido, é possível identificar grandes focos de desperdício, fazer novas sugestões e apresentar alternativas para um plano de ação com as etapas que deverão ser desempenhadas para alcançar a situação ideal [8].

2.2 Estudo das Filas

É possível definir fila como o processo de acesso de entidades a uma operação, da qual a demanda é superior a capacidade de atendimento. A formação de filas se dá em razão do fluxo [9]. A Teoria das filas é definida como um ramo da probabilidade que estuda a formação de filas, por meio de análises matemáticas precisas e propriedades mensuráveis das filas. Ela provê modelos para demonstrar previamente o comportamento de um sistema que ofereça serviços cuja demanda cresce aleatoriamente, tornando possível dimensioná-lo de forma a satisfazer os clientes e ser viável economicamente para o provedor do serviço, evitando desperdícios e gargalos [10].

Se os gargalos resultam em maior tempo de espera, a qualidade e a produtividade do sistema de atendimento inteiro caem, gerando tendência de aumento do custo total desses sistemas. Porém, exceder a capacidade do sistema, de forma a eliminar as filas, também resulta em aumento nos custos operacionais. Portanto, os modelos propostos pela Teoria das filas, são importantes para auxiliarem a compreensão e análise de equilíbrio entre o tempo de espera em fila e o custo operacional [11]. A simulação é uma metodologia que tem tido sua aplicação cada vez mais expandida, especialmente em estudos de fila complexos, que devem atender um conjunto de hipóteses para o funcionamento [12].

2.3 Simulação de Eventos Discretos

A simulação computacional vem a cada ano sendo utilizada em inúmeras companhias e direcionada para diversas aplicações no processo de apoio à tomada de decisão. É possível encontrar inúmeros *softwares* de simulação que diferem em complexidade de programação, apresentação dos resultados, custos e formas de aquisição. Esses programas podem ser adaptados a diversas situações, fazendo com que esta ferramenta seja utilizada por empresas de qualquer ramo de atividade e de qualquer porte.

O uso da simulação na resolução dos problemas de filas apresenta boas vantagens em relação a outras soluções principalmente pela sua maior aplicabilidade. Outra vantagem é com relação a representação gráfica do sistema, que além de facilitar a análise e interpretação dos resultados, se caracteriza pela flexibilidade de adaptação à realidade. [13]

2.4 Software de Simulação Arena®

O *software* escolhido para o desenvolvimento deste trabalho foi o Arena®. Desenvolvido pela *System Modeling* em 1993. Graças a sua disseminação no mercado e nas universidades brasileiras, o seu ótimo custo benefício e presença de ferramentas suficientes para a modelagem do sistema proposto. Assim como a maioria dos *softwares* de simulação, o Arena® visualiza o sistema a ser modelado como constituído de um conjunto de estações de trabalho que contém um ou mais recursos que prestam serviços a clientes (também chamados de entidades ou transações) que se movem através do sistema. O movimento pode ser feito pela própria entidade ou por transportadores (empilhadeiras, por exemplo). A entrada de dados no modelo pode ser realizada por meio de arquivos (MS Excel, por exemplo) contendo informações referentes as entidades que entram no sistema (informações como nome, prioridade, quantidade, tempo de chegada).

3 Materiais e Métodos

Nesta seção, os materiais e métodos empregados para a realização do trabalho são detalhados. Uma visão geral das etapas realizadas pode ser visualizada na Figura 1. Em seguida, uma apresentação da empresa estudada e o detalhamento de cada uma das etapas são apresentados.

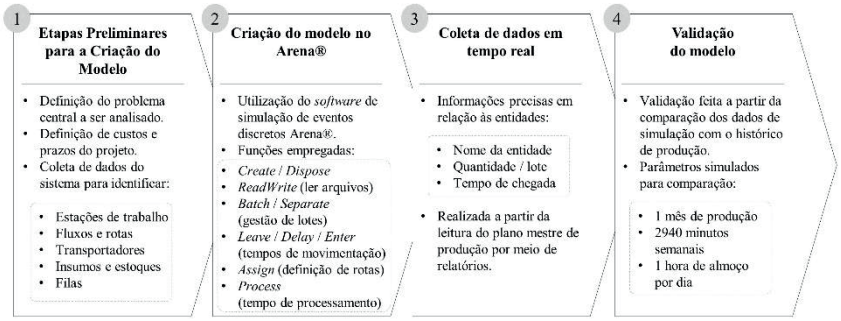

Fig. 1. Etapas da pesquisa.

3.1 A Indústria Moveleira em Estudo

A indústria moveleira em estudo está localizada no município de São Bento do Sul, interior do estado de Santa Catarina. É uma empresa média que conta com cerca de 120 funcionários. O produto principal são as camas e beliches, cujo o principal mercado é externo. Este trabalho tem como objetivo trazer melhorias para o setor de preparação da madeira, portanto será o único setor a ser analisado.

O setor de preparação é composto por: uma máquina de serra circular; uma máquina destopadeira manual; uma máquina otimizadora; uma máquina moldureira, associada a duas estações de trabalho que recebem diferentes tipos de produtos; uma prensa de alta frequência, associada a duas estações de trabalho que recebem os mesmos produtos; e por fim, uma máquina seccionadora. Cada máquina está equipada com um controlador de coleta de dados. Cada controlador apresenta dados importantes para o modelo, como: produtividade, parada e disponibilidade.

3.2 Etapas Preliminares para a Criação de um Modelo no Arena®

O projeto de simulação deve ter um objetivo claro, ter um tempo e custo aceitável de desenvolvimento, deve ser bem documentado e atingir o seu objetivo. Este objetivo primário deve ser claro para todos os envolvidos no projeto. Para isso, Prado (2010) define um projeto de simulação em duas etapas: Planejamento e Execução [14]. Nesse sentido, o planejamento se iniciou pela definição de um problema central a ser analisado, e pela definição de custos e prazos para a realização do projeto. Em seguida, foi realizada a coleta dos dados do sistema submetido à simulação. Essa coleta tem como objetivo a criação de um desenho que explicite o *layout*, permitindo a identificação de: equipamentos e estações de trabalho, rotas e fluxos de materiais, transportadores de materiais, insumos e estoques ao longo do processo produtivo, e também filas de entrada e saída das estações de trabalho. Ademais, a coleta dos dados é importante para o levantamento de anomalias no sistema, além do levantamento dos tempos de processamentos e das capacidades das filas e dos estoques.

3.3 Criação do Modelo no Arena®

Após a etapa preliminar de planejamento, a execução da modelagem foi realizada no *software* Arena®, a partir do emprego de algumas funções. A função *Create* foi utilizada para definir a cadência de entrada de novas peças no sistema, enquanto a função *dispose* foi utilizada para representar a saída de produtos do sistema. A função *ReadWrite* foi empregada para ler arquivos de texto, planilhas do *MS Excel* e planilhas do *MS Access*. As funções *Batch* e *Separate* foram utilizadas, respectivamente, para unir peças em lotes e separar peças de lotes. No âmbito das movimentações de peças entre máquinas, quatro funções foram utilizadas: a função *Delay* foi empregada para definir um tempo para a movimentação de uma peça, a função *Assign* foi usada para definir a rota que uma peça deve seguir, a função *Leave* foi utilizada para definir um período de tempo para que ocorra a saída de uma peça de uma estação, e a função *Enter* foi utilizada para definir um período de tempo para que ocorra a entrada de uma peça em uma nova estação. Por fim, a função *Process* foi empregada para indicar o tempo de processamento de uma peça em uma máquina.

3.4 Coleta de dados em tempo real

Uma parte importante do modelo de simulação é ter acesso a informações precisas de como as entidades a serem analisadas se comportam na entrada do sistema. É vital que dados como nome da entidade, quantidade, lote, tempo de chegada sejam o mais precisos possível. Por outro lado, o modelo deve simular em tempo real os cenários em que a fábrica se encontra. Portanto, a coleta de dados diretamente do plano mestre de produção é uma opção adequada. Periodicamente são gerados relatórios em formato MS Excel, contendo todos os dados de entrada importantes. Esses relatórios foram utilizados para alimentar o modelo de simulação, gerando previsões em tempo real conforme a demanda.

3.5 Validação do modelo

A validação do modelo foi feita com base no histórico de produção. O modelo reproduziu um mês de funcionamento da fábrica (2940 minutos semanais com 1 hora de almoço por dia) com base em dados de entrada já conhecidos. Os dados de saída do modelo foram comparados à produção ocorrida neste mês estudado.

4 Resultados e Discussão

O primeiro passo tomado foi a definição da entidade que seria analisada. O metro linear foi a melhor unidade de medida encontrada, que podia ser medida na vida real e aplicada no Arena®. Seguindo para a coleta de dados, foi desenvolvido um desenho do *layout* do setor de preparação. O desenho, que pode ser observado na Figura 2, contém as estações de trabalho, estoques e suas disposições no chão de fábrica.

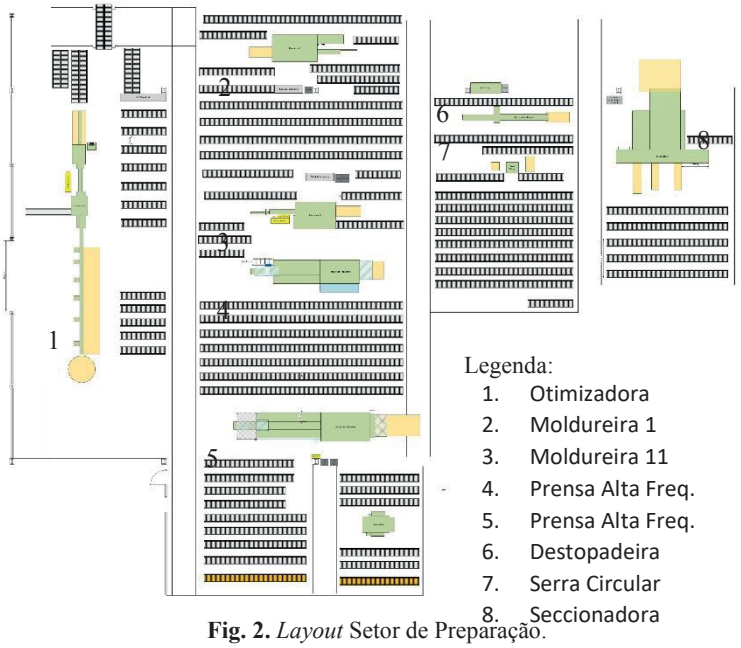

Fig. 2. *Layout* Setor de Preparação.

Em seguida, foi desenvolvido um fluxograma dos processos, apresentado na Figura 3. No fluxograma estão explícitas todas as rotas possíveis e seus destinos.

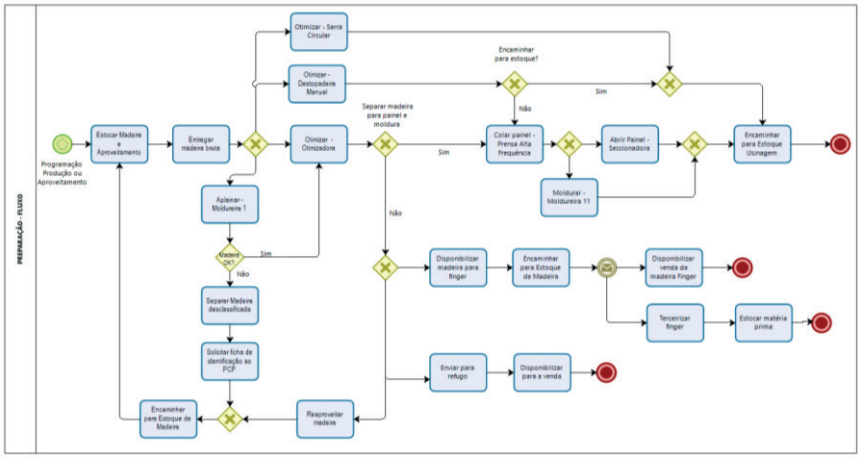

Fig. 3. Fluxograma de processos.

Devido a quantidade de produtos distintos que entram simultaneamente no sistema, foi necessária a separação das rotas. Ao todo foram identificadas 15 rotas. Cada rota representa uma família de produtos. A separação em rotas além de representar de maneira mais fiel a realidade, também torna possível um melhor controle de cada família

de produtos. Com essa separação também se torna possível uma melhor coleta de dados como tempo de um produto no sistema, valor agregado a esse produto. Podendo ao final do trabalho ser definido quais produtos devem ter prioridade no setor.

Tabela 1. Principais Rotas Identificadas.

Rotas Identificadas no setor de Preparação							
1	Estoque	Serra Circular	Estoque Usinagem				
2	Estoque	Destopadeira	Estoque Usinagem				
3	Estoque	Destopadeira	Prensa Alta Freq	Seccionadora	Estoque Usinagem		
4	Estoque	Destopadeira	Prensa Alta Freq	Seccionadora	Moldureira 11	Estoque Usinagem	
5	Estoque	Destopadeira	Prensa Alta Freq	Moldureira 11	Estoque Usinagem		
6	Estoque	Otimizadora	Prensa Alta Freq	Seccionadora	Estoque Usinagem		
7	Estoque	Otimizadora	Prensa Alta Freq	Seccionadora	Moldureira 11	Estoque Usinagem	
8	Estoque	Otimizadora	Prensa Alta Freq	Moldureira 11	Estoque Usinagem		
9	Estoque	Otimizadora	Moldureira 11	Estoque Usinagem			
10	Estoque	Otimizadora	Estoque Finger				
11	Estoque	Moldureira 1	Otimizadora	Prensa Alta Freq	Seccionadora	Estoque Usinagem	
12	Estoque	Moldureira 1	Otimizadora	Prensa Alta Freq	Seccionadora	Moldureira 11	Estoque Usinagem
13	Estoque	Moldureira 1	Otimizadora	Prensa Alta Freq	Moldureira 11	Estoque Usinagem	
14	Estoque	Moldureira 1	Otimizadora	Moldureira 11	Estoque Usinagem		
15	Estoque	Moldureira 1	Otimizadora	Estoque Finger			

Por fim, foi desenvolvido o modelo no Arena®, apresentado na Figura 4. Na figura, os módulos da esquerda representam as entradas do sistema. Como são analisados 15 produtos diferentes, foram criadas 15 rotas distintas. Os módulos utilizados foram:

- Módulos "*Create*". Cada módulo "*Create*" recebe os dados de entrada de cada produto no sistema (identificados como Estoque de Madeira Rota);
- O módulo "*ReadWrite*" permite que o modelo faça a leitura do plano mestre de produção;
- O módulo "*Separate*", associado ao módulo "*ReadWrite*", tem a função de coletar a sequência de valores lidos no módulo "*ReadWrite*";
- O módulo "*Delay*" (identificado como Logística interna de entrega de madeira ...) atribui um valor de tempo entre a saída de madeira do estoque inicial e a chegada em suas respectivas estações de trabalho;
- O módulo "*Assign*" tem a função de definir quais estações de trabalho (rotas) cada produto irá seguir;
- O setor de preparação faz o planejamento por meio de lotes, portanto, por meio do módulo "*Batch*", será possível unir o metro linear de madeira em um único lote para a sua movimentação.
- O módulo "*Leave*" permite a conexão entre os módulos acima citados e os módulos referentes as estações de trabalho.

Os módulos do meio representam as estações de trabalho, para cada uma foram adicionados os seguintes módulos:

- Módulo "*Enter*", adiciona um valor de tempo para a entrada do lote na estação de trabalho;
- Módulo "*Separate*", separa os produtos unidos com o módulo "*Batch*", ou seja, separa o lote de madeira em valores de metro linear;

- Módulo "*Process*" (identificado pelas máquinas) representa cada processo produtivo propriamente dito. Este módulo irá receber os tempos de processamento de cada máquina, coletados pelo controlador;
- Módulo "*Batch*", associado com o "*Process*", permite a união dos metros lineares em um lote;
- Módulo "*Leave*" adiciona um valor de tempo para a saída do lote da estação de trabalho;
- Os módulos "*Decide*", presentes após a otimizadora e a moldureira 11, separam o percentual de refugo e madeira de reutilização que saem dos respectivos processos.

Por fim, os módulos mais a direita representam as saídas do sistema. Neles foram adicionados os seguintes módulos:

- Módulo "*Enter*", representa o tempo de saída dos lotes de suas estações de trabalho até o estoque destino;
- Módulo "*Separate*", separa os lotes em metro linear;
- Módulo "*Dispose*" (identificados como Estoque Usinagem, Estoque Finger, Estoque Refugo, Estoque de Madeira), representa cada uma das saídas do sistema.

Além disso, foi definido que o modelo deverá simular um mês de produção. Por meio do módulo "*Schedule*", presente na definição de parâmetros do modelo, foi definido os horários em que cada estação de trabalho está disponível (de segunda-feira à quinta-feira das 07:00 às 17:00 e sexta-feira das 07:00 às 16:00, com pausa, todos os dias, das 12:00 às 13:00, para o almoço).

Para uma maior precisão do modelo, também são levantadas informações como: prioridade das rotas, percentual de refugo, falhas e manutenção.

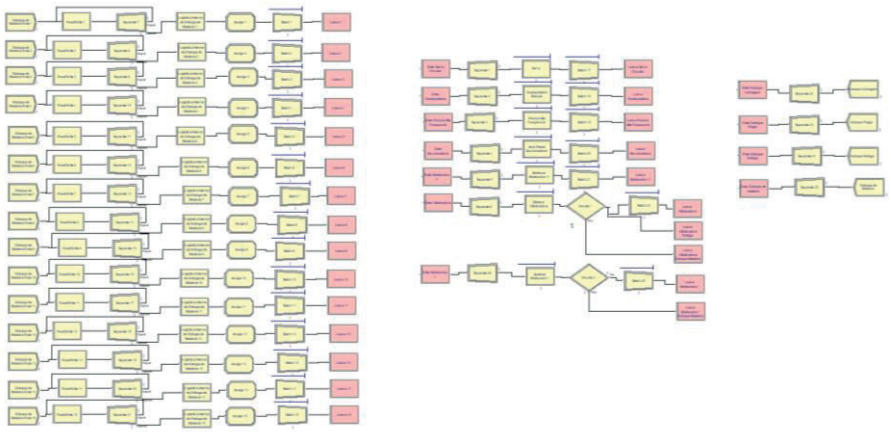

Fig. 4. Modelo desenvolvido no Arena®.

5 Conclusão

Para que o modelo de simulação seja funcional é necessário que todos os processos que ocorrem no ambiente de estudo sejam bem definidos, os tempos coletados de cada processo sejam precisos, os dados de entrada do sistema sejam os mais próximos do mundo real. Por meio da metodologia utilizada neste trabalho espera-se que o modelo tenha um alto índice de similaridade com a realidade. Após a validação do modelo, será possível identificar os seguintes dados:

- Quantidade total de metros lineares produzidos;
- Porcentagem da produção destinada para os diferentes estoques de saída;
- Quais produtos possuem maior valor agregado;
- Quais rotas possuem gargalos;
- Quais estações de trabalho estão sobrecarregadas;
- Qual a produtividade real de cada máquina.

Em seguida, por meio do relatório gerado pelo *software*, será possível identificar quais dados estão fora dos parâmetros ideais. Propostas de mudanças podem ser estudadas e aplicadas no modelo para que esses índices sejam atingidos. Dentre as possíveis mudanças:

- Mudança de *layout* atual;
- Compra de novas máquinas;
- Manutenção ou adaptação das máquinas atuais;
- Adaptação no transporte das peças.

Espera-se que após todo o processo, o modelo de simulação possa dar subsídios para a tomada de decisão da empresa. Vale ressaltar que os dados de entrada registrados no plano mestre de produção devem ser os mais precisos possíveis.

Do ponto de vista de oportunidades para trabalhos futuros, uma das possíveis propostas de melhoria para o modelo seria a adoção de um sistema automatizado que faça o registro de entrada das peças no sistema. Nesse sentido, o modelo de simulação pode incrementar suas capacidades de reconfiguração em tempo real, para garantir uma correspondência atualizada de seus parâmetros com as condições vigentes do sistema produtivo. A adição de tais capacidades aproximam o modelo das arquiteturas tecnológicas propostas no contexto da manufatura digital.

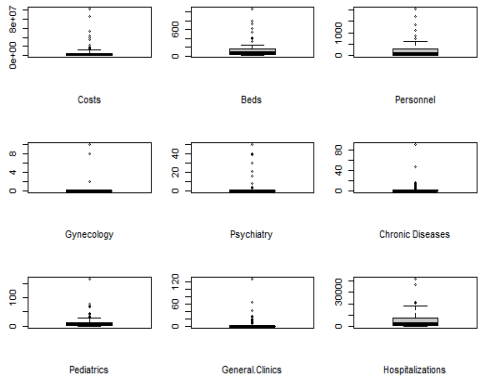
Abstract. The recent pandemic crisis has highlighted the importance of efficiency-oriented strategies to prevent the collapse of health systems under limited resources over the world. This assessment combines the advances in the outranking Multicriteria Decision Aid to the frontier estimations of Data Envelopment Analysis to support resource management in hospitals during the pandemic. The methodology involves determining an optimal direction for input contraction using the PROMETHEE method based on health experts' value judgments to estimate hospitals' production capacity through linear programming. The assessment aims at providing an avenue for local administrations' strategic planning.

Keywords: Data Envelopment Analysis, Directional Distance Functions, Multicriteria Decision Analysis, Resource Allocation, Hospitals, Covid-19, Brazil.

1 Introduction



The recent pneumonia outbreak evidenced critical limitations in health systems around the world. Because several patients needed intensive care simultaneously, hospitals and other health support administrations with limited resources were unable to meet all the demand for health care services. As a result, health systems in many countries and regions collapsed due to the unavailability of beds, ventilators, personal protective equipment (PPE), human and other technical resources for new hospitalizations [1], testifying the need for efficient hospital resource management and evacuation protocols to increase the response capacity during this crisis.

Data Envelopment Analysis (DEA) is widely recorded in efficiency studies of hospitals [2]. DEA uses the ratio between output and input variables to calculate the relative efficiency of production units in a given context. The DEA application in hospitals offers performance indicators favoring guidelines for reducing the operational cost of medical units through the efficient use of resources [3], [4], [5]. In this work, an extension of the Directional Distance Function (DDF) for the inclusion of multiple subjective directions based on outranking procedures developed by Nepomuceno, Daraio & Costa [6] is used to support resource management in hospitals during the COVID-19 pandemic.

This methodology's value is noticeable in our decision problem, which is estimating the feasible efficient production capacity for hospitals based on both technical parameters and subjective evaluation of health professionals. This assessment offers an optimized measure for how many resources (beds) each health service unit can spare and reallocate through best practices. The considered inputs are the number of assistants and technicians, nurses, hospital beds, and hospitalization costs. The produced output is admissions (hospitalizations). The decision criteria for defining the feasible direction are the severity, flexibility, complexity of needs, assistance utility, and potential for replacement in the ten most recurrent medical specialties (in the number of hospitalizations). The 88 most essential hospitals and health care units in Pernambuco were selected for this analysis.

2 Data and Methodology

Hospitalizations under an operational perspective can be comprehended as a production system composed of technical (beds, personnel, equipment) and financial (costs) inputs used to produce several hospital internments (admissions or hospitalizations) with a final objective of providing sufficient care for a patient recovery[7]. In the directional efficiency assessment for hospitalization management, the number of beds for some recurrent and particular specialties was considered the analysis's inputs, having hospitalizations as the output. The total cost (investment) in hospitalizations for each health service unit was included as an additional input for controlling the scale and size of units. Another assessment (for comparison purposes) considered the costs, beds and staff (assistants and technicians) as the production inputs. Fig. 1 illustrates in boxplots a summary of descriptive statistics (range, mean, median, quartile, intervals, and outliers) for the considered variables.

Data corresponds to 88 public and private health service units in Pernambuco, Brazil. Some hospitals do not serve all types of specialties considered in this assessment. We used the costs of hospitalizations as a control input for the size and scale of units. Fig. 1 reports only the final considered specialties after outranking directions for the efficiency analysis and support reallocating beds and associated resources.

Fig. 1. Boxplots for Inputs and Output Data.

Directional Distance Functions Chambers et al. (1998) and Färe and Grosskopf (2004), Nepomuceno et al. (2020) are a flexible non-parametric alternative for meas-

uring the technical production capacity of health units generalizing the radial projection of traditional DEA methodologies. The efficiency is assessed by choosing a feasible direction $g = \mathrm{g}_{(x,y)} \geq 0$ where the resources (inputs) must be contracted and/or the outputs expanded in order to attain the efficient frontier. The inclusion of subjective judgments over input/outputs configurations in the definition of an objective efficiency measure is an interesting perspective when there is a clear preference for reducing (and reallocating) some specific inputs compared to others.

In the case of this assessment, the choice for the most appropriate resource contraction (and reallocation) was based on a multiple criteria evaluation of specialties that could contribute more significantly to minimizing the impact of the current pandemic. The PROMETHEE II [8][9] was used to defining directions for prioritizing the medical specialties where reallocations of beds and associated resources can be made. Formally, the directional efficiency model takes the following statement:

$$\mathrm{D}_t\,(\mathrm{x},\mathrm{y},\mathrm{gx},\mathrm{gy}) = max\ \beta$$

$$s.t. \quad \sum_{j=1}^{n} z_j\, y_{jr} \geq y_{or} + \beta g_{y_r} \quad r = 1,\ 2,\ \ldots,\ s$$

$$\sum_{j=1}^{n} z_j\, x_{ji} \leq x_{oi} - \beta g_{x_i} \quad i = 1,\ 2,\ \ldots,\ m$$

$$\sum_{j=1}^{n} z_j = 1,\ z_j \geq 0, \quad j = 1,\ 2,\ \ldots,\ n$$

Where $g_{x_i} = \frac{Q_i - \min(Q_i)}{\max(Q_i) - \min(Q_i)}$ is the rescaled input directional vector for the feasible contractions based on the PROMETHEE II complete preorder of alternatives given by the outranking net flow $Q_i = \sum_{i' \neq i}^{s} P(i,i') - \sum_{i' \neq i}^{s} P(\,i',i)$, which is the difference between the positive and negative outranking flows [9]. The rescaled input directional outranking vector defines an intensity of preference for input *i* to be reduced over input i' as a function of performance differences on decision criteria. The decision criteria considered in this elicitation process were the severity, flexibility, complexity of needs, assistance utility and potential for replacement on 10 crucial types of hospitalization: Gynecology, Psychiatry, Chronic Diseases, Pediatrics, General Clinics, Orthopedics/Traumatology, General Surgery, Obstetrics, Cardiology and ICU. Two health professionals responded to a 7–point Likert scale, and a public authority provided some valuable feedback for the consolidation of the analysis.

3 Results and Brief Discussion

The ranking of specialties in Table 1 reports the results of PROMETHEE outranking methodology [8]. The clinical specialties favorable to prioritization in evacuating beds and reallocating medical resources are Gynecology, Psychiatry, Chronicles Diseases,

Pediatrics and General Clinics. Figure 1 illustrates the overall production capacity with the efficiency frontier estimation by enveloping data under variable returns to scale technology. The frontier points represent the efficient hospitals working at full capacity (producing the maximum possible hospitalizations), which are benchmarks for best practices.

The remaining inefficient units (under the frontier) have about 4 thousand beds and more than 5 thousand human resources (mostly nurses) feasible to be reallocated in one year for new cases COVID-19. Managing these resources can only be effective by considering the formalization of new service protocols, postponing surgeries and decreasing the patients' length of stay in hospitals through best practices from their peers. Some of the hospitals with the best potential for reallocating beds and personnel are private institutions, which presents the challenge of planning and managing the medical resources by the local and state administrations.

Table 1. PROMETHEE Prioritization and Directions.

Position	Medical Specialty	Net Flow	Direction
1	Gynecology	0.74822	0.874110
2	Psychiatry	0.63933	0.819665
3	Chronic Diseases	0.25372	0.626860
4	Pediatrics	0.25372	0.626860
5	General Clinics	0.19372	0.596860
6	Orthopedics/Traumatology	-0.01888	0.490560
7	General surgery	-0.18039	0.409805
8	Obstetrics	-0.24854	0.375730
9	Cardiology	-0.79897	0.409805
10	ICU	-0.84194	0.375730

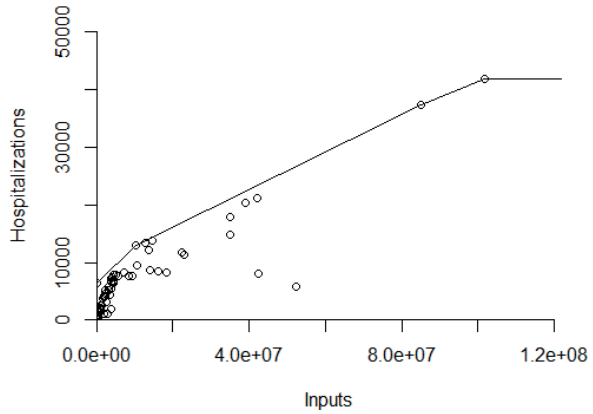


Fig. 2. Efficient Frontier of Hospitalizations.

Table 2 reports this analysis's main results regarding the allocation of beds and investments among specialties and health service units. The total number of beds that are feasible to be reduced (and reallocated) for other types of hospitalizations (e.g., COVID-19 cases) considering all 88 hospitals for each specialty is provided in the third column. Units (+) represent the number of inefficient health service units with the potential to provide beds or reallocate investments through best practices. Units (-) is the number of (efficient) hospitals working at full capacity considering each specialty, which cannot provide an additional resource for other units. The Gynecology specialty does not have sufficient data for coherent results because most units do not operate this specialty.

Table 2. Main Results.

Inputs	Directions	Reallocation of Inputs	Units (+)	Units (-)
Gynecology	0.874110	-	-	-
Psychiatry	0.819665	229	10	78
Chronic Diseases	0.626860	83.5	14	74
Pediatrics	0.626860	341.9	29	59
General Clinics	0.596860	264	9	79
Costs	0	140784626.14	12	76

Some interesting methodologies for resource allocation and investigating exogenous determinants of those reported metrics are provided by Nepomuceno et al. [10], [11]. The prospects of combining Multiple Criteria and DEA methodologies for assessments of this nature are not limited to this investigation's results. Additional considerations concerning the benchmarking of strategies for reducing the length of stay and service protocols are expected to focus on future investigations.

Abstract. Although Paraguay is one of the world's largest exporters of electrical energy, its energy matrix depends mainly on biomass and hydrocarbons, the latter being imported. Based on this, this study evaluated efficiency measures for the main final use of hydrocarbons identified, namely long-distance land transport of cargo. Long-term diesel and electric rail transport scenarios were studied using an energy model developed in the Long-range Energy Alternatives Planning software and an energy, economic and environmental (related to emission savings) analysis was carried out. The results obtained show the great potential for economic, energy and environmental savings with the application of measures to replace end-use technologies and primary energy source, in the long term, in all branches of energy demand.

Keywords: Efficiency, diesel rail transport, electric rail transport, energy prospective, environmental analysis, cost-benefit analysis.

1 Introducción

Desde la década de 1970, Paraguay abastece su demanda eléctrica en base a aprovechamientos hídricos (inicialmente con la Central Hidroeléctrica Acaray), que fueron ganando participación con la construcción de dos grandes emprendimientos binacionales: Yacyretá con Argentina e Itaipú con Brasil. Actualmente, esta producción de electricidad llega a 6.199,4 miles de toneladas equivalentes de petróleo (tep) y está planificado aprovechar aún más el potencial hidroenergético del país, mediante proyectos como Aña Cuá, Itacora Itatí, Corpus y la adición de unidades generadoras en Yacyretá [1].

Sin embargo, a pesar de la abundancia de hidroelectricidad, la demanda energética del país es abastecida en base a biomasa e hidrocarburos, éste último es netamente importado, implicando un importante flujo de divisas al exterior [2]. Analizando los usos finales de hidrocarburos, se observa que el consumo principal se da en el transporte, dejando a este sector a entera dependencia de costos y disponibilidad de hidrocarburos en mercados internacionales. De los hidrocarburos importados, en el año 2014 la demanda de diésel representó 63.9% de importaciones de derivados de petróleo y un aumento del 14.6% respecto al año anterior [3]. Es importante destacar que para el transporte de cargas y pasajeros la principal fuente utilizada es el diésel.

Paraguay es predominantemente un país agropecuario y entre sus principales productos se pueden citar maíz, arroz, soja, carne vacuna, entre otros [4]. Según proyecciones del Plan Nacional de Logística (PNL) la producción llegaría a aproximadamente 157 millones de toneladas en el año 2030. Un porcentaje importante de esta producción es exportada, por lo que es transportada por vía terrestre [5] hasta los principales puertos fluviales del país, que se encuentran en las ciudades de Asunción (Central), Villeta (Central), Carmen del Paraná (Encarnación) y Pilar (Ñeembucu), como se observa en la Tabla 1 y Figura 1.

Table 1. Ubicación de los principales puertos

Ciudad	Departamento
Villeta, San Antonio, Villa Elisa, Zeballos Kue, M. R. Alonso, Ita Pyta Punta, Puerto Pabla	Central
San Juan del Paraná, Pacú Cuá, Hohenau, C.A. López,	Itapúa
Villa Hayes	Presidente Hayes
Villa del Rosario, Antequera	San Pedro
Concepción	Concepción
Pilar	Ñeembucú

Esta particularidad, de amplia disponibilidad de recursos hidroeléctricos y gran dependencia de hidrocarburos importados para un sector de la demanda, da cuenta de un potencial de eficiencia energética y ahorro económico en base al reemplazo de tecnologías de transporte de cargas. Este reemplazo/migración de tecnologías es planteado y estudiado en este trabajo, mediante un análisis energético, económico y ambiental a largo plazo, dentro de la matriz energética del Paraguay.

Este artículo está estructurado de la siguiente forma: en la Sección II, se presenta la metodología y la herramienta utilizada. En la sección III se exponen los resultados obtenidos. Finalmente, en la Sección IV, se concluye el trabajo.

2 Objetivo y Justificación

El principal objetivo de este estudio es proponer y evaluar medidas de eficiencia energética asignativa y sustitutiva de fuentes de energía para el transporte de carga Terrestre, buscando obtener un ahorro energético y económico, al mismo tiempo de emitir menos cantidad de gases de efecto invernadero (GEI), a largo plazo, aplicando medidas de eficiencia energética en el sector transporte de cargas, mediante sustitución de tecnologías de uso final para transporte y reemplazo de energía primaria para abastecer a estas nuevas tecnologías. Esto se traduce en realizar el transporte de cargas de larga distancia en base a trenes (eléctricos o diésel) para dejar de realizar este transporte mediante tracto camiones (diésel).

Según casación de datos de lugares y volumen de producción y exportación de bienes desde Paraguay, se puede identificar que gran parte de la importación de hidrocarburos

(diésel), es consumida en el sector transporte para acercar bienes producidos a lo largo del país, a puntos de exportación, ver Figura 1 y Figura 2. Cuando se mencionan producción de bienes, este trabajo se refiere a producción agropecuaria, específicamente granos.

3 Marco teórico y metodológico

Para realizar un análisis energético exhaustivo, se elaboró un modelo energético integral del Paraguay, donde se representó la estructura de energía primaria y secundaria, centros de transformación de energía y todos los sectores de demanda, con especial desagregación en el área de transporte, ya que el presente análisis se desarrolla en esta área. Este modelo es elaborado mediante la herramienta Long-range Energy Alternatives Planning (LEAP©) que permite simular escenarios de evolución de variables energéticas, alternativas de sustitución de fuentes energéticas y tecnologías de uso final, al mismo tiempo de realizar análisis ambiental de los escenarios propuestos [6].

3.1 Hipótesis consideradas

En este trabajo, la variable energética simulada, es la demanda del sector transporte de cargas de larga distancia, y las alternativas de reemplazo de tecnologías de uso final propuestas que son: tren diésel y tren eléctrico. Se planteó que estas tecnologías reemplazarán, en el largo plazo, un porcentaje del transporte de carga terrestre realizado mediante tracto camiones en el año base [7].

El modelo energético desarrollado en LEAP©, evoluciona desde un año base a un horizonte seleccionado, año 2030, tomando como fundamento de evolución ciertas variables conducentes, seleccionadas por el usuario.

Debido a la disponibilidad de datos energéticos desagregados para el año 2011, se seleccionó este año como año base para el presente estudio y se tomaron datos energéticos y desagregación del sistema energético paraguayo en base al balance de energía útil de la república del Paraguay del año 2011 (BEU) [8].

Además, en el desarrollo del modelo energético, se consideraron otras hipótesis constructivas explicadas a continuación.

Variables conducentes

Las variables conducentes de demanda, consideradas en este trabajo, que determinaron el comportamiento del modelo son: variables macroeconómicas y demográficas. En el modelo desarrollado se establecieron proyecciones del producto interno bruto (PIB) de los sectores de demanda, proyecciones valor agregado bruto del relacionadas al sector transporte (VAB) en estudio, proyecciones de crecimiento de la población, evolución de cantidad de hogares, proyecciones de producción de bienes y proyecciones de flota vehicular.

El desarrollo de este trabajo se centra en el sector transporte, con desagregación específica en el transporte de cargas a larga distancia. Por ende, todas las ramas del modelo energético fueron modeladas en base a sus respectivas variables conducentes sin

ninguna modificación en el largo plazo, al igual que no se consideró ninguna medida de reemplazo de tecnologías o fuentes energéticas en sectores distintos al de transporte.

Análisis de la Prospectiva Energética

El análisis prospectivo a largo plazo se realizó mediante la técnica de escenarios, donde se tiene como base un escenario business as usual o tendencial, donde no se contempló ningún tipo de modificación en la matriz energética. Luego, se plantearon dos escenarios alternativos, donde, en el primer escenario alternativo, el transporte de cargas se realizó mediante trenes a diésel, y en el segundo por medio de trenes eléctricos.

En este estudio prospectivo, se mantuvo la desagregación propuesta en el BEU y, además, se agregó una desagregación específica en el transporte de cargas a larga distancia, lo que posibilitó el análisis de las hipótesis planteadas.

4 Desarrollo del Estudio

Con base a la propuesta metodológica presentada, se consideraron tres escenarios de transporte descritos a continuación:

4.1 Primer Escenario: Escenario Tendencial o business a usual

En el escenario tendencial no se propuso ningún tipo medidas de eficiencia, sustitución de tecnologías o fuente energética. Este escenario representa las tendencias del sector energético si no se realizan cambios en la matriz energética. Ya que el modelo evoluciona la demanda en todos los sectores de consumo en base a las variables conducentes.

Además, analizando correlaciones dentro del sistema energético, se observa que, al aumentar la producción de bienes, aumenta la demanda de diésel para transportar estos bienes para su consumo y exportación, lo que al mismo tiempo implica el aumento del parque vehicular para este tipo de transporte.

En base al comportamiento de este escenario tendencial, se obtuvieron datos que fueron base para los siguientes escenarios propuestos. Entre los principales datos, se determinó el consumo específico de tracto camiones para transporte de cargas, varios puntos de origen (que se corresponden con puntos de producción de bienes) y destino de estas cargas (que se corresponden con puertos hídricos, para acceso a hidro vías para exportación de estos bienes). En base a esto y comprobando con datos de exportaciones de bienes [5], se determinó el peso de estos bienes exportados, un dato importante para los escenarios alternativos que propuestos a continuación.

En la Figura 1 se observan las rutas nacionales existentes, franja de dominio de ferrocarriles, hidro vías y puertos principales, luego, En la Figura 2 se observan las áreas de mayor producción de bienes en el país.

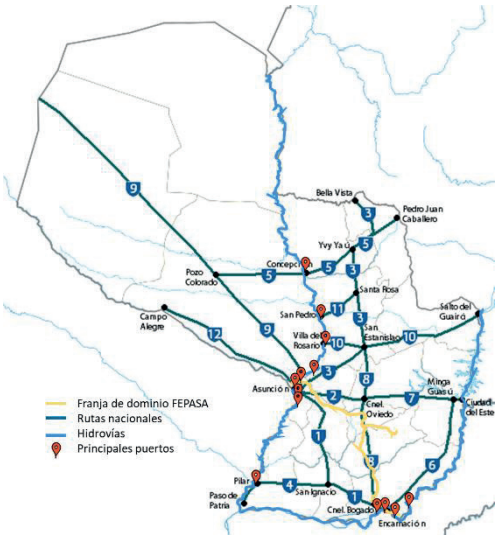

Fig. 1. Rutas nacionales, puertos e hidro vías principales.

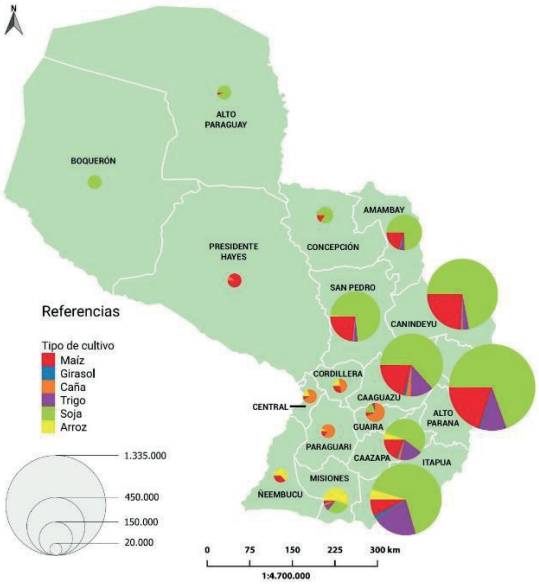

Fig. 2. Productos más exportados.[9]

4.2 Segundo Escenario: Escenario con tren diésel

En base a los datos obtenidos en el primer escenario, se propuso trayectos/tramos potenciales de transporte ferroviario movido a diésel para transporte de cargas que se

representaron en la Figura 3, donde se aprovecharon las franjas de dominio ya existentes para transporte (vial y ferroviario) que pasan por los puntos más productivos del país.

De estos tramos/trayectos propuestos, se resalta la ventaja de que se cuentan con instalaciones de acopio de productos, al igual que se utilizarían franjas de dominio existentes de FEPASA, evitando expropiaciones para nuevas franjas y se consideran los puntos de mayor producción del país. Según los trayectos trazados y en base a los puntos de producción afectados, se determinó que el 72% de la producción nacional es transportada mediante transporte ferroviario hasta los puntos de entrega.

El trayecto completo con los tramos que fueron considerados para transporte ferroviario, son explicados en detalle a continuación, al mismo tiempo de estar ilustrados en la Figura 3.

El tramo NORTE se considera desde la intersección entre la ruta 3 y la ruta 5 en la ciudad de Yby Yau. El tramo continúa siguiendo la dirección sur hasta la intersección entre la ruta 3 y la ruta 8, posteriormente recorriendo la ruta 8 hasta la ciudad de Villarrica. Desde allí llega a Paraguarí a través de la franja de dominio de FEPASA [10] finalizando en la ciudad de Villeta.

El tramo ESTE considera todo el recorrido de la ruta 7, continuando desde la ciudad de Coronel Oviedo por la ruta 8 hasta la ciudad de Villarrica, posteriormente siguiendo con el mismo trayecto que se consideró en el tramo Norte, culminando en Villeta.

El tramo SUR recorre la franja de dominio desde la ciudad de Encarnación hasta la ciudad de Paraguarí, continuando hasta Villeta, con el mismo tramo considerado en el tramo Norte entre las dos ciudades.

Los departamentos que afectan dichos tramos son: Concepción, San Pedro, Guaira, Caaguazú, Caazapá, Itapúa, Paraguarí, Alto Paraná, Central.

La producción en estos departamentos es de aproximadamente el 72% de toda la producción de bienes. En este trabajo, se consideró que el resto de la producción (28%) seguiría siendo transportada en tracto camiones, que anteriormente transportaba el 100% de la producción. Dicha sustitución se considera que entrará en vigencia en el año 2020.

Como puede observarse en la Figura 3, el punto de convergencia de todos los tramos propuestos es la ciudad de Villarrica, y el punto de llegada final es la ciudad de Villeta debido a que en la localidad se encuentran los puertos principales sobre el rio Paraguay, la hidro vía más importante para importación y exportación de bienes (punto de conexión con el transporte fluvial).

4.3 Tercer Escenario: Escenario con tren eléctrico

En el escenario Tren Eléctrico se tuvieron en cuenta las mismas consideraciones que en el segundo escenario con respecto al recorrido y porcentaje de bienes a transportar.

En este caso, el diésel se sustituye por electricidad. Al igual que el escenario de Tren Diésel, el Tren Eléctrico estaría sustituyendo a un sector de los Tracto Camiones, es decir, al 72% de la producción transportada. El año de entrada de dicho escenario es en el año 2020.

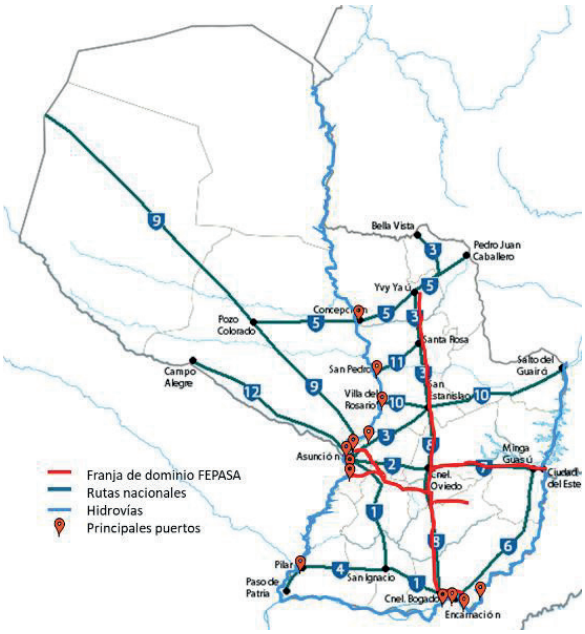

Fig. 3. Tramos y trayectos propuestos para transporte ferroviario.

5 Resultados

Para el cálculo de resultados, se tuvieron en cuenta consumos específicos de diésel y electricidad [11], y el nivel de demanda dependió del volumen y peso de los bienes que se consideran para transporte ferroviario.

En las tablas a continuación, se presentan los resultados de cada escenario calculado. En la Tabla 1, que corresponde al escenario tendencial, se presenta el consumo de las demandas en miles de toneladas equivalentes de petróleo (mtep), el aumento de la es determinado por las variables conducentes del modelo.

Table 2. Consumo del escenario tendencial para todas las ramas de demanda y todas las fuentes energéticas. Valores en miles toneladas equivalentes de petróleo.

Escenario Tendencial				
Rama	Año			
	2015	2020	2025	2030
INDUSTRIA	7.026	15.606	25.217	35.860
PUBLICO Y OT	584	1.195	1.826	2.477
COMERCIAL	2.918	5.821	8.699	11.546
RESIDENCIAL	4.437	9.216	14.312	19.700
TRANSPORTE	8.253	19.461	35.126	56.287
Total	23.219	51.299	85.181	125.871

En la Tabla 2 y Tabla 3 se presentan los resultados de demanda del escenario tren diésel y tren eléctrico respectivamente. Como se mencionó anteriormente, no se realizaron modificaciones de eficiencia o reemplazo de tecnologías ni fuentes energéticas,

por lo que los valores correspondientes a consumos para todas las ramas diferentes de transporte, son los mismos.

Table 3. Consumo del escenario tren diésel para todas las ramas de demanda y todas las fuentes energéticas. Valores en miles de toneladas equivalentes de petróleo.

Escenario Tren diesel				
Rama	Año			
	2015	2020	2025	2030
INDUSTRIA	7.026	15.606	25.217	35.860
PUBLICO Y OT	584	1.195	1.826	2.477
COMERCIAL	2.918	5.821	8.699	11.546
RESIDENCIAL	4.437	9.216	14.312	19.700
TRANSPORTE	7.546	14.882	22.917	31.304
Total	22.512	46.720	72.972	100.888

Table 4. Consumo del escenario tren eléctrico para todas las ramas de demanda y todas las fuentes energéticas. Valores en miles de toneladas equivalentes de petróleo.

Escenario Tren eléctrico				
Rama	Año			
	2015	2020	2025	2030
INDUSTRIA	7.026	15.606	25.217	35.860
PUBLICO Y OT	584	1.195	1.826	2.477
COMERCIAL	2.918	5.821	8.699	11.546
RESIDENCIAL	4.437	9.216	14.312	19.700
TRANSPORTE	7.546	14.882	22.458	30.235
Total	22.512	46.720	72.513	99.819

Como se puede observar en las tablas presentadas, la rama de transporte presentó una disminución considerable en el consumo para los escenarios alternativos propuestos. Para cuantificar este ahorro con cada escenario, se presentan los consumos porcentuales para cada escenario, pero puntualmente para la rama de transporte. En la Tabla 4 se puede apreciar que tanto el escenario de tren diésel como el escenario de tren eléctrico, presentan una disminución importante del consumo energético (ya sea diésel o electricidad) de entre 76% y 54%, tomando como base el escenario tendencial.

Table 5. Consumos porcentuales, en base al escenario tendencial, de escenarios alternativos para la rama de transporte.

Escenario	Año			
	2015	2020	2025	2030
Tendencial	100%	100%	100%	100%
Tren diesel	91%	76%	65%	56%
Tren eléctrico	91%	76%	64%	54%

6 Análisis económico

Para el análisis económico, se calculó el costo de oportunidad de cada alternativa en comparación con el escenario tendencial (no es un análisis de viabilidad financiera), sólo teniendo en cuenta las variables energéticas involucradas, mediante costos

incrementales acumulativos de cada escenario, y cada costo fue descontado a una tasa del 10% anual desde el año 2020.

Se tomaron datos históricos de costos de adquisición de fuentes energéticas. Ya que sólo se analizó el reemplazo de tracto camiones a tren diésel (misma fuente energética, cambio de tecnología de uso final) y de tracto camiones a tren eléctrico (diferentes fuentes energéticas y diferentes tecnologías de uso final), se tienen en cuenta los costos del diésel y de la electricidad.

Se tuvo en cuenta el valor actualizado neto del costo de las fuentes energéticas involucradas en los escenarios propuestos, ya sea que éstas dejan de importarse (diésel) o dejan de exportarse (electricidad). En este análisis económico no se consideró el costo de instalación de infraestructura necesaria, adquisición de nuevas tecnologías ni la operación y mantenimiento de estas nuevas tecnologías.

Para el escenario de tren diésel, se tomaron datos históricos de precios internacionales referenciales del diésel 2011 a 2018 [12] y se extrapolaron al 2030 (se estiman valores futuros en base a series de datos históricos). Para datos de electricidad, se tomaron datos de compra de energía eléctrica de Itaipú de 43 USD/MWh, este valor se mantuvo constante durante todo el periodo de análisis.

En la Tabla 5 se presentan el análisis de costo beneficio, con respecto al escenario tendencial. Se evidencia una diferencia considerable de costo de oportunidad de ambos escenarios, para el escenario de tren eléctrico el beneficio está relacionado a dejar de importar diésel y para el escenario de tren diésel el beneficio representa la disminución del consumo de diésel y por ende menor importación. Además, en el escenario de tren eléctrico se tiene una consecuencia en la disminución de la exportación de energía eléctrica.

Si además se valoriza la disminución de gases de efecto invernadero (GEI), se puede aumentar el costo de oportunidad del escenario de tren eléctrico. Si bien existe un mercado de bonos de carbono, estos precios aún son insuficientes para incentivar a una economía de descarbonización, de igual forma, se tomaron valores de costo tonelada de CO_2 equivalente en mercados de bonos de carbono, valores tomados del LEAP©, para presentar el valor actualizado neto, expresado en dólares por toneladas de CO_2 equivalente, de las emisiones que se dejaron de emitir, última línea de la Tabla 6.

Table 6. Análisis costo beneficio de escenarios alternativos en comparación con el escenario tendencial. Valor actualizado neto al año 2030, en millones de dólares.

Sector	TREN ELECTRICO	TREN DIESEL
Imports	3.157	2.854
Exports	-58	-
Total Net Present Value	166.640	217.678
Cost of Avoided GHGs (USD/Tonne CO2e)	2.193	3.078

7 Impacto ambiental

7.1 Emisión de gases de gases de efecto invernadero (GEI).

Para realizar el análisis ambiental, se comparan los ahorros en emisión de GEI de los escenarios alternativos en comparación con el escenario tendencial. Estos datos están comparados al año 2030.

En el año horizonte del escenario tendencial, se tiene un nivel de emisión de 160 millones de toneladas de CO_2 equivalente, mientras que en los escenarios alternativos se tienen valores muy inferiores, en el escenario de tren diésel, 89 millones de toneladas de CO_2 equivalente por la disminución en el consumo de diésel, y en el escenario de tren eléctrico se evidenció una disminución en comparación al escenario tendencial, de 84 millones de toneladas de CO_2 equivalente.

Esta situación se debe a que, si bien hay un reemplazo de fuente primaria de energía, de diésel a electricidad, el consumo de diésel en el escenario de tren diésel es muy reducido, lo que lleva a que la diferencia de las emisiones sea pequeña en comparación con las emisiones totales del sistema energético, datos que pueden observarse en la Tabla 6.

Table 7. Ahorro de emisiones de GEI de escenarios alternativos en comparación con escenario tendencial. Valores en millones de toneladas de CO_2 equivalentes.

Sector	TREN ELECTRICO	TREN DIESEL	TENDENCIAL
GHG emission (Mill Tonnes CO2e)	84,31	89,59	160,30
GHG Savings (Mill Tonnes CO2e)	75,99	70,71	-

Como se puede apreciar los escenarios que presentan una disminución considerable en la emisión de gases de efecto invernadero de ambos escenarios propuestos, con respecto al tendencial.

8 Discusiones

En base a todos los resultados y análisis realizados, se evidencia el potencial de ahorro energético, económico y social en la rama de transporte, para el transporte de cargas.

Sin embargo, el consumo de hidrocarburos sigue siendo elevado, teniendo en cuenta la disponibilidad de hidro electricidad disponible para uso interno del país. Lo que denota que aún existe un potencial importante para ahorros energéticos, económicos y ambientales.

En este trabajo no se tuvieron en cuenta costos de inversión, instalación, operación y mantenimiento de nuevas tecnologías, pero, este análisis podría explorarse en trabajos futuros, en conjunto con la cuantificación de disminución de tiempos logísticos para transporte de carga y la consideración de la posible reconfiguración de transporte de carga aérea con las facilidades ofrecidas por el transporte ferroviario.

9 Conclusiones

Del análisis energético del Paraguay, se observó que es un país con amplia disponibilidad hidro eléctrica, pero gran dependencia de hidrocarburos y biomasas para fines energéticos, lo que llevó a proponer medidas de reemplazo de fuentes energéticas y tecnologías de uso final en el sector transporte.

Con este trabajo se demostró que existe una oportunidad importante de ahorro económico, energético y ambiental al implementar opciones de transporte ferroviario de cargas, sin embargo, estos ahorros pueden ser aún mayores si se estudian medidas de reemplazo de fuentes energéticas y tecnologías de uso final en otros sectores de la demanda, especialmente los dependientes de hidrocarburos y biomasa.

Si bien el análisis económico realizado es de costo de oportunidad, se puede considerar, muy a grandes rasgos, la influencia en la matriz/balance económico del país los beneficios económicos de ambos escenarios alternativos propuestos, y se puede concluir que tendrán un impacto positivo al disminuir la dependencia de importaciones para el sector energético.

Aunque el alcance de este trabajo no cubre un análisis de transporte por hidro vías, transporte de cargas aéreo, ni transporte de pasajeros en corta y larga distancia, los resultados de este trabajo son un punto inicial que dan cuenta de los beneficios económicos para el uso de la hidro electricidad disponible para consumo interno. Si bien, para realizar un análisis integral se deben considerar costos de inversión, operación y mantenimiento de nuevas tecnologías, los ahorros ambientales y energéticos justificarían estas inversiones, ya que Paraguay está adherido al acuerdo Paris y precisa de acciones concretas en el mediano y largo plazo para el cumplimiento de este acuerdo.

Además, es importante mencionar que la metodología aplicada en el análisis realizado, puede replicarse para analizar otras ramas de demanda, otros países, regiones y proyectos de integración de varios países.

Resumen. El artículo analiza el problema de tomar decisiones con enfoque multicriterio, en grupos cuyos miembros comparten objetivos y decisiones de rutina. Estos procesos ofrecen ventajas: aprendizaje colaborativo y compromiso con las acciones acordadas. Como contrapartida, las decisiones grupales requieren tiempo y pueden ser afectadas por la presión grupal o por perturbaciones en la información disponible (imprecisión, incertidumbre o carencia de algunos datos). Se estructura un problema frecuente en una organización, con una cantidad finita de criterios y se adoptan para cada uno, categorías que permiten clasificar a las alternativas analizadas. Las prioridades de los criterios y las preferencias de las categorías, se representan mediante utilidades cardinales de tipo subjetivo. El método incluye dinámicas orientadas a reducir la presión de grupo, las perturbaciones y los tiempos de análisis. El documento analiza una aplicación al tratamiento de no conformidades, en un proceso productivo. En las conclusiones, se destaca que los participantes adoptaron la metodología y lograron consensuar las categorías. Además, valoraron que esta aproximación permite reducir los tiempos de análisis.

Palabras Claves: Toma de decisiones en grupo – Apoyo multicriterio a la decisión - Toma de decisiones de rutina – Evaluación por categorías

1. Introducción

La necesidad de tomar decisiones en grupo, es un requerimiento habitual en las organizaciones. Con frecuencia, la estructura del problema de decisión permite la aplicación de métodos de decisión multicriterio discreta, donde las preferencias y prioridades de los integrantes del equipo de trabajo, se expresan mediante utilidades de tipo cardinal.

En Luoma (2016), se postula que las situaciones de toma de decisiones pueden dividirse en dos clases: rutinarios (problemas recurrentes) y de acciones para la mejora. En situaciones rutinarias, el problema puede ser complejo y aplicar un procedimiento de toma de decisiones, puede convertirse en una tarea exigente.

Sin embargo, es importante buscar el mejor modo de sustentar esas actividades decisionales, porque cuando es posible reducir y controlar las perturbaciones que los afectan, estos procesos generan compromiso con las acciones decididas y empoderan

a los participantes (Brocklesby, 2016), (Montibeller y Winterfeldt, 2015), (Staggs SM., Bonito JA., Ervin JN., 2018).

Al respecto, este trabajo aplica un método de toma de decisiones en grupo, que estructura un problema frecuente de decisión con criterios subjetivos y un conjunto de clases, previamente definido y valorado que facilitan la evaluación dentro de cada criterio. Para establecer la valoración relativa de las categorías, las preferencias se representan mediante utilidades cardinales. Luego, se clasifican las alternativas consideradas en la estructura de criterios previamente definida.

2. Metodología propuesta

La propuesta tiene dos fases: la primera, permite estructurar el problema de decisión y estimar los parámetros del mismo, la segunda, consiste en aplicar en forma recurrente el modelo obtenido, cada vez que se repite la necesidad de adoptar un tipo de decisión rutinaria.

En la primera fase, se define el grupo de trabajo y se realizan entrevistas individuales y semi estructuradas, destinadas a identificar los criterios y las categorías a considerar para cada criterio. Una vez definidos y verbalizados los criterios y las categorías, para valorizarlos se utiliza un método para la toma de decisiones grupales conocido como Procesos de Decisión con Reducción de Variabilidad (Procesos DRV). De este modo, es posible asignar utilidades cardinales a los criterios y sus categorías (Zanazzi, 2016). Las fases generan un ciclo de aprendizaje grupal que se integra con diversas actividades (ver Fig. 1).

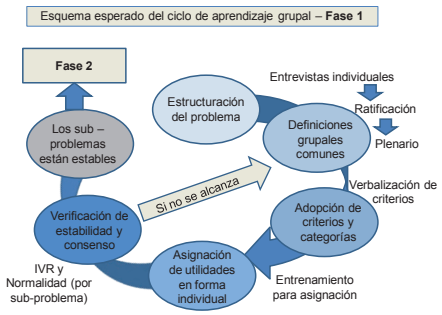

Fig. 1. Actividades desarrolladas en la fase 1(Fuente: elaboración propia).

La segunda fase consiste en la aplicación recurrente del modelo adoptado, cada vez que se repite el problema en la dinámica organizacional. En esa fase, el grupo de decisores solo debe clasificar cada alternativa en una categoría por criterio y determinar, mediante ponderación lineal, el valor global de la misma.

3. Resultados y discusión

El método se aplicó en un proceso de producción de bienes, con la finalidad de establecer prioridades para el tratamiento de no conformidades (fallas en el producto). Participaron dieciséis personas en el ejercicio inicial. Los criterios adoptados fueron: Urgencia; Complejidad; Costo Promedio de Resolución; Gravedad y Ocurrencia. Para cada criterio se utilizaron categorías. La siguiente Tabla 1 resume los criterios y las categorías obtenidas.

Tabla 1. Tabla con criterios y categorías.

CRITERIOS	CATEGORIAS
COSTO PROMEDIO DE RESOLUCIÓN (CPR): Se aplica el valor promedio de resolución de la IMNC resultante de la cantidad de horas de mano de obra directa e indirecta y el costo de materiales.	Bajo
	Medio
	Alto
OCURRENCIA: Frecuencia de la aparición de las novedades	Muy frecuente
	Frecuente
	Poco frecuente
COMPLEJIDAD: Está asociado al tiempo de resolución de la novedad. Se tiene en cuenta el análisis de la no conformidad y el tiempo de ejecución del retrabajo.	Alta
	Media
	Baja
URGENCIA: Se valora como la proximidad de ejecución de las tareas siguientes afectadas por alguna o varias novedades.	Muy Urgente
	Poco Urgente
	Nada Urgente
GRAVEDAD: Evalúa el impacto que la novedad produce. Para esto se define si el producto afecta o no la seguridad en vuelo, conforme requisitos de la norma.	Afecta
	No afecta

En la estimación de parámetros mediante Procesos DRV, fueron necesarios tres ciclos de análisis hasta lograr estabilidad y consenso, en las ponderaciones de los criterios. En cambio, para las categorías para cada criterio, demandó un sólo ciclo de intercambio. La síntesis de las ponderaciones puede verse en la Tabla 2.

Tabla 2. Resultados estimación de parámetros.

CPR			Ocurrencia			Complejidad			Urgencia			Gravedad		
Parámetros	*0,343*	*0,056*	Parámetros	*0,314*	*0,041*	Parámetros	*0,195*	*0,053*	Parámetros	*0,079*	*0,017*	Parámetros	*0,069*	*0,030*
Categorías	*Prom*	*Desv*	Categorías	*Prom*	*Desv*	Categorías	*Prom*	*Desv*	Categorías	*Prom*	*Desv*	Categorías	*Prom*	*Desv*
Alto	0,468	0,096	Alta	0,438	0,067	Alta	0,447	0,060	Alta	0,435	0,069	Afecta	0,752	0,026
Medio	0,353	0,082	Media	0,347	0,061	Media	0,367	0,051	Media	0,343	0,066	No afecta	0,248	0,026
Bajo	0,179	0,071	Baja	0,215	0,061	Baja	0,187	0,045	Baja	0,222	0,045			

Para ejercitar la mecánica de la segunda fase, en su primera aplicación, los participantes clasificaron cinco informes de no conformidad (IMNC). Se toma una

alternativa y se la clasifica en las categorías adoptadas para cada uno de los criterios conforme Tabla 3.

Tabla 3. Clasificación de alternativas.

Despcripción	CPR	Ocurrencia	Complejidad	Urgencia	Gravedad
IMNC 1	Bajo	Alta	Media	Media	Afecta
IMNC 2	Alto	Baja	Alta	Baja	Afecta
IMNC 3	Medio	Media	Baja	Alta	No afecta
IMNC 4	Alto	Alta	Alta	Alta	Afecta
IMNC 5	Bajo	Baja	Baja	Baja	No afecta

Por último, se calculan los valores estimados de media y desvío. Finalmente, se obtienen las valoraciones globales por ponderación lineal.

4. Conclusiones

Los procesos de toma de decisiones rutinarios configuran una actividad habitual y compleja en las organizaciones. La instancia grupal permite la construcción colaborativa de conocimiento y sus desventajas pueden modelarse con Procesos DRV.

El grupo demostró una participación activa y sus integrantes adoptaron sin inconvenientes la metodología. Lograron acordar categorías y percibir mejoras en los tiempos de análisis. El modelo puede ser utilizado cada vez que sea necesario, sin tener que realizar nuevas comparaciones. La estructura de criterios y categorías ponderados se mantiene para priorizar las demás no conformidades. Esta oportunidad brinda flexibilidad y rapidez para su uso.

Para futuras investigaciones se identifica la posibilidad de trabajar con otros criterios y más cantidad de categorías, así como la utilización de indicadores de gestión o priorizaciones previas, realizadas con otras herramientas.

Abstract. Industry 4.0, the fourth phase of Manufacturing and IT is one of the pioneering research areas, especially in the last half of a decade, with a profound impact on economic and societal progress. Software has become a transversal and foundational element of this new industrial revolution; so the quality of the software has a direct impact on the quality of the processes of digital manufacturing, user experience, and product quality. This new era requires new methodologies and techniques to verify and validate the foundations of Industry 4.0. In this paper, we present a new framework for testing Object-Oriented Software developed using Java. It was designed and implemented to detect failures in the sequence of calls that objects make without the need to modify the source code. This framework is open source and is freely available.

Keywords: Verification and Validation, Testing, Message Sequence Specification, Aspect-Oriented Programming, Software

1 Introduction

Software quality has become one of the most important factors in determining the success of products or companies in the era of Industry 4.0. As stated by Oztemel et. al [11] "...the superior quality of the manufacturing industry strictly depends on its high quality applied production technology..." and "...there are now companies having the largest part of business in their sector with only running a software...". Lee et. al [8] also highlighted the key role of software in this new industry "The Fourth Industrial Revolution is ubiquitous and will increasingly transform and reshape operations/production, supply-chain, management, and governance as well as products and services. Whatever could be codified of the organizational life will be put into codes and software and embedded into cybernetics systems that will replace human work activities". Yang [9], as well, described that "Industry 4.0 has two key factors: integration and interoperability. Integrated with malicious applications and software systems, Industry 4.0

will achieve seamless operations across organizational boundaries and will realize networked organizations". To a great extent, the success of Industry 4.0 rests on the quality of the software, which has the responsability to ensure that it is error-free.

This new context forces us to design and develop new methodologies and tools to find and correct errors in the software. Various methodologies, techniques and frameworks have been developed to achieve a high-quality software product. Each development and adaptation was for specific areas or features of the software under review with a focus on particular types of errors. In 1994, Kirani and Tsai [3] presented a technique called Message Sequence Specification (MSS) that, in the context of an Object-Oriented program, describes the correct order in which the methods of a class should be invoked. This methodology has never been implemented as a framework for software verification and validation until our development.

In this paper, we present TAPIR, a framework designed to detect failures in the sequence of method calls. It relies on the concept of Message Sequence Specification and implements it as a dynamic testing tool. The implementation was done using Aspect-Oriented Programming (AOP) [4] and, therefore, it can be used in any Java project without the need to modify the implementation of the project. This work continues the one carried out in [6] and presents the latest updates. This new version can test multiple instances of multiples classes in the system. The rest of the paper is structured as follows. Section 2 provides background information about the MSS. In Section 3 we detail how MSS has been used so far. Then, we present our work in Section 4 with all its features. We later introduce two usage examples of the framework. Finally, we conclude with a brief discussion on the limitations and advantages of our approach and the future work.

2 Message Sequence Specification

In 1994, Kirani and Tsai [3] presented a technique called Message Sequence Specification (MSS) that, in the context of an Object-Oriented program, describes the correct order in which the methods of a class should be invoked by its clients. The MSS associated with an object specifies all sequences of messages that the object can receive while still providing correct behavior. Their strategy used regular expressions to model the constraints over the correct order of the method invocation, i.e. the regular expression is the test model. Method names were used as the alphabet of the expression which was then used to statically verify the program's implementation for improper method sequences. A runtime verification system identifies incorrect method invocations by checking for sequence consistency with respect to the sequencing constraints. According to Kirani and Tsai's specification, if a class C has a method M_1, this is noted as C_{M_1}. Sequence relationships between two methods were classified into three categories, sequential, optional, and repeated. If the method M_1 of C should be invoked before the method M_2 of the same class, then this relationship is sequential and

is represented as

$$C_{M_1} \bullet C_{M_2} \tag{1}$$

If only one of the methods M_1 and M_2 can be invoked, then this relationship is optional and is represented as

$$C_{M_1} | C_{M_2} \tag{2}$$

Finally, if the method M_1 can be invoked many times in a row then this is a repeated relationship and is represented as

$$(C_{M_1})^* \tag{3}$$

For example, if a class X has three methods called *create*, *process*, and *close*, a possible sequencing constraint based on MSS could look like

$$X_{create} \bullet (X_{process})^* \bullet X_{close} \tag{4}$$

If class X is part of a larger system S, then we could statically check the source code of S to see if all calls to X's methods follow the defined expression. If a static analysis is not enough, a runtime verification system can track all calls to X's methods and dynamically check the sequence of calls against the regular expression. This technique can also be used to test the robustness of a system: method sequences that are not derived from the regular expression [3], i.e. incorrect method sequences, can be used to test how the class handles a misuse. For example, to test how the class X responds to the following sequence of calls:

$$X_{create} \bullet X_{close} \bullet X_{process} \tag{5}$$

3 Previous Applications of Message Sequence Specification

Daniels and Tsai [2] extended the work of Kirani and Tsai [3] by testing with some sequences generated by the expression and others not generated by the expression. Also in 1999, Tsai et al. [13] presented Message Framework Sequence Specifications (MfSS), for generating scenario templates that can be used to generate test cases to test applications developed using extensible design patterns and an object-oriented framework. This framework aims to test the dynamic typing and dynamic binding of an Object-Oriented program. MfSS involves multiple objects; thus, a sequence expression must use the object name together with its method name. The framework is suitable for the application of several testing techniques such as positive testing, negative testing, test slicing, partition testing, boundary testing, random testing and stress testing based on scenario templates. The MSS presented in that paper is far more expressive than the one we are presenting but, as far as we know, there is no tool or software that implement this full methodology. The application of the MfSS shown in the original paper was done by hand and not with a software.

In 2003, Tsai et al.[12] used MSS as a verification mechanism to the UDDI servers in the context of Web Services (WS) since they are particularly interoperable with each other. This kind of complex relationship was expressed using the MfSS presented in [13]. This approach was part of a larger set of testing mechanism for WS presented in that work. Unfortunately, the approach was only partially implemented and it did not include the MfSS.

In 2014, a Java-based tool for monitoring sequences of method calls with similar objectives than our work was introduced [10]; however, they used annotations, instead of AOP, to specify method-call sequences in terms of regular expressions of method-call signatures. They included an implementation of the proposal in the form of a tool called JMSeq. This tool runs alongside the application under test, but in a different Java Virtual Machine, hence two virtual machines are running at the same time: one for the program under test and the other for the JMSeq execution. Moreover, since the annotations must be included in the source code of the program to test, these modifications may, potentially, arise new errors. In our approach, AOP avoids the need for modifying the source code, hence reducing the possibility of inducing new bugs.

We introduced MSS as a black-box technique for testing visualizations interactions [7] in 2018. The technique is built on constraints imposed over the sequences of low-level interactions available in the visualization with User Action Notation and MSS. Instead of specifying a sequence constraint on the methods of a class, in this work we specified a Sequence Constraint on the Interactions (SCI) available in the visualization. This research also included the definition of coverage criteria for the technique, both for valid and invalid sequences. The work aimed to generate two types of testing tools: one to dynamically test the correct usage of a visualization tool, i.e. while the user is using the visualization our method checks that the interactions are being used accordingly to the SCI; and the other, to generate the test cases based on the SCI. So far, this research is only available as theory without a proper implementation. Turner used sequence specification for GUI testing in her Ph.D. thesis in 2019, with previous publications about this topic [17], [14], [15],[16]. In these articles, interaction sequences are used as an abstraction of the interactive system to inform a model-based testing approach using lightweight formal methods. Interaction sequences provide an abstract view of the point at which the functional and interactive components intersect. The formalization of interaction sequences and the modelling of those sequences was done using Finite State Automata.

4 TAPIR - An Object-Oriented Programming Testing Framework

TAPIR is a testing framework for object-oriented source code based on MSS and implemented using AOP. AOP allows us, without modifying the source code, to create test cases that execute automatically with each execution of the program under test. The use of MSS allows the developer to describe a regular expression for each class, which represents its correct behavior. The framework executes

the program, and it checks whether the methods are invoked according to the regular expression in the class specification. Thus, TAPIR can be classified as a dynamic analysis testing tool.

A major feature of our framework is to be easy to use, with an easy to read and understand representation of the correct usage of each class' methods. In particular, the user of the framework does not need to be a testing specialist since it was developed to be used directly by the developer. The first thing the developer must do to use the framework is to create the regular expressions associated with the classes under test. These regular expressions must specify the correct behavior or invocation order of the classes' methods. To simplify the regular expression writing, symbols (i. e. characters) are used instead of the actual names of the methods. However, to be able to interpret it, the developer must specify a mapping between the actual methods' names and their corresponding symbol. Any method not included in the class's regular expression is ignored by the framework. Hence, the developer is not required to use all the class's methods in the regular expression. The developer must also specify how the framework should behave in the event of an error. When the framework detects a sequence of calls that does not derive from its associated regular expression, it reports the error and can either abort the execution or allow it to continue. This decision is in the hands of the developer and it can be specified independently for each defined regular expression. The regular expressions and the maps between methods and symbols are set in the *TestingSetup.java* class.

The framework consists of two main components: an aspect, and a java class. The aspect is named *TestingCore.aj* and it contains the implementation of the framework's core. Listing 1.1 shows an example with two classes: CA and CB. In this case, the correct usage of class CA states that, after the creation of the object, there should be a call to *f()* followed by a call to *g()*. After that, there can be as many calls as desired to either *g()* or *h()*. The final call of the sequence must be to *h()*. To correct use class CB, there should be first a call to *alpha()* followed by a call to *gamma()*, or a call to *gamma()* followed by a call to *beta()*. Afterward, any method between *alpha()*, *beta()*, or *gamma()* can be called. Listing 1.1 shows the implementation of the *TestingSetup.java* class that defines this information to TAPIR.

Listing 1.1: TAPIR configuration for classes CA and CB

```
//Class CA: Definition of the methods and their corresponding symbols
mapObjectsToCallSequence = new HashMap<Integer, String>();
mapMethodsToSymbols = new HashMap<String, String>();
mapMethodsToSymbols.put("main.CA.<init>", "c");
mapMethodsToSymbols.put("main.CA.f", "f");
mapMethodsToSymbols.put("main.CA.g", "g");
mapMethodsToSymbols.put("main.CA.h", "h");
//Definition of the regular expression
regularExpression = Pattern.compile("cfg(g|h)*h");
//Initializing the regular expressions controller
matcher = regularExpression.matcher("");
//A TestingInformation instance stores all information related to how the class is tested
```

```
TestingInformation ti = new TestingInformation(CA.class.toString(),
    mapObjectsToCallSequence, mapMethodsToSymbols, regularExpression, matcher,
    true);
TestingCore.mapClassToTestingInformation.put(CA.class.toString(), ti);
//Class CB: Definition of the methods and their corresponding symbols
mapObjectsToCallSequence = new HashMap<Integer, String>();
mapMethodsToSymbols = new HashMap<String, String>();
mapMethodsToSymbols.put("main.CB.alpha", "a");
mapMethodsToSymbols.put("main.CB.gamma", "g");
mapMethodsToSymbols.put("main.CB.beta", "b");
//Definition of the regular expression
regularExpression = Pattern.compile("(ag|gb)(a|g|b)*");
//Initializing the regular expressions controller
matcher = regularExpression.matcher("");
//A TestingInformation instance stores all information related to how the class is tested
ti = new TestingInformation(CB.class.toString(), mapObjectsToCallSequence,
    mapMethodsToSymbols, regularExpression, matcher, false);
TestingCore.mapClassToTestingInformation.put(CB.class.toString(), ti);
```

In Listing 1.3, we can see the framework output when the code portion of Listing 1.2 corresponding to the CA class is executed. In this case, the last call to *f()* does not follow the MSS specified for the *CA* class. As mentioned above, when an error is detected, TAPIR informs by console the class and object that produced the error. The method that violated the MSS, the MSS in question and the actual sequence of calls are also shown in the console. Finally, the system aborts the execution, as indicated by the last parameter of method *TestingInformation* in the configuration.

Listing 1.2: Two snippets of code showing examples of wrong usage of class CA and class CB.

```
CA ca1 = new CA();
ca1.f();
ca1.g();
ca1.h();
ca1.f();
```

```
CB cb1 = new CB();
cb1.alpha();
cb1.alpha();
cb1.gamma();
cb1.gamma();
```

Listing 1.3: Error example for the CA class. The execution is aborted when the error is found.

```
---      ERROR FOUND   ---
Class: class main.CA
Object Code: 977993101
Method Executed: main.CA.f
Regular Expression: cfg(g|h)*h
Execution Sequence: cfghf
----- SYSTEM ABORTING... -----
```

Listing 1.4: Error example for the CB class. The execution is allowed to continue when the error is found.

```
−−−  ERROR FOUND  −−−
Class: class main.CB
Object Code: 859417998
Method Executed: main.CB.alpha
Regular Expression: (ag|gb)(a|g|b)∗
Execution Sequence: aa
−− CONTINUING EXECUTION... −−−
```

```
−−−  ERROR FOUND  −−−
Class: class main.CB
Object Code: 859417998
Method Executed: main.CB.gamma
Regular Expression: (ag|gb)(a|g|b)∗
Execution Sequence: aag
−− CONTINUING EXECUTION... −−−
```

Listing 1.4 shows the framework output when the code portion of Listing 1.2 corresponding to the class CB is executed. In this case, the second call to *alpha*() does not follow the MSS specification for class *CB*. As configured in Listing 1.1, yhe last parameter in the call to method *TestingInformation* is false, indicating that the execution must continue despite the existing errors. This is why, Listing 1.4 shows multiple errors. The next section shows how the framework can be useful in a more complex real-life situation.

5 Case Study. Rock.AR, a software solution for point counting

Point counting is the standard method to establish the modal proportion of minerals in coarse-grained igneous, metamorphic, and sedimentary rock samples. This requires to make observations at regular positions on the sample, namely grid intersections. Rock.AR [5] is a visualization tool with a user-friendly interface that provides a semiautomatic point-counting method and is available as open-source.

5.1 First Detected Bug

The main class of this application contains three important methods: *LoadSample()*, *AddNewRockType()* and *MoveSelectedCell()*. *LoadSample()* loads the rock thin section sample, *AddNewRockType()* links a type of mineral with the selected cell in the grid, and finally, *MoveSelectedCell()* selects a cell in the grid. First, at least one sample must be loaded. Then, before linking a mineral type to a cell, a point (also known as a cell) must be selected. Hence, the following regular expression can be defined:

$$(LoadSample \bullet LoadSample^* \bullet (MoveSelectedCell \bullet MoveSelectedCell^* \bullet AddNewRockType^*)^*)^* \quad (6)$$

or in a simpler way:

$$(l \bullet l^* \bullet (m \bullet m^* \bullet a^*)^*)^* \quad (7)$$

Listing 1.5: Class *TestingSetup* to test Rock.AR with the expression from Equation 7.

```
// Specification of the test class
TestingCore. targetClass = ViMuGenMain2.class.toString();
// Definition of the methods and their corresponding symbols
TestingCore.mapObjectsToCallSequence = new HashMap<Integer, String>();
TestingCore.mapMethodsToSymbols = new HashMap<String, String>();
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.main.ViMuGenMain2.LoadSample", "l");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.main.ViMuGenMain2.MoveSelectedCell", "m");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.main.ViMuGenMain2.AddNewRockType", "a");
// Definition of the regular expression
TestingCore. regularExpression = Pattern.compile("ll*(mm*a*)*");
// Initializing the regular expressions controller
TestingCore.matcher = TestingCore. regularExpression .matcher("");
```

A particularity of this regular expression is that, between loading a sample and adding a new rock type, at least one cell must be selected. We created this regular expression and input it into the framework as shown in Listing 1.5. Once this expression was defined and provided to the framework, we started using Rock.AR. After several runnings, the test framework detected an error and output the sequence of calls that did not comply with the regular expression. The sequence was:

$$l \bullet m \bullet m \bullet a \bullet l \bullet l \bullet a \tag{8}$$

The last three symbols in the sequence indicated that the application allowed a calling to *AddNewRockType()* right after *LoadSample()*, i.e. without calling *MoveSelectedCell()* in between. This calling sequence was not allowed in the regular expression. With this information, we discovered that when the user loaded a second sample, two variables were not re-initialized, causing this incorrect behavior. Before using our framework, there was no evidence of this error. The application did not generate any exception since the program was using old values for those not re-initialized variables.

5.2 Second Detected Bug

In order to help the domain expert to visualize the grid intersection, a colored grid is drawn on top of the mineral image. Each intersection is represented in the implementation by an instance of the class *SampleCell*. Usually, a mineral image requires around 1250 cells. The *SampleCell* class offers methods to set and get the dimensions of the cell and the mineral type. However, once the dimensions are set, they can not be changed. This is because the size of each cell is calculated automatically and the user cannot modify it. Since the mineral type of each cell depends on the user's subjective appreciation, it can change more than once. The following regular expression represents this behavior:

$$CreateSampleCell \bullet (setDimension \bullet setRockType | setRockType \bullet setDimension) \bullet (setRockType | getRockType | getDimension)^* \quad (9)$$

or in a simpler way:

$$x \bullet (d \bullet r | r \bullet d) \bullet (r|w|e)^* \quad (10)$$

As described in this expression, after the creation of the sample cell, both the dimension and mineral type must be set but in no particular order. After that, the mineral type can be set and get as many times as necessary. The dimension, however, can only be retrieved. Listing 1.6 shows the definition of class *TestingSetup* to test RockAR accoding to this regular expression.

Listing 1.6: Class *TestingSetup* to test Rock.AR with the expression from Equation 10.

```
// Specification of the test class
TestingCore. targetClass = SampleCell.class. toString();
// Definition of the methods and their corresponding symbols
TestingCore.mapObjectsToCallSequence = new HashMap<Integer, String>();
TestingCore.mapMethodsToSymbols = new HashMap<String, String>();
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.data.SampleCell.<init>", "x");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.data.SampleCell.SetDimension", "d");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.data.SampleCell.GetDimension", "e");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.data.SampleCell.SetRockType", "r");
TestingCore.mapMethodsToSymbols
    .put("ar.edu.uns.cs.vyglab.vimuge.data.SampleCell.GetRockType", "w");
// Definition of the regular expression
TestingCore. regularExpression = Pattern.compile("x(dr|rd)(wer)*");
// Initializing the regular expressions controller
TestingCore.matcher = TestingCore. regularExpression .matcher("");
```

As in the previous study case, we ran Rock.AR several times to test the last regular expression. The framework detected an error and output the message shown in Listing 1.7. By inspecting the execution sequence we could see that a mineral type was retrieved from a sample cell without being previously set. This error occurred every time the user loaded a previously saved work.

When users saved their work, Rock.AR only saved to a file the sample cells with a mineral type assigned. The system keeps two arrays, one for all sample cells (with or without an assigned mineral type) and the other to map those sample cells to the assigned mineral type. In order to save the work, the application goes through this mapping array and retrieves those cells with an assigned mineral. The method responsible for this operation had an error in a boolean

condition: instead of iterate until $amount - 1$, it went until $amount$. This error caused the last cell to be always saved on file, with some assigned mineral, even when it had no one associated.

Listing 1.7: Error message by the framework on Rock.AR

```

6 Case Study. Earth Defender

Earth Defender is a video game developed in one of our programming courses at the university. It is a classic vertical shooter as Space Invader [1] but with more modern features. It has 28000 lines of code distributed in 217 classes. It was developed in Java 1.8 with Eclipse IDE 4.4. Listing 1.8 shows the setup of TAPIR to test three classes of the system: *PlayerInteractionMananger*, *Enemy* and *GUI_Game*. The *PlayerInteractionMananger* class is responsible for capturing the user interactions that control the space ship's movements and shots. The *Enemy* class's responsibility is to manage each enemy ship of the game; in particular, how each ship returns a power-up when destroyed. Finally, the *GUI_Game* class deals with all the graphical user interfaces of the game.

Listing 1.8: The complete setup method of the TestingSetup class for the Earth Defender game.

```
HashMap<Integer, String> mapObjectsToCallSequence = null;
HashMap<String, String> mapMethodsToSymbols = null;
Pattern regularExpression = null;
Matcher matcher = null;
//Specification of the test class
TestingCore.mapClassToTestingInformation = new HashMap<Integer, String>();

//Testing setup for PlayerInteractionMananger class
//Definition of the methods and their corresponding symbols
mapObjectsToCallSequence = new HashMap<Integer, String>();
mapMethodsToSymbols = new HashMap<String, String>();
mapMethodsToSymbols.put("Main.PlayerInteractionMananger.playerStartMove", "a");
mapMethodsToSymbols.put("Main.PlayerInteractionMananger.playerStopMove", "b");
mapMethodsToSymbols.put("Main.PlayerInteractionMananger.playerShoot", "x");
//Definition of the regular expression
regularExpression = Pattern.compile("((a|b)*x)*");
//Initializing the regular expressions controller
matcher = regularExpression.matcher("");
//A TestingInformation instance stores all information related to how the class is tested
```

```
TestingInformation ti = new
    TestingInformation(PlayerInteractionMananger.class.toString(),
    mapObjectsToCallSequence, mapMethodsToSymbols, regularExpression, matcher,
    false);
TestingCore.mapClassToTestingInformation.put(PlayerInteractionMananger.class.toString(),
    ti);

//Testing setup for EnemyTracker class
//Definition of the methods and their corresponding symbols
mapObjectsToCallSequence = new HashMap<Integer, String>();
mapMethodsToSymbols = new HashMap<String, String>();
    mapMethodsToSymbols.put("Entity.Enemy.takeDamage", "t");
    mapMethodsToSymbols.put("Entity.Enemy.dropPowerUp", "d");
//Definition of the regular expression
regularExpression = Pattern.compile("t*d");
//Initializing the regular expressions controller
matcher = regularExpression.matcher("");
//A TestingInformation instance stores all information related to how the class is tested
ti = new TestingInformation(Enemy.class.toString(), mapObjectsToCallSequence,
    mapMethodsToSymbols, regularExpression, matcher, false);
TestingCore.mapClassToTestingInformation.put(Enemy.class.toString(), ti);

// Testing setup for GUI_Game class
//Definition of the methods and their corresponding symbols
mapObjectsToCallSequence = new HashMap<Integer, String>();
mapMethodsToSymbols = new HashMap<String, String>();
    mapMethodsToSymbols.put("GUI.GUI_Game.inicializar", "a");
    mapMethodsToSymbols.put("GUI.GUI_Game.initLifeBar", "b");
    mapMethodsToSymbols.put("GUI.GUI_Game.initScore", "c");
    mapMethodsToSymbols.put("GUI.GUI_Game.shoot", "h");
    mapMethodsToSymbols.put("GUI.GUI_Game.changeLevel", "i");
    mapMethodsToSymbols.put("GUI.GUI_Game.stopGame", "j");
//Definition of the regular expression
regularExpression = Pattern.compile("((bca(h)*)i)*(bca(h)*)j");
//Initializing the regular expressions controller
matcher = regularExpression.matcher("");
//A TestingInformation instance stores all information related to how the class is tested
ti = new TestingInformation(GUI_Game.class.toString(), mapObjectsToCallSequence,
    mapMethodsToSymbols, regularExpression, matcher, true);
TestingCore.mapClassToTestingInformation.put(GUI_Game.class.toString(), ti);
```

For the *PlayerInteractionMananger* class, the three main methods to test are *playerStartMove*, *playerStopMove* and *playerShoot*. Its MSS is $((a|b)^*x)^*$, where a stands for *playerStartMove*, b for *playerStopMove* and x for *playerShoot*. This means that, under a correct behavior, the player can move several times before shooting. This can be repeated multiple times during a game session. Two methods are considered for the*Enemy* class's MSS; those are *takeDamage*, represented with a t, and *dropPowerUp*, with a d. The MSS for this class is t^*d; this means that each enemy in the game can take much damage until it is

destroyed and drops its power-up. Finally, the *GUI_Game* class has the more complex MSS. Six methods are used: *inicializar* starts the GUI game level, *initLifeBar* draws the life bar on screen, *initScore* draws the initial score of the player on screen, *shoot* draws the shooting effects on screen, *changeLevel* starts the next level once the player completes the current one and, finally, *stopGame* deals with the player's death. These methods are represented by the symbols a, b, c, h, i, and j, respectively. The MSS for the *GUI_Game* class is $((bca(h)^*)i)^*(bca(h)^*)j$. The $bca(h)^*$ part of the MSS represents the user playing a level. If the user wins the level, then he/she moves to the next one. This is shown in $((bca(h)^*)i)^*$. The game continues until the players dies, which is the second part of the MSS, $(bca(h)^*)j$.

6.1 Testing Earth Defender

As Listing 1.8 shows, TAPIR should stop the execution of the game only when it encounters an error on the *GUI_Game* class. If errors are founds on the other two classes, TAPIR will inform them but allow the execution to continue. On the first test run of the game, we played the first level and lost. When we finished playing we found that TAPIR had reported three errors. The output of the framework can be seen in Listing 1.9. The errors correspond to three different objects of the *Enemy* class. We can affirm that they are different objects because the object code that is reported in each error is different. In all three cases, by observing the execution sequence, we can detect that once a ship delivers its power-up, meaning it was destroyed, it still takes new damage. This should not happen since the ship was already destroyed. An analysis of the code involved with this situation showed that the problem was how the enemies were removed from the game. Each time an enemy's life reached 0, the power-up was first delivered, then the score and other features of the game were updated and, finally, the enemy was removed from the level. Since the instance is eliminated last, any other shot that was on the way could still impact it. Consequently, the code was modified to remove the enemy immediately after its life reached zero.

Listing 1.9: TAPIR output of the first test run of Earth Defender

```
−−−  ERROR FOUND  −−−
Class: class Entity.Enemy
Object Code: 1256786520
Method Executed: Entity.Enemy.takeDamage
Regular Expression: t∗d
Execution Sequence: tttdt
−− CONTINUING EXECUTION... −−−
−−−  ERROR FOUND  −−−
Class: class Entity.Enemy
Object Code: 1337065869
Method Executed: Entity.Enemy.takeDamage
Regular Expression: t∗d
Execution Sequence: ttttdt
−− CONTINUING EXECUTION... −−−
```

```
---      ERROR FOUND   ---
Class: class Entity.Enemy
Object Code: 1128333601
Method Executed: Entity.Enemy.takeDamage
Regular Expression: t*d
Execution Sequence: tttttttdt
-- CONTINUING EXECUTION... ---
```

We successfully completed the first level, however, since TAPIR detected errors in the *GUI_class* and it was configured to abort execution in that case, the game closed abruptly at the end of the level. The output of TAPIR can be seen in Listing 1.10. Two errors were found for the same instance of the *GUI_Game* class since the object codes reported are the same. We believe that TAPIR reported two errors that should have aborted the execution because, while processing the first one, the second error occurred. Method *initLifeBar*, represented by the symbol *b*, caused the first error. The last shot of the player can lead to two possible following actions: if with that last shot the player won the level, then the *changeLevel* method must be executed; on the other hand, if after that last shot the player dies, then the *stopLevel* method must be executed. As can be seen in the first error reported by TAPIR, after the last shot, represented in the sequence with *h*, the method *initLifeBar* was executed. As we know that we successfully completed the level, the correct thing would have been the execution of the method *changeLevel*, symbol *i*. The second error reported is a consequence of the first, so correcting the first should fix the second. After inspecting the code, it was discovered that the method *initLifeBar* was called twice each time a level ended. This error was not noticeable from the graphical interface. One of the calls was made after changing levels, this call was correct; the second call was part of the logic that prepares the level change. This line of code should have been deleted in a game update but it was not. By removing this line, both errors detected by TAPIR were corrected. Three more executions of the game were made after this and the framework reported no errors.

Listing 1.10: TAPIR output after the first test run of Earth Defender

```
---      ERROR FOUND   ---
Class: class GUI.GUI_Game

7 Conclusions & Future Work

Industry 4.0 requires new methodologies to ensure the quality of its software, a key element in its production chain. Because of this, we present a new testing technique together with a framework that implements it. Our proposal is a testing framework for object-oriented programming. The framework was designed and implemented to detect flaws in the sequence of method calls that objects make. It is suitable for Java projects and can run without modifying the implementation of the project under test. The objective of this framework is to find those vulnerabilities that allow breaking the expected order of execution of the methods of a class. As shown in the case studies, the framework helps with the detection of errors that would otherwise be difficult to find.

As mentioned above, our goal from the beginning was to create an easy-to-use framework for developers to test their Java source code without any modifications, thus reducing setup and testing times and the possibility of introducing new errors. The next step for this line of research is to test the framework with software of an Industry 40 company. For such a case, we have begun to make the corresponding contacts with a company whose solutions are based on blockchain technologies. We hope that the results obtained in this new case can be published shortly. We will also begin to translate our framework into other programming languages with AOP support, such as C# and Python. The framework is available for downloading[1]. The source code is available and licensed under a Creative Commons Attribution-ShareAlike 4.0 International License.

Abstract. "Digital twining" is one the main ways of establishing data channels in cyber-physical systems using both the outputs of running a virtual model and real time data collected by sensors. The purpose to this paper is to outline the digital twin of a cyber-physical *production* system. We apply the System Dynamics paradigm to the case of a shop-floor factory devoted to cloud manufacturing. The digital twin uses data from the real production line, providing assistance to maintenance procedures triggered by inconsistencies between the real and the virtual processes.

Keywords: Digital Twin, Cyber-physical Systems, System dynamics, Simulation.

1 Introduction

One of the main components of the Industry 4.0 infrastructure are "smart factories", able to adapt their production processes to demand, assigning their resources more efficiently than traditional factories. The key technologies enabling smart factories are the Internet of Things [2], Cyber-physical Systems (CPS) [3] [4], cloud computing [4] and big data [5] [6].

These technologies allow the efficient integration of different functionalities of the control specification ISA-95 into a single production system. In terms of its five levels, all the processes that can be digitalized can be thus absorbed in Industry 4.0 systems [7] [8]. This integration can be both at horizontal and vertical levels. The vertical integration extends from the physical process level (level 0 of ISA-95) to Manufacturing Execution Systems (level 3 of ISA-95) [9]. These levels, handled by CPS, translate the physical events into digital data, creating a digital twin (DT) of the production system. The digital twin provides useful information about the real workload of the production system, which can be used in planning and business management process-

es [10] [11]. Managers can simulate the inner workings of the plant under different scenarios, gaining further information contributing to make better decisions. The ultimate objective of digital twins is to improve the operation and efficiency of manufacturing assets, reducing costs by forecasting future states and supporting advanced decision-making throughout the entire manufacturing lifecycle [12].

A DT of a production system is a type of simulation that allows the real-time control of production. Ding et al. [1] use the term "digital twining" to refer to the process of building a digital twin in the cyber world of physical objects and systems, establishing data channels for cyber-physical connection and synchronization. The implication of this definition is that a DT should use both simulated values and real time data collected by sensors. The simulation has the ability to compress time running ahead the real world process since the digital twin simulation clock is set at one relevant period ahead of real time. If at time t_r a sensor reports a machine failure that was not generated in the simulation when its internal clock was at t_r, the latter should be reset at t_r updating its state with this new information. This feature enables a DT to keep the simulation running at a par with the real production line.

The aim of this work is to describe a simulation model for a digital twin cyber-physical system. In order to define the guidelines for a smart plant environment, the modelling methodology of System Dynamics can be used to handle the uncertainties and nonlinear relationships among interacting system components [13] [14]. The complexity in the definition of the model may ensue from structural or dynamic aspects. Structural complexity refers to the number of components in a system, or the number of combinations involved in making a decision. Dynamic complexities result from the nonlinear and history-dependent nature of self-organizing and adaptive systems [15]. System Dynamics addresses these two kinds of complexity by postulating that the behavior of complex systems results from an underlying structure of flows, delays, and feedback loops [16]. The emphasis in System Dynamics is not on forecasting the future, but on learning how the actions in a period of time can trigger reactions in the future [17] [18].

The paper is organized as follows. Section 2 presents concepts drawn from the literature on manufacturing processes, providing information about the system to be modelled. Section 3 presents the running example that will illustrate the main notions presented in this article. Section 4 introduces Causal Loop diagrams, the basic graphic modelling tool needed to sketch the description of the system. Section 5 presents Stocks-and-Flow diagrams, which allow developing a full model of the system. Section 6 shows how this model provides the grounds to simulate different scenarios using the digital twin to support decision-making. Finally, Section 7 concludes.

2 Conceptual model of the smart factory

The digital twin concept was first devised as a rich digital representation of actual devices, being widely used in the aerospace field [19]. In 2015, the scope of the original definition was expanded, opening the possibility of using it in other fields [20]. Virtual factories were characterized as the digitalization of plants integrated with the

real systems assisting the production process along the lifecycle of each asset [21]. This development led to two different concepts of what a digital twin is: some researchers believe that it can be identified with its virtual component (i.e. the simulation process) while others emphasize on the connections between the virtual and the physical aspects [22]. Tao *et al.* [23] present a design for a smart factory including four main components: a physical shop-floor (PS), a virtual shop-floor (VS), the data generated by the digital twin (D), and a shop-floor service system (SSS).
The physical part includes entities such as human, machines, and materials. The virtual part refers to the digital twin of the physical shop-floor which supports the decision-making and control of the physical part [23]. It provides control orders for the PS and optimization strategies for the SSS. The data component integrates physical, virtual, and service data with the aim of providing consistent information. The service component embodies services like the definition of production and resource allocation plans as well as guidelines for data fusion. These services, in turn, provide information for both the physical and the virtual shop-floor. The authors propose a three stage operation of the digital twin:

- Before production, the SSS defines a production plan based on data collected from different sources (customer orders, real-time data read by sensors, outputs from the simulation, as well as business data) and transmits it to the VS for verification.
- The VS simulates the production plan and if it works correctly, it sends control orders to the PS to start production. The real-time data generated by the PS is then recorded by the VS.
- Once the production process finishes, its recorded history is analysed to extract knowledge that can be used by the VS to simulate future production plans.

In the digital twin shop-floor framework, physical and simulated data are synchronized. The operational implication is that the simulation is fed with real-time sensor data, sending back controls to the PS in a continuous interaction between the physical and virtual components. Tao et al. [23] framework is the basis for implementing the simulation model of a *digital twin cyber-physical system*. We, in turn, add on top of that the process of updating in real-time the production plan in the context of a cloud manufacturing environment. The ensuing digital twin embodies many specialized digital twins: parts DT, machines DT, and a shop-floor DT. The model assumes the use of real-time production data (shop-floor and cloud-shop floor) to support the factory operations.
While simulation has been traditionally used to identify bottlenecks in production plan, it can now be incorporated into smart machines or tools equipped with devices able to capture, process and transmit data. A simulation fed with such information becomes able to check whether the behavior of the physical factory is consistent with the "simulated" behavior. In particular, when (real) data indicates an unforeseen failure, the simulation synchronizes accordingly (data fusion), updating its behavior, and transmitting new control orders to smart devices. Hence, such simulation of the digital twin cyber-physical system helps to handle failures. Figure 1 depicts our simulation model of a digital twin cyber-physical system.

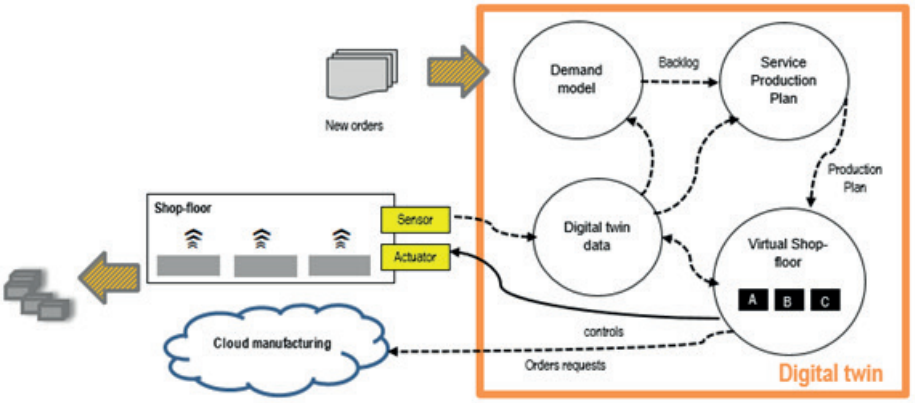

Fig. 1. Simulation model of the digital twin cyber-physical system. Dashed lines: data flow, solid lines: control flow.

3 Running example

Let us consider a smart factory consisting of two production lines A and B. Orders are scheduled on line A. If A is operating above its capacity or it is being repaired, the orders are sent to line B. If line B is operating above its capacity, then the remaining orders are assigned to cloud manufacturing suppliers. For simplicity, we assume that only line A suffers failures and the time to repair is of 3 time units. The cycle times of production lines A, B as well as that of the cloud suppliers are represented by the probability distributions detailed in Table 1. These normal distributions are assumed to have been fitted with historical data of demand.

Table 1. Probability distributions describing cycle time of production facilities.

Production facilities	Cycle time (in days)
A	Normal distribution (mean=2, st. deviation=2%).
B	Normal distribution (mean=4, st. deviation=2%)
Cloud manufacturing suppliers	Normal distribution (mean=2, st. deviation=2%)

4 Causal loop diagrams

The first step towards creating a dynamic model of the digital twin CPS is to draw its Causal Loop diagram [18]. In a Causal Loop diagram variables are connected by arrows denoting the causal influences among them: $x \rightarrow y$ means that the input variable x has some causal influence on the output variable y. A positive influence, denoted by +, means "a change in x, being the rest of variables unchanged, causes y to change in the same direction". In turn, a negative influence means "a change in x, being the rest of variables unchanged, causes y to change in the opposite direction". An increase in a cause variable does not necessarily mean the effect will actually increase

[15]. Since a variable may have more than one input, a change depends on the combined effect of all its input variables. The process wherein one component x initiates changes in other components, and those modifications lead to further changes in x itself is said a feedback loop [24].
According to the system of interest, the diagram may be decomposed in several subdiagrams. For the model of the digital twin cyber-physical system, we developed five diagrams. To save space we include only a partial view of the full causal loop diagram.

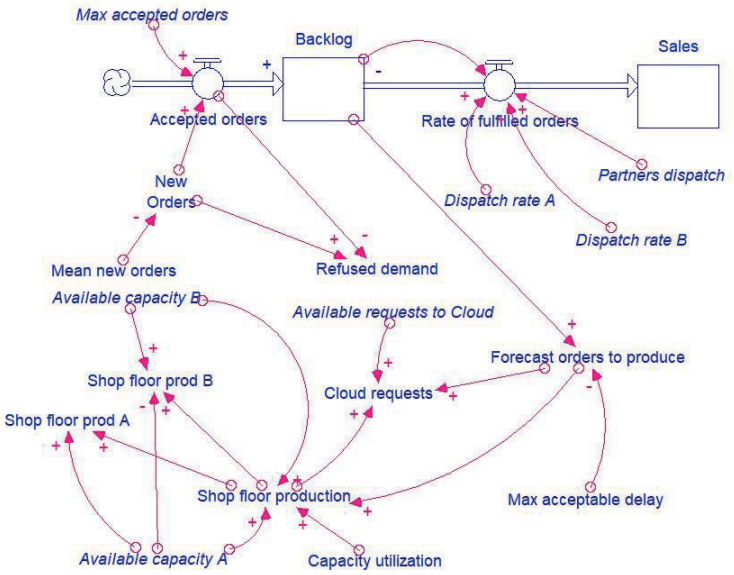

Fig. 2. Causal loop diagram of demand and the production plan. This represents a partial view of the causal loop diagram of the complete system (Generated with Stella™).

Figure 2 depicts the interaction between demand and the production plan. The diagram shows the causal links among the state of the backlog and the accepted orders rate, the dispatch rate of production lines A, B and cloud manufacturing, and the sales volume. As orders increase, the backlog grows, increasing the forecasted number of orders to produce. An increase in the capacity of the production line A adds up the number of units it produces but decreases the shop floor production of line B as well as the production in cloud manufacturing. In turn, increases in failures of production line A decreases its running time and thus its available capacity. As shop-floor production increases, the work in progress and the required dispatch rate grow in time. Finally, increases in the dispatch rate impacts positively on the rate of fulfilled orders and on sales.

The accumulation of resources in a system (stocks), their rates of change (flows) and the feedback loops are the main components of the syntax of dynamic systems models. Stocks are represented by rectangles, inflows and outflows represented by pipes pointing into or out of stocks; valves that control the flows indicate the rates of

change; and clouds represent the sources and sinks for the flows originating outside the boundary of the model. Converters representing processes that convert inputs into outputs are depicted as circles.

5 Stocks and flows diagrams

We structured the smart shop-floor simulation model in five interacting sectors. Cloud manufacturing requests are incorporated in addition to the physical shop-floor production in such a way that production is not limited by plant capacity. The overall structure of interactions between customer demand and flows of orders and products is based on the supply chain models in Sterman [15].

Demand sector. The stock Backlog is the accumulation of accepted orders less the satisfied orders (Fig. 3). It is assumed that orders cannot be changed or cancelled.

$$\text{Backlog}(t) = \text{Backlog}(t-dt) + (\text{Accepted orders} - \text{Rate of fulfilled orders}) * dt \quad (1)$$

There is a cap on the amount of production based on the capacity of the plant and the number of manufacturing orders that can be requested to other manufacturers in the cloud. This cap sets the theoretical maximum production rate that may depend on constraints such as the availability of materials, labor, equipment in the plant and equipment of partners in the cloud. The fulfilled orders rate is given by equation (2).

$$\text{Rate of fulfilled orders} = \text{Dispatch rate A} + \text{Dispatch B} + \text{Partners dispatch} \quad (2)$$

Fig. 3 depicts the Stock and flow diagram for the Demand sector. There are converters and flows defined in such a way as to capture the logic of the synchronization when the behavior of the simulation is not consistent with sensor data. The *Real time gap* is set to 10 meaning that the simulation clock is 10 time units ahead of real time (this value is arbitrarily defined only for illustration). Let the simulation clock be t_s. *Sync backlog* is a variable recording the value of *Backlog* at period $t_s - Real\ time\ gap - 1$. The initial value of converter *Reboot simulation* is 0 and is set to 1 when simulation synchronization is required. Then, if *Reboot simulation* is 1 at simulation time t_s, then the *Backlog* stock is emptied (the flow *Empty Bck* is habilitated) and set to the historical value at $t_s - Real\ time\ gap - 1$.

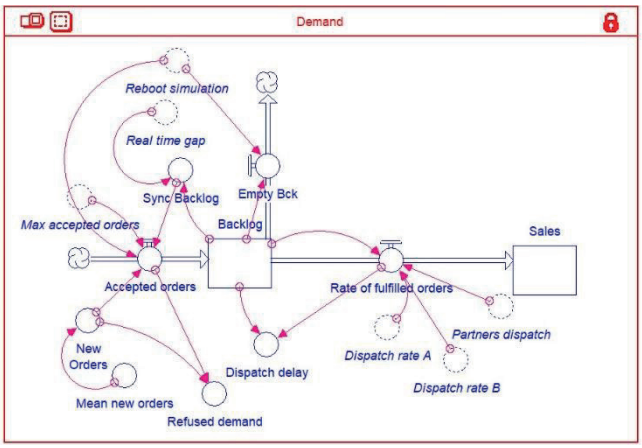

Fig. 3. Stock and flow diagram of Demand (Generated with Stella™).

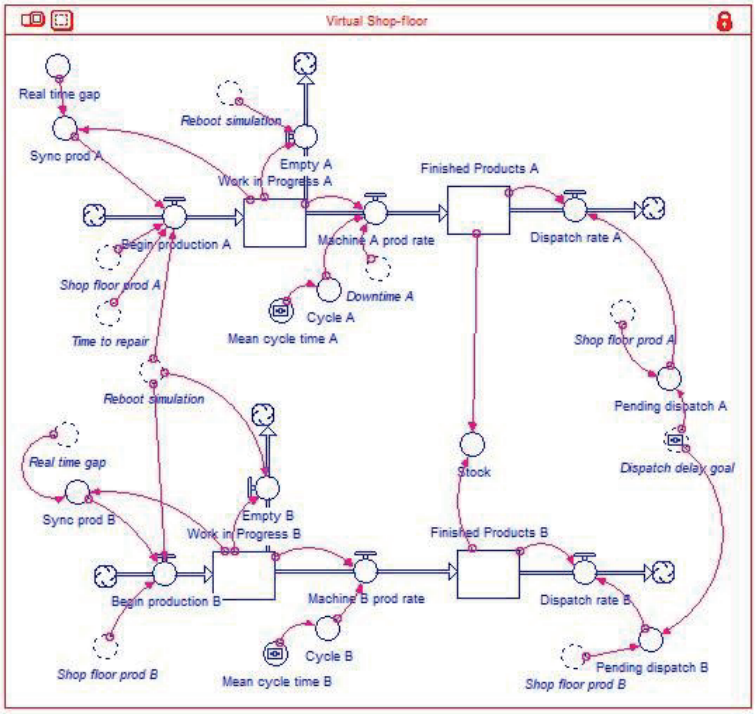

Fig. 4. Stock and flow diagram of the Virtual Shop-floor (Generated with Stella™).

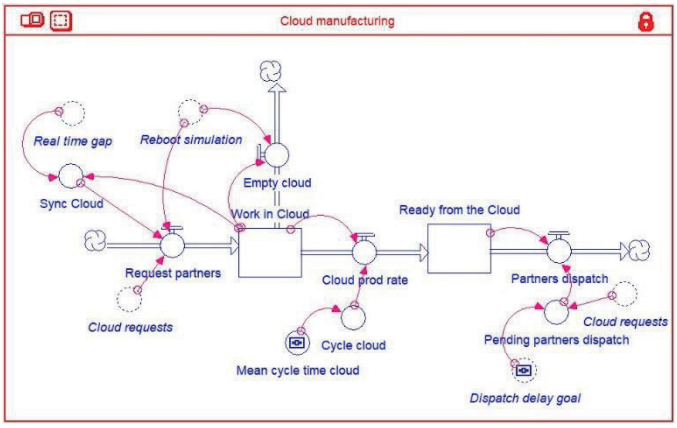

Fig. 5. Stock and flow diagram of Cloud manufacturing (Generated with Stella™).

Virtual shop-floor sector. Production is captured with a chain of two stocks: *Work in progress* and *Finished products* (Fig. 4). For the purpose of this model, all stages of the production process are aggregated together into the *Work in progress* stock as prescribed in Sterman [15].

There are two manufacturing facilities in the plant (A and B) and if necessary, requests are made to cloud manufacturing partners. As mentioned in the description of the Demand sector, there are stocks and flows defined to support synchronization.

Orders are scheduled on production line A. If A is operating above its capacity or it is being repaired, the orders are sent to line B. If also B is operating above its capacity, the required orders are placed to cloud manufacturing providers (Figure 5-8). There exist a maximum of orders that can be requested from the cloud depending on previous agreements with partners. The cycle time is dependent on process-technology and product design (converters *Mean cycle time A*, *Mean cycle time B*). Also, plant A is subject to failure events and the rate of production is thus dependent on the availability of the plant. The stocks, inflows and outflows are formulated as

$$\text{Work in Progress A(t)} = \text{Work in Progress A (t-dt)} + (\text{Begin production A} - \text{Machine A prod rate} - \text{Empty A})*dt \quad (3)$$

$$\text{Empty A (t)} = \begin{Bmatrix} \text{Work in Progress A(t), for Reboot simulation=1} \\ \text{0, for Reboot simulation=0} \end{Bmatrix} \quad (4)$$

$$\text{Machine A prod rate} = \begin{Bmatrix} \text{(Work in Progress A/Cycle A), for Downtime A=0} \\ \text{0, for Downtime A=1} \end{Bmatrix} \quad (5)$$

Most of the time, the inflow *Begin production A* assumes the value *Shop floor production A*. However, when simulation synchronization is required at instant t_s, the simulation should reflect machine A failure at time t_s, and a downtime interval of length $t_s + Time\ to\ repair$, resetting stock *Work in Progress A* with the value at period $t_s - Real\ time\ gap - Time\ to\ repair$ (value recorded by converter *Sync prod A*). Hence, the inflow *Begin production A* is defined as

$$\text{Begin production A(t)} = \begin{Bmatrix} \text{Sync prod A(t-Time to repair), if (Reboot simulation(t)=0} \\ \text{AND Reboot simulation(t-Time to repair)=1)} \\ \text{Shop floor production A(t), otherwise} \end{Bmatrix} \quad (6)$$

We assume that products are dispatched taking into account the dispatch delay goal. For example, if the dispatch delay goal is set to be 3 days and current time is t_s, then finished products which orders were placed at time $t_s - 3$ become dispatched.

$$\text{Finished products A (t)} = \text{Finished products A (t-dt)} + (\text{Machine A prod rate-Dispatch rate A})*dt \quad (7)$$

$$\text{Dispatch rate A} = \text{Min (Pending dispatch A, Finished products A)} \quad (8)$$

$$\text{Pending dispatch A(t)} = \text{Shop floor production A(Max(0, t-Dispatch delay goal))} \quad (9)$$

The dispatch delay takes into account the time since an order is included in the backlog until it is ready for dispatch.

$$\text{Begin production B} = \begin{Bmatrix} \text{0, for Reboot simulation=1} \\ \text{Sync prod B(t-1),} \\ \text{for (Reboot simulation=0 AND Reboot simulation(t-1)=1)} \\ \text{Shop floor production B, otherwise} \end{Bmatrix} \quad (10)$$

Service production plan sector. This sector is in charge of recommending orders of production to each production line (Fig. 6). The number of orders to produce is dependent on the dispatch delay goal and on the available capacity of production lines A, B and of the cloud manufacturing providers. Calculations use data provided by (a) simulations (the available capacity of production lines A and B), and (b) production managers (capacity utilization and the dispatch delay goal).

$$\text{Max acceptable delay} = \text{Dispatch delay goal} \quad (11)$$

$$\text{Forecast orders to produce} = \text{Backlog}/\text{Max acceptable delay} \quad (12)$$

The following formulas represent the scheduling criteria for production lines A, B and cloud manufacturing. The production volume is based on forecasts, assuming that no more than the available capacity is allowed.

$$\text{Shop floor production} = \text{Min ((Available capacity A + Available capacity B)*Capacity utilization), Forescast orders to produce)} \quad (13)$$

$$\text{Shop floor production A} = \text{Min (Available capacity A, Shop floor production)} \quad (14)$$

$$\text{Shop floor production B} = \begin{cases} \text{Min(Available capacity B, Shop floor production-Available capacity A),} \\ \text{for (Shop floor production>Available capacity A)} \\ \text{0, otherwise} \end{cases} \quad (15)$$

$$\text{Cloud requests} = \text{Min(Available requests to cloud,Max (Forecast orders to produce-Shop floor production, 0))} \quad (16)$$

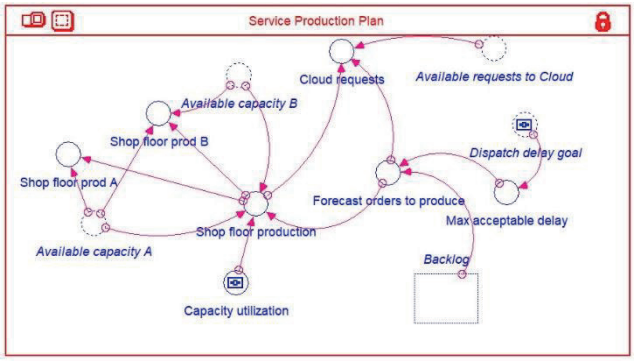

Fig. 6. Stock and flow diagram of Service Production Plan (Generated with Stella™).

Digital twin data sector. The digital twin data sector emulates (Fig. 7) the digital twin data component introduced by Tao [23]. This component is in charge of calculating measures used by the Service Production Plan and the Virtual Shop-floor. These measures are ratios between the capacity utilization of plants A and B, the number of orders that can be requested to cloud partners, and the maximum number of order that can be accepted considering the current level of utilization of plants A and B and cloud services. The dispatch performance rate compares the current dispatch delay and the dispatch goal defined by the firm's goals. The time to repair machine A is defined as constant, but it can be also represented with a probability distribution function or can be a simulation input entered by the operator.

The most relevant part of the digital twin sector is the comparison between data retrieved by sensors and simulated data. For simplicity, we only consider a sensor for machine A (converter *Sensor A*). The sensor detects machine A failures. If this information does not agree with simulated data (converter *Failure A*) at period t_r, then the behavior of the simulation after t_r should be updated to take into account this (the converter *Reboot simulation* is set to 1). In a more realistic setting, the presence of failures should be checked on a time interval (not a point interval).

$$\text{Reboot simulation(t)} = \begin{cases} \text{1, for Sensor A AND (Failure A(t-Real time gap)=0} \\ \text{0, otherwise} \end{cases} \quad (17)$$

The current available capacity of machine A is restricted to its maximum (physical) capacity. In addition, the downtime in case of failure and the reboot of the simulation are also taken into account.

$$\text{Available capacity A} = \begin{cases} 0, \text{ for Downtime A}=0 \text{ AND } \begin{pmatrix} \text{Reboot simulation}=0 \text{ AND} \\ \text{Reboot simulation}(t\text{-Time to repair})=1 \end{pmatrix} \\ \text{Max(Initial capacity A-Work in Progress A, 0), otherwise} \end{cases} \quad (18)$$

$$\text{Available capacity B} = \begin{cases} 0, \text{ for Reboot simulation}=1 \\ \text{Max(Initial capacity B-Work in Progress B, 0), otherwise} \end{cases} \quad (19)$$

6 Scenario modelling

By using the System Dynamics diagrams as a modeling tool and its derived equations we are in conditions of computing numerical solutions. Tools such as Stella™ allow automatizing this computation. There are many techniques of numerical integration of differential equations that can be used to solve the resulting system. The most popular are the Runge-Kutta methods, although their use of finite steps and the approximation to average rates over the interval introduce errors, affecting the results.

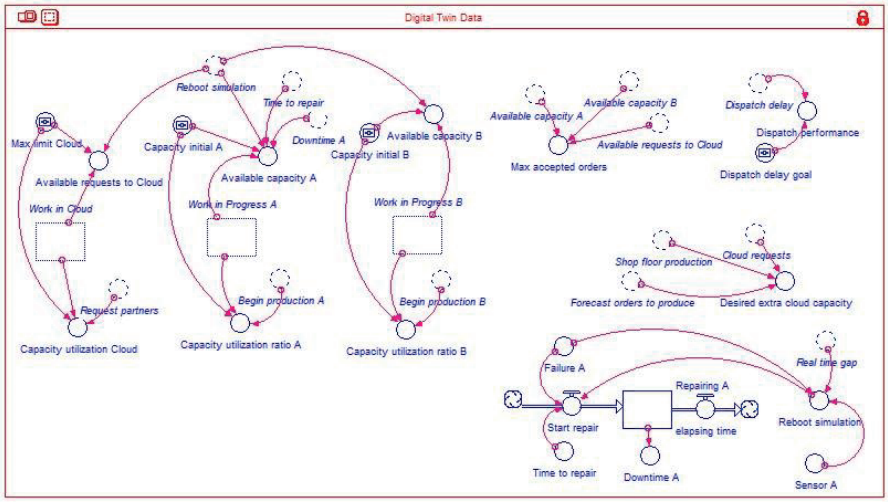

Fig. 7. Stock and flow diagram of Digital twin data. Source (Generated with Stella™).

Table 2. Parameters for the scenario simulation

Parameter description	Value
Demand (number of orders)	Normal distribution (mean=500, st. deviation=10%)
Dispatch delay goal	3 days
Initial capacity of line A	500 units
Initial capacity of line B	400 units
Available cloud capacity	1000 units

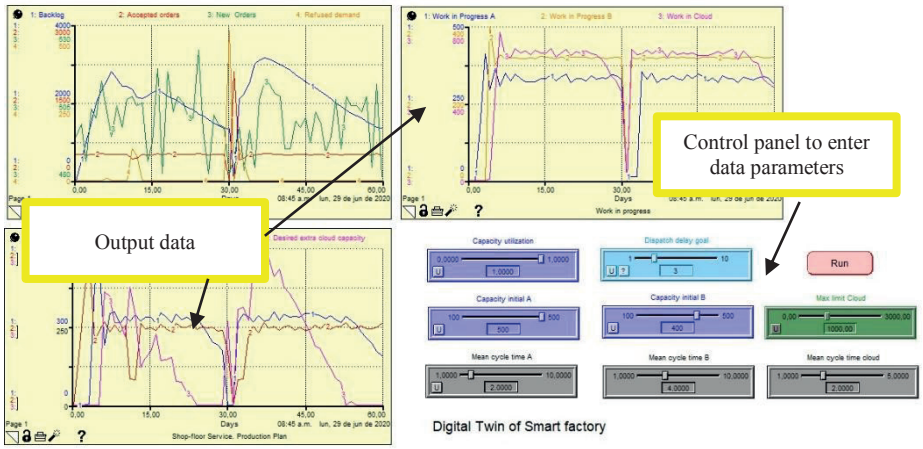

Fig. 8. Digital twin interface including graphics depicting the state of the smart factory and slider input devices to set values of capacity utilization, dispatch delay goal, initial capacity of production lines A and B, maximum limit of requests to cloud manufacturers, and mean cycle times (Generated with Stella™).

Running our system we find that during the first five days, the system is unstable and dominated by the details of the initial conditions. So this period is discarded for analytical purposes. There is a simulated failure of production line A at time 10 and the line is down for 3 days. There is an increase in line B and cloud production (Fig. 9).

There is a failure of line A (detected by sensor data) at real time 20 (the simulation clock is set 10 units ahead of real time). Since the simulation behavior did not consider a failure at time instant 20, then production lines A, B and cloud are set to 0 and re-initialized with real values recorded at simulation time 20 (Fig. 9). In addition, line A is down for 3 days. Simulation forecasts are "corrected" by incorporating real time data when available. Hence, a synchronization of the physical and virtual factory takes place. The available cloud capacity is not enough (notice that *Desired cloud capacity* in Fig. 10 increases after the simulated failure at period 10 and after synchronization due to a real failure of A). This suggests that during downtime plant periods (or an abrupt increase in demand), improving the access to more cloud providers would be recommended. The maximum acquired cloud capacity is not enough to satisfy the desired dispatch delay of 3 days.

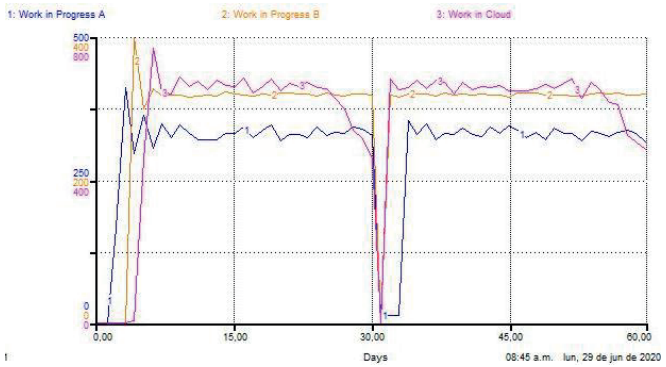

Fig. 9. Production of lines A, B and cloud partners (Generated with Stella™).

In [25] the authors use sensitivity analysis to evaluate the way that behavior patterns vary with different parameters values. We do this to assess the impact of different levels of cloud manufacturing capacity. An increase in that variable would reduce the number of rejected orders. At the same time, such increment entails higher costs incurred in partner agreements.

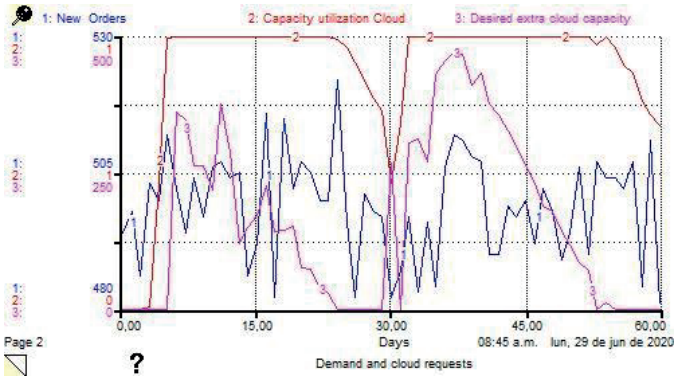

Fig. 10. Demand represented by the *New orders* line; cloud manufacturing capacity utilization (between 0 and 1); and desired extra cloud capacity (defined as the difference between forecasted production orders and available shop-floor and cloud capacity) (Generated with Stella™).

7 Conclusions

The purpose to this paper was to lay down the guidelines for a digital twin of a cyber-physical production system based on a System Dynamics approach. Although we did not intend to cover all systems that may interact with the digital twin, we described how to synchronize the simulation when an inconsistency is detected when

data comes from different sources (data retrieved from sensors and simulated data). It is possible to extend the model to integrate the digital twin with different databases of the organization.

Due to the anticipatory nature of simulation runs, different production plans can be examined to choose the most convenient one according to criteria like optimizing cost, dispatch rate or rejected orders. This information may be useful to support human decision-making or to control a physical machine. This enhances the value of a digital twin (simulation) by supporting real-time production control.

Other simulation paradigms can be used to model and implement a digital twin. For example, discrete event simulation [26] is adequate to model the shop-floor production lines. However, a digital twin of a cyber-physical production system is a complex system (many components or subsystems interact and the knowledge of the impact of a change in a variable over another is incomplete). To model problems with such levels of uncertainty an iterative learning process and modeling tools able to deal with incomplete information are required [18]. The model presented in this work serves as a basis to add interactions with other subsystems belonging to different tiers of the supply chain.

The system dynamics paradigm is adequate to model uncertainty and study the evolution of the system over time (for example, the interactions among demand, logistic disruptions, and machine fatigue). System dynamics shows its potential in forecasting or understanding the far future. Hence, a promising approach is to use an hybrid method based on discrete event simulation to handle short term phenomena (machine failure) and system dynamics comprising all subsystems and assess the far future.

Resumen. Los gemelos digitales emplean la simulación en conjunto con una variedad de datos provenientes de diferentes equipos y sistemas físicos de planta, para mantener actualizados continuamente sus modelos digitales del mundo en un esquema de retroalimentación en un entorno virtual que facilita la toma de decisiones. La heterogeneidad de hardware y software existente requiere del desarrollo de arquitecturas de software para que los diversos componentes se integren e interactúen mediante el intercambio de información. En este trabajo se propone el diseño y construcción de una arquitectura de software que integra un simulador de procesos de manufactura con el sistema operativo de robots (ROS-*Robot Operating System*). La propuesta se prueba con el simulador *Tecnomatix* de *Siemens*® y la distribución libre ROS *Melodic*. Se presenta una instancia de la arquitectura de software para un caso de estudio complejo típico de plantas de manufactura y se demuestra su fácil integración con un sistema autónomo de toma de decisiones.

Palabras Claves: *Gemelo Digital, Industria 4.0, ROS, Tecnomatix*

1 Introducción

Debido al crecimiento exponencial de la tecnología, los hábitos de consumo globales manifiestan una tendencia cambiante que exige un ritmo cada vez más rápido de adaptación de las industrias de manufactura para poder atender una demanda variable que requiere multiplicidad de productos para ser satisfecha y una producción más personalizada. Esto lleva a los sistemas productivos a buscar una alta flexibilidad y capacidad de reconfiguración, por ejemplo utilizando recursos y/o servicios rentados [1]. En contrapartida, estos sistemas son cada vez más complejos, ya que generalmente reúnen otros sub-sistemas automatizados y/o robóticos para la realización de múltiples tareas a lo largo de todo el proceso productivo [2]. Por lo tanto, en esta nueva

configuración de sistemas de producción existen inevitablemente interferencias dinámicas asociadas con diversas fuentes, como por ejemplo la aleatoriedad de los pedidos de los clientes, la dinámica de la demanda de producción, la baja repetitividad del proceso productivo, el uso de servicios y recursos externos, etc. que hacen que la producción sincronizada pueda verse perturbada en detrimento de la efectividad de respuesta del sistema productivo [3].

Para analizar el comportamiento y el desempeño de los sistemas de manufactura, se ha adoptado la simulación como base para representar sistemas complejos a través de modelos simples y fáciles de comprender [4]. Una variedad de modelos de simulación han sido construidos como base para la toma de decisiones en la industria de manufactura [5]. Así, la simulación se convirtió en una de las herramientas utilizadas, por excelencia, para analizar el impacto de las decisiones tomadas sin afectar la operación del sistema real [6].

En las configuraciones actuales de los sistemas productivos intervienen una variedad de equipos, recursos de software y hardware y, también, recursos humanos que deben actuar coordinadamente y de forma autónoma para hacer frente a la variación y alta frecuencia de las tareas de producción causadas por los requisitos personalizados de los clientes [7]. En este contexto, el paradigma de simulación clásico (dinámica y de eventos discretos) ha dejado de ser el componente central para la formulación de sistemas autónomos de toma de decisiones debido a su característica estática. Por ello, y dada la fuerte irrupción de internet industrial de las cosas junto a los sistemas ciberfísicos [8], su lugar ha sido ocupado por el concepto de gemelo digital (GD) [9]. Sin embargo, los métodos y técnicas de simulación de sistemas tienen un papel preponderante para la abstracción y representación de los sistemas productivos [10]. En este sentido, los GDs emplean la simulación en un esquema de intercambio de información con una variedad de datos provenientes de los diferentes equipos y sistemas físicos, para mantener actualizados continuamente los modelos digitales con el fin de reflejar cualquier cambio que ocurra en los equivalentes físicos en el tiempo[11]. De esta manera, se puede lograr un esquema de retroalimentación en un entorno virtual adaptativo que facilita la toma decisiones apoyándose en estos GDs.

Hasta ahora, la integración entre diferentes tecnologías para el desarrollo de los GDs es una cuestión que ha sido abordada de una forma heterogénea y algunos trabajos han puesto el foco en organizar algunos conceptos claves [11], [12], cuestión que es de vital relevancia para la formulación de propuestas que empleen el uso de gemelos digitales, como por ejemplo en el desarrollo de sistemas de manufactura flexible [13]. Recientemente en el trabajo [14], se formuló una propuesta de arquitectura modular para implementar GDs, probándolo en un clasificador (*sorter*) pequeño y analizando los tiempos de la comunicación entre partes; y en el trabajo [15] realizan una propuesta de integración entre un simulador de eventos discretos y un software de dinámica de sistemas para resolver un caso de un problema de control. En este trabajo, se presenta una arquitectura software para el desarrollo de GDs mediante la integración del bien conocido sistema operativo de robots (ROS) y un simulador de procesos de manufactura flexible, el *Tecnomatix Plant Simulation – Siemens*® (TPS).

2 Metodología

En esta sección introducimos brevemente los principales componentes metodológicos hacia la formulación de un GD para un sistema de manufactura flexible. Para más detalle, el lector podrá referirse a las citas oportunamente indicadas.

2.1 Simulación

La metodología de simulación se ha transformado en una herramienta de análisis indispensable para evaluar el impacto de cambios sin que sea necesario modificar el sistema real. Particularmente, los sistemas de producción manufacturera son un caso especial de sistemas dinámicos híbridos, conocidos como sistemas de eventos discretos [14]. En este sentido, pueden ser modelados y simulados bajo el paradigma de simulación de eventos discretos [6]. La simulación de eventos discretos es una herramienta de análisis ampliamente difundida en el ambiente empresarial y ha comprobado su utilidad para apoyar la toma de decisiones relacionadas con la planeación de la producción e inventarios así como con el diseño de los sistemas de producción y sus cadenas de suministro [5].

Los modelos de simulación representan procesos y situaciones complejas de la realidad en función de los eventos que puedan ocurrir, por lo que pueden representar, tanto situaciones típicas de un proceso productivo (rotura de inventarios, fallas de equipos, aparición de imponderables), como así también estimar un determinado nivel de utilización de recursos relacionados con dichas situaciones. Asimismo, contempla las probabilidades de que ocurran cada uno de los eventos según se asocian con las características de cada uno de los elementos que intervienen. En su conjunto, todos estos elementos simulan la evolución natural del proceso analizado. De esta forma los modelos permiten conceptualizar sobre un proceso productivo y su gestión en términos de los eventos que puedan suceder y cuyo impacto afecta tanto a los clientes como a otros componentes del sistema (p. ej., el uso de recursos). En definitiva, la simulación de eventos discretos es una técnica que se puede utilizar para estudiar los sistemas y procesos cuyos estados van cambiando con el tiempo de forma discreta.

2.2 Gemelos digitales

La irrupción de los sistemas ciberfísicos ha cambiado paradigmáticamente la forma en que se conciben los sistemas industriales, permitiendo la integración de todas las entidades que intervienen en un sistema productivo [15]. Así, es posible lograr la integración y la interacción en tiempo real entre los diferentes componentes de un sistema productivo lo que hace posible gestionar las entidades físicas de manera confiable, segura, colaborativa, robusta y eficiente [16]. Desde esta perspectiva, los sistemas de fabricación integrados podrían pensarse compuestos por dos partes principales: una parte física y una parte digital. Como se muestra en la Fig. 1, la parte física comprende todas las entidades y recursos empleados para la fabricación mientras que la parte digital contiene aplicaciones y servicios ubicuos, incorporando subsistemas con capa-

cidades para el procesamiento y gestión de datos, simulación y análisis junto a sistemas inteligentes para la toma de decisiones.

En la parte física, representada esquemáticamente en la parte inferior de la Fig. 1, se encuentran interconectadas las diferentes entidades involucradas en el proceso de producción y, en una clasificación general, pueden ser agrupadas como Equipos, Materiales, Operarios y Herramientas. Todas estas entidades pueden compartir información y mantener actualizado su estado en tiempo real gracias a las diferentes tecnologías actuales como, por ejemplo, los protocolos Ethernet, ROS, sistemas de georeferenciación, etiquetas/lectores RFID, etc. De esta forma, en la parte física no sólo se recopilan e intercambian datos, sino que también se comunica con la parte digital donde se generan decisiones o acciones que posteriormente se ejecutan en la parte física. Es decir, mediante esta comunicación, la parte digital puede afectar los procesos físicos y viceversa.

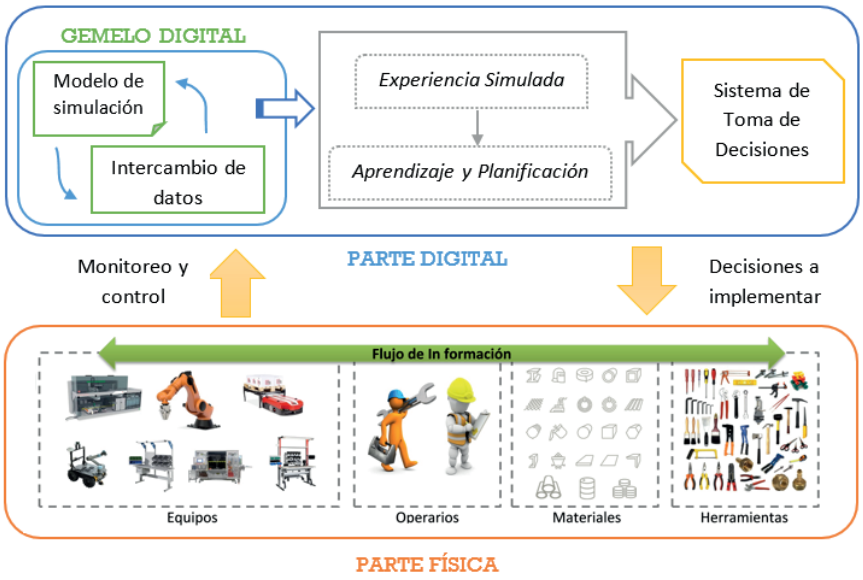

Fig. 1. Entidades y relaciones para un sistema de manufactura flexible.

La parte digital, representada en el fragmento superior de la Fig. 1, contiene distintos subsistemas, servicios y aplicaciones que desarrollan distintas funciones que permiten a las entidades intervinientes en la fabricación operar coordinadamente para optimizar el desempeño del sistema productivo en su conjunto. Actualmente, muchos campos de investigación enfocan sus esfuerzos hacia el desarrollo de propuestas para este sistema virtual. Particularmente, todos ellos buscan aprovechar las bondades y beneficios de diferentes metodologías para generar propuestas que sustenten el desarrollo de sistemas autónomos de toma decisiones, los cuales deben establecer las acciones que se deben ejecutar para gestionar el sistema físico de producción [18]. En este sentido, el concepto de GD ocupa un lugar clave y está centrando la atención de

muchas investigaciones para el desarrollo de metodologías y técnicas que permitan la creación de manera fiable de tales GDs [19].

La función principal de los GDs es proporcionar una descripción física, funcional e integral del sistema en su conjunto. Los GDs son modelos virtuales para reproducir de manera realista las propiedades, comportamientos y reglas de las entidades de la parte física [20]. En otras palabras, los modelos virtuales y las entidades físicas tienen una apariencia y comportamientos similares, es decir, son *gemelos*.

Para el desarrollo de los GDs, las técnicas de simulación tienen un rol central y deben operar en un esquema de intercambio de información con una variedad de datos, provenientes de los diferentes equipos y sistemas físicos de planta, para mantener actualizados continuamente los modelos digitales con el fin de reflejar cualquier cambio que ocurra en los equivalentes físicos en el tiempo. La interacción entre el mundo físico y los GDs tiene una importancia clave debido a que los modelos virtuales y el mundo físico deben evolucionar conjuntamente, ya que este último posee un comportamiento dinámico y, por ejemplo, una misma entidad puede mostrar diversas propiedades en diferentes momentos. Por esto, los datos recogidos en tiempo real del mundo físico se deben compartir con el mundo virtual en un esquema sincronizado para mantener actualizados los modelos virtuales que permiten simular el proceso físico y su evolución.

2.3 Jerarquía de los Gemelos Digitales

Desde una perspectiva jerárquica, los GDs pueden pensarse compuestos por tres niveles diferentes: Entidades, Información y Sistema.

En un primer nivel se encuentran los modelos de todas las entidades que intervienen en el sistema físico. En este nivel, cada una de las entidades debe ser modelada digitalmente con la mayor fidelidad posible. Actualmente, existen muchas soluciones y plataformas disponibles empleadas en el ámbito industrial que proveen soluciones para cada una de las entidades. En concreto, para diferentes tipos de entidades se han desarrollado potentes simuladores computacionales que ya han dado cuenta de su eficacia. También, es común que intervengan personas para desarrollar tareas específicas, los cuales pueden ser modelados digitalmente, empleando un simulador adecuado [7]. De la misma forma, cuando intervienen entidades que realizan operaciones unitarias pueden ser modeladas mediantes entornos de simulación específicos. En definitiva, una vez que se identifican todas las entidades intervinientes en el proceso productivo, cada entidad puede ser comprendida como un subsistema dentro de otro sistema más amplio, y a su vez, existen herramientas computacionales de simulación que permiten crear los modelos digitales más apropiados de cada una de ellas.

Cada uno de los subsistemas modelados no opera de manera aislada, sino que tiene asociado un comportamiento en el que realiza intercambios (por ej. de materiales, energía, insumos, datos, etc.) con otras entidades en el proceso productivo. Es decir, cada una de las entidades presentes tiene un propósito específico y, en consecuencia, tienen asociados un conjunto de funciones con lo cual continuamente están generando datos y/o información que pueden ser almacenados y/o compartidos entre las distintas entidades físicas y sus modelos digitales.

En el sistema productivo, las entidades están relacionadas y comparten datos e información, es decir tienen una relación sinérgica y son parte de una estructura sistémica. Por ello, cada una de estas entidades debe estar adecuadamente modelada y vinculada entre sí cuando se genera el modelo del sistema productivo en su conjunto. En otras palabras, de nada sirve, por ejemplo, modelar perfectamente y de forma aislada un centro de trabajo, un robot manipulador y un operario si no se lo hace con todas las relaciones y propiedades requeridas en el entorno fabril en el que se están empleando.

Dada la heterogeneidad y la complejidad de las entidades que pueden intervenir en un sistema de manufactura flexible y por lo tanto, para generar los mejores GDs, es conveniente utilizar los simuladores específicos y adecuados para cada entidad acorde a su complejidad y especificidad. En el desarrollo de GDs para sistemas completos de producción manufacturera, la vinculación entre diferentes entornos de simulación y las entidades físicas ha sido poco desarrollada en la literatura. Por ello, en este trabajo se propone una arquitectura de software que permite integrar diferentes entornos de simulación, útiles para modelar cada una de las entidades comúnmente usadas en los entornos de manufactura flexible, así como con los dispositivos físicos propiamente dichos. Esta propuesta se desarrolla en la próxima sección.

3 Integración Tecnomatix & ROS

Hoy en día, es muy común que los fabricantes de robots y equipos automatizados para la industria provean simuladores computacionales de sus productos, los cuales son la base para la creación de los GD de cada equipo o entidad en cuestión. Sin embargo, muchas de estas soluciones disponibles no ofrecen una solución integral desde la perspectiva del sistema industrial. La diversidad y complejidad de cada una de las entidades que intervienen en un proceso productivo hacen que los simuladores destinados a modelar íntegramente un sistema productivo (por ejemplo los simuladores de eventos discretos), puedan no reflejar con suficiente grado de fidelidad el sistema en su conjunto ya que tienden a simplificar la dinámica de las entidades que lo componen, lo cual va en detrimento de la calidad de un GD del sistema industrial que se pretenda crear. Por esto, la integración de un simulador de eventos discretos con las entidades reales junto con sus simuladores especializados, representa una opción prometedora para la creación de un verdadero GD de un sistema industrial.

3.1 El Sistema Operativo Robot - ROS

En el pasado, la interacción y la comunicación con y entre los robots eran complejas y dependientes de la plataforma robótica empleada. Durante la última década, esta situación ha sido facilitada y potenciada debido al creciente desarrollo del Sistema Operativo Robot, conocido como ROS[1].

[1] https://www.ros.org/

ROS consiste de un conjunto de procesos heterogéneos e independientes denominados nodos ejecutados al mismo tiempo y teniendo la capacidad de intercambio de mensajes entre ellos. La conexión entre los nodos se denomina tópico. Un nodo puede publicar mensajes o subscribirse a un determinado tópico [21]. ROS es ampliamente utilizado en la comunidad de diseñadores y fabricantes de robots debido a sus características de software abierto, que permite encapsular nodos desarrollados en diferentes lenguajes de programación, facilitando enormemente el crecimiento incremental del sistema y su prototipado. En efecto, la incorporación de nuevos nodos que manejen nuevos dispositivos, tanto sensores como actuadores, se realiza de forma inmediata y homogénea, aún para dispositivos con drivers realizados en software propietario y muy diferente entre sí. Estas características le confieren a toda la arquitectura una gran versatilidad, fundamentalmente para el trabajo de investigación tecnológica.

Resumidamente, las principales características y ventajas de ROS son: (1) abstracción de hardware y control de dispositivos de bajo nivel; (2) intercambio de mensajes entre procesos; (3) gestión de paquetes; (4) herramientas para desarrollar, probar y ejecutar código en varios tipos de lenguajes de programación; (5) computación distribuida; (6) reutilización de software; y (7) pruebas rápidas. En este sentido, todos los robots equipados con ROS tienen el mismo criterio de comunicación.

Para la creación de los GDs, la estandarización de los protocolos de comunicación juega un papel central. Teniendo en mente que los GDs están constituidos por modelos simulados, con fusión de datos reales, es atinado pensar en la creación de estos gemelos considerando la posibilidad de interactuar con las entidades reales.

3.2 Simulador de planta *Tecnomatix*

En esta sección presentamos brevemente el paradigma de programación del simulador de procesos de manufactura TPS.

Una particularidad que, en principio, vuelve atractivo al software *Tecnomatix* es que, por una parte, se pueden explorar sus capacidades con licencias de prueba libres y con un número máximo de hasta ochenta entidades, lo cual muchas veces es suficiente para modelar, por ejemplo, un sistema productivo de una pequeña/mediana empresa. Por otra parte, permite la interconexión con software y *hardware in the loop* tipo PLC (*Programable Logic Controller*) y la integración con los productos Siemens es aún más sencilla. En la práctica esto puede ser ventajoso dado que es muy común la existencia de este tipo de equipamiento en las plantas industriales.

Finalmente otra de las ventajas que brinda el software del TPS a la hora de modelar es que tiene una interface gráfica amigable que permite modelar un sistema de manufactura simplemente seleccionando cada uno de sus componentes, ubicándolo y estableciendo las relaciones con los demás componentes del sistema. También permite programar lógicas de actuación a cada instancia utilizada con su lenguaje propietario. Asimismo, otra cualidad que lo vuelve aún más atractivo es que cada una de esas instancias permite una conexión directa con Python. Para nuestra propuesta, esto es de suma importancia dado que es posible la conexión con otras instancias cuyo comportamiento sea el del elemento real o su homólogo simulado mediante su específico simulador dinámico.

3.3 Arquitectura de Integración

La Fig. 2, esquematiza la combinación de los elementos individuales descriptos en la secciones previas para desarrollar la arquitectura de software propuesta que integra ROS y el simulador de procesos de manufactura TPS, con la posibilidad del agregado de un sistema de decisión autónoma para optimización de procesos.

Observando en la parte superior izquierda de la Fig. 2, tenemos encerrado en una línea de color gris el ROS. Este componente se encuentra integrado por dos nodos, o procesos heterogéneos e independientes, denominados *roscore* y *Simulación de Planta*. El nodo *roscore* representa generalmente una colección de procesos y programas del ROS que permite que una red heterogénea de nodos puedan comunicarse entre sí. El nodo *Simulación de Planta* representa el proceso que tiene la responsabilidad de dirigir una planta de manufactura simulada. A su vez, este proceso puede comunicarse con otros nodos por medio de tópicos del tipo suscriptores o publicadores. Por ejemplo, el conocimiento de optimización de procesos obtenido en el nodo de *Simulación de Planta* en base a simular una planta de manufactura puede ser publicado directamente a través de un tópico que modifique el comportamiento de una entidad de planta real. Por otro lado, el nodo *Simulación de Planta* puede suscribirse a un tópico de datos proporcionado por una entidad real que altere el proceso de optimización de una planta de manufactura en particular simulada, proporcionando conocimiento que nuevamente puede ser aplicado a una entidad real, teniendo como resultado un GD para un sistema industrial.

Por otro lado en la parte superior derecha de la Fig. 2, se encuentra encerrado en una línea de color celeste el simulador de procesos de manufactura TPS. Con este software es posible diseñar plantas de manufactura adaptadas a cada problemática en particular con el objetivo de simular sus procesos de producción. Cada una de las plantas de manufactura se almacena en archivos externos con extensión .spp. Por ejemplo, en la Fig. 2 se muestra el modelo desarrollado en el simulador TPS para un GD de un problema puntual de manejo de materiales en un piso de planta flexible. Este caso de estudio se aborda en detalle en la Sección 4.

En la parte central de la Fig. 2, delimitada por una línea de color verde, se encuentra la integración entre ROS y el software TPS. Como se puede ver, se propone un patrón de diseño de clases siguiendo el paradigma de programación orientada a objetos para el desarrollo de la arquitectura de software propuesta en este trabajo. El diseño propuesto se implementó y testeo íntegramente utilizando el lenguaje de programación Python. La comunicación entre ROS y el software TPS se realiza mediante la clase denominada *Interfaz de Conexión*, que tiene la responsabilidad de proporcionar puntos de acceso externos que realizan alteraciones dentro del software de simulación. Estos puntos de acceso comprenden la carga de una planta en particular para ser procesada por el simulador, establecer y obtener datos de una entidad cualquiera simulada, comenzar, parar y pausar simulaciones, entre otras alteraciones permitidas por el software TPS. Para implementar esta comunicación se utilizó la librería *win32com* la cual permite intervenir de forma externa cualquier sistema que sea ejecutado dentro del sistema operativo de Windows®. La clase *Interfaz de Conexión* representa el patrón de diseño *Mediator* utilizado comúnmente en el desarrollo de

software de la programación orientada a objetos, el cual tiene la responsabilidad de encapsular la comunicación entre los objetos [22].

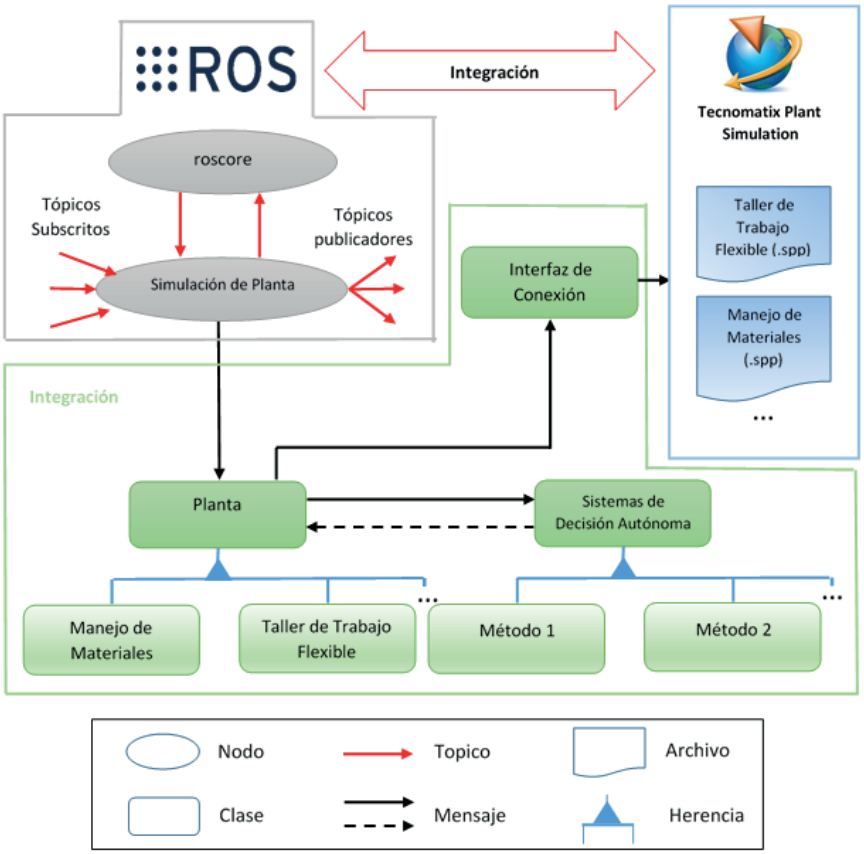

Fig. 2. Arquitectura de software propuesta para integrar ROS y un simulador de procesos de manufactura TPS, con la posibilidad del agregado de un sistema de decisión autónoma.

Siguiendo con el diseño de la arquitectura de software propuesta se observa que el nodo *Simulación de Planta* del ROS ejecuta procesos mediante el pasaje de mensajes, de una planta en particular utilizando la clase *Planta*. La clase *Planta* representa una clase abstracta y sigue el patrón de diseño denominado herencia simple, la cual abstrae todo el comportamiento general de cualquier planta de manufactura simulada [23]. Precisamente, la clase *Planta* ejecuta procesos mediante el pasaje de mensajes por medio de la clase *Interfaz de Conexión*, la cual representa un comportamiento general que requiere cualquier planta de manufactura simulada coordinada externamente. En esta jerarquía simple se tienen por ejemplo dos clases de plantas de manufactura concretas denominadas *Taller de Trabajo Flexible* y *Manejo de Materiales*, entre otras plantas que pueden ser implementadas. Cada planta concreta implementa el comportamiento de coordinación de una planta simulada por el software de simula-

ción. Por ejemplo, la clase concreta *Manejo de Materiales* tiene la responsabilidad de cargar dentro del software de simulación el archivo *Manejo de Materiales* con extensión spp, cambiar el comportamiento de la planta simulada ante establecimiento de datos a entidades simuladas, comenzar, parar y extraer resultados de una simulación, siempre a través de los puntos de accesos brindados por la *Interfaz de Conexión*. Se debe tener en cuenta que cada comportamiento específico de cada clase concreta de planta depende de la simulación abordada para cada planta en particular. Asimismo, debe notarse que la extensión de una nueva planta concreta que dirija de forma externa una planta simulada por el software TPS es directa, simplemente se debe crear una nueva clase que herede de la clase *Planta* y codificar el comportamiento simulado requerido, promoviendo la escalabilidad de la arquitectura de software propuesta.

Paralelamente a la jerarquía de planta, se tiene una herencia simple con la clase abstracta *Sistemas de Decisión Autónoma*. Esta clase abstrae todo el comportamiento general de cualquier método de toma de decisiones autónoma provista por la inteligencia artificial. Una clase concreta, y como se mostrará en la Sección 4, representa la aplicación de un método particular de aprendizaje por refuerzo. Notar, que el agregado de un nuevo método de decisión autónomo es directo, simplemente se debe crear una clase que herede de la clase *Sistemas de Decisión Autónoma* y codificar el método en particular, nuevamente fomentando la escalabilidad de la arquitectura de software propuesta.

Estas jerarquías paralelas interrelacionadas entre las clases abstractas *Planta* y *Sistemas de Decisión Autónoma* representa una combinación de patrones de diseño conocidos como *Factory Method* y *Observer* o *Publish-Suscribe* utilizados comúnmente en el desarrollo de software de la programación orientada a objetos [22]. El patrón *Factory Method* tiene la responsabilidad de construir o fabricar objetos de un subtipo determinado, es decir, plantas simuladas, en la que se le puede o no aplicar dentro de cada subtipo un método en particular, en este caso, un proceso del sistema de decisión autónoma. Por otro lado, el patrón y *Observer* o *Publish-Suscribe* define una dependencia entre el observador (la clase *Planta*) y observado (la clase *Sistemas de Decisión Autónoma*). De esta manera, una planta cualquiera, es decir, el observador, ejecuta un proceso en particular del sistema de decisión autónoma, es decir, el observado (ver Fig. 2 el paso de mensaje de una flecha color negra). Luego, cuando el observado cambia de estado, por ejemplo, cuando el método de sistema de decisión autónoma obtiene un resultado en la optimización de un proceso en particular, el observador es notificado automáticamente (ver Fig. 2 el paso de mensaje de una flecha color negra a trazo), teniendo nuevamente el control de la planta, y a su vez, el resultado del proceso de optimización para que seguidamente altere con el resultado obtenido la planta simulada en cuestión.

Observando con una mirada abstracta la Fig. 2 podemos notar que desde cualquier nodo del ROS podemos crear numerosas plantas de manufactura a la vez de igual o de distinto tipo, que interactúen con el simulador de procesos de manufactura TPS, y a su vez a cada tipo de planta se le puede aplicar o no métodos de un sistema de decisión autónoma.

3.4 Gemelo digital para la TDDs

Como ya hemos señalado, el paradigma de fabricación centrado en el cliente requiere que las empresas se esfuercen en buscar alternativas para mejorar su competitividad. El hecho de desarrollar sistemas autónomos de toma de decisiones (SATDD), capaces de optimizar productividad global del sistema de fabricación y consecuentemente el uso de recursos, es una ventaja distintiva para la determinación de una variedad de decisiones que deben tomarse constantemente, y en tiempo real, para hacer frente tanto a las variaciones de demanda de clientes, como así también, a las perturbaciones propias de un sistema productivo. Los SATDDs, para ser eficaces, necesitan información precisa y en tiempo real para determinar su política de actuación [8].

En el pasado, los modelos digitales se usaban casi exclusivamente para analizar y validar los comportamientos de los sistemas e instalaciones industriales de producción altamente automatizados. En la actualidad, las tecnologías modernas, la digitalización y la inteligencia artificial fomentan la necesidad de desarrollar aún más las herramientas de planificación digital a la vez que promueven el desarrollo de métodos SATDD

La propuesta de desarrollo de GDs para sistemas de manufactura, es justamente, uno de los pilares para el desarrollo de SATDD basados en el paradigma del aprendizaje por refuerzos (AR) [24]. En este esquema un agente inteligente (SATDD) interactúa con su entorno (GD) eligiendo acciones cuyo objetivo es maximizar la recompensa esperada. Formalmente, este problema se describe como un problema de decisión de Markov el cual requiere que se defina un vector de estado del sistema, el conjunto de acciones posibles a tomar en cada estado y una función de recompensa que premie los efectos de las acciones tomadas. En la Sección 4.3 se detalla cada uno de los elementos en base al caso de estudio abordado.

4 Caso de estudio

En los sistemas de manufactura flexible el manejo de materiales es un problema difícil y que afecta directamente la eficiencia y productividad del sistema de fabricación. Mejorar la eficiencia de los procesos complejos de fabricación, en particular la logística y el manejo de materiales, es un problema difícil y que ha recibido especial atención, principalmente para la planificación de tareas en esquemas de producción estáticos. Sin embargo, no hay demasiada evidencia para esquemas de producción dinámicos, cuando cambian por ejemplo, alguna de las condiciones de los pisos de planta flexibles y/o también varía la demanda. En esta sección presentamos la creación de un GD para un sistema de manufactura de manejo de materiales. La creación del modelo digital en el software TPS y su integración con ROS para el desarrollo de los correspondientes GDs, se realizó siguiendo los pasos descriptos en las secciones anteriores. Finalmente, se presentará una propuesta de integración con un sistema de toma de decisiones que emplea un agente artificial de AR.

En un problema de manejo de materiales se busca minimizar las distancias recorridas, el uso de los medios de transporte y las demoras en las entregas que interrumpan el sistema productivo. Durante la resolución de un problema de este tipo, se debe evitar la interrupción del flujo de trabajo asegurando la provisión en tiempo y forma

de los insumos necesarios para las diferentes estaciones de trabajo procurando lograr el normal funcionamiento del sistema de producción.

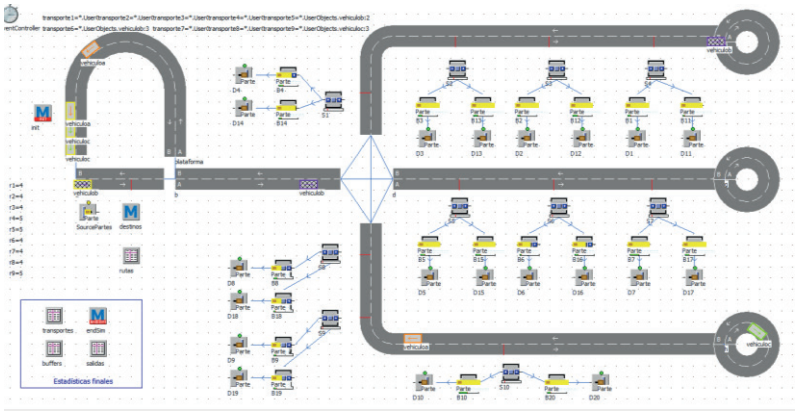

Fig. 3. Modelo de simulación en TPS.

4.1 Definición del modelo de simulación

Particularmente, para el análisis se toma el caso de estudio presentado en el trabajo de [25]. Para más detalles se recomienda recurrir al trabajo mencionado.

El sistema está compuesto por diez estaciones de trabajo ($S_i \; \forall \; i = 1, 2, \dots, 10$) que consumen dos tipos de parte (P_1, P_2) cada una simultáneamente; en cada estación existen buffers ($B_k \; \forall \; k = 1, 2, \dots, 20$) de almacenamiento para cada parte cuyas capacidades son iguales al doble de la cantidad de partes de cada tipo consumidas en una hora; hay nueve vehículos de tres tipos diferentes ($V_{je} \; \forall \; j \in \{1, 2, 3\} \; \vee \; e \in \{1, 2, 3\}$ y se desarrollan distintos planes de manejo de materiales. Cada plan de manejo de materiales tiene asociado una ruta a seguir (W_c), un transporte específico (T_d), partes y cantidades de partes a llevar a las estaciones. Los equipos de transporte no son todos iguales, es decir, cada tipo de vehículo tiene su propia capacidad de carga y puede llevar cualquier tipo de parte.

La Fig. 3 muestra el modelo desarrollado en el software TPS. Como se puede observar, en este modelo están presentes todas las entidades que forman el sistema en estudio. Asimismo se aprecian, las vías de circulación con sus respectivos sentidos, los puntos de carga/descarga, los equipos de transporte y las partes.

4.2 Integración digital

El modelo en el simulador TPS queda definido mediante un conjunto de parámetros, los cuales pueden accederse externamente mediante el nodo ROS creado. La Fig. 4 muestra los resultados finales de una simulación que sirven de entrada a un sistema de toma decisiones. Para poder cambiar los planes se recolectan: distancias recorridas por cada medio de transporte y nivel de ocupación de los mismos (Fig. 4a), nivel máximo de llenado de los buffers respecto a la capacidad definida y porción del tiempo

en que se llenan completamente (Fig. 4b) y porcentajes de trabajo y espera en cada salida que consume partes (Fig. 4c).

string 0	real 1	real 2
string	Distancia recorrida	Porcion ocupado
1	Transporte1	611.93	0.11
2	Transporte2	612.33	0.10
3	Transporte3	628.73	0.11
4	Transporte4	613.13	0.15

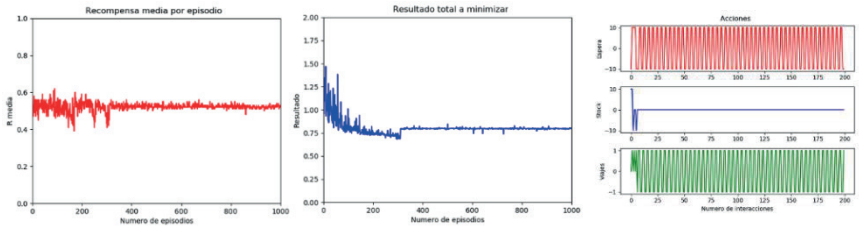
(c)

Fig. 4. Resultados obtenidos en el simulador TPS.

4.3 SATDD para el manejo de materiales

A continuación se presentan los elementos para la formulación del problema de AR. A menos que se diga lo contrario, se omite el subíndice t de representación del tiempo a efectos de simplificar la notación.

Estado del sistema



Para la representación del estado, del sistema se consideran las magnitudes de tres de las variables a saber: el tiempo de espera al cargar (T_l), el stock inicial (s_0) y la cantidad de viajes por vehículos (M), manteniéndose constantes los demás parámetros de sistema. De esta manera, el vector de estado del sistema es $\mathbf{s}_t = (T_l, s_0, M)$. Para la discretización del estado del sistema, el tiempo T_l se discretiza con un paso de 10 segundos en el intervalo [60, 300]; el stock s_0 puede tomar valores entre [10, 50] con un paso de 10 unidades; la cantidad de viajes por vehículos debe estar en el intervalo de enteros [1, 5].

Acciones

En cada estado en que se encuentre el sistema el agente podrá aumentar/disminuir en 10 segundos el tiempo de espera en cargar, aumentar/disminuir en 10 unidades el stock inicial y aumentar/disminuir en 1 los viajes por vehículo. En todos los casos, para cada variable, el agente también puede tomar la decisión nula, es decir, no modificar alguna (o todas) las variables de plan. De esta forma, el vector de acción tomado por el agente es $\mathbf{u} = (u_1, u_2, u_3)$, tal que $u_1 = \{-10; 0; 10\}$, $u_2 = \{-10; 0; 10\}$, $u_3 = \{-1; 0; 1\}$.

Función de recompensa

En este problema, se busca optimizar el desempeño del sistema en base al grado de movimientos, uso de los *buffers* y tiempos de espera. De esta forma la función de recompensa planteada devuelve un valor + 1 sí y sólo sí el plan mejora y 0 de otra forma. Para poder evaluar la mejora del plan se comparan resultados en dos momentos sucesivos: $\mathcal{L}(\mathbf{u}|\mathbf{s}) = C_1 w_1 + C_2 w_2 + C_3 w_3$; tal que C_1 es el porcentaje de ocupación de los transportes; C_2 es la porción de tiempo en que los buffers se llenan completamente y C_3 es el porcentaje de tiempo de espera total para consumir las partes. Los factores de peso w_1, w_2 y w_3 se fijaron en 0.3, 0.3 y 0.4, respectivamente. Si el resultado disminuye respecto al anterior, entonces se confirma la mejora del plan.

(a) (b) (c)

Fig. 5. Resultados del algoritmo Q-*learning*. **a**) Evolución de la recompensa media por episodio. **b**) Evolución de la función $\mathcal{L}$ a minimizar **c**) Acciones tomadas por el agente para una prueba de 200 interacciones.

Para el entrenamiento del agente artificial se aplicó el conocido algoritmo Q-*learning* usando una estrategia de exploración $\epsilon - greedy$, con un decaimiento de ϵ con el transcurso de los episodios desde $\epsilon = 1$ hasta un valor mínimo $\epsilon = 0.01$. La tasa de aprendizaje usada es $\alpha = 0.1$ y el factor de descuento es $\gamma = 0.9$. Los resultados obtenidos se muestran en la Fig. 5. La Fig. 5a muestra la recompensa promedio obtenida por el agente durante 1000 episodios de entrenamiento. Cada episodio contempla 100 instancias de interacción. Como puede verse, el agente logra converger a un valor medio de recompensa a lo largo de los episodios. La Fig. 5b muestra la minimización de la función $\mathcal{L}$ durante los mismos 1000 episodios y por último, la Fig. 5c detalla las acciones escogidas por el agente en una prueba de testeo de 200 interacciones. En conclusión este ejercicio demuestra la factibilidad de integración entre un agente de toma de decisiones autónomo y un gemelo digital creado mediante la arquitectura de integración presentada.

5 Conclusión

En este trabajo se presentó una arquitectura de software para el desarrollo de gemelos digitales mediante la integración del sistema operativo de robots y un simulador de procesos de manufactura flexible. La misma permite la interconexión e interacción entre diferentes componentes (tanto de subsistemas de hardware como de software) que pueden estar presentes en un sistema de fabricación flexible. También, se presentó una metodología sistemática para el desarrollo de un gemelo digital de un sistema de manufactura y su integración con un sistema autónomo de toma de decisiones y de esta manera, queda habilitado un entorno que, conectándose naturalmente a través de ROS con la planta de manufactura real, permitirá realizar optimizaciones con el paradigma de GD presentado. Adicionalmente, se desarrolló un sistema de toma de decisiones autónomo basado en un algoritmo de aprendizaje por refuerzos para el problema de manejo de materiales en piso de planta. En un futuro inmediato se tiene como objetivo ampliar los desarrollos de este trabajo a casos con más componentes de hardware y software para abordar otros casos de estudio en vistas a analizar el desempeño de la arquitectura de software propuesta.

Abstract. Given the nature of agricultural activities and the environment that they are managing, it is necessary to develop different plans that integrate available resources and climatic conditions to achieve positive results in the future. In many cases, there are different types of errors such as the use of a selective averaging method that ignores uncontrollable factors negatively impacting your forecasting and planning. In the case of banana crops, the climatic factor has relevant affects the harvest, and poor planning seriously impacts the supply chain since delivery times to countries that do not have the necessary conditions to harvest are very high. As a solution, this work develops the integration of two models, one for forecasting and the other for harvest cutting, which seeks to minimize cost variations and allows the desired synchronization in the process of managing the operation. First, the relevant factors to make a correct prediction was identify including non-controllable variables such as rain and associate it with an autoregressive model, resulting in the relationship between precipitation and the percentage of bananas harvested, then developed a planning model as support to find efficient use of the available resources and determine a harvest schedule that responds to the best possible fulfillment of the company's demand, finding the best results through the optimization of a non-linear mathematical model. The results obtained in this paper generated a prediction with higher reliability and a capable harvest cutting planning model, deep food safety, and following the objectives of the company.

Keywords: Agri-business, Integrated Business Planning, food security

1. Introduction

Numerous studies in nutrition show that a healthy meal always begins with the consumption of at least one fruit a day. Banana is one of the fruits with the highest nutritional content, also it is the most important tropical fruit of the world, there are as more than 200 cultivars existing in countries that grow them. (Pareek, 2016) This is evidenced in that 20% of the world banana production is destined for world trade, which makes it, together with apples, grapes and citrus fruits, the most important set of fruit products marketed in the world. Knowing the value of this fruit, which extends worldwide, there is an interest in knowing the conditions in different aspects that surround or make possible its commercialization at such scales. This involves, the places where it is produced and how they do it; On an economic level, the impacts it can have to be sustainable and how they can transform or influence elements that go beyond the economy. Although, the fruit is present in many places given its nature, Colombia, due to its characteristics at the geographical level, has important advantages, as well as difficulties that can be decisive in the execution of objectives.

Within trade, Colombia is currently the fifth largest exporter of bananas worldwide, after Ecuador, the Philippines, Costa Rica and Guatemala. It is estimated that its fruit production reaches 106,000 tons per year on average (Redaccion caribe, 2018). Colombia has had a relatively long tradition as a net producer and exporter of Cavendish Valery type export bananas although it also grows another type known as Creole banana. Banana agribusiness has developed as a traditional agricultural export chain, generating important foreign exchange for the country, maintaining its position as a net exporter, after coffee and flowers. This generates in the country, 95 million cases a year, with an approximate value of US $ 700 million a year and constitutes 3.0% of total exports and 6.0% of non-traditional ones, participating with 0.4% of GDP ((FINAGRO), 2018)

Banana cultivation, given its natural characteristics or because of the context in which it develops, needs planning that considers several aspects from the land where it will be planted until its commercialization and each stage itself can be a planning situation, where they influence External factors such as transport and the destinations where they are going. This work focuses on a part of the whole process concerning the harvest stage and seeks to design a plan that meets one of the fundamental objectives of any industry, supply-demand synchronization and cost minimization.

We describe our main findings as: (1) we give a geo-spatial analysis for farm banana production, and replaced previous prediction methods for the cutting orders, then (2) we develop a model for optimizing the cutting order for banana production. Finally, (3) all things together make the best of our new proposed problem setting: A Geo-Prescriptive Integrated Planning Optimization Model for Banana crop production. This article is composed of the following sections: In Section 2 we present the literature review about the problem under study; section 3 includes methods and procedures;

section 4 provides experimental/numerical settings; section 5 results and discussions. Finally, we end up with the conclusions of the paper and some future research.

2. Literature review

This paper seeks to solve the problems of synchronization of supply and production adapted to a agriculture specifics case in banana crops. models of demand forecasts and predictions through data analytics that automatically affects production to product cut planning were used, considering the available resources and external factors that can have an impact on the entire chain of activities that make it possible to satisfy demand knowing the importance of in supply chain sustainability (Hazen, Skipper, Ezell, & Boon, 2016) and analysing multiple factors that are related to the moment of making decisions. .

One of the most important factors to bear in mind when analysing agriculture are the climatic changes, which has been of great scientific interest lately, due to the way they impact principally in food security. Between 2007 and 2017, the European Union allocated more than 1500 million euros to more than 250 programs led the Food and Agriculture Organization of the United Nations (FAO) in 60 countries, to address food insecurity and issues of agricultural development related to conflict, migration, environment and the challenges of climate change. and many of the investigations aim to control this in regions of difficult water management, as part of the fulfilment of goal 2 of the Sustainable Development Goals - European Commission: end hunger, achieve food security and improve nutrition and promote sustainable agriculture ((FAO), 2018). Research like (Campbell, 2016) names it as of the major challenges of the 21st century and explains in detail the importance of this branch of science. On the other hand, (Myers, 2017) reviews the main pathways by which climate change may affect our food production and make an interesting analysis of the pathways for impacts of climate change on food systems, food security, and undernutrition.

Banana crops are not unrelated to these factors, especially if they are grown in tropical regions where changing rains become a deciding factor in knowing the exact time of harvest and cultivation. To do this it is very important to determine patterns of rain behavior and its effect on the crop. (De Perez, 2019) demonstrates that the combination of rainfall observations with seasonal forecasts can further change the range of possible outcomes to indicate a greater or lesser risk of food insecurity. (Generoso, 2015) finds for a particular household how the variability of interannual and seasonal rainfall has an impact on food security and (Iizumi & Ramankutty, 2015) analyses how climate might influence crop production, including cropping area (area planted or harvested) and cropping intensity (number of crops grown within a year) and finally (Caicedo Solano et al., 2020) define complete a methodology to minimize waste in agricultural banana production systems to ensure sustainability.

Make Forecasting for agricultural data presents great challenges, especially nowadays with the ever-changing climate. (Srinivasan, Giannikas, Kumar, & Guyot, 2019) pose an interesting question to the problem of crop production planning. They estimated suitability and risk parameters and used them in a mean-variance analysis to calculate the optimal sourcing decision under a data-driven modelling approach. Furthermore, (Majumder & Kumar, 2019) present a good study on how accurate weather forecasts improve the predictions for better crop planning. In their case, they study the effect on adaptive farmers, but the method is still of great value for all types of crops. ((Rebortera & Arnel , 2019) , propose a recurrent neural network- long short-term memory (RNN-LSTM) has been used as a new alternative model in time series (TS) forecasting. They proved their method using a banana harvest data from Philippine's cooperative of producers. To our knowledge, this is the most advanced implementation of new prediction techniques for banana crop harvesting.

By viewing the crop processor from a global processor and comp parts of a supply chain, various authors aim to analyse crops comprehensively (Fuchigami, Severino, Yamanaka, & De Oliviera, 2018) presented a literature review of mixed-integer programming (MIP) applications in the fresh agri-food supply chain (ASC). They show that, because of the strong need to increase the efficiency of the supply chain, the planning models have become of increasing importance to producers and companies. However, none of the articles cited in their document relate to banana crops. Also, (Soto-Silva, Nadal-Roig, & González-Araya, 2016) review some of the literature on operational research models applied to the fresh fruit supply chain. They conclude with an outline of the significant new problems facing the industry like the lack of holistic approaches for the design and management of fresh FSC and give directions for future research. Also, (Villalobos, Soto-Silva, & González-Ara, 2019)- from the same group - presented another review on research directions in technology development to support real-time decisions of fresh produce logistics.

In one of the most relevant studies published for fresh fruit supply chain tactical modelling, ((Ahumada & Villalobos, 2011) presents an integrated tactical planning model for the production and distribution of fresh produce. The main objective of the model is to maximize the revenues of a producer that has some control over the logistics decisions associated with the distribution of the crop. (Le Gal, Mérot, & Moulin, 2010) propose a conceptual framework based on three sub-systems (biophysical, technical, and decisional) interacting within the farm is proposed to guide this process. An important part of agricultural production is to handle risks while appropriately managing costs. (Voldrich, Wieser, & Zufferey, 2019) study how, in the context of a global food supply chain, the combination of processing time and cost (PT&C) with operational risk (ORk) yield a novel integrated

3. Methods and procedures

For the application of this methodology, a company in charge of the harvest and logistics of banana plants was analyzed, which currently like many others, uses a method whose success is based on the experience and predictive capacity of the analysts involved in defining the forecast. At this point the data is not completely analyzed, nor are technological tools used to automate and improve the forecasts made. Instead, the company uses a method were defined as a mechanism based on the calculation of a selective moving average that depends entirely on the analyst's decisions to subjectively define the weeks in which the demands behaved similarly, and based on this, generate a forecast from which the company gives the order to harvest.

The banana supply chain has a complex procedure due to be a perishable food product. To develop the operation along the chain, it is necessary to analyze from the components of the land where it will be sown until the detail of how the packaging and transportations system will be to reach the final clients. The planning process begins by calculating the numbers of clusters to be harvested according to their age (from 8 to 12 weeks), the total banana ratio, and the percentage of short-type fruit. With these forecast values, and the historical data the following elements are calculated:

- Quantity of fruit clusters to be harvested (Rac Cos) for each farm and total, this by adding the forecast of racism harvested by age and each of the farms respectively.

- Premium banana percentage (% Premium), which corresponds to the highest quality fruit, is calculated by complementing the forecast of the percentage of short fruit (% Short).

- The ratio of the short banana is calculated by the product of the percentage of short fruit and the predicted total time. The Premium fruit ratio is the complement concerning the total ratio and that of the short fruit.

- The number of short fruit boxes (short boxes), corresponds to the product of short fruit ratio with the number of clusters to be harvested. In the same way, we proceed to calculate the number of Premium boxes and the total amount of boxes refers to the sum of these two quantities.

- The quantity of cut clusters, refers to the number of clusters that were collected (if they are previous weeks) or predicted (if it is the following week) in the corresponding week.

- The clusters harvested by tape and pocketed by age, refers to the harvests by age of specific land, where week 12 corresponds to the forecast of clusters to be cut with this age of this week. So that the numbers 8 to 13 correspond to the age of the fruit. Following this logic, the value for 11 corresponds to an approximation of the amount of fruit cut with this age in the previous week (week 31), that of 10 to the approximate age of the previous 2 weeks (week

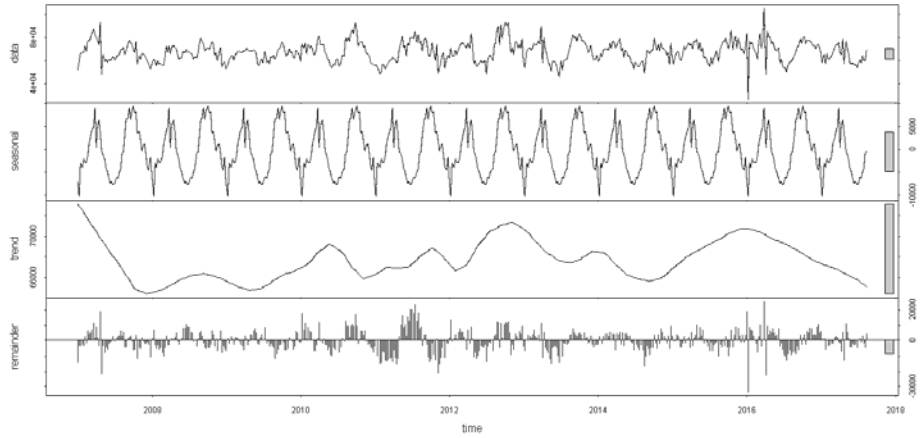
30), so on. Therefore, the total corresponds to the approximation of what is harvested by a plantation that began the ripening cycle 12 weeks ago (week 20).

- The values of week x (week 8, week 9, …, week 13), correspond to the percentages of the harvested (if they are previous weeks) or forecast (if it is a subsequent week) in the corresponding week. Calculated by the reason of real packing (Emb Real), the number of banana bunches that are demanded from the farm, and the value of bunches cut by age. The recovery is the estimate of the percentage of demand covered by the plantations that began to mature 12 weeks ago.

- The year and week of packaging (Year Emb and Sem Emb) refer to the calendar year and week of the period.

- The year and week of harvest (Year Emb and Sem Emb) refer to the year and week relative to which the harvesting began, with a lag of 11 weeks concerning the calendar week.

- The abbreviation "Has" refers to the size of each farm in hectares and Bell/ha is the yield of fruit clusters per hectare, calculated as the ratio between the actual packaging and the size of the farm.



For the beginning of the design process, information on the behavior that the system and its results with the current methods implemented were gathered with real data of what has been its sales, demand, and the costs that having been incurred, principally the operational costs specifically in the harvest, this was obtained to perform the analyzes and made the design process of each section validating with data the fulfillment of objectives by the general design. It should be noted that due to the industry in which the company develops, it is divided into groups of farms for production, some of them own and others that respond to suppliers or subcontractors. For the purposes of the study, this research was done with a small group of farms of the company and the one that has the greatest contribution in terms of production. This paper proposes an integrated planning optimization model which is a process to better match a manufacturer's offer with demand by better planning the operations to create a single production plan. The broadest objective is to obtain an integrated vision of planning by extending the forecasting process to sales, marketing, finance, and operation for its contribution and collective adjustments.

4. Results and Discussion

To carry out the statistical analysis of the behavior of the harvests, weekly harvest data were analyzed over 10 years between 2008 and 2018, the graph below was developed with information of the harvest and made through the software R initially shows the

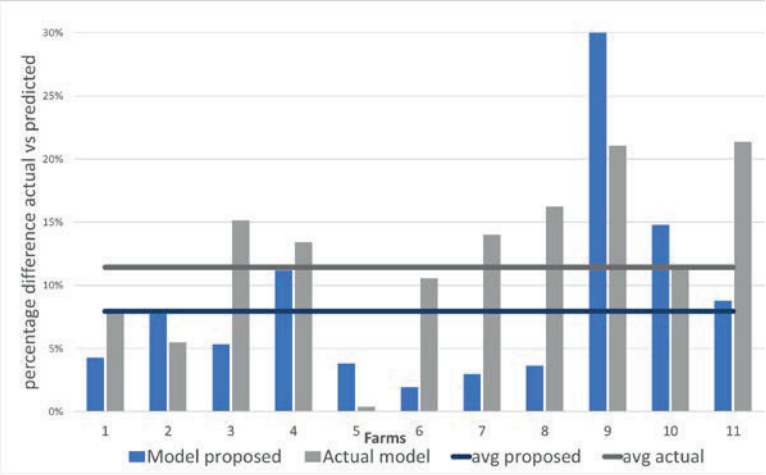
natural behavior, then what would be its seasonal behavior, its trend and finally the behavior of errors based on the behavior of the trend, showing that there is no constant trend in this process, but a seasonality in the series

Fig. 1. Decomposition of the time series for banana crop harvested

4.1 Forecasting Methods

we propose to find the relationship for the inclusion of rainfall in the forecast through a correlation model. The sectors included were defined when presenting rainfall data. Next, the correlation model for each sector will be calculated and the data is fed to the optimization model. Generated a relationship factor through the correlation coefficient between rainfall and cutting percentage. In this way, the Spearman correlation coefficient for each sector was calculated. Also, in order to define the percentage of fruit that will be cut with respect to the forecast, the average rainfall per sector is needed, the formula to define the percentage of what will really be cut considering the rains are:

$$\%\ Cut\ with\ rainfall\ _{i,t} = 1 + \left(\frac{(Correlation\ coefficient_i\ , * rainfall\ precipitation\ _t)}{average\ rainfall\ of\ the\ sector_i}\right)$$



Where i is the sets of possible locations and t is the sets of the weeks of a year. However, the sensitivity of each sector to rains must be taken into account, that is, the higher the average rainfall in a specific sector, it means that both farms and crops located there are more accustomed to rainfall compared to others that have a lower average, therefore it is likely that the cutoff percentage is less susceptible to the rainfall generated. In this way, the higher the average rainfall value in the sector, the percentage of cut is less sensitive to rainfall and therefore increases. From this formulation the

adjustment to the forecast is made by multiplying the percentage of cut including the rains with it.

The R-project software tool was used using time series analysis particularly the ARIMA model due to the seasonal characteristics of the data, which were repeated every year or 52 weeks. For reducing the bias on the forecast the average error was calculated training the model with the forecasts for week 2 harvest until week 31. With the mean error (ME) calculated, a forecast correction was made with the subtraction of the ME and a fixed value. To carry out the correction test, the correction was predicted and applied for the weeks of 32 from a year to week 9 of the next year, this analysis was done for all farms, and for all types of fruit, the adjustment of the forecast given by the ARIMA models, through the ME results in the reliability of 99.426%. This reliability is superior to that resulting without the adjustment of ME 98,724% and that of the current process 99,059%. That is, an improvement is made with respect to the current model at 0.367%.

Figure number 2 is observed the percentage difference related to the quantity of real cut banana and the forecast using the current and the proposed model, out of the 11 cases analyzed, 9 won the proposed model with an average approach of 6% when the current one had 12%. In general, the model proposed using the correlation coefficient shows improvements of 6% compared to the current one used. This impact could also be associated with food security, since a better approach to reality can cut the fruit in the exact moment to be transported.

Fig. 2. Percentage difference related to the quantity of real cut banana and the forecast using the current model and the one proposed in 11 farms

Once important elements of the system were identified, their current status and the harvest was forecast, a mathematical model was designed to plan the cut based on the

search for the lowest operating cost and considering the restrictions associated with the operation.

4.2 Mathematical Formulation of harvest cutting plan

In what follows, the integrated production planning model follows.

Indices for the model:

- *t:* index that identifies days of the week for cutting, $t = 1, ..., 7$

The variables used for the model

.

- *Xt*: Clusters to be cut in week
- M_t: Clusters to cut day *l*, in week *i* of the farm *f*
- H_t : Cutting clearances in week *i* of day *l* of the farm *f*

System Parameters

.

- *D:* Demand to replace in the week considering the rains
- *R:* number of clusters that can cut a person
- *r*: ratio of farm cluster by box
- *A*: capacity of clusters in the farm
- O_t: designation of cut for day *l* E (0,1). at least one must have the value of 1 and least one must have the value of cero for transport
- P_t: people required for the *l* day of the week *i*
- *Cw*: cost by worked required
- *Cm*: aggregated cost by produced box
- *M*: dummy variable cost

Objective function

.

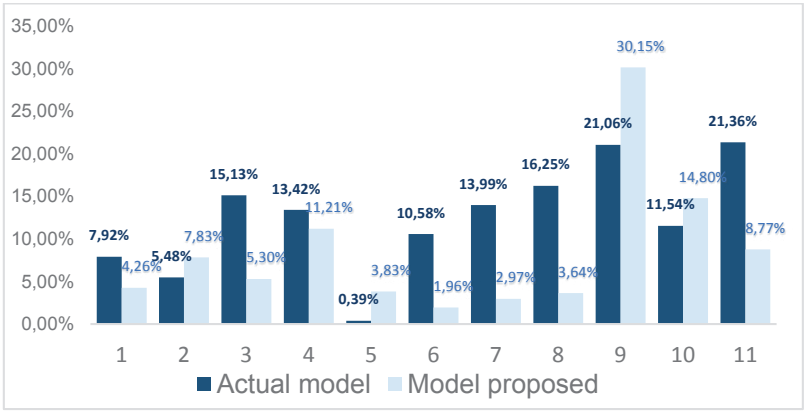
$$\text{Zmin} = \sum_t \left(\left(\frac{M_t}{R} + 4 \right) * O_t \right) * \text{Cw} + \sum_t \left(\frac{M_t}{r} * O_t \right) * \text{Cm} + \sum_t H_t * M \quad (1)$$

Constraints

$$\sum_t M_t * O_t + \sum_t H_t * O_t = D \quad (2)$$

$$\frac{\sum_t M_t * O_t}{R} \leq A \quad (3)$$

$$\sum_t (M_t * O_t) = X \qquad (4)$$



$$M_t = \frac{X}{\sum_t O_t} * O_t \quad \forall\, t \qquad (5)$$

$$M_t, X \geq 0 \quad \forall\, t \qquad (6)$$

Equation (1) represents the objective function within it containing 3 summations associated with each cost; The first of these is related to labor costs, the second is associated with the costs of materials required and the last one takes into account the costs required to meet demand. Within the constraint equation (2) is associated with meeting demand, equation (3) has to do with meeting the capacity of bananas cut on a farm, equation (4) is used to calculate the total value cut in one week and equation (5) is associated with balancing the cuts per day, that is, every day that can be cut, the same amount is cut. Finally, equation (6) is the equation related to non-negativity. This optimization model seeks to reduce operation costs to the maximum by considering weekly demands. The idea is that this model be replicated in each farm for each type of banana and in each week and thus ensure the optimal way to make the cuts considering the demand forecast above

Comparing the model to the one used before in 11 farms in a period, it is observed that the precision (different between real and model) of the cut order generated through the planning model and methodology used in the project is 91.39% while the precision of the current cut order model generated is 87.54%. In this way observed that with the proposed method a better cutting order is 3.85% more precise than that generated by the company.

Fig. 3. Comparison of both cutting orders with respect to the actual cost

Using the method proposed including the rainfall correlation factor the company could have to buy 2594 bunches less than using the normal methods, this means spent less on buying bunches to cover the demand due to the increase in the accuracy of the generated order. On the other hand, to evaluate the impact that the inclusion of the precipitation factor has and the quality of the calculated ratio factor in the generated prediction, rainfall is shown as well as the comparison of cut orders generated with and without rains. Considering a total real packing of this week, this is 79013 bunches, in this way it is determined that the inclusion of rainfall in the model improves the accuracy of the cutting order by 0.475% taking as reference the total real packing.

Impact of rain consideration		**Precision**
Total to be cut (excluding rains)	79688,22849	99,146%
Total to be cut (considering the rains)	79312,36128	99,622%

Table 1. Comparison of cutting order with and without rains

5. Conclusions and future research

The use of formal methods, the inclusion, and considerations of uncontrollable factors and the evaluation of their impacts, as well as the correct identification of restrictions and changes of the system, allow designing a mathematical model suitable not only to minimize costs but can synchronize the best possible supply-demand relations, general objective to which this project responds successfully. With the improvement of the forecast and delivery of prediction, the planning process undergoes an improvement. From a forecast with better reliability, a more accurate cut order is generated.

The use of computer tools (R-project) for the generation of forecasting models allows better accuracy when forecasting, compared to the current intuitive forecasting model. Obtaining a comparative improvement of 0.367% of confidentiality in the long term in our forecasts. The inclusion of the factor of rain in the prediction model makes that the forecast is closer to the real, in this way the veracity of the ratio factor between the rains and the cut percentage is validated and also an improvement in accuracy of 0.475% in the forecast is established final for the cut order. The cultivation and harvesting models are integrated through a set, which expresses a production system that must be fully optimized, resulting in the reduction of production costs due to the overproduction of waste, quality, workers, raw material, and machinery, among others. One of the most relevant contributions of this work was the implementation of mathematical models, which, as in this work is focused on profit in the cutting processes, can be focused on optimizing the safety and control of the operation and also apply it in other activities as irrigation or sowing processes. Collecting the information of each one of the factors was one of the most important barriers to this work, the low access to effective telecommunications make it impossible to communicate and access IoT media that facilitate monitoring and control tasks and allow and implement 4.0

technologies in the agricultural industry giving the possibility to automate different tasks, improving food safety and profits.

Future work must include fruit transportation and the choice of the appropriate transportation system. We have been dealing with different types of equipment configuration for improvements on the transport of fruit, such as the use of 45" reefer containers, bi-train trailers, smaller batch trucks, and more.

A proposal Roadmap to implement Industry 4.0 in SMEs

José Maurício Mottin de Andrade[1] , Eduardo de Freitas Rocha Loures[1] , Anderson Luis Szejka[1], Osiris Canciglieri Junior[1]

[1] Industrial and Systems Engineering Graduate Program,
Pontifical Catholic University of Paraná, Curitiba - Paraná, Brazil

Abstract. Small and medium-sized enterprises (SMEs) represent a large portion of the economy and the availability of countries' jobs. These organizations, compared to large ones, have some advantages such as the faster response to changes and adoption of new systems and new technologies, as well as some limiting factors, such as financial capacity to investments, and reduced human resources to perform all necessary tasks. With the advent of the so-called Fourth Industrial Revolution, new technologies emerge, with its multiple trends in applications and integration of physical and cyber systems, leading to new production strategies necessary for companies to position and competitive advantage in the long-term market. The great challenge for organizations, especially for SMEs, is to perceive and understand quickly, appropriately and assertively, the movement of abrupt changes resulting from these trends of convergence of technologies and systems, which requires training and guidance for the people involved in the process to implement Industry 4.0. The present work proposes a Roadmap for the implementation of Industry 4.0 for SMEs, based on the concept of Lean Thinking. It is intended to present a new perspective through a guideline that supports and allows decision makers to better understand the process to adopt the digital transformation in their SMEs organizations.

Keywords: Industry 4.0, SME, Roadmap, Lean Six Sigma.

1 Introduction

In order to improve production, from the mid-eighteenth century, man experienced three Industrial Revolutions: (1) mechanization at the end of the 18th century, (2) electrification in the early twentieth century and (3) Computing in the early 1970s [24][36]. In the early of XXI century there is the movement towards the Fourth Industrial Revolution, theme presented in 2011 Hannover - Germany, and which has been denominated in different ways in each country, relating to its programs of innovation and technological integration of manufacturing.

This Fourth Industrial Revolution is comprehensive, being defined in several ways by authors in the literature, still without a consensus of a standard description, but which basically synthesizes and refers to the integration and convergence of current technologies manufacturing field [16]. The name that gained greater prominence and popularity to refer the Fourth industrial revolution was the originally presented in the Germany in

2011: "Industrie 4.0" or "Industry 4.0" [4] [10]. In this digital revolution technologies are present simultaneously, both in the various personal devices such as smartphones, tablets, smart products, etc., as well as in industrial control and automation equipment.

Due to its scale, scope and complexity, this industrial transformation is already different from everything humanity has experienced so far [31]. The process requires from people and organizations, greater perception, understanding and preparation to be able to deal with the digital technologies that come up every day, and that generate other new technologies constantly [14]. In this context are small, medium and large organizations, which are all challenged to keep up with the changes brought by the digital transformation of Industry 4.0, so that they stay in the market and do not run the risk of succumbing quickly by not updated. Large companies have greater resources to meet these challenges, but however, small and medium-sized enterprises have several limitations that hinder, delay and prevent the implementation of Industry 4.0.

The SMEs plays a key role in the world economy, and even if their classification changes according to each country, depending on the number of employees they employ, as well as the value of their gross revenues. Such kind of company represents a large portion of national economies, in various sectors with industry, trade, services, agriculture, among others. The great challenge to the SMEs, lies in understanding this movement and digital transformation, and simultaneously overcoming its internal barriers of limited resources - financial, human resources, knowledge in new technologies - to adopt and implement the concept of Industry 4.0.

This scenario leads to the following problem to be explored in this work: "How to support Small and Medium-sized Enterprises (SMEs) so that they can implement the concept of Industry 4.0?". Our proposal is, based on the latest published scientific papers on the subject, to propose a Roadmap that allows SMEs to implement the concept of Industry 4.0 directed to their reality. This proposed guideline will be based on Lean Thinking combined with multiple perspectives of people management, organizational change and digital maturity of SMEs, allowing discovered knowledge to be adopted by professionals from various sectors.

2 Industry 4.0: Technologies, People and Organizations

A "revolution" alludes to an abrupt and radical change, which in history began with agriculture and domestication of animals, moved to the production, transport, urbanization and arrived in industrialization [31].

We understand that the great differential between the four revolutions, is that the first three originally occurred within the factories, and then set out to be adopted by the whole society. The movement started from industrial steam-powered machines to trains, from the electrified lines production, to daily life of homes and commerce, and finally, from the large central computers "Mainframes" and industrial automation controllers, to personal computers [27][33]. In this new context of industry 4.0, technologies, people and organizations will be fully integrated into a complex physical cybernetic

system, which will need to meet new technological, human and organizational requirements, as well as face and overcome barriers and challenges.

2.1 Enabling digital technologies

The integration of cyber-physical systems (CPS) unite the real and virtual worlds, through the various digital technologies present today in our daily lives like: 3D Printing, Virtual Reality and Increased, Big Data, Data and Process mining, Artificial Intelligence, Machine Learning, Mobility, Cloud Computing, Gemini and Digital Shadow, Internet of Things, Collaborative Robots, and smart concept in Factory, Products and Cities, among others [1] [11] [12] [14] [35].

The Industry 4.0 are guided by principles as interoperability, real-time decision making, decentralization, virtualization, modularity and service guidance. The expected benefits and results are the improvements of production processes, greater human-machine-machine interaction, ubiquity of information. Also, increased safety and reliability, resource optimization, cost reduction and waste, large-scale personalization and technological innovation [4] [9]. Therefore, the transformations brought by digital technologies take people in a new direction in which the development of new capabilities and skills will be necessary.

2.2 People

The development of human skills and capacities is fundamental for the implementation of Industry 4.0. It is important to consider techno-social aspects like knowledge in technology information and new technologies, information analysis, organizational and business understanding. Also, must be consider the ability to work and interact with modern interfaces and media, integration of different processes, management and transfer of knowledge, networking, communication, linguistic skills, teamwork and self-management [8] [36].

Studies on the subject, for the most part, however, still address more the technical aspects of technologies relevant to Industry 4.0, than the management issues and organizational culture. The effort is so that there is a balance of skills simultaneously in the fields of technical, social, personal and methodological knowledge, conflict resolution, decision-making, adding values. In this context it is important consider the norms, beliefs, attitudes such as how the activities are performed, the way people behave, their flexibility, change tolerance, leadership, motivation to learn, commitment and cooperation, ability to work under pressure, thinking about sustainability and ethics [8] [21].

Human Resources Development (HRD) will be important in this context to define the technical-social role of people within the new processes. This can be done through a systematic approach evaluating people´s maturity levels with appropriate tools and support them in order to reduce the level of inhibition and support the process of change, by a transparent and open communication culture [27].

Professional Management includes studies with proposals for HR-oriented life cycles, which consider planning, attraction, recruitment, support, skills areas, retention and output of a system employee. After that, a new cycle starts with a new planning [28] and where the new requirement for Leadership 4.0 is defined as well [26]. It seems that

the fourth industrial revolution is only at a very early stage, not yet fully understood by people, what will affects on society, organizations and individuals. Also, how companies will deal with a paradox between be open and adaptable to external effects and simultaneously how to keep knowledge and intellectual property internally [28].

2.3 Organizations

Because people´s personality is unique and individual, their combinations when grouped, build organizations also unique which makes the entire system very complex and dynamic. Traditional hierarchical models of shop floor, office and peripheral departments of logistics, inventory and support; do not fit the new concept of the fourth industrial revolution [24].

The new industry presents an autonomous and intelligent manufacturing model, where physical and cyber systems interact instantly in a collaborative work, controlling and monitoring the entire process without human intervention. This new configuration will be supported by an information technology infrastructure and Communication, digital modeling, data collection, storage and processing advanced system [36].

What is required here is a long-term transformation of our global perception of industrial production through the perfect connection of the digital and real worlds. The principles of this new factory design are modularity, decentralization, virtualization, service guidance and real-time capacity and interoperability [1] [11] [13]. This new manufacturing configuration is a four-dimensional physical-cybernetic system: the factory and smart products composing the real physical world; and data-oriented operations and services, these in turn, composing the virtual world [14] [17].

Interoperability functions as a catalyst, as it allows continuous communication between machines and systems, in open standards with flexible interfaces, providing a layer where everything works in an integrated way - information, services and processes. Some authors include other perspectives like, economic, technological and social [5] [9], which makes the whole process of implanting Industry 4.0 challenging with many barriers to be overcome.

2.4 The requirements, challenges and barriers to Industry 4.0

The challenges and barriers to be transposed into the implementation of Industry 4.0 are multifaceted and related to cultural factors of people and organizations, technology and innovation, infrastructure, workforce qualification, communication. Additionally, must be considered factors related to economy, jurisdiction, policy, environmental, social, accelerated pace of new technologies and difficulty understanding and absorption of the theme because it is still very incipient [30][33].

The main feature of the Fourth Industrial Revolution is real-time decision making and response, and following in this sense, companies should be agile to develop in an environment still uncertain and turbulent. They should perceive changes in a competitive environment, with immediate demands from integrated platforms and data-based business models [18].

The Implementation of the innovative project of Industry 4.0 is a challenging process that requires a long-term plan – the so-called Roadmap or Technological Roadmaps.

Such kind of plan will evaluate internal (vertical) and external (horizontal) scenarios of organizations, under the strategic perspective, considering existing technologies and experiences, combined with the research of new solutions and markets [9]. In more elaborate long-term plans, are considered in Roadmaps the vertical and horizontal perspectives of integration in the value chain, the product and project lifecycle, personnel infrastructure and the development of new associated technologies [4].

In this respect, a recent study [29] proposes the introduction of a methodology using multicriteria decision analysis (MCDM/A), which allows the evaluation of local and legacy systems for the implementation of projects related to Industry 4.0. The methodology consists in six stages: (1) Process Evaluation, (2) Project Definition, (3) Evaluation of Local Systems, (4) Evaluation of Legacy Systems, (5) Choice of the best solution and (6) Final decision making. Therefore, the Roadmaps for the implementation of Industry 4.0 must consider the socio-technical aspects, from the training of people, the assessment and preparation of organizations regarding the processes of change, in the context of new technologies brought about by digital transformation.

3 Small and Medium Enterprises into Industry 4.0 context

SMEs need special support in the process of implementing Industry 4.0, due to their specific limitations in understanding the digital transformation movement, their internal barriers of limited financial and human resources, and acquisition of knowledge in new technologies, which must be overcome. SMEs have specific management and business models that should be considered in the process of implementing industry 4.0. In a recent study Moeuf et al. [20] highlight that such kind of companies are not directed to the transformation of your business model, since they are not yet as well equipped, and prepared to implement Industry 4.0.

According to this study, SME´s initiatives still are cost-oriented, exploring IoT and Cloud Computing technologies, only for tasks of monitoring of production, and improving the capabilities and flexibility of current processes. Also, SMEs have an analytical structure composed by: (1) Industrial performance objectives; (2) Management capabilities of industrial processes and (3) Means for the realization of Industry 4.0 for its technologies [20].

According to Müller et al. [23], the business models of SMEs should consider three points: (1) Value Creation, (2) Value Capture and (3) Value offer; and the main issues are how such companies perceive and understand the phenomenon of Industry 4.0. The authors also highlight how SMEs can innovate their business models as a result of this transformation movement into the dimensions of process digitization, intelligent manufacturing and connectivity between companies. Finally, the study encourages SMEs managers to explore other forms of innovation in their business models, with customer orientation and not to the product, search for new methods of payment by customers and individual adaptation to each customer, that is, customization.

The difficulties encountered by The SMEs to implement Industry 4.0, according to Sevinç et al. [32], reside in four main areas: 1) Innovation relative advantage, complexity, relevance, relationship and Intelligibility, 2) Organization to support of high

management, organizational size and specialization of the IT area, 3) Environment the competitive pressure, external support and distrust of the real benefits and 4) Costs related to the transition, maintenance, technical support and training. Within this context, the Lean Thinking and Six Sigma concept can be applied into the Roadmap to provide an underlying support base for SMEs to implement Industry 4.0.

3.1 Lean Thinking and Six Sigma (LSS)

The Lean Thinking was developed from the Toyota Production System (TPS)[37] and Six Sigma was developed at Motorola in the mid-1980s [34]. In general terms both concepts are focused in improve process efficiency, eliminate causes of defects or errors, eliminate of losses and waste, and resources optimization, which are fully adherent to Industry 4.0 philosophy.

For this reason, both concepts can provide an underlying foundation and can be applied in the digital transformation implementation. Important to remark that the application of those methods can be alone or combined and depends on the field and degree of the problem to be evaluated and the problem which is intended to be solved [2] [34]. In a recent study Moya et al. [22], highlights 5 hierarchical groups of critical success factors for SMEs to implement Lean Six Sigma:(1) External relations, (2) HR management; (3) Project Management; (4) Strategies and (5) Process Management.

According to Müller et al. [23] SMEs tend to view Industry 4.0's new business models with caution due to their resource limitations and specific difficulties, and therefore require differentiated and adapted solutions. According to Sevinç et al. [32], SMEs have greater difficulties with their own organizational structure and costs to implement Industry 4.0 and less difficulty in understanding the issues of the environment and innovation.

Antony et al. [3] proposes two questions should be asked for a Lean and Six Sigma application approach: "(1) Is the solution known or unknown? and (2) Is the root cause of the problem believed to be in a value aggregation step in the process, or in the links between the value addition steps?". Both questions must be considered during maturity analysis and implementation of Industry 4.0 from technology, people and organizational changes point of view.

3.2 Digital Maturity

In his study, Mittal et al. [19], points out that Strategies of SMEs often depend on the owner, leader or manager, and the adoption of Industry 4.0 depends on their understanding of the theme, and its willingness to proceed with the necessary change. As barriers relevant to digital maturity, it highlights the resistance to the adoption of advanced technologies and digitization, the high training of employees, the highly centralized processes, non-compliance with technological norms and protection of intellectual property rights. Related to the dimensions of digital maturity, the author highlights: Strategy, Leadership, Customers, Products, Operations, Culture, People, Governance and Technology. As a great highlight the authors note that there are initial technological conditions for each SME, which should be considered in maturity models adapted to this type of organizations.

In a recent study North et al. [25] points out that there are a growing number of maturity models for companies, many of which were developed by consulting firms, are focused on large corporations, and aimed at processes, not training, not being fully suited to small and medium size companies. The level of maturity perceived in this study is moderate and indicates that SMEs are more focused on perceiving the environment, and less about taking advantage of the opportunities offered by Industry 4.0. The maturity evaluation is an important step in the Roadmap for SMEs to do an assessment of their real situation face to digital transformation in order to identify the opportunities to take, needs of knowledge to be acquires and barriers to overcome.

3.3 Strategic Digital Roadmap and Framework

The Roadmap developed by researchers consider different perspectives structured in phases or steps that address in general the creation of an initial common understanding, identifies and evaluates the different scenarios relevant to the organization, prioritizes and prepares the implementation plan [10] [15]. In his study North et al. [25], presents a Framework for SMEs that considers dynamic growth capabilities digitally enabled holistically and oriented, as a proposal to fill a gap for such companies on their self-assessment of digital maturity. The study highlights four main points: (1) Detection of potentials of digital growth; (2) Development of a strategy and mentality for such growth; (3) Digital learning and (4) Resource management for digital transformation.

Ghobakhloo [7] in turn, reviews the ongoing research on Industry 4.0 and seeks to offer a strategic Roadmap, which serves manufacturers and serves as a guide to the digital transition process. This guideline presents six main steps: (1) Strategic Management; (2) Marketing Strategy; (3) Human Resources Strategy; (4) IT Maturity Strategy; (5) Intelligent Factory Strategy and (6) Value chain management strategy. Considering the descriptions in previous section 2 and 3 related to technologies, people, organizations, barriers and difficulties and Lean Six Sigma in the SMEs context, we propose our Roadmap in the next section.

4 The proposed Roadmap model for SMEs 4.0

The digital transformation brought by the fourth industrial revolution has required attention from small, medium and large organizations to update themselves and adapt to this new reality, so that they remain in the market and do not succumb in a short time.

Technologies are increasingly present in the daily lives of people and companies, both in product production and service delivery. The integration of such technologies in the structure of the business model requires perception, analysis, decision making and actions from the managers to monitor this movement. Because it is still an incipient topic, many people do not have a clear view on how to visualize, understand and implement Industry 4.0 in their organizational reality, and for this, a Roadmap becomes a fundamental tool in this process.

As for large organizations, many of them already have maturity and a plan to implement Industry 4.0, some of them are at the forefront as forerunners in the subject, they are large, have more resources and structure to take the lead in the adoption of Industry

4.0. However, most global companies are small and medium-sized, where resources and structure are limited and scarce. These limitations are a huge barrier for such categories of organizations to also adopt the context of digital transformation.

One of the most challenges for SMEs lies in the fact that they are at a beginning where they do not even fully perceive and understand the concept and importance of Industry 4.0 in their business models, and precisely because they are not understand, run the risk of ignoring and neglecting and to succumbing in a short time. In this context, this research aims to fill a gap of knowledge, proposing a Roadmap applicable to small and medium-sized enterprises, so that they can perceive, visualize, understand, adopt and implement Industry 4.0. Therefore, SMEs will have support from that tool from its strategic planning to its operational processes.

During the development of this work, papers were consulted that address different points of Industry 4.0: global overview and trends of Industry 4.0 [13] [16] [24], enabling digital technologies [5] [12] [35], people management issues [28] and leadership 4.0 [26], organizations change factors [18] [21], maturity digital analysis [1] [11] [19] [25]. Also was found considerations related to requirements [17], challenges [30], success factors and barriers [33] related to Industry 4.0, the SMEs inside this context and also into Lean Six Sigma concept [20] [22] [23] [32]. Also, other issues were addressed like the Roadmap for the implementation of Industry 4.0, from the perspective of the organization and technologies [4] [6] [10], standardization [15], and the necessary human resources skills [8].

Those studies show that organizations develop their business plans considering the strategic, management, culture and people perspectives. They highlight the data generated by their most diverse systems and equipment, seeking to discover patterns and knowledge so that decision-making in its operations is aligned with their business models and strategic plans [18]. Those work, also address the perspective of organizations and enabling digital technologies, their areas of knowledge, the guiding principles of this industrial revolution. Are mentioned also the strategies, investments, infrastructure and physical-digital systems, maturity analysis and implementation of Roadmap with analysis of benefits, capacities and filling of knowledge gaps [4] [6] [10].

Taking all considerations above, we propose a Roadmap according to Figure 1.

Figure 1. Roadmap. (Source: prepared by the authors)

This guideline addresses six main steps as described below:

1) **Vision** – The necessary work of raising awareness of managers and decision makers in SMEs related to Industry 4.0, its strategic importance for their organizations in the short, medium and long term. At this stage the objective is to detect the primary needs for organizations, sensitize managers so that there is an initial understanding and alignment within the context of digital transformation and its technologies.

2) **Strategy** – At this stage the organization will evaluate its strategic positioning considering the internal and external environments, its business model, its vision of the objectives and goals to be achieved, or even altered in the face of the new reality that Industry 4.0 offers. As well as the definition of expected results, identification of new opportunities that can be taken advantage, also barriers and challenges to be overcome.

3) **Organization** – At this stage, managers need to self-evaluate their current conditions and future needs to implement Industry 4.0. On this phase are considered: organizational structures, IT infrastructure, R&D development, their processes, the knowledge needed to monitor this new industrial revolution, mainly current human resources, their skills and capabilities, the needs of new training and the gaps that should be filled.

4) **Analysis** – This important step will be dedicated to an evaluation of the organization's maturity in Industry 4.0: where the company is located, where it intends to be in a soon future, what it will need to do and what it will need to change to achieve its goals. Here are all the steps discussed above, to support decision-making regarding the selection, prioritization and evaluation of projects and objectives to be achieved.

5) **Planning** – It will be dedicated to the issues of available resources and the new one necessary, the standards to be followed, the procedures and methods that will compose the work plan for the implementation of lean six sigma concepts and Industry 4.0.

6) **Development** – It will cover the implementation of a short-term, high-impact pilot project that delivers visible and consistent results for an assessment of the effectiveness of the workplan, with the necessary adjustments for its definitive implementation of Industry 4.0.

5 Conclusions

SMEs face challenges and barriers for the implementation of Industry 4.0 to a higher degree than large organizations, due to their major limitations on lack of resources, support and access to technological knowledge and methodologies, as well as to people management issues and organizational changes.

Therefore, for the implementation of lean thinking concepts and Industry 4.0 for SMEs, a Roadmap is an important tool that can shorten and facilitate such a process, where they are considered the critical success factors related to technology, culture, politics, social, environment and financial.

We understand that the Roadmap proposed in this work will serve as a practical guide where technical, social and strategic aspects of SMEs are considered. Such guideline offers an underlying basis for decision makers to understand, assimilate and adopt the concept of Industry 4.0 effectively, and thus overcome barriers and challenges, take advantage of the benefits brought by transformation digital.

Our perception when developing the present work was that in the consulted studies, the authors focus and deepen aspects related to digital transformation from technical, organizational or social point of view, but not combined in a guidance to fully support SMEs. Therefore, we decided to gather and address in the proposed Roadmap, considering the combination of Technology People and Organization in order to offer a guide which can support and contribute to SMEs in the Industry 4.0 implementation.

Abstract. Manufacturing execution concepts at the highest level of automation and interoperability are proposed by Industry 4.0. This is thanks to a group of information and communication technologies capable of creating integrated and connected systems, known as – cyber-physical systems. This network of integrated systems has been promoting gains in productivity, altering the profile of the workforce and the very conception of the work that will have more cognitive demands, increasing competitive potential. Therefore, organizations are more than ever willing to adapt for this scenario. Aiming to facilitate this digital transformation, avoiding an inefficient allocation of financial and human resources, the present work proposes a framework that provides the necessary guidelines for such a transformation becomes viable. This will be done by a series of analysis using multicriteria decision making methods (MCDM), evaluating the maturity of legacy systems, with a focus in the field of industrial maintenance. Those analysis are also based on the RAMI4.0 architecture, Total Productive Maintenance (TPM), Framework for Enterprise Interoperability (FEI), and will provide companies with guidelines for adequacy plans. To test and validate this framework, a multinational industrial entity belonging to the automotive sector was selected as a case study. The application results confirm that such tool can help in digital transformation projects and indicates adjustments for this to be done in a better way.

Keywords: Industry 4.0, Industrial Maintenance, Multicriteria Decision-Making Methods (MCDM), Interoperability, Digital Transformation.

1 Introduction

In the midst of a highly informational scenario, interoperability is an element to be measured by organizations. Such term represents the capacity of a system to communicate between two or more others, in order to use the shared data and access external functionalities [1]. Among the technologies that seek to consume interoperability in manufacturing, the Internet of Things (IoT), Big Data, Artificial

Intelligence (AI), 3D-Printing, Augmented Reality, Machine to Machine (M2M), Analytics and Cloud Computing stand out. Classified as information and communication technologies (ICTs), they are the basis for Industry 4.0 (I4.0), enabling the emergence of cyber-physical systems. According to [2], some of the benefits that such systems' network have provided to organizations are: increased productivity, alteration of the workforce profile and increased competitive potential. However, for the implementation of those technologies to be assertive, it is necessary that conceptual, technological and organizational requirements are satisfied. As the world experience a time of transition to I4.0, this adaptation recurrently involves legacy systems that [3] characterize as those with high usage times, which are vital to the organization's business, and does not fit into future IT strategies.

Notwithstanding, modernization is not easily prioritized by organization, similarly for the maintenance sector, which is seen more as an inevitable necessity than as a goal to pursue. However, the role of industrial maintenance has become a strategic element to achieve business objectives [4]. To [5] the maintenance goals involve: Safety, expressed through a higher reliability coefficient of equipment prone to critical failures; Availability when considering the time when the equipment is producing at full capacity; Budget, involving the reduction of maintenance costs. Those goas are easily related to the benefits provided by I4.0.

Given the difficulty evidenced by digital transformation initiatives for legacy systems and the expressed close relation between maintenance and modernization goals, the research developed here sought to answer the following research question: "How to define a technology prioritization plan, in the field of industrial maintenance, in order to adapt legacy systems for Industry 4.0 requirements?". Therefore, focusing on the industrial maintenance area and based on an assessment of qualifying attributes of a given organization, this work seeks to establish a digital transformation framework with a set of models based on Multicriteria Decision Making Methods. Our hypothesis suggests that such tool will make it possible to elaborate more assertive guidelines, capable of aligning legacy maintenance systems with the vision of a highly interoperable manufacture, necessary to fully access the benefits brought by Industry 4.0.

2 Theorical Dimensions and Scientific Scenario

The disruptive technologies envisioned for I4.0 promotes to escalate industrial productivity, putting current economic models in check, foster the growth of industrial organizations, changing the profile of the workforce and ultimately increase the competitiveness of companies [2]. Thus, the proximity with the term "interoperability" is evident because of the prominence of such technologies, which will increase the collaboration between systems, machines and people; that way, enabling greater speed, flexibility and efficiency in production processes, resulting in higher quality at reduced costs. The researches presented here will show how those gains can be achieved in the maintenance sector, before exploring others horizons.

Nonetheless, implementing a system with the maturity level necessary to operate in the Industry 4.0 bias will require a digital transformation project. With this in mind, and understanding that every project must operate with a budget, or maximum expenditure's cost, the present work explores a premise that "not everything which is wanted to be implemented (e.g., maintenance functions of a I4.0 system), can actually be implemented".

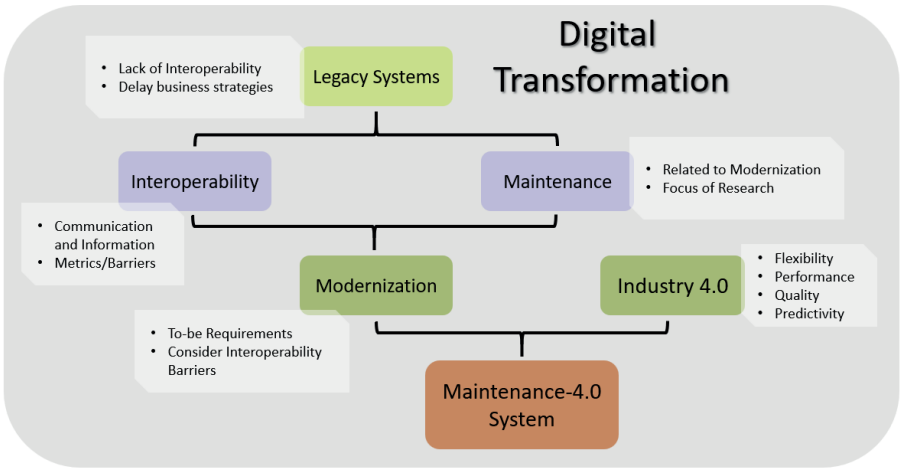

Fig. 1. Research elements.

Considering the Fig. 1 elements overview, the researches in this work explores how to adequate maintenance legacy systems requirements for the I4.0 scenario. By hypothesizes, the technologies suggested for implementation will increase the maturity of a systems considering interoperability barriers, i.e. without harming subjacent systems in the process of implementing those technologies.

2.1 Legacy Systems

Even after three decades of research in modernizing legacy systems, it is notable that many remain in operation. This is due to the fact that these systems are generally very comprehensive [6, 7]. They interoperate with other processes or subsystems, only remain in operation due to their technical complexity of replacement and/or adaptation and criticality in the organization's operations, in such a way that remain in constant activity. Every system is likely to become legacy at some point and its data is characterized as valuable, since its history can be used to understand its behavior in search of optimization [3]. However, to remain competitive, companies must continually change their processes, sometimes radically, and legacy systems can delay modernization processes and directly influence the company's business strategy [8].

2.2 Maintenance-4.0 Technologies

The legacy systems scenario researched for this particular work was constrained to the industrial maintenance, a sector easily impacted by I4.0. With an exploratory character,

a literature review was focused on the Industry 4.0 base technologies that are relevant to the maintenance sector. Here, three research rounds were carried out.

First round. A first research round was sought to understand a general context of I4.0 technologies, and for that, reports with frameworks already formalized in the literature were used. The objective was to gain an overview of I4.0 technologies, in the view of different technology consultants, which were [2, 9–18].

Second round. In the second round, the results from the overviewed technologies where validated in academic articles, focusing on solutions for the maintenance sector. This research round was conducted as follow: (i) was searched the relation between "technology" AND "maintenance" (e.g., Cloud AND Maintenance; or, Augmented Reality AND Maintenance); (ii) only open access articles were searched; (iii) time period from 2014 to 2019 was considered mature since the term "Industry 4.0" appeared by 2011. The research platforms used were: ScienceDirect and Archive Ouverte HAL. At the end, 59 articles were considered.

Third round. Finally, in the third round, I4.0 technologies applied in industrial maintenance were filtered and allocated into categories, regarding more tangible examples of them being applied in manufacture. The whole literature database ended with 87 articles and reports. From it, nine Maintenance-4.0 technology groups were identified: Big Data, Analytics, Artificial Intelligence and Cloud Computing, formalized as cyber-physical subgroup; Advanced Machines, Advanced Materials, Flexible Connection Devices and Digital-to-Real Representation (i.e. encapsulating Digital Twin applied in maintenance activities), formalized as application subgroup; and Sensors (i.e. encapsulating IoT and Smart Sensors, formalized as the bridge to digitalize physical operations).

2.3 Models and Requirements

To allocate maintenance into the conformities of I4.0 in an organized way, two different architectures were approached. The first, Framework for Enterprise Interoperability (FEI) from [19], was considerate by the premise that interoperability might be a relevant metrics to understand what can or cannot be implemented to a system. This possibility is considered because FEI relates conceptual, technological and organizational barriers linked between the enterprise layers, that could be generated by two systems trying to communicate. Coupled with that, the prerogative that interoperability barriers could difficult the insertion of a technology seems feasible, once legacy system and others adjacent systems/processes may share communication-dependence.

The second is a reference architecture model for Industry 4.0 (RAMI4.0) [18], converging multi-stakeholder views on how I4.0 can be accomplished based on existing communication standards and functional descriptions [20]. Analogously to the FEI, which has a broad organizational view but it is not linked to Industry 4.0, the RAMI4.0 presents a similar enterprise's layers perspective. Considering that this research investigates interoperability barriers which might appeared by implement I4.0

technologies in maintenance legacy systems, those frameworks were merged (see Fig. 2).

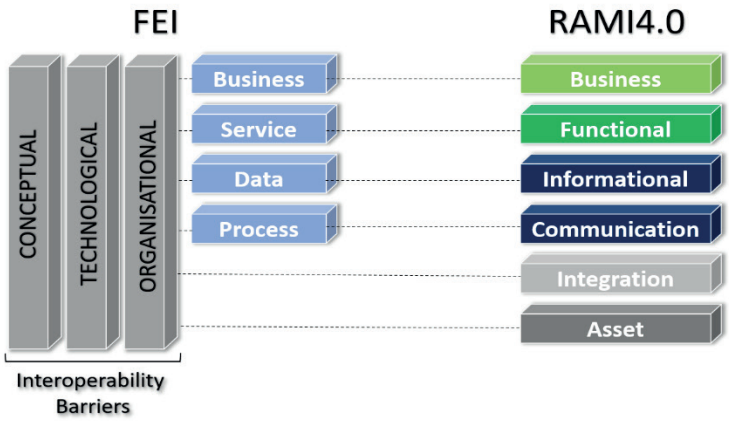

Fig. 2. (FEI barriers) x (RAMI4.0 layers) composed frameworks.

This composed framework was used to promote interoperability elements to an I4.0 referential architecture. The following section explains how industrial maintenance was focused in such vision.

As-is functions. The work [21] describes a study of industrial maintenance through the lens of RAMI4.0 architecture, indicating attributes and functional requirements, which gives this present work directions in how to analyses maintenance systems in an a priori state. Further, the presented case study details this analysis.

To-be model. In order to achieve I4.0 requirements for the maintenance sector, the Total Productive Maintenance (TPM) six big losses [22], were also considerate (see Fig.3).

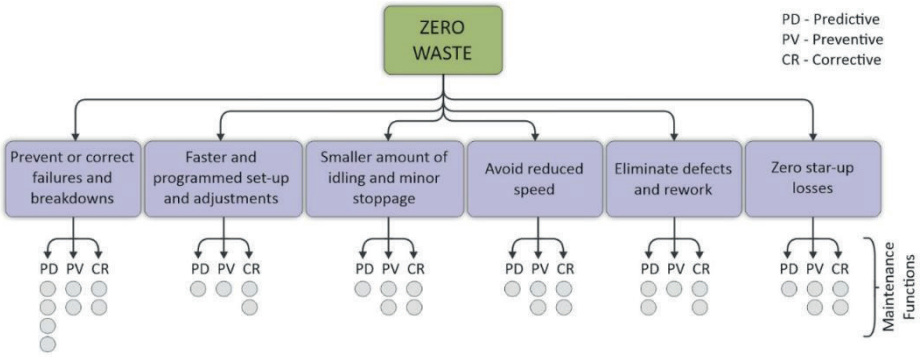

Fig. 3. Referential Maintenance-4.0 reference model based on TPM.

For those losses this model formalizes "courses of action", meaning that, for each loss there is a course of action based on I4.0 vision. Moreover, those courses of action are categorized in three main maintenance approaches: predictive, preventive and corrective [23]. Therefore, the spheres tagged as “maintenance functions” represent Maintenance-4.0 enablers for predictive, preventive and corrective approaches. Our premise is that, the full potential of a maintenance system can be achieved with the technology groups proposed in (2.2).

In resume, aiming to guide maintenance processes to “zero waste” using disruptive technologies, this proposed model serves as a To-be guide, for an As-is analysis [21], due to interoperability barriers. Alternatively, what is needed to implement (i.e. disruptive technologies) according to what is possible to be implemented (i.e. interoperability barriers).

2.4 MCDM

Multicriteria decision making/analysis (MCDM/A) methods, emerged in the search for solutions to complex problems that are difficult to measure. In this work they were used as tools for more assertive decisions in systems optimization, also following a couple of referential researches that applies decision making assessment in the dimensions of interoperability, maintenance and Industry 4.0 are [21, 24–28]**.**

There are four important elements that involve the MCDM methods: Set of “alternatives”, from which the decision is chosen; set of “criteria”, or factors related to making a good decision; the “preferences” of the decision maker, being clear, the problem becomes more understandable; and the “result” of each choice, measured in terms of criteria according to the decision maker's preferences.

Two different MCDM are used for the three steps framework, detailed in the next section. For the Step 01 and 02, the Analytic Hierarchy Process (AHP) [29] is used in order to derive priorities based on sets of peer comparisons, thus it is structured on the intrinsic ability of being to ponder their perceptions or ideas hierarchically [30]. In Step 03, the Preference Ranking Organization Method for Enrichment of Evaluations

(PROMETHEE II) is used, an interactive method designed to deal with quantitative, qualitative criteria and discrete alternatives. This method can classify alternatives that are difficult to compare due to a commitment to standards of evaluation as non-comparable alternatives [31]. According to [32] this method have been applied in varied fields such as industrial locations, labor planning, investments, medicine, chemistry, tourism and ethics.

3 Framework

The framework proposed in this article it is structured in three steps. In Step 01 the AHP method is used to assess the organization's maturity, relating the I4.0 requisites in a maintenance bias. In the Step 02 is also build for the application of AHP method, which will provide the allocation of weights for functions of a Maintenance-4.0 architecture, in order to obtain a selection of the most needed ones. Finally, at Step 03, the PROMETHEE II method will be applied to prioritize the technologies that will best adapt to the functions selected in the previous step (see Fig.4).

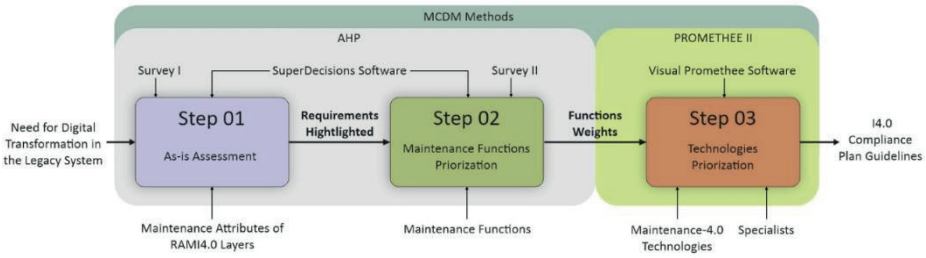

Fig. 4. Framework overview.

It is expected that after applying the framework, a legacy maintenance system will have its main requirements highlighted, indicating what needs to be improved according to I4.0 technologies. The decision methods analysis considers not only what needs to be implemented to improve the system, but also what is feasible through interoperability barriers.

3.1 Maturity Assessment (Step 01)

Once the organization's need to optimize its systems to I4.0 standards is confirmed, in Step 01 an assessment of its maturity in relation to the desired requirements is carried out. For this, engineers and maintainers must be made available, since they will be in the role of decision makers, answering the proposed survey model. Here the AHP method is executed in the "SuperDecisions" software. Its model reflects a maturity assessment that, through the construction of classification structures from the six layers of RAMI4.0, describes the decomposition of a machine in its structured properties, enabling its virtual mapping (see Fig. 5).

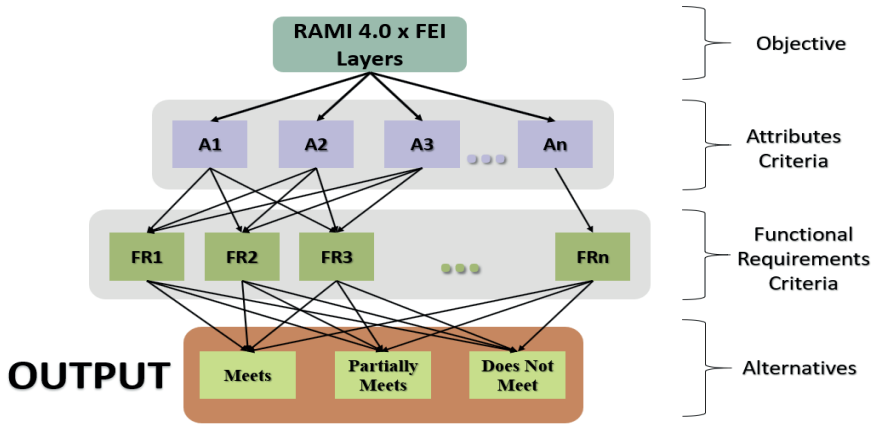

Fig. 5. Step 01 – Maturity Assessment (AHP method model 1).

The name of the analyzed layer will be located at the top level of the decision model, representing the model objective. The intermediate level will consist of attributes and functional requirements belonging to the domain of industrial maintenance, distributed among the six layers to be analyzed [21]. The relation, attributes-requirements, qualifies the analyzed system. At the end, the lower level presents the alternatives: meets, partially meets, and does not meet; related to each functional requirement of the intermediate level. After performing the peer review survey with the decision makers, with no inconsistency value identified by the software, it will perform the AHP synthesis in order to rank the three alternatives, thus providing the result of the maturity assessment for each layer of RAMI4.0. When all six layers are evaluated it will be possible to obtain the degree of maturity, related to the requirements of Industry 4.0.

3.2 Maintenance-4.0 Functions Prioritization (Step 02)

Having delimited the areas with the greatest lack of industrial maturity in Step 01, the objective of Step 02 is to prioritize the maintenance functions that will be used in the optimization process to implement I4.0 capabilities to the legacy systems analyzed. The AHP will be used again in order to assign weights to the functions accordingly to the preferences from the decision makers, not synthesizing the alternatives, as done previously (i.e., this step uses the method to gather the functions weights solely, and not to support a final decision).

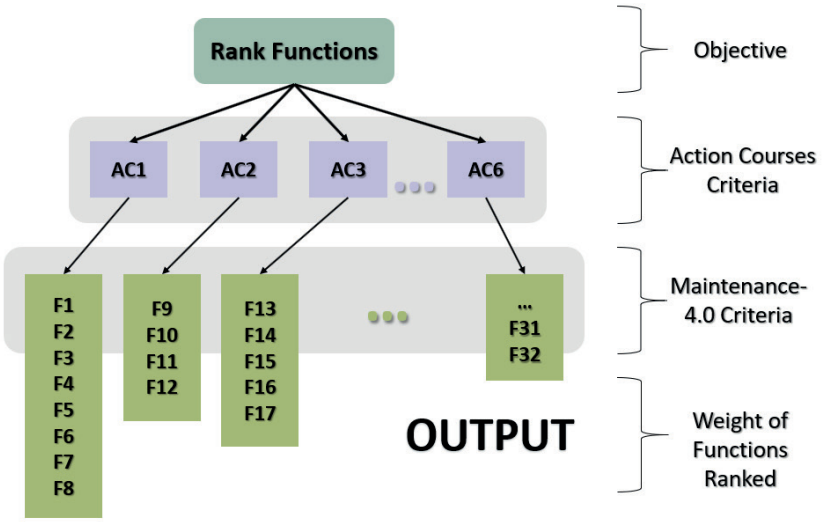

Fig. 6. Step 02 – Maintenance-4.0 Function's Rank (AHP method model 2).

At this stage, the survey reflects the Maintenance-4.0 model (see 2.3, To-be model), which presents a series of maintenance systems function's and their application in the light of I4.0. Based on the TPM's six main losses, the engineers and maintainers must consider their decisions regarding predictive, preventive and reactive approaches, that will guide maintenance processes to zero waste. At the end of the analysis, each function of the proposed Maintenance-4.0 model is ranked by weights in the AHP method in the "SuperDecisions" software, according to the decision makers preferences.

3.3 Maintenance-4.0 Technologies Prioritization (Step 03)

Based on the maintenance functions weighted in the previous stage, Step 03 objective is the prioritization of I4.0 technologies which best suit those functions. Here, the framework does not require a survey for engineers and maintainers, leaving the role of decision maker to a specialist. In the case study presented in section 4, one of the authors with access to the organization fill that specialist role. This suggests that is necessary an expert view of possible solutions to be used. The literature review on I4.0 technologies under the maintenance domain was used at this stage.

A decision model using the PROMETHEE II method in "Visual Promethee" software, was build. The weights of each Maintenance-4.0 function, from the previous step, will be inserted and related to the nine technology groups from the literature review. At the end of this analysis the software will provide several types of reports based on the hierarchy carried out by the method, and the specialist is responsible to decide the technologies necessary to cover the maintenance functions.

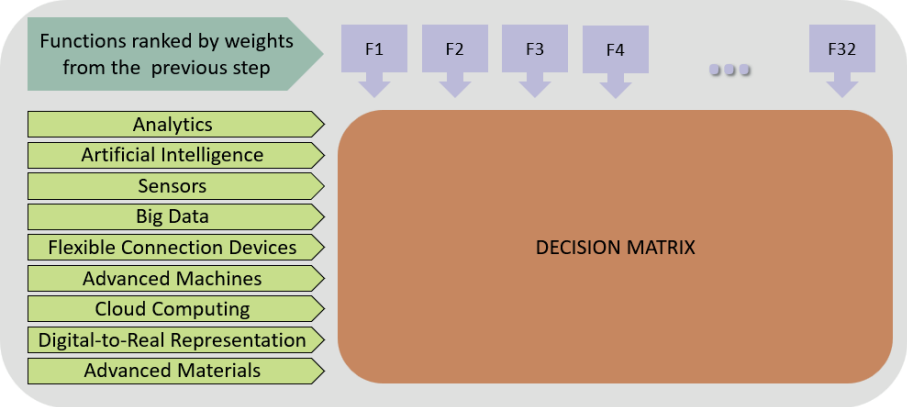

Fig. 7. Step 03 – Maintenance-4.0 Technologies Prioritization (Promethee method model).

After completing all the stages of the framework, there will be enough information for the specialist to develop assertive guidelines for an I4.0 compliance plan. Such plan suggests that: The Maintenance-4.0 technologies selected in the Step 03 enable the functions prioritized in the Step 02, which will act on the diagnosed areas arising from the Step 01 maturity assessment.

4 Results

To test the framework, a case study was applied to a multinational vehicle manufacturer. With a presence in more than 120 countries, the manufacturing complex in the southern region of Brazil employs approximately 8 thousand employees and has a production capacity of 320 thousand vehicles per year. We sought an area that offered a wider range of equipment, which is why the recently expanded engine factory has become the best option, mixing a wide range of modern and antique machinery. In Step 01, the industrial maturity assessment made in the "SuperDecisions" software, resulted in the analysis from Fig. 8, accordingly to the maintainers and maintenance managers' preferences.

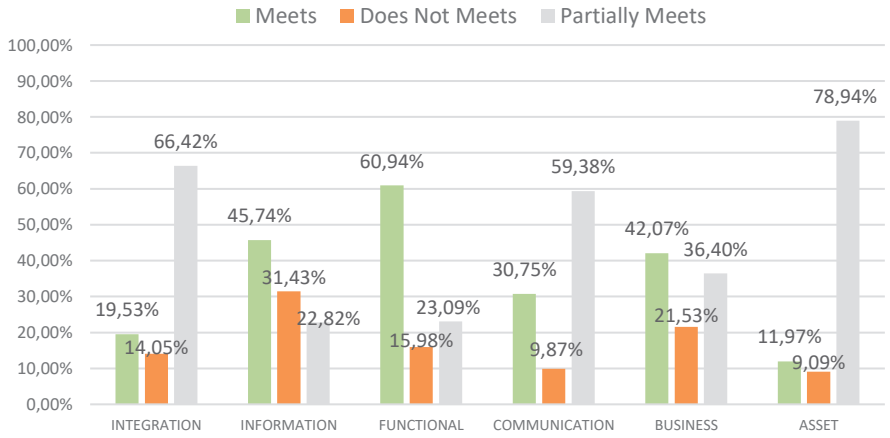

Fig. 8. RAMI 4.0 Layers individual Interoperability Assessment from AHP model 1.

Based on RAMI4.0/FEI, and again, following the preferences of managers and maintainers in the role of decision makers, the Information, Functional and Business layers presented the degree of adequacy "meets" while the Integration, Communication and Asset layers are classified as "partially meets". Also, with a deeper analysis, even though Business and Information layers meets the level of maturity, in both cases the alternatives "does not meets" and "partially meets" together exceeds 50%. This means that the AHP method is pointing out the preference (i.e. acknowledgement) of decision makers, that the factory is at a level that "meets" the requirements, but with more uncertainty than the "Functional" layer, for example. Such fact highlights the importance of choosing decision makers whom knows their processes and systems.

In the second stage, the maintenance functions of the Maintenance-4.0 model were ranked by relevance level, also following the preference of the same decision makers from the previous stage. Because this works focused in the application of the decision-making methods for adequacy of systems, this rank will not be displayed.

For Step 03, one of the authors played the role of decision maker as specialist. Using the "Visual Promethee" software, the weights of the functions obtained in Step 02 were inserted, and chosen by their level of need (i.e., syntactic graduation from 1 to 9), measured with the nine groups of Maintenance-4.0 technologies, as alternatives. Table 1 presents the ranking of the nine most relevant maintenance technology groups to meet the functions required to achieve a Maintenance-4.0 system, where phi, represents the preference index used by the method.

Table 1. Table captions should be placed above the tables.

Rank	Technology	Method Relevance
1st	Analytics	Phi 0,4245
2nd	Artificial intelligence	Phi 0,3455

3rd	Sensors	Phi 0,2342
4th	Big Data	Phi 0,1930
5th	Flexible Connection Devices	Phi 0,1713
6th	Advanced Machines	Phi 0,1566
7th	Cloud Computing	Phi -0,1923
8th	Digital-to-Real Representation	Phi -0,4994
9th	Advanced Materials	Phi -0,8334

It is noticed the predominance of technologies that operate at the Cyber-Physical level: Analytics, A.I. and Big Data, together with Sensors; being responsible to collect, interpret and store a large amount of data, enabling actions that are lacking in the factory, established in Step 02.

5 Conclusions and Future Works

The research developed here sought to answer the following research question: "How to define a technology prioritization plan, in the field of industrial maintenance, in order to adapt legacy systems for Industry 4.0 requirements?". For this, a framework was built, based on the RAMI4.0 and FEI architectures, assessing the maturity of legacy systems in the field of industrial maintenance under the requirements of I4.0 and considering interoperability barriers, with the hypothesis of providing assertive guidelines for adequacy plans for manufacturing industries. This need is part of the demand for adaptation to I4.0, where the reconditioning of legacy systems becomes the objective of organizations that seek to assign new functionalities to their equipment through digital transformation/modernization processes. Multicriteria decision making methods were the elements that encapsulated this work, giving a tooling bias to the framework.

Among the main difficulties encountered are the long questionnaires that need to be filled out in the steps. The professional involved spends a lot of time to fill them out, away from his activities. Although the framework has been positively validated, its complexity hinders its use. Many judgments are necessary and it is essential that all the components of the process are clarified in order to avoid mistaken considerations. With this in mind, parallel studies seek to alleviate the complexity of such digital transformation projects and open the scope for guidelines in addition to maintenance. A more mature initiative to design this framework will also be tested, using a different MCDM in the Step 02, solving only the most decisive Maintenance-4.0 functions, with the prerogative that "not everything that is necessary to implement, can actually be implemented – so the focus will be on the decisive aspects". This initiative could reduce the framework complexity focusing on decisive functions only. Further, this could be applied more than once, encountering new decisive functions each time the previous ones were resolved, corroborating with a gradual digital transformation.

Therefore, analogous with the empower of people with decision support tools, we emphasize as a final consideration that, digitalization of information, processes,

functions that make up the operations of a business and transforming the business's strategies are necessary, but not enough. Most importantly, digitalization is essentially about technology, but digital transformation is not. The digital transformation is about people. It is how to improve the quality people's life at work and how to improve the performance of organizations.

The emergence of new business and operating models under the Industrial Digital Paradigm

Industrial Internet of Things (IIoT), Platforms, and Artificial Intelligence/Machine Learning (AI/ML)

Abstract. This paper pretends to approach and analyse opportunities and risks that arises under the Industrial digital paradigm. Known by different names like Industry 4.0, Smart Manufacturing, or Production 4.0, among other terms digitalization in industry is advancing at a tremendous speed, and is pushing stablished firms to change and adopt new tools. Besides it opens opportunities to technological startups to deliver new products and services to the industrial market.

As an example of opportunities in operating models, it is clear that digitalization under the model Industry 4.0 and the advantages of Industrial Internet of the Things (IIoT), allows faster response to customer demands, increase flexibility allowing the adaptability to manufacturing processes, and provides a tremendous amount of tools for quality improvement in the processes, among other advantages.

This article addresses the data driven organization as digitalization evolves and the progress of Artificial Intelligence (AI) and Machine Learning (ML) solutions for industry.

Keywords: Industry 4.0, Industrial AI/ML, Data driven management.

1 Introduction

This work approaches one of the edges that shows the Industry 4.0 paradigm, and aims to explore opportunities and challenges that arise from its adoption, transforming traditional value chains to facilitate the creation of value and reach new levels of competitiveness.

The fourth industrial revolution, commonly termed as industry 4.0, is not just about industry. It is about overall transformation using digital integration and intelligent engineering. It is quoted as the next level of manufacturing where machines will redefine themselves in how they communicate and perform individual functions (Muhuri et al. 2019).

Another point of view about Industry 4.0 is given by Ibarra et al. (2017), according this work the new model has been brought into the manufacturing world by the increasing fusion of Industrial Production and Information and Communication Technologies (ICT). This phenomenon is making possible to connect information, objects and people due to the convergence of the physical and the virtual (cyberspace) worlds in the form of Cyber-Physical Systems (CPS). Therefore, it is enabling the transformation of factories into smart environments.

Sarmiento et al. (2020) stablish that a key principle of the Industry 4.0 paradigm is that processes and machinery must be networked as a collaborating community for the collection, exchange and analysis of data in order to predict future behaviours and pursue optimal solutions to possible problems. In the paper the author considers that nowadays, this principle is beginning to be achievable thanks to the development of a number of promising technologies. One of these technologies is the so-called Cyber–Physical Systems, which refers to systems with integrated computational and physical capabilities that can be interfaced in different ways. These systems are enhanced with features from the Internet of Things (IoT) technology, providing them with the ability to continuously obtain information from sensors or processes across the factory, and securely forward it to (generally cloud-based) data centres. This massive data production implies the development of new tools based on Big Data techniques, for storing, managing, and processing it. This set of technologies is completed with the Internet of Services (IoS) one, which takes the processed information from Big Data tools and deploys it at the right place and in the right form.

IoT is referred more specifically as Industrial Internet of Things (IIoT) when referred to its adoption in Industry. Porter and Heppelman (2015) uses the concept of IIoT and describes the way it makes possible to connect devices and obtain data from reading the devices. In the same work is explained that linking combinations of readings to the occurrence of problems can be useful, and even when the root cause of a problem is hard to deduce, those patterns can be acted on. Data from sensors that measure heat and vibration, for example, can predict an impending bearing failure days or weeks in advance. Capturing such insights is the domain of big data analytics, which blend mathematics, computer science, and business analysis techniques.

This paper pretends to go further from previous work regarding opportunities and risks that arises from digitalization, and specifically at the Industry 4.0 model and the emergence of new business models, Walas Mateo (2020). This paper pretends to go

deeper into opportunities around solutions on IIoT, platforms, and Artificial Intelligence/Machine Learning (AI/ML).

2 Conceptual Framework

To start the discussion of the subject it is aimed to approach, the definition de business operating model and business model by Iansity and Lakani (2020) it is put on consideration. The authors define that the value of a firm is shaped by these two concepts. The firm's business model, defined as the way the firm promises to create and capture value. The firm's operating model, defined as the way the firm delivers the value to its customers.

Searching for the drivers of competitiveness in digital business models under Industry 4.0 model, Grover et al. (2018) considers big data as a new yet powerful source for potentially immense economic and social value and for gaining a competitive advantage on par with an organization's capital assets and human talent. In this article it is affirmed that according to a 2016 report from PromptCloud, big data has grown from a $6.8 billion industry to a whopping $32 billion industry in just three years. IDC forecasts the market of big data technology and services to grow at a 23.1 percent compound annual rate, reaching $48.6 billion in 2019.1 Therefore with the volumes of organizational data moving past terabytes to tens or even hundreds of petabytes, businesses and information technology (IT) leaders are embracing unique opportunities to capitalize on big data to gain the competitive advantage. It is also considered in this article that companies are reported to spend more than 10 percent of their IT budget on data alone and are undergoing a revolution by leveraging big data and analytics (BDA) as a strategic asset to guide their decision-making and improve business processes and outcomes.

An interesting article about the evolution of Artificial intelligence (AI) is brought by Thomas Davenport (2018). In this work he states that analytics 4.0 is the next step in analytical sophistication for organizations, and it is the era of artificial intelligence or cognitive technologies. It became widely adopted – with adoption rates, depending upon geography, of 20 to 30% across large enterprises in 2016 and 2017. It features not only the use of AI methods, but also greater use of autonomy in the execution of the methods, particularly automated machine learning (ML).

A recent article by Davenport (2020), which is based on a research by Deloitte on the use of AI tools in Industry highlights how barriers to the adoption of artificial intelligence tools have decreased. Based on a survey of more than 2727 global executives from nine countries, and their organizations have all adopted AI. The key facts that emerge from the article is that the respondents feel that AI is getting easier, and will continue to do so.

Then there are two interesting insights from this article. The first one, is the preference for buying ready-made AI technology over building it. Indeed, at some point it will be difficult not to buy. Another item points that 74% of these executives agreed that "AI will be integrated into all enterprise applications within three years." In terms

of today's practice, 50% say they will either "buy all" of their AI capabilities. The second, is about the risks the adopter see about AI. Some of the specific risks that most concerned respondents were cybersecurity issues, AI failures that might affect business operations, misuse of personal data, and regulatory changes involving AI/ML.

Iansiti & Lakani (2020) conceptualize the Artificial Intelligence (AI) Factory as the core of the modern firm, where it is industrialized data gathering, analytics, and decision making. The AI factory is the scalable decision engine that powers the digital operating model, where value is created, of the twenty-first-century firm. Managerial decisions are increasingly embedded in software, which digitizes many processes that have traditionally been carried out by employees. Digital operating models can take various forms, AI factories are at the core of the model, guiding the most critical processes and operating decisions, while humans are moved to the edge, off the critical path of value delivery. From the concepts of these authors two points should be considered in this paper. The first one is transforming the industrial environment to an AI Factory environment, and the second one is the new role of the industrial operator or the industrial engineer.

A concept that needs to be consider when talking about new business models under Industry 4.0 paradigm is uncertainty. To cope with this fact, sensing and rapid response when planning a new strategy is critical. A tool that could help to develop and find a product and business model that really works is an Agile methodology called Lean Start Up. The real challenge is to develop and validate the value proposition, and look for a profitable business model that allows to consolidate sales and scale the volume of business.

The Lean Start Up methodology created by Eric Ries (2010), collecting the adjective "lean" widely disseminated when describing production methods developed by Toyota and other Japanese manufacturers for dispense with everything that is left over, hinders and lengthens the Productive processes. The fundamental objective of Lean Startup is shortening the product development cycle and employing agile development methods, with validation tests by the market, to match the processes to the acceptance of the clients, adjusting and pivoting -when needed-Indicators are used incremental to measure the result of the actions on the interested customers and sales and the model is analysed and controlled appropriate growth based on acquisition costs, of customer retention and the value of customers throughout its life cycle. In sum, a set of techniques for match the product development processes with the customer discovery and development.

A last issue to consider is what Ibarra et al. (2017) mention about the effects of the phenomenon considered as the Fourth Industrial Revolution. In the paper by this author is stablished that it will be the most powerful driver of innovation over the next few decades triggering the next wave of innovation. Thus, the main features related to the Industry 4.0 such as real-time capability, interoperability and the horizontal and vertical integration of production systems through ICT systems, are regarded to be the response to current challenges that companies must face to stay competitive in terms of globalization and intensification of competitiveness, the volatility of market demands, shortened innovation and product life-cycles and the increasing complexity around products

and processes. The adoption of data models, especially when working with heavy industries where is not possible to change to last generation equipment and machines, and digitalization could help to improve the performance of assets with decades in use in steel or energy generation industries.

3 Objective of the work, hypothesis of the research

Having enough evidence about the use and benefits of data analytics in the productive environment under Industry 4.0 framework, this work it is aimed to study and analyse opportunities and difficulties that arise to create new business and operating models from the use of IIoT, Artificial Intelligence and Machine Learning in the industrial environment to improve industrial processes.

This paper aims to take in consideration the issues in the above paragraphs, in the framework of the adoption of IIoT and AI/ML solutions. A key topic to explore is how open innovation, Lean startup and platforms, among other methodologies can help with the challenge that means the disruption that is produced in the industrial scenario when adopting data models.

A paper of the Boston Consulting Group (2015), states that the model Industry 4.0 allows faster response to customer demands, increase flexibility allowing the adaptability to manufacturing processes, and provides a tremendous amount of tools for quality improvement in the processes, among other advantages.

Another observation that is object of this work is what is said by Muhuri et al. (2019) about studies that have shown that digitization of products and services has become a necessity for a sound industrial ecosystem. However, these requirements and advanced technologies have made the systems more complex and led to many other challenges such as cybersecurity, reliability, integrity, etc. These are the major bottlenecks which needs to be overcome for the successful design and deployment of Industry 4.0.

This work aims to approaches one of the edges that shows the Industry 4.0 paradigm, and to explore opportunities and challenges that arise from its adoption, transforming traditional value chains to facilitate the creation of value and reach new levels of competitiveness.

4 Some interesting findings

Iansiti & Lakhani (2014) establish in their work that adapting to ubiquitous digital connectivity is essential to competitiveness in most sectors of the economy. They reinforce the concept by saying that they have examined transformation across dozens of industries and companies—both traditional and born-digital, talked to hundreds of executives in an effort to understand how traditional modes of innovation and operational execution are changing. (Disclosure: they have consulted with or have interests in several of the companies mentioned in their article.) They have seen that digital transformation is no traditional disruption scenario: The paradigm is not displacement and replacement but connectivity and recombination.

The concept product as a service has broaden to anything-as-a-service (XaaS). An article from Deloitte, by Sharma et al (2019) suggest that the ever-changing technology landscape—currently shaped by technologies such as cloud computing, anything-as-a-service (XaaS), and the Internet of Things (including industrial IoT)—has solidified the need for businesses to adopt a customer-in mindset, shifting focus from selling a product to nourishing a customer relationship: understanding expectations and maximizing customer value from offerings.

Walas Mateo (2020) give a brief description of how the robotic industry is changing business models through connected products with the case of Universal Robots (UR). Today it is possible for UR industrial robots and other robots suppliers to implement as a service business models to facilitate any firm to afford having a robot. Beyond that UR introduced the concept of collaborative robot or cobot, making possible human and robots to work very close each other in the industrial environment.

In this work Walas Mateo (2020) points that there are three different kind of disruptive business models, some of them derivate from digital transformation, economy of platforms, decentralized models or superfluid economy. The new business models and the companies that represent them lean on a series of repeating premises: personalization, pay per use, collaborative model, agile and flexible organizational models, and the data.

The paper of the BCG (2015) approach the cooperation in Industry 4.0 where companies, departments, functions, and capabilities will become much more cohesive, as cross-company, universal data integration networks evolve and enable truly automated value chains. In this line, it is presented an example of how Dassault Systemes and BoostAeroSpace launched the platform AirDesign, for the European aerospace and defense industry as a common workspace for design and manufacturing collaboration. This platform is available as a service on a private cloud. In this way it can be managed the complex task of exchanging product and production data among multiple partners.

Iansiti & Lakhani (2020), refers to platforms and their integration that allows an effect of extraordinary scope when talking about digital operating systems, allowing disruptive business and work models. The authors especially mentions Alibaba and Amazon cases. A platform is an environment where an application runs, and based on network connectivity, this definition has been extended to a space where different users can interact with each other or with physical objects. As a result, suppliers, customers, and other partners become part of a networked ecosystem around the CPS.

The integration and scope of the platforms are generated by being connected through APIs. An API, an acronym for Application Programming Interface, is the mechanism that allows devices and platforms to be integrated. It is something that facilitates, for example, that applications using georeferencing to access information from Google Maps.

This phenomenon of liquid marketplace, as it is called by Iansiti & Lakhani (2020) from the possibility that generates Internet and ubiquity, makes possible to reconfigure global value chains, and integrate different platforms to make easier operations management.

In line with this Walas Mateo (2020) presents the case of the European network of Kiala that count on 7,200 Points and 1,050 Click & Collect Points distributed in 5 European countries. In this way the company offers a delivery service without a single drop-off or pick- point in a building of its own. This is an example of a new level of liquid business that is becoming increasingly common.

An interesting view regarding innovation, platforms, and digital disruption is brought by Cozmiuc, & Petrisor (2018) they say that business models have become key to digital disruption, and the latest business models shift from pipeline material flow to knowledge creation in platforms. They remark the importance of open innovation as part of platform business models, and that business models are now financed directly, which has created the lean startup movement. Startups enter markets with no barriers and force incumbents to race them with the ability to compete based on business models and match start-up agility and creativity. In this work they describe the case of the world's top innovators, Siemens, and the way the company uses the latest tools for innovation: open innovation for technology invention, business models to turn invention into innovation, and finances business models. Siemens has created an inner structure that intends to bring the advantages of the lean start-up movement indoors.

In the framework of what is described above, arise the Siemens Next47 initiative. According to Hilse & Susemihl (2018) in their work on successful cooperation between companies and startups, develop the case extensively. It is an accelerator of technological startups with products and services for IIoT, AI/ML, and other disruptive digitization solutions.

In Gradient Ventures, Google's AI-focused venture fund investing in and connecting early-stage startups with resources in artificial intelligence. Searching in its portfolio of startups founded, Canvass Analytics, www.canvass.io, is one of them. This startup that aroused interest for this research had developed a business model based on an AI-powered predictive analytics platform for Industrial processes. Its customers include leading manufacturing and energy companies globally.

At its web site the startup says that its platform automates the entire data science process, eliminating consulting data science projects. They affirm that the platform approach has accelerated the time to insights 12 times faster than other solutions and approaches. The solution is developed specifically for the industrial sector.

A paragraph in the findings deserves the importance of the Customer when adopting a new business model. Cornella & Planellas (2020) conclude in their work that customers will also be part of the company, especially those who prove to be the best 'sensors' for real demand.

At the end, it should be considered the success in adoption of the new models. An interesting aproach is given by Sailer (2019) in a paper where it is stated that it has been identified three key imperatives in successful digital transformations. These imperatives have shaped their Integrated Change Management methodology:

- Instituting an integrated approach across facts – i.e., tangible elements such as technology, processes and social interactions – i.e., intangible elements such as culture and teams throughout the transformation journey and across the entire company.

- Living agile by proactively updating change measures to meet both current needs and overall objectives effectively
- Adapting "classic" Change Management levers such as communication, leadership, team setup, training, etc. for digitalization needs

5 Conclusions and future work

Different firms in a broad spectrum of sectors are shifting value from manufacturers and distributors to companies that operate end-to-end platforms and provide outcomes as-a-service. Many firms face growing threat of market obsolescence, and then constant change seems to be the golden rule.

Regarding the role of the customer and operators in the shop floor, seems people have a central role in new operating and business models. It can be said that each new opportunity will require the participation of people and departments who are today isolated in their silos, and so creating multidisciplinary teams. Collaboration with other companies will be the norm once it is understood that the world is too complex to be solved in isolation.

A point to consider when thinking in new operating or business model in any firm, is the need for agility. A Lean startup approach to test the new model and go for a fast ROI seems a good option.

This paper left some questions to be studied in future work. The first one in this line of research, is the data driven organization as IoT evolution from leading edge innovation mainstream technology and its business potential. Also very important is to watch the progress of Artificial Intelligence (AI) solutions for industry, such as those presented by new technological startups. New firms appear everyday to provide tools for smart manufacturing environments, capturing and delivering value in Industrial environment. New companies like LLamasoft, which provides AI for supply chain management (SCM), and the mentioned before in this paper, Canvass Analytics are examples of this dynamic.

Another key topic to explore in future work, is how process operators or industrial engineers can cope with the challenge that means the disruption that is produced in the industrial scenario when adopting data analytics models. Therefore the question is the way the shop floor will capture the value that generates the AI/ML, should the process operator or industrial engineer at the process level go further in the master of analytics tools, or the solutions that managers should buy according to Davenport (2020) will be tuned to the language and needs of the people that work in the process.

Finally, another issue that awake curiosity regarding AI/ML as process optimization driver is the integration with IoT and its evolution from leading edge innovation mainstream technology, and potential to produce data to feed AI/ML models.

6 Acknowledgments

The authors wish to thank two research projects that made possible the content of this article. The projects are "Análisis del abordaje de herramientas de Producción 4.0 en PyMEs locales", approved by Resolution (R) No. 148-18- UNAJ INVESTIGA 2017 Program, and “Mejora de Procesos, Optimización y Data Analytics: Aplicación en Procesos e Industrias de Interés Regional Mediante Estudios de Casos Reales”, approved by Resolution Res. Engineering Faculty C.A. 001 – 12/02/2019.

Abstract. A Indústria 4.0 é o novo estágio produtivo que está impulsionando a quarta revolução industrial, muitas empresas esperam um impacto significativo em suas operações, cadeia de suprimentos e modelos de negócios. As dificuldades de adaptação a esta nova abordagem colocam desafios para as empresas de Países Emergentes, tanto pela complexidade de suas características, que ainda não foram compreendidas totalmente, quanto pelas suas limitações derivadas de seus países onde atuam. Para implementar um roteiro de forma adequada, ferramentas como Modelos de Maturidade (MM) podem ser muito úteis, pois auxiliam na avaliação do estado inicial da organização e no planejamento de um roteiro de desenvolvimento. Nos últimos anos, diversos MMs foram desenvolvidos para a Indústria 4.0, alguns deles para contextos de aplicações específicos. No entanto, não há nenhum modelo desenvolvido especialmente para os Países em Desenvolvimento. Este artigo, apresenta um novo MM para esse contexto, o modelo é composto por sete dimensões e cinco níveis de maturidade para cada dimensão. A metodologia abrange uma etapa multicriterial, com a aplicação do método Processo de Análise Hierárquica (AHP) e 2-Tuple. Por se tratar de um estudo preliminar, a aplicação e validação do modelo é esperada em uma etapa futura no desenvolvimento do modelo.

Keywords: Indústria 4.0, Países Emergentes, Modelo de Maturidade.

1 Introdução

A Indústria 4.0 pode ser entendida como um novo estágio industrial e, atualmente, o qual se trata de um dos tópicos mais populares nos campos profissional e acadêmico [7] [21]. Este conceito tem o smart manufacturing como seu elemento central [16]. A indústria 4.0 depende da adoção de tecnologias digitais para coletar dados em tempo real e analisá-los, fornecendo informações úteis ao sistema de manufatura [20]. Isso é possível, graças ao advento da Internet das Coisas (IoT), big data, analytics e serviços em nuvem, criando o conceito cibernético da Indústria 4.0 [40] [22].

Espera-se que a Indústria 4.0 tenha um impacto significativo na cadeia de suprimentos, no modelo de negócios e processos. De acordo com [16], as mudanças fundamentais que serão possibilitadas pela quarta revolução industrial são as seguintes: flexibilidade, tomada de decisão otimizada, atendimento personalizado aos clientes, produtividade e eficiência de recursos, criação de valor através de novos serviços dentre outras.

No entanto, a adoção de tecnologias avançadas para os países emergentes pode ser mais desafiadora [14] [18]. Uma vez que os países emergentes têm sua economia mais direcionada à extração e comercialização de commodities, as empresas destes países estão frequentemente atrás em termos tecnológicos quando comparadas com seus similares nos países desenvolvidos [6]. Fatores como cultura, nível de escolaridade, instabilidade econômica e política e infraestrutura de TIC, também podem impactar na percepção de valor e, consequentemente, no nível de investimentos em tecnologias avançadas [10].

Quando se fala em países emergentes, não se pode deixar de citar os países que compõem o BRICS e as rupturas tecnológicas que impactaram de forma positiva no desenvolvimento de suas economias. Para o Brasil, a Rússia, a Índia e a África do Sul, as rupturas ocorreram imediatamente após o fim da Guerra Fria, durante o período 1991-94. Após o restabelecimento da democracia em 1986, o Brasil implementou o Plano Real de ajuste estrutural em 1994; a Rússia, após o colapso da União Soviética, experimentou um "tratamento de choque" através da rápida adoção do livre mercado em 1992; a Índia começou a liberalizar a "licença Raj" de 1991 em diante, e, em 1994, a África do Sul pós-apartheid iniciou sua longa caminhada na direção da liberdade política e econômica. A China seguiu por um caminho diferente e, seguindo as reformas fundiárias e da agricultura de 1949 aos anos 1960, começou sua segunda Longa Marcha em 1978, desta vez pela via do capitalismo [37]. Essas rupturas, tiveram impacto no momento atual, no entanto, frente a Quarta Revolução Industrial ainda não se desconhece os impactos destas recentes rupturas.

Muitas empresas enfrentam o desafio de avaliar a diversidade de desenvolvimentos e conceitos sob o termo Indústria 4.0 e desenvolver suas próprias estratégias corporativas [2]. As empresas instaladas em países emergentes tentam remodelar suas operações de acordo com tecnologias emergentes, com o objetivo de permanecerem competitivas e garantir a continuidade no mercado. Como a Indústria 4.0 está nos estágios iniciais de seu desenvolvimento, a definição da estrutura e a metodologia das diretrizes de implantação se torna essencial [11]. Sendo assim, há uma demanda em ajudar as organizações que estão fazendo essa transição para o novo ambiente industrial e também orientá-las para a melhor utilização de seus recursos.

Abordagens estruturadas, como modelos de maturidade (MM) ou estruturas de apoio, tem por objetivo ajudar as organizações, fornecendo orientações abrangentes e permitindo avaliar um roteiro adequado de implementação sustentável das novas tecnologias do novo paradigma. A noção de maturidade é usada para definir, avaliar e formar uma diretriz e uma base para mensurar a evolução nos negócios, ou seja, a maturidade de um processo ou de uma tecnologia [26]. A ideia principal para a utilização do MM é descrever o nível de perfeição de uma organização, como um novo modelo de negócio empregado ou um novo processo desenvolvido. Outra suposição para o uso de MM é que à medida que o grau de maturidade se torna maior, um progresso melhor é alcançado em aspectos diferentes que contribuem para a evolução da organização. Sendo assim, o modelo de maturidade é considerado como uma linha de base deste estudo.

Diante deste contexto, este artigo analisa os modelos de maturidade disponíveis atualmente para Indústria 4.0. Em seguida, ele discute os modelos de maturidade em relação à sua "adequação" as economias emergentes. No processo, se discute as lacunas da pesquisa e, finalmente, propõe-se uma possível via para resolvê-las, criando ou adaptando um modelo de maturidade dedicado para as economias emergentes.

2 Referencial teórico

2.1 Construção do Portfólio Bibliográfico

Para composição da base teórica deste trabalho, foi realizado o processo de revisão sistemática da literatura. As bases *Web of Science*, *Scopus* e *Science Direct* foram selecionadas, as quais, seguindo critérios de classificação, possuem artigos de maior relevância sobre o tema.

Para realização desta pesquisa, foram definidos eixos de pesquisa onde os mesmos foram formados pelos tópicos Indústria 4.0, Modelos de Maturidade e Países Emergentes. Realizou-se combinações de palavras através da utilização de palavras-chaves propostas para cada eixo. Foram utilizadas as palavras-chave “smart manufacturing”, “Industry 4.0”, “*fourth industrial revolution*”, “*assessment*”, “*maturity model*” e “*emerging markets*” de modo a abranger todo o conteúdo relacionado a temática.

Após as combinações das palavras-chave e a definição dos critérios a serem utilizados para as buscas, todos os artigos resultantes foram agrupados, obtendo um resultado de 10 artigos, conforme pode ser conferido na Tabela 1. Esse portfólio bibliográfico é constituído pelos MM resultantes de nossa pesquisa e serão utilizados como base para o desenvolvimento do nosso trabalho.

Tabela 1. Portfólio de Pesquisa

Título	Autores
Development of maturity model for assessing the implementation of Industry 4.0: learning from theory and practice	Wagire, Anituddha; Joshi, Rohit; Rathore, Ajay; Jain, Rajesh
An Industry 4.0 maturity model proposal	Santos, Reginaldo; Martinho, José

A maturity assessment approach for conceiving context-specific roadmaps in the Industry 4.0 era	M. Colli; U. Bergerb; M. Bockholta; O. Madsena; C. Møllera; B. Vejrum Wæhrens
Defining and assessing industry 4.0 maturity levels – case of the defense sector	Bibby, Lee; Dehe, Benjamin
Three Stage Maturity Model in SME's	Ganzarain, Jaione; Errasti, Nekane
Development of an Industry 4.0 maturity model for the delivery process in supply chains	Asdecker , Björn; Felch, Vanessa
A fuzzy rule-based industry 4.0 maturity model for operations and supply chain	Caiado, Rodrigo; Scavarda, Luiz; Gavião, Luiz; Ivson, Paulo; Nascimento, Daniel; Garza-Reyes, Jose
A Maturity Level-Based Assessment Tool to Enhance the Implementation of Industry 4.0 in Small and Medium-Sized Enterprises	Rauch, Erwin; Unterhofer, Marco; Rojas, Rafael; Gualtieri, Luca; Woschank, Manuel; Matt, Dominik
An Industry 4.0 maturity model for machine tool companies	Lizarralde, Rafael; Ganzarain, Jaione; López, Cristina; Serrano, Ibon
Digital readiness assessment of Italian SMEs: a case-study research	Pirola, Fabiana; Cimini, Chiara; Pinto, Roberto

2.2 Indústria 4.0 nos Países Emergentes

A Indústria 4.0 tem como alvo a implementação de estruturas e processos interconectados, inteligentes e autocontrolados de processos e sistemas [1]. Portanto, os processos de negócios baseados nas tecnologias subjacentes à Indústria 4.0 fornecem processos inovadores de valor agregado, proporcionando operações mais flexíveis, confiáveis e eficientes. Em geral, os últimos desenvolvimentos em tecnologia por si só oferecem novas oportunidades e criam novos modelos de negócios; enquanto a Indústria 4.0 é vista como um desenvolvimento tecnológico disruptivo que traz uma inovação no novo modelo de negócio no setor manufatureiro [16]. Como ainda está em fase inicial de desenvolvimento, é essencial definir a estrutura e a metodologia das diretrizes de implementação da Indústria 4.0 nas organizações para que esse processo seja bem sucedido.

A Indústria 4.0 tem origem em países desenvolvidos, que possuem os conceitos da terceira revolução industrial já desenvolvidos como o uso das TIC`s (tecnologias de informação e comunicação) e automação, sendo conceitos inerentes à Indústria 4.0 [16]. Nesse sentido, países emergentes podem enfrentar uma lacuna importante para implementação da Indústria 4.0 em função da baixa maturidade dos estágios industriais de terceira revolução industrial [17]. No contexto da indústria brasileira, a adoção da TIC aumentou significativamente, ocasionando uma melhora na produtividade industrial [9]. Contudo, no estudo de [10] através de um levantamento em larga escala da indústria brasileira, os investimentos em software não incorreram em resultados positivos em se tratando de benefícios de mercado ou melhoria interna nos processos de fabricação. Os autores argumentam que as empresas estão automatizando suas rotinas operacionais e não objetivando a busca de ferramentas avançadas de TIC para ganho de vantagem competitiva real no desenvolvimento da inovação [10].

No mesmo estudo, com relação às tecnologias de fabricação, os autores argumentam que a estratégia de aquisição de máquinas e equipamentos não trouxe benefícios satisfatórios em inovação quando comparadas a outras atividades de inovação de indústrias no Brasil. Os autores sustentam a ideia de que a maioria das empresas não adquire tecnologias de ponta – como da Indústria 4.0 -, mas apenas aquelas necessárias para a atualização de equipamentos antigos [10], estudos anteriores em países emergentes corroboram esta afirmação [41]. Outro fator relevante que impacta diretamente na inovação em países emergentes, refere-se ao fato de que a população destes países possui renda mais baixa que de países em desenvolvimento, o que torna os produtos de baixo custo preferíveis no consumo e, por consequência, o fator competitividade sobressaindo sobre a inovação [27]. Esse comportamento de Mercado pode influenciar diretamente os investimentos em tecnologia. Normalmente, empresas de países emergentes estão mais propensas a investirem em tecnologias já estabelecidas para ganhos de produtividade ao invés de investirem em tecnologias avançadas para diferenciação de produtos. Dessa forma, pilares base da Indústria 4.0 – TIC e automação – encontram-se em um estágio aquém do esperado para o avanço ruma a quarta revolução industrial.

Desafios estruturais enfrentados pelas economias de países emergentes também podem impactar no processo de adoção das tecnologias da Indústria 4.0. Um desses desafios diz respeito à cadeia de suprimentos da indústria da manufatura, pois tende a ser menos integrada em comparação aos países desenvolvidos [24] [23]. A força de trabalho de baixo custo, em especial nas atividades de manufatura, pode desencorajar ou atrasar investimentos em automação e tecnologias avançadas, visto que são mais caras nesses países [32]. Poucos investimentos em P&D [29], instabilidades política e econômica [14] são mais alguns exemplos que configuram um cenário desfavorável para adoção de tecnologias da Indústria 4.0.

Está claro que os desafios para adoção de tecnologias da Indústria 4.0 em países emergentes são diferentes daqueles em países desenvolvidos. Por se tratar de um conceito relativamente novo, existe uma alta incerteza e falta de conhecimento sobre o verdadeiro impacto e contribuição dessas tecnologias no contexto de países emergentes em sentido geral. Isso torna ainda mais importante a definição da estrutura e das metodologias de implementação da Indústria 4.0 nas organizações. A fim de investigar o sucesso da maturidade de fabricação no contexto da Indústria 4.0, vários modelos de maturidade já foram desenvolvidos, conforme será discutido adiante.

2.3 Modelos de Maturidade da Indústria 4.0

Um modelo de maturidade pode ser definido como uma estrutura conceitual, constituído por partes que definem a maturidade, ou o estado de desenvolvimento, de uma determinada área de interesse, e em alguns casos identifica e descreve processos que uma organização precisa desenvolver para atingir um determinado cenário futuro desejado. Estes modelos tipicamente contemplam dimensões e níveis. O conteúdo de cada dimensão pode ser derivado de métodos qualitativos de pesquisa, incluindo estudos de caso, grupos focais, e outras metodologias de geração de ideias e tomada de decisão [28]. Os níveis são rótulos ordinais que significam estágios de maturidade, enquanto as dimensões representam capacidades específicas do domínio de interesse. Um nível de

maturidade consiste na consolidação de práticas gerais e específicas relacionadas a um conjunto de processos predefinidos que aumentam a performance geral de uma empresa, ou de um objetivo específico [36].

A transformação para a Indústria 4.0 envolve um aumento significativo das competências digitais na manufatura, e provoca mudanças ao longo de toda a organização. Considerando a alta complexidade desta transformação, é esperado que ela leve muitos anos, e deve ser planejada e implementada de modo a garantir impactos positivos na lucratividade, por exemplo através de ganhos de eficiência, e deve ocorrer em etapas incrementais. Pode não ser exatamente sincronizada em todos os processos de negócio, todas as plantas industriais, linhas de produção, ou mesmo em todas as células de produção em uma unidade. Fica a critério de cada empresa decidir qual estágio de desenvolvimento que representa um bom equilíbrio entre os custos e os benefícios da mudança, de acordo com as circunstâncias que envolvem o negócio, com a visão de um estado futuro desejado ao final do processo de transformação [35].

Antes de engajarem-se em projetos ou atividades de transformação, as empresas de manufatura precisam reconhecer o estado atual de aderência aos conceitos e tecnologias da Indústria 4.0, através de uma análise sistemática e estratégica, que envolva não somente o desempenho da empresa em si, mas de todas as partes envolvidas no negócio, tais como fornecedores, clientes e investidores.

Desta forma, serão apresentados e analisados os modelos que avaliam a maturidade na Indústria 4.0 encontrados através da revisão de literatura (Tabela 1). A partir da pesquisa bibliográfica, foram estudados alguns modelos de maturidade da Indústria 4.0, com objetivo de conhecer o que existe na literatura, e para fundamentar a aplicação do novo modelo, que contemple as melhores práticas dos modelos existentes (Tabela 2):

Tabela 2. Modelos de Maturidade da Indústria 4.0

Artigo	Dimensões	Níveis	Limitações
Development of maturity model for assessing the implementation of Industry 4.0: learning from theory and practice	Pessoas e Cultura; Conscientização da Indústria 4.0; Estratégia Organizacional; Cadeia de Valor e Processos; Tecnologia de Manufatura Inteligente; Tecnologia Orientada a Produtos e Serviços; Tecnologia de Base da Indústria 4.0	Outsider; Iniciante Digital; Experiente; Especialista	- opinião dos especialistas com certo nível de subjetividade
An Industry 4.0 maturity model proposal	Estratégia; Estrutura e cultura organizacional; Força de trabalho; Fábricas inteligentes; Processos inteligentes; Produtos e serviços inteligentes	Baixo; Desenvolvimento; Iniciado; Parcial; Avançado; Referência	- pequeno número de profissionais que participaram da validação do modelo

A maturity assessment approach for conceiving context-specific roadmaps in the Industry 4.0 era	Governança; Tecnologia; Conectividade; Criação de valor; Competências	Nenhum; Básico; Transparente; Informado; Autônomo; Integrado	- ferramenta apresentada precisa ser refinada e tornada mais robusta; - grande necessidade de recursos, limitando a aplicação em PMEs
Defining and assessing industry 4.0 maturity levels – case of the defense sector	Fábrica do futuro; Pessoas e cultura; Estratégia.	Mínimo; Desenvolvimento; Definido; Excelência	- design da estrutura pode favorecer uma organização mais focada em uma característica tecnológica.
Three Stage Maturity Model in SME's towards Industry 4.0	Visão; Capacidade; Ação	Inicial; Gerenciado; Definido; Transformado; Modelo de Negócios Detalhado.	Não apresenta
Development of an Industry 4.0 maturity model for the delivery process in supply chains	Processamento de pedidos; armazenamento; envio	Digitalização básica; digitalização entre departamentos; digitalização horizontal e vertical; digitalização completa; digitalização completa otimizada	- opiniões e julgamento de especialistas conferem certo grau de subjetividade; - população e processo de avaliação do modelo com viés regional;
A fuzzy rule-based industry 4.0 maturity model for operations and supply chain management	*Supply Chain Management*; Produção e Gerenciamento de Operações & *Supply Chain Management*; Produção e Gerenciamento de Operações	Não existente; Conceitual; Gerenciado; Avançado; Auto otimizado	- não avaliado em diferentes contextos
A Maturity Level-Based Assessment Tool to Enhance the Implementation of Industry 4.0 in Small and Medium-Sized Enterprises	Operações; Organização; Sócio Cultural; Tecnologia	Cinco níveis foram definidos onde cada um dos 42 itens possui sua descrição	- esforço de avaliação alto (tempo dispendido para realização)
An Industry 4.0 maturity model for machine tool companies	Funcionários; Estratégia e organização; Fábrica Inteligente; Orientação à Dados; Operações Inteligentes; Produtos Inteligentes	Não iniciado; Iniciante; Intermediário; Experiente; Especialista; Melhores desempenhos	Não apresenta

Digital readiness assessment of Italian SMEs: a case-study research	Estratégia; pessoas; processos; tecnologia e integração	DRL 1; DRL 2; DRL 3; DRL 4; DRL 5	Não apresenta

É possível observar que os artigos não levaram em conta todos os componentes contextualizados sobre a Indústria 4.0, como por exemplo, recursos voltados para segurança de informação. Verifica-se assim, que os modelos não trazem todas as informações necessárias para analisar a maturidade da Indústria 4.0, tendo em vista que o tema vem sendo construído, bem como seus conceitos, características e componentes, o que mostra a necessidade de melhoria e evolução dos modelos.

A partir dos modelos de maturidade descritos nota-se a ausência de uma abordagem voltada para as organizações de países emergentes, estas por sua vez, possuem um ambiente organizacional mais fraco e menos sofisticado e isto traz implicações para a estratégia e para a gestão destas empresas [12]. Diferentemente das organizações de países desenvolvidos, estas organizações sofrem forte influencia segundo aspectos de custos de operação, sistemas de distribuição, relacionamento com governos e infraestrutura de comunicação, aspectos estes que merecem atenção pois podem afetar o desenvolvimento da Industria 4.0 dentro destas organizações.

3 Metodologia

Modelos de maturidade geralmente definem seus níveis em termos de componentes e subcomponentes, e esses elementos são validados principalmente com o auxílio de pesquisas dentro das indústrias [19]. Dessa forma, os modelos de maturidade se tornam viáveis para apoiar as empresas de manufatura em países emergentes na realização com sucesso a avaliação e implementação dos recursos da Industria 4.0.

Ao adotar o modelo proposto, uma organização poderá avaliar, dentro das dimensões propostas, e se posicionar dentro dos níveis de maturidade para cada dimensão. Assim, a organização é capaz de identificar os pontos necessários para alcançar o nível seguinte de maturidade em uma determinada dimensão.

3.1 Identificando as dimensões com base na revisão de literatura

A indústria 4.0 trata da conectividade, integração dos sistemas de manufatura e vai além. O foco está nos ganhos das operações de fabricação. A exposição destes cenários irá impactar positivamente no desenvolvimento da Indústria 4.0 tendo em vista que as organizações têm de buscar o equilíbrio em diferentes fatores decorrentes do avanço dos sistemas de fabricação [38]. Essas informações foram levadas em consideração ao projetar as dimensões incluídas no modelo de maturidade (Tabela 3). Todas foram designadas com base na perspectiva de uma organização que opera em um país emergente com suas premissas específicas.

Tabela 3. Dimensões do Modelo de Maturidade

Dimensão	Descrição	Autores
Estratégia	A dimensão estratégia abrange: integração com a estratégia da empresa, roteiro para implementação, gerenciamento estratégico de dados, informações e conhecimento, modelo de negócios voltados para Indústria 4.0.	(Wagire, Anituddha; Joshi, Rohit; Rathore, Ajay; Jain, Rajesh); (Santos, Reginaldo; Martinho, José)
Pessoas e Cultura	Engloba aspectos culturais e organizacionais que envolvem liderança e colaboradores, competências em TIC, inclusão , autonomia, interdisciplinaridade e flexibilização do trabalho.	(Wagire, Anituddha; Joshi, Rohit; Rathore, Ajay; Jain, Rajesh)
Produtos	A dimensão engloba aspectos como: individualidade, flexibilidade e modularidade, desenvolvimento de novos produtos, sistemas embarcados nos produtos e digitalização.	(Santos, Reginaldo; Martinho, José);(Bibby, Lee; Dehe, Benjamin)
Clientes	A dimensão Clientes aborda aspectos relacionados à integração dos clientes aos processos de desenvolvimento e fabricação, integração e utilização de dados, digitalização de serviços e vendas e integração do cliente com ferramentas digitais.	(Pirola, Fabiana; Cimini, Chiara; Pinto, Roberto)
Operações	Aborda tecnologias tais como: modelagem e simulação dos processos, integração vertical e horizontal, digitalização, automação, flexibilidade, autonomia e descentralização. são tecnologias que compõe o processo de transformação do produto, bem como recursos utilizados para integração dos processos.	(Caiado, Rodrigo; Scavarda, Luiz; Gavião, Luiz; Ivson, Paulo; Nascimento, Daniel; Garza-Reyes, Jose)
Governança	Aborda aspectos como: normas trabalhistas, terceirização do trabalho, gerenciamento de dados, políticas de desenvolvimento e inovação, políticas públicas voltadas para o desenvolvimento da Indústria 4.0.	(M. Collia; U. Bergerb; M. Bockholta; O. Madsena; C. Møllera; B. Vejrum Wæhrens)
Tecnologia	A dimensão Tecnologia aborda: utilização de dispositivos móveis, sensores RFID, sistemas embarcados em máquinas e equipamentos, comunicação *machine to machine* (M2M), *cloud computing*.	(Pirola, Fabiana; Cimini, Chiara; Pinto, Roberto);(Rauch, Erwin; Unterhofer, Marco; Rojas, Rafael; Gualtieri, Luca; Woschank, Manuel; Matt, Dominik)

3.2 Definindo os Níveis de Maturidade

Através de pesquisas para estruturação do modelo de maturidade, foi identificado que o modelo CMMI (*Capability Maturity Model Integration*), transformou-se em referência mundial para avaliar a maturidade nas indústrias de diversos segmentos. Para este trabalho, será utilizado o modelo CMMI, onde os níveis representam o status da indústria dentro do contexto da indústria 4.0. Tais níveis variam de 1 (nível baixo) a 5 (nível alto), e são detalhados na Tabela 4 para as dimensões Estratégia, Pessoas e Cultura e também de forma geral, que será apresentada pelo modelo.

Tabela 4. Descrição dos Níveis do Modelo de Maturidade

Dimensão	Descrição do nível de Maturidade
Geral	Nível 1 – Crítico, representa organizações que desconhecem a Indústria 4.0 como novo paradigma industrial Nível 2 – Alerta, significa um conhecimento básico e recente sobre Industria 4.0 Nível 3 – Aceitável, é a organização que já apresenta em fase de experimentação alguma tecnologia relacionada ao novo paradigma Nível 4 – Ótimo, aplica-se as organizações com projetos bem sucedidos com as tecnologias da Indústria 4.0 Nível 5 – Ideal, trata-se de uma organização que utiliza tecnologias da Indústria 4.0 de forma estratégica no negócio e pode ser chamada de organização 4.0
Estratégia	Nível 1. Não existem estratégias para implementação da Indústria 4.0 Nível 2. Estratégias para desenvolvimento da Indústria 4.0 estão sendo desenvolvidas dentro da organização Nível 3. Existem estratégias para o desenvolvimento da Indústria 4.0 em andamento Nível 4. Existe alinhamento entre a estratégia geral da organização e a estratégia voltada para a indústria 4.0 Nível 5. As estratégias da organização são desenvolvidas tendo por base a indústria 4.0
Pessoas e Cultura	Nível 1. A cultura da organização não permite e as pessoas desconhecem a Indústria 4.0 Nível 2. Existem ações planejadas para integração da Indústria 4.0 dentro da cultura da organização e uma preparação das pessoas Nível 3. A cultura da organização permite ações voltadas para Indústria 4.0 e as pessoas estão preparadas Nível 4. A cultura está alinhada com a Indústria 4.0 e as pessoas apoiam as ações Nível 5. A cultura da empresa é voltada para Indústria 4.0 e os colaboradores atuam no desenvolvimento da Indústria 4.0

3.3 Avaliação do Modelo

Para a avaliação do Modelo proposto, optou-se pelo questionário como instrumento para coleta de dados, por suas vantagens em relação aos demais instrumentos. O instrumento de pesquisa proposto, além das características das dimensões, dos níveis de maturidade, será proposto também o questionário para avaliação dos níveis de maturidade em cada dimensão.

Para aplicação do questionário proposto, será necessário aplicá-lo a partir de uma base matemática. Através da revisão de literatura, tendo em vista as dimensões propostas, constatou-se que as dimensões não possuem importância linear, ou seja, as mesmas não são igualmente importante. Desta forma, para determinação dos pesos das dimensões de avaliação, será utilizado o método *Analytic Hierarchy Process* (AHP).

O AHP é uma metodologia de Auxilio Multicritério à Decisão (AMD), que propõe o tratamento de problemas de escolha complexos de forma simples. Este método está baseado em três princípios do pensamento analítico:

- Construção de hierarquias: no AHP o problema de escolha é decomposto em níveis hierárquicos, como forma de buscar uma melhor compreensão e avaliação do mesmo;
- Priorização: o ajuste das prioridades no AHP fundamenta-se na habilidade do ser humano de perceber o relacionamento entre objetos e situações observadas, comparando pares à luz de um determinado foco ou critério (julgamentos paritários);
- Consistência lógica: no AHP é possível avaliar o modelo de priorização construído quanto a sua consistência.

Após a atribuição de pesos às dimensões propostas, será aplicado o método de decisão multicritério baseado em variáveis linguísticas conhecido como 2-tuple. A representação é feita na forma (s, $\propto$), onde s é um rótulo linguístico e $\propto$ é um valor numérico que representa um valor [15]. O método 2-tuple apresenta melhores resultados na modelagem e gerenciamento de incertezas em processos com o uso de palavras [25].

O primeiro passo para a análise dos dados é estabelecer o conjunto de termos linguísticos que serão utilizados no processamento da informação proveniente do questionário. Segundo passo, converter as variáveis linguísticas. Terceiro é identificar as soluções positivas e negativas ideais. Quarto, calcular a distância entre as alternativas até as soluções negativas e positivas ideais. Quinto, é calcular a semelhança com a solução positiva ideal. Sexto, calcular a variável linguística correspondente, com base no passo anterior e por fim, classificar em ordem das variáveis linguísticas. Dessa forma, tem-se os níveis de maturidade das organizações de acordo com cada dimensão proposta.

4 Resultados e Discussão

Este artigo apresentou um modelo de maturidade composto por sete dimensões e cinco níveis de maturidade, destinados a apoiar as organizações de países emergentes em sua transformação digital para a Industria 4.0. Com base nos modelos de maturidade avaliados pelo processo de revisão sistemática de literatura, pode-se notar que nenhum dos modelos contempla a abordagem em países emergentes.

Para atingir o objetivo foi adotado método de decisão multicritério utilizando a abordagem AHP e 2-tuple. No modelo proposto é realizada uma comparação par a par das dimensões estabelecidas e aplicando a ferramenta AHP um peso para cada dimensão é obtido, tendo em vista que graus de importância das dimensões podem variar de acordo com a aplicação do modelo. Por fim esse peso é combinado com a avaliação de cada dimensão e utilizando a ferramenta 2-tuple um ranking é construído e utilizado para determinação do nível de maturidade em cada dimensão proposta.

Por se tratar de um estudo preliminar, não foi realizada a aplicação do modelo proposto. O trabalho futuro irá se concentrar no aprimoramento e validação do modelo de maturidade através da aplicação em organizações, validação dos dados e no desenvolvimento posterior das diretrizes de implantação das ações para o alcance de níveis desejados.

Abstract. This paper addresses the challenge of developing an ontology for manufacturing process capability. This is important task needed to achieve the semantical integration of various manufacturing planning and execution software and hardware (equipment) systems. The research presented has been performed within a framework of Industrial Ontology Foundry (IOF) in which the authors are active participants. Manufacturing process capability is seen as a composition or combination of capabilities and functions of resources participating in the process. Theoretical foundation for the capability composition is presented. Individual participant resource functions are established using axiomatic design principles. The function and capability of the whole manufacturing processes is derived from individual resources using axiomatic design composition of functions. The overall approach is applied on example prismatic parts, their features, and simple machining processes. For each machining process, the machine tool brings one set of functions, while the cutting tool (mill or drill) brings its own functions. When combined for the manufacturing process those functions become capabilities in the whole process. The approach is illustrated on several feature geometries (holes, slots and pockets).

Keywords: First Keyword, Second Keyword, Third Keyword.

1 Introduction

In recent years, researchers envisioned the adoption of cloud computing and service-oriented architectures (SOA) to achieve a high degree of decentralization and flexibility in distributed manufacturing - commonly termed as Cloud Manufacturing (CM). CM is poised to level the manufacturing industry (Igoe & Mota, 2011) by bringing manufacturing resources in reach of inventors, amateur designers, small businesses, and start-ups. CM services (e.g. IaaS, PaaS, and SaaS) aim to virtualize a wide variety of resources: both tangible (hardware, e.g. machine, equipment, server, tools, and material and Software e.g. CAD, CAM, and CAPP) and intangible (e.g. "know-hows", data, standards, employees) (Xu, 2012). Smart Manufacturing in the US and Industry 4.0 in Europe also advocate for the deployment of cyber-physical systems, cloud-based 'servitization' of both tangible and intangible resources, and decentralized production to make production systems autonomous, self-maintainable, adaptive, and flexible (Chituc & Restivo, 2009).

A major challenge in enabling the interoperability of technically disparate manufacturing resources is the inability to codify and integrate manufacturing knowledge. Manufacturing capability is one type of manufacturing knowledge that is not only complex and elusive but to maintain competitiveness different industries have traditionally resorted to developing and protecting their unique capability. Manufacturing capabilities have traditionally been formalized by manufacturers in three forms:

1. machinists' handbooks (Oberg, D. Jones, L. Horton, & H. Ryffel, 2000) and shop-floor manuals - capture the manufacturing knowledge accumulated by the generational experience and experiments.
2. machine and tool vendors - advertise the capabilities of their products (manufacturing resources).
3. technical and mechanical theory - provide scientific (both rule-based and numerical) models for the capabilities of mechanical devices and related processes. Additionally, manufacturing organizations may also advertise their competency in terms of their production performance and quality of the output in a format that is comprehensible and enticing to the targeted customers.

This paper includes - discussion on research new representations of process capabilities, a brief discussion on representing manufacturing systems with ontologies, the presentation of a limited ontology-based process capability model and a case study of how this ontology can represent a representative selection of manufacturing processes.

2 Literature Review

2.1 Process capability in machining

Process capability is defined as historical and scientific knowledge about manufacturing processes (Tien-Chien, Wysk, & Wang, 2006). The authors define three levels of process capabilities: a universal level, a shop level, and a machine level, where the universal level is governed by materials and physics to provide general knowledge about processes (like twist drilling), but other levels focus on true capability within a certain factory or specific machine (drill press or milling machine) which is bound by both physics of the generalized capability and the constraints the machine and tooling providing the capability. For example, the maximum spindle speed of the drill with a certain diameter bit. Important process capability parameters include shape and sized that a process can produce, and dimensions and tolerances that can be produced by various processes. Many manufacturing handbooks contain general capabilities of various manufacturing processes (see for example(Boothroyd, Dewhurst, & Knight, 2010)).

Formal analysis of process capability in research on process planning has been usually done by applying some form of decision rules and/or tables. For example, ref(Wang & Li, 1991) describes detailed reasoning for hole-making operations. Those procedures have been formalized in the research report (Khoshnevis, Tan, & Sormaz, 1993) and implemented in the research process planning system IMPlanner. Details and examples for hole making and milling are provided in (D. N. Sormaz, Khurana, & Wadatkar,

2005) and (D. Sormaz, Gouveia, & Sarkar, 2018). While this approach gives detailed reasoning concerning process capabilities for achieving required dimensions and tolerances, the research on more rigorous formalisms for process capability from first principles has not been covered. For example, the compatibility of various machines, tools, and manufacturing processes is seen as just a binary relation as shown in Fig. 1. For example, milling and drilling tools can be mounted on milling machine, while turning cutters cannot accept milling tools.

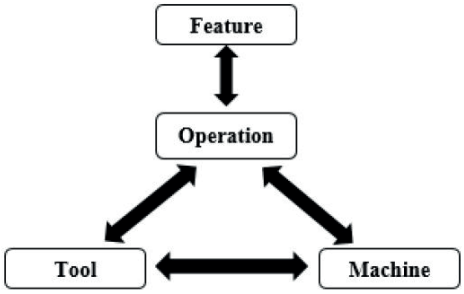

Figure 1. Relations between features, operations, tools, and machines

2.2 Ontologies

Ontologies are structured definitions of real-world entities, their hierarchies, and relationships. An ontology can lay a foundation for an application neutral definition to guide the creation, transformation, and integration of data or knowledge within and across organizations and domains. Creating an ontology demands a thorough examination of the systems being modeled and requires adherence to a rigorous methodology that preserves the philosophical constructs of both the system and the modeling methodology. This development process provides insight into the domain, and the resultant ontology can support data processing, storage, translation, and integration. And the rich and complete representation of a system that an ontology can support, it makes a strong foundation for relational or object-based formats.

While the developer of an ontology should strive to be general and neutral, there will be an implied perspective that the creator (single or group) imparts on their design. Termed as concept orientation, this bias is formed from the creator's perspective and understanding of the system and the ontology methodology being used (Arp, Smith, & Spear, 2015). Couple this bias with breadth and depth bounds imposed by the intended purpose of the ontology and opportunity exists for a design that results in usage limitations. When developing an ontology for manufacturing capability, formalizing existing industry biases will necessarily limit generalization and applicability. Any effort to build such an ontology should respect the three levels of capability of encoding already present – machinist's handbooks, organizational capabilities, and unique machine/tool combinations.

Early attempts to build ontologies for manufacturing domain focused on describing products, manufacturing process, resources, and controls which describe the relations among resources and processes. One early work on the core terms of manufacturing was conducted by Borgo and Leitão, who proposed a set of such core concepts related to manufacturing based on foundation ontology DOLCE (Borgo & Leitão, 2007). The behavior and function of the manufacturing artifacts were developed in their later works (Borgo & Vieu, 2009)(Borgo, Carrara, Vermaas, & Garbacz, 2006)(Borgo, Carrara, & Garbacz, 2010). Although these studies established the functionality of products and resources based on behaviorism and provide some of the conceptual guidelines for understanding capability, they are not exclusively about the manufacturing capability. Another ontology called MASON described by Lemaignan et al. also provided a taxonomy of the core elements of manufacturing, such as process, resources including machine, tool, and raw material but generally lacks entities describing their capability (Lemaignan, Siadat, Dantan, & Semenenko, 2006).

Ameri et al. developed an ontological model describing manufacturing processes and resources as services, which included a detailed study on the capability of machine and tool (Ameri, Urbanovsky, & McArthur, 2012). They also conducted a thesaurus-guided discovery of capability related terms (Sabbagh, Ameri, & Yoder, 2018) as well as developed a process and resource selection module leveraging the capability knowledge (Ameri, 2013). Lu et al. (Lu, Shao, Singh, Xu, & Ye, 2014) developed a taxonomic representation of manufacturing process and resource capabilities directly translating concepts from STEP-NC (ISO) standards using the OntoSTEP methodology proposed by Barbau and Krima (Krima, Barbau, Fiorentini, Sudarsan, & Sriram, 2009). Luo et al. developed a DL based language called MCDL, which utilized the fuzzy-DL concepts in modeling capability ranges for manufacturing resources (Luo et al., 2013). In a recent publication, Järvenpää et al. described a new ontological model for manufacturing capability, named MaRCo (Järvenpää, Siltala, Hylli, & Lanz, 2019), which supports capability matchmaking for resource discovery.

The recent development in the ontology application is Industrial Ontology Foundry (IOF) [ref iof web site]. This effort is based on developing the industrial ontology framework that enables seamless data integration base din semantic marking of data from various applications (such as PLM, ERP, MEs, and others). The framework is based on the adoption of the Basic Formal Ontology (BFO)[1] and layered development of industrial ontologies. The initial effort was devoted to building core common terms for all industrial applications (Smith et al., 2019) and the current work is in developing modules for process planning, supply chain, maintenance, and few other areas. The authors of this paper are active participants in the IOF activities and this work is being done in the IOF framework.

3 Manufacturing Resource and Process Capabilities Model

3.1 Capability of a resource

Colloquially, the term 'capability' is used in describing the ability of some object to achieve a goal. In manufacturing, objects may be items like consumable or capital resources, e.g. material, machine, tool, fixture, die, mold, vehicles, or non-consumable assets, e.g. land, building, and workers. It is also apparent that the capabilities of a resource or asset can only be described in a particular context, which is composed of two different conditions: there must be a method or process in which the object is to be used and there must be a purpose which is expected to be fulfilled. This observation is demonstrated from the following descriptions of capability.

1. An LED light bulb can provide more brightness but consume less energy than a CFL.
2. The two pentalobe screws located on the bottom of an iPhone 6 can be unscrewed by a 5-point pentalobe screwdriver.
3. A robotic hand can pick and remove defective parts from an assembly line.

The notion of the capability bears a phenomenological aspect as some capabilities of an artifact manifest in the context of some benefit which some agent intends to derive from the realization of that capability.

Premise : For every c as Capability, when realized in a Process p, some purpose (of an agent) is fulfilled or some intention is realized (of an agent).

Several analyses resort to behaviorism and model this aspect of capability as a behavior of an artifact, ranging from radical stances such as explaining the outcome or trait of an artifact based on its responses caused by some external stimuli interacting with the internal structural state of the artifact to a more teleological interpretation by avoiding to use the internal causal factors of the artifact in the explanation for the behavior of the artifact in a certain process but posit it as an outcome of the process.
Despite the rigor, radical behaviorism faces hurdles when used in practical situations, some of which are discussed in the publication (Sarkar & Šormaz, 2019). In this paper, 'capability' is classified as a type of 'disposition' (Spear, Ceusters, & Smith, 2016). Being a subtype of disposition, any instance of capability is by default a realizable entity, which is realized when putting in a specific situation ("special physical circumstances," – BFO). This situation-specific realization, which in a way captures the modal aspect of behavioral tendencies of artifacts, covers premise 1.

We further define capability of the manufacturing resource in terms of the function of the resource. The term 'function', as defined in BFO, contains the basis of etiological

selection or artificial creation (Spear, Ceusters, & Smith, 2016), that what the artifact is capable to do is the original purpose of the artifact's existence.

This normative purpose (and the original intention) of an artifact is encapsulated in the functional property of that artifact. Therefore, the premise 2 can be rewritten by using the term function as 'For every c as Capability, when realized in a Process p, some function f, that inheres in the bearer of c, is also realized'.

The restatement also assumes the premise that for a capability to be realized, the bearing artifact must participate in a process. This is because capability, being a realizable entity (BFO), can only be realized in a process, of which the bearer object is a participant. Furthermore, the function being a normative purpose of the artifact (Spear et al., 2016), it must be the case that the process, which realizes that function, occurs in a prescribed manner.

In an aim to derive an OWL-friendly definition (Def. 1) for capability, we introduce a new relationship appraises, which is further axiomatized below.

Axiom1:$Capability(c) \equiv Disposition(c) \wedge \exists f\ appraises(c, f) \wedge (Function(f) \vee Role(f))$

Axiom 2: $appraises(c,f) \rightarrow \exists p, \forall o\ inheresIn(c,o) \wedge inheresIn(f,o) \wedge participatesIn(o,p) \wedge realizes(p,c) \rightarrow realizes(p,f)$

The definition given in Axiom 1 restricts the range of relationship appraises to be either function or role. The reason for including the role in the definition is two fold. Although this paper focuses only on the capability of manufacturing resources, such as machines and tools, which are classified under 'material artifact' in BFO, human beings, such as artisans, operators, and workers, and collectives, such as manufacturers, land, and organization, also possess the capability. However, upon being realized in some manufacturing activity, the capabilities do not necessarily realize any function of these agents as it is debatable in the first place that agents can bear such function (abilities are not functions as most of them are acquired in a lifetime of an agent and thus not etiologically selected. They are also not engineered as the physical structure bearing the capability is not modified while acquiring that capability (Merrel, Limbaugh, Anderson, & Smith, 2019)). to another question: which way is the realization of a capability different from the corresponding realization of a function? It is necessary to disseminate the implication 'realizes(p,c)→realizes(p,f)' further. Functions are always end-directed, that one must find the world in a specific state if they are realized in a process. On the other hand, when some capability is realized, the bearing artifact or some other object, which also participate in process p, is expected to be in a certain state(s). What we broadly mean by the statement 'capability appraises function' is that capability demarcates or predicts the extent by which some function is realized. To be specific, the process, which realizes both the capability and the function, brings forth some state of the world which is commonly contained by the state descriptions associated with both.

However, the capability of a resource is always graded, that it is expressed as a range of expected outcomes. It is thus necessary for the predicted range of the capability to

be such that it overlaps the set of outcomes specified by the function either completely or partially. For example, a lightbulb being capable of producing warmer color temperature (e.g. there are instances of it producing a color temperature of 2700–3000 K in some occurrences of glowing) implies that the light bulb is suitable for making a room cozy (e.g. it has a function of keeping the color temperature of the room at around 2800K). Based on the above evidence one may follow Axiom 1 to say that the capability of producing warmer color temperature appraises the function of making the room cozy.
In a an earlier work (Sarkar & Šormaz, 2019), we presented a formal axiom to capture this granular notion of capability being realized in a process based on fluent, considering that the state description for the function and the capability, which appraises (labeled as demarcates) the function, is a quality measurement and a set of tolerance limit for that measurement In practical application, this exposition based on the process-specific behavior of resources is not necessary to talk about the function or capability of resources. Furthermore, the first-order axioms cannot express the function of a system based on its process-specific behavior completely as it is not expressive enough to capture the modality imbued in such models. On the other hand, the teleological approach adopted in Axiom 1 is more straightforward: "A resource has a function by virtue of its capability."

3.2 Capability of a system

In the modern manufacturing industry, most operations are conducted on complex systems integrating several types of machines, tools, and equipment. Functional decomposition is a popular reductionist strategy, adopted for modeling complex systems by engineers. This method aims to decompose a higher-order function into sub-functions in such a way that if every such sub-functions is realized then the higher-level function is also realized. One of the utilities of functional decomposition is system design, which is to find a suitable mereological hierarchy of subsystems, assembly, and components, that can be assembled into a complete system, capable of achieving such function. This method is also applied in modeling the system architecture as a logical sequence of the functions, which is commonly recorded as a functional flow block diagram in system analysis (US Department of Defense Systems Management College, 2001).

The aggregation among sub-functions mirrors the interdependency of functions as described by Kitamura and Mizoguchi: "A function is achieved by performing(achieving) a series of sub-functions which is called a method of function achievement" (Suh, 1998). In their model, the judgment for the realization an upper-level function in a process is derived from comparing the behavior displayed by the system, due to the underlying structure of the system or its component, to the behavior, expected by the function. The crux of this idea is derived from the FBS ontology of Gero (Gero, 1990). However, modeling functional decomposition based on process-specific behavior of systems and its components is not trivial as such causal-interaction is often emergent and greatly influenced by the experience of the observer.

Axiomatic design (AD) theory, developed by Nam P. Suh, is an integrated model that can be applied in both system design and analysis. AD uses the functional decomposition method in mapping a set of objectives to solution space. By applying the transformation iteratively, more details of the solution unfold, ultimately generating a mereological hierarchy of the complete system (Suh, 1998). AD fits perfectly with the teleological basis of the function we adopted in our definition of capability as it can help in axiomatizing the linear mappings (design matrix) among a set of objectives (functional requirements) and a set of solutions (design parameters of a system). To illustrate the method, the case in example 3 is modeled with AD by constructing the transformation matrix from the capability matchmaking.

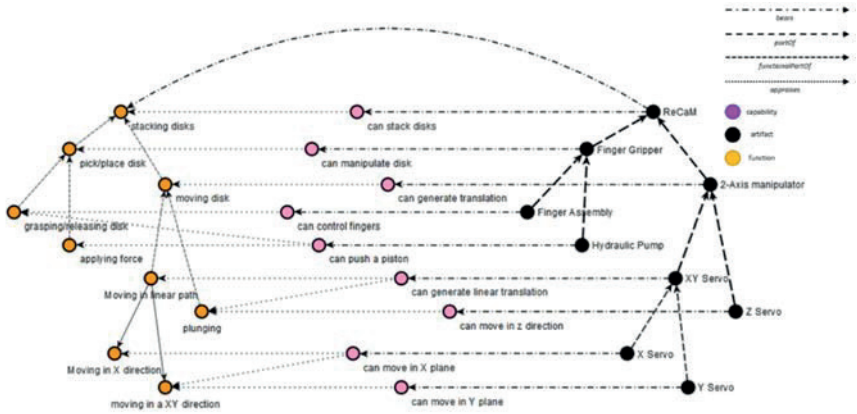

Figure 2 Axiomatic Design principle applied to derive the structural decomposition of a robotic hand which can fulfil the functional requirement of stacking disk on a pallet by collecting them from a conveyor belt.

The term function used in the definition of capability is based on teleological sense and deviate from the behavioral perspective, adopted in DOLCE (Borgo et al., 2006) and YAMATO (Kitamura & Mizoguchi, 2004). However, the teleological interpretation of function is useful in describing the concept of functional decomposition as every sub-function plays some role in achieving the end-goal prophesied by the parent function. We define the relation decomposition based on the result of the process in which these functions are realized without assuming any parthood among its bearers. Although AD links components of a system to the sub-functions, not all types of parthood are described along the functional line.

Axiom 3: $\forall f,\ f' decompose(f', f) \rightarrow \exists f_1 f_2 \dots f_n\ \wedge_{i=1}^{n} decompose(f_i, f) \wedge f' \in list(f_1, f_2, \dots f_n) \wedge \exists p p_1 p_2 \dots p_n realizes(p,\ f) \wedge \wedge_{i=1}^{n} realizes(p_i, f_i) \rightarrow \exists o o_x p_x achieves(p, o) \wedge achieves(p_x, o_x) \wedge o_x = o \wedge generalOccurrentSumOf\left(p_x, list(p_1, p_2, \dots p_n)\right)$

Axiom 3 states that for every function, that decomposes another function, is a member of a list of functions such that if all functions in the set are realized then the parent function is also realized. This implies that the objective (state description(s)) achieved by the process that realizes the parent function is the same as the objective achieved by the general composition of the processes that realize the sub-functions. It is to be noted that 'list' is a function (not to confuse with the term 'function') which returns a list of the elements given as input. The relationship '*generalSumOf*' holds between the general mereological sum of some occurrents and a list of those occurrents.

In Figure 2, the primary function of "stacking disk" is realized when two sub-functions "pick/place disk" and "moving disk" is realized. These sub-functions are realized only when processes, such as picking, placing, and moving, occur in a suitable order or in parallel. In other words, the combined effect of these processes results in a disk being stacked.

In the AD method, a design matrix maps the vector of functional requirements to a vector of design parameters, which are components of the purported system that bears the parent function. Each element of the matrix denotes the extent in which a function is 'satisfied' (as a requirement) by a component, that if greater than 0 then the component may bear that function. For example, the vector of functions In Figure 1, i.e. {'manipulating disk','moving disk'}, can be mapped to the vector of components, I.e. {'finger gripper','CNC'} using the design matrix A, as,

$$\begin{Bmatrix} 'manipulating\ \text{disk}' \\ 'moving\ \text{disk}' \end{Bmatrix} = A \begin{Bmatrix} 'finger\ gripper' \\ 'CNC' \end{Bmatrix}, where\ A = \begin{bmatrix} X & 0 \\ 0 & X \end{bmatrix}$$
$$, X\ \text{being a non} - \text{zero number greater than 0.}$$

However, not every design matrix yields in a valid design as AD dictates that the independence of sub-functions is ensured by using a design matrix which is either diagonal or triangular (Suh, 1998). Before axiomatizing the independence axiom, a special parthood relationship among components of a system is given in Axiom 4 based on the functions they bear. This relationship, *functionalPartOf*, is a sub-property of proper parthood but only holds between the parent and child components only when at least one function inhering in the child component decompose some function inhering in the parent component.

Axiom 4: $FunctionalPartOf(a', a) \rightarrow ContinuantPartOf(a', a) \wedge \exists f f' inheresIn(f, a) \wedge inheresIn(f', a') \wedge decompose(f', f)$

The independence axiom of AD requires that the list of sub-functions, which decomposes a parent function, should contain the minimum number of independent functions necessary to satisfy the parent requirement: "each one of the functional requirements can be satisfied without affecting the other functional requirement" (Suh, 1998). Therefore, it is not guaranteed that every system containing some components as its functional part is a valid assembly. AD prescribes that the design matrix must be either diagonal or triangular to satisfy the independence axiom. Before we can add that

constraint in an ontology, we need to formulate a scheme to derive the matrix on the logical consequence.

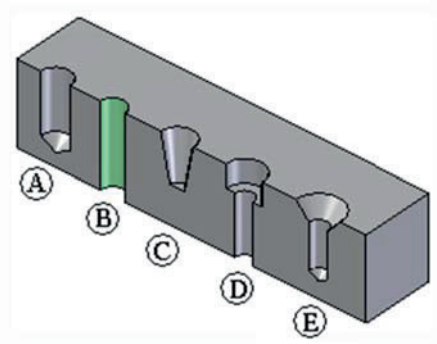
As we exposited in the previous section that a function of an artifact exists in virtue of the artifact's capability. For manufacturing resources, they are primarily designed and built to have certain capabilities. Therefore, a resource is suitable for achieving a functional requirement only when it has some capability that appraises such capability. The design matrix then can be formulated as

$$A = \{Aij = 0..1 \wedge \mathbb{I}|1: \exists c\ inheresIn(a_i, c) \wedge appraises(c, f_i), 0: otherwise\}$$

Based on this definition, for aggregation of components is valid only when every component has some capability which either appraises a capability independently without any other capability also appraising the processor along with another capability that again appraises another sub-function independently. We can classify the capabilities in this line as independent capability and enabled capability. An enabled capability is a capability that is enabled by either some independent capabilities or enabled capabilities. An enabled capability that enables another enabled capability cannot be enabled by that capability it enables. Therefore, the relationship *enable*, given in Axiom 5, is transitive, non-reflexive, and anti-symmetric.

Axiom 5: $enable(ci,cj) \rightarrow \exists fi\ \ appraises(cj,fi) \wedge appraises(ci,fi) \rightarrow \exists fofj\ decompose(fi,fo) \wedge decompose(fj,fo) \wedge appraises(ci,fj) \wedge \neg appraises(cj,fj)$

4 Case Study



The illustration of a capability ontology will be illustrated on building ontologies for the case of machining prismatic features. Most discrete manufacturing industries have parts of generally prismatic shape (usually produced on milling and drilling machine tools) with so-called prismatic features as components of the part design (shape). Most common features are either direct or derived from holes, slots, and pockets (J. J. Shah & Rogers, 1988) (J. Shah & Mantyla, 1995) which, when combined generate a variety of complex shapes. The features and their attributes form the functional requirement for the machine-tool selection. As explained in the earlier sections, machining systems capable of satisfying these functional requirements should have some capability that can appraise the corresponding functions (no distinctions between function and its requirement is made in this study). In Table 1, some of the typical form features and required capabilities of the machine are given.

Obtaining a certain feature is all dependent on a combination of several factors such as a method of tool entry, the primary cutting motion of spindle, and the direction of cutting. For example, a small hole requires plunging, the rotational motion of the spindle, and axial cutting. Following the AD method, a suitable machine should have some components which bear these capabilities individually. However, the overall requirement also needs to be decomposed to deduce the correct assembly and combination of

these components. In most of the CNC machining, a suitable tool is also required. In this study, we only focus on drill bits, which are used for making a hole.

Table 1 Machining Features

	Feature	Method of Tool Entry	Primary Cutting Motion (feed) of Spindle	The Direction of Cutting
	Closed pocket	Ramping	XY path	Radial Cutting
	Large hole (circular pocket)	Helical interpolation	Circular XY	Radial Cutting
	small hole	Plunging	Rotation	Axial Cutting
	Slot	Ramping	X or Y	Radial Cutting

A. Simple hole
B. Threaded hole
C. Tapered hole
D. Counterbore
E. Countersink

Figure 3. Common hole types[2]

The type of drill bit you need typically depends on the type of hole being created. For example, a counterbore hole - Round bottom requires a step drill and a round bottom profile as given in Table 2.

[2] http://www.soliddna.com/SEHelp/ST6/EN/feature_modeling/feat11c.htm

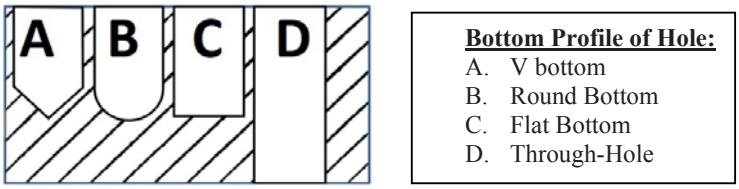


Figure 4 Common types of hole bottoms

Table 2 Matching between holes and drilling tools

Side Profile	Type of drill bit	Bottom Profile of hole
Simple Hole-Round Bottom	Conventional/Spur/Spade	B
Simple holes- Flat bottom	Conventional/Spur/Spade	C
Simple holes- V bottom	Conventional/Spur/Spade	A
Counterbore holes- Flat bottom	Counterbore	C
Counterbore holes- Round Bottom	Step Drill	B
Counterbore holes- V bottom	Counterbore	A
Countersink- Flat bottom	Countersink	C
Countersink- Round bottom	Countersink	B
Countersink- V bottom	Countersink	A
Threaded holes- Flat bottom	Tap Drill	C
Threaded holes- Round bottom	Tap Drill	B
Threaded holes- V bottom	Tap Drill	A

The decomposition of function 'drilling small hole' is given in the diagram shown in Figure 5. The parthood among the corresponding CNC drill machine and a drill bit is also shown. The capabilities presented in figure 5 present the ability of a machine/tool combination to produce the defined hole feature.

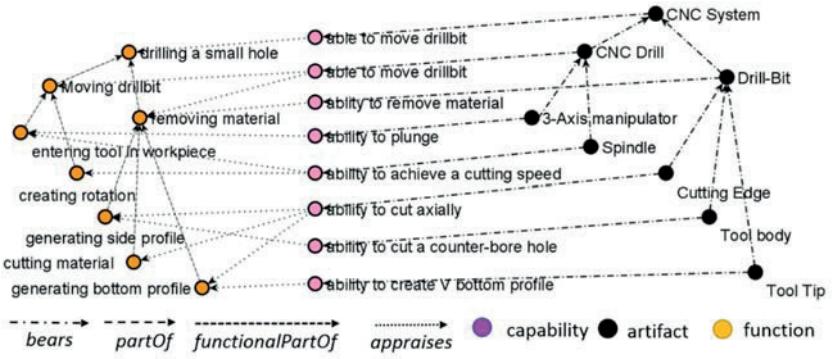

Figure 5. Relations between resources, functions, and capabilities

The OWL file contains a list of rules which capture the knowledge of what type of capability appraises what type of function (see Figure 6). Other rules implement the axioms given in the previous section in description logic-friendly way.

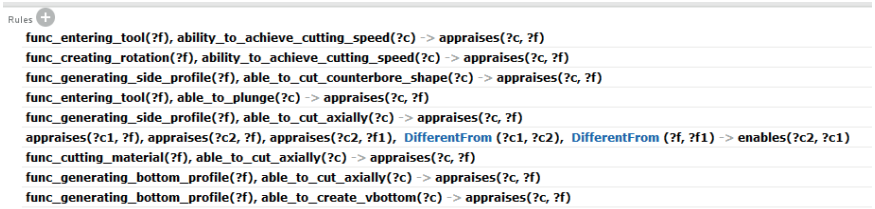

Figure 6. Relation definitions as part of ontology in OWL file

The hierarchy is automatically verified by running reasoner (Pellet) in Protégé. The result of *enable* property assertions are shown in the Figure 7.

Figure 7. Results of the reasoner processing in OWL

5 Conclusions

In this study, we described the manufacturing resource capability as the evaluator of its function. Based on this concept, we derived a logical method to model a machining system by combining suitably capable components, which satisfies the overall function by satisfying the sub-functions. The major contribution of this study is to derive relationships based on the independence axiom of AD. A case study is also conducted to show that suitable CNC machining systems for generating prismatic form features of a part design can be built based on primitive capabilities of machine components and tools. There can be a variety of tools and machine which has similar capabilities. The appraises relationship can be deduced based on numerical ranges. In that sense, many alternative machine and tool combinations may be derived. For finding the best system design, the second axiom of AD, called the information axiom, should be applied. Also, the functional decomposition shown in the case study does not consider the flow of material, energy, and information. These flows are useful for designing the connections among the components. The information axiom and the flow among functions are not covered in this study and will be addressed in a future effort.

Process Plan Reasoning based on SPARQL Extension

Arkopaul Sarkar[1] and Dušan Šormaz[1]

ISE Department, Russ College of Engineering and Technology, Ohio University, Athens, OH 45701, USA,
sormaz@ohio.edu

Abstract. Industry 4.0, Smart Manufacturing, and Digital Twin are technologies that penetrate modern companies in various industries, from automotive, to aerospace, and further to food, chemical, and oil and gas industries. Ubiquitous nature of digital data about variety of processes, the use vast range of software system pose a significant problem for efficient operations. The need to share the data requires that the data are uniformly understood by those software products. This paper presents the result of achieving semantic data integration between product design and manufacturing based on manufacturing process planning ontology as canonical model. First, we present the framework for semantic knowledge in process planning that includes manufacturing features, their tolerance requirements, precedence between them, and necessary processes for their completion. This semantic knowledge has been organized into a manufacturing planning ontology SIMPOM. From the given ontology process planning is executed by developing SPARQL queries, which match the feature requirements with process capabilities and select appropriate processes for each feature. Depending on requirements one or more processes are needed for each feature. The reasoning process in the second phase, also using SPQRQL, includes generation of possible sequences of those processes with consideration of necessary precedences. The process is illustrated of few common features in prismatic parts (holes and slots) and then applied few industrial parts with satisfactory results.

Keywords: process planning, ontologies, SPARQL

1 Introduction

According to Groover [1], "Process planning consists of determining the most appropriate manufacturing and assembly 'processes' and the sequence in which they should be accomplished to produce a given part or product according to the specifications set forth in the product design." In recent times, growing trend in decentralized manufacturing demands that such planning to be conducted by considering distributed manufacturing vendors and partners, where there capability is not known beforehand. Semantically tagged linked data may prove beneficial in integrating the manufacturing processes they can perform and range

of capability of various machining resources they posses. In the past, a number of ontology models were proposed for capturing product design and manufacturing process related information - some of which are given in section 2. These researches build the supporting environment for such distributed planning but any effort to select suitable processes and deduce ordering among the processes for a given product design by using pure logical reasoning is not known to the authors at the time of writing.

As the primary focus of this paper, a set of axioms is designed to represent manufacturing process planning as totally ordered instances of process. Next, we use the proposed semantics in a set of SPARQL queries which can actually build all possible alternative machine routing (a total ordered sequence of occurrences of process instances) from a given part design. In Section 3 we present the ontology for capturing and validating these alternative routes. In order to generate these routes, the queries are executed using a framework which helps them to be executed individually, in a group, once or perpetually until failure. The framework is not part of this paper, which presents three main queries in Section 4 to briefly describe the way a tree-like linked data is generated, which captures every possible routes for each feature of a part design and thus represents the entire process plan as an integrated structure carrying both design and production elements.

2 Literature Review

Utilization of ontology for knowledge based process planning slowly gained the attention of researchers around mid-2000. Two of the notable early knowledge modeling efforts are: foundation of core ontology in manufacturing by Borgo and Leião [2] and formalization of product life cycle semantics (PSRL) by Patil et al. [3]. Since then, a number of manufacturing ontology were proposed, for capturing both upper level and domain specific manufacturing concepts. ADACOR is developed based on DOLCE to facilitate a holonic manufacturing platform [2]. Open assembly model (OAM) proposed by NIST [4] for capturing product design including components and assembly. OAM extends object-oriented Core Product Model (CPM), an earlier model proposed by NIST [5].

In an attempt to provide semantics to STEP standards, ONTOStep provided an ontology to map the STEP functions in OWL model [6]. ONTO-PDM is an ontology developed based on STEP PDM to define fine-grained knowledge structure for product assembly, bill-of-material, and material types [7].

One of the early works on the core terms of manufacturing resources and their capabilities was conducted by Borgo and Leitão based on foundation ontology DOLCE [8]. The behavior and function of the manufacturing artifacts were elucidated in their later works [9,10,11]. MASON ontology proposed by Lemaignan et al. tried to capture the precedence relationship among different manufacturing operations required to produce a part with the desired quality [12]. Assembly Relation Model (ARM) proposed by Kim et al. describes a number of widely used assembly processes, such as joining, bonding, riveting, welding,

and their sub-processes [13]. Ameri et al. [14] developed an ontological model describing manufacturing processes and resources as services, which included a detailed study on the capability of machine and tool. Lu et al. [15] developed a taxonomic representation of manufacturing processes and resource capabilities, by directly translating concepts from STEP-NC (ISO) standards, using the OntoSTEP methodology, proposed by Barbau and Krima [6]. Luo et al. developed a DL based language called MCDL, which utilized the fuzzy-DL concepts in modeling capability ranges for manufacturing resources [16]. In a recent publication, Järvenpää et al. described a new ontological model for manufacturing capability, named MaRCo [17], which supports capability match-making for resource discovery.

Early knowledge-based CAPP systems remain a popular branch of CAPP research since the 1980s. Several CAPP systems, e.g. GARI by Descotte and Latombe [18], EXCAP by Davis and Darbyshire, SIPP by Nau and Chang, and XPLAN by Lenau and Alting, all of which were developed in the early 90s, can be classified as knowledge based expert system (KBES). A framework of data integration of CAD, CAM, CAPP, NC and MRP systems was developed by Dhamija et al., based on Unified Data Meta Model (UDMM) [19].

A long-standing research in knowledge-based CAPP was initiated by Sormaz and Khosnevis[20,21], which followed some forebearing works, such as HiMapp [22] and RTCAPP [23]. HiMapp uses a revised form of a planner called 'Deviser' in its core. RTCAPP consists of frame representation of knowledge, connecting processes, machines, and tools, and a cost based system for concurrent part and process design[24]. Advancing on these early works on knowledge-based process planning Sormaz et al. addressed the technologies necessary to achieve distributed, integrative product configuration and mass customization, such as knowledge engineering, alternative process selection, visualization of decision space, product, and process by XML-based data exchange [25]. The foundation of these developments was a 3D planning model which integrates aggregation, time and variety, which guided the process selection and ordering.

In this study, the process planning concepts and related class and properties are discussed based on a product design ontology and process capability ontology; both of which were developed in our earlier studies [26,27], based on basic formal ontology (BFO) [28] (ISO/IEC DIS 21838-2) as top level ontology. every class and property, used in the axioms, contains an IRI. Separate IRIs are used to distinguish among concepts for design, process, resources, and planning. Moreover, the classes and relationships of these ontology are inherited from bfo and common core ontology (cco) which can be found at https://github.com/CommonCoreOntology/CommonCoreOntologies. In this section and nexts, the classes and properties bear their respective IRI, which we represent by prefixes.

3 Semantic knowledge of process plan

A process plan is essentially a collection of planned processes (instance of `PlannedProcess`). The process plan may be defined by adopting the 'temporal parthood' among processes, following the sub-activity relationship of PSL [29]. Based on the aggregation axis of three-dimensional process plan model [21], many different ways of aggregating processes in a process plan are formally defined in [30]. In this study, the machine, tool, and setup based aggregations are ignored, as our primary goal is to define the ordering among the leaf activities of the activity tree (borrowed from PSL [29]).

The precedence relationship among the instances (occurrence) of a process (universal process type or an activity) is the basis of the 'occurrence tree' in PSL [29]. Every node of an occurrence tree is the primitive or atomic activity occurrence, which are occurrences of the activities at the leaf nodes (which are not decomposed further into sub-activities) of the activity composition hierarchy. Every occurrence in the tree denotes a single step in a possible routing. Therefore every path from the root to leaf occurrence of the occurrence tree provides a possible routing.

As the first criteria for an occurrence to be part of a valid route is that the occurrence should be able to satisfy some of the specification associated with the given design. Following our earlier work [31] on specification-capability matching as a method of evaluating the suitability of a process, we appropriated the *legal* predicate from PSL to state that every occurrence (o) is a member of the occurrence tree ($\mathcal{O}$) if process has some capability which satisfy (function `doesMatch`) any specification associated with some features of a part design (Axiom 1).

Axiom 1 $\forall o, \mathcal{O}\ o \in \mathcal{O} \rightarrow \exists f_s\ f\ q_s\ q\ p\ c\ hasSpecification(f_s, q_s) \wedge occurrenceOf(o, p) \wedge hasCapability(p, c) \wedge inheresIn(q, f) \wedge ((doesMatch(c, q_s) = q) \rightarrow concretizes(q, q_s))$

Next, two types of precedence constraints govern the validity of a process plan. The first one stems from the processing order among features of a part, and the second one from the type of processes to be applied for producing a feature.

Features (e.g. Hole, Slot, Pocket, Chamfers, and Bevel) in product design can only be machined in a specific order due to their overlapping spatial location (position) and orientation (vector) [32]. In general, this type of precedence constraints is imposed by design specification, such as the dimension datum reference and tolerances. In Axiom 2, *psl:minPrecedes* (variant of *psl:successor*) relationship among two occurrences when the activity of the first occurrence is meant to *achieve* (proposed relationship following fluent notion) some quality improvement in a feature, which should be processed before (expressed by using *nextFeature* relationship among features) the feature to be handled by the second occurrence.

Axiom 2 $\forall o, o_s, o'_s minPrecedes(o_s, o'_s, o) \rightarrow \exists a, a_s, a'_s, f, f'$
$occurrenceOf(o, a) \wedge occurrenceOf(o_s, a_s) \wedge occurrenceOf(o'_s, a'_s) \wedge$
$achieves(a_s, partOf(p, f) \wedge achieves(a'_s, partOf(p, f') \wedge nextFeature(f, f')$

Similar to the precedence among features of the part, a valid process plan also needs to follow a particular ordering for the processes applied in order to make one feature meeting its specification. This sort of situation is normal for CNC machining, in which more than one machining step may be required in order to make the product feature in order to meet tolerance specification such as dimension, tolerance, and surface finish. The precedence among processes is best handled if an intermediate object is generated for every step. Following this approach, we may generate intermediate features for the part design whenever more than one process is required to satisfy the specified tolerance requirements. In Figure 1, the precedence among its four features, given in the left graph, is extended by accommodating intermediate features in the graph on the right. The corresponding activity hierarchy is generated by first aggregating the complete plan for the part by machine, then setup, then features, and by step activities in the end, each of which generates one of the intermediate feature. For this particular case it can be stated that to make the feature 'Slab1' we need only milling process ('Step1'), while for the other three features we need two processes for each: for Hole we need twist drilling ('Step3') and boring ('Step3i'), for Slot we need rough ('Step4') and finish ('Step4i') milling operations.

In this particular case, when applied as subactivity of the same `FeatureAct3`, twist drilling (`Step3i`) should precede boring (`Step3`), which can be stated as $\forall \mathtt{o_b} occurrenceOf(\mathtt{o_b}, \text{`}\mathtt{Step3}'\text{)} \wedge legal(\mathtt{o_b}) \rightarrow \exists \mathtt{o_t}, \mathtt{o}\ occurrenceOf(\mathtt{o_t}, \text{`}\mathtt{Step3i}'\text{)} \wedge$ $occurrenceOf(\mathtt{o}, \mathtt{FeatureAct3}) \wedge nextSubocc(\mathtt{o_b}, \mathtt{o_t}, \mathtt{o})$.

It is apparent that without any constraint on the sequence of the steps, every branch of the occurrence tree is a viable route, or in other words, a possible plan for the part. The portion of the occurrence tree, given in Figure 2, is built by considering the feature activities in the activity hierarchy as the atomic activities. It is to be noticed that, only three routes, which are marked by green, are valid routes as per the original feature precedence network, given in the graph in Figure 1.

4 Methodology

The ontological theory presented above may be used to reason over an occurrence tree already built. First the set of occurrences, which satisfy the Axiom 1 may be selected and then the precedence relationship among them may be computed by evaluating constraints arising from feature and process precedence. It is not effective to run reasoner to validate enormous number of combinations of such process occurrences. In stead, a set of SPARQL queries are written by closely following the axioms. These queries run in iterations to gradually build the occurrence tree by only possible occurrences of processes by following the given precedence among features, and then processes, each time also evaluating

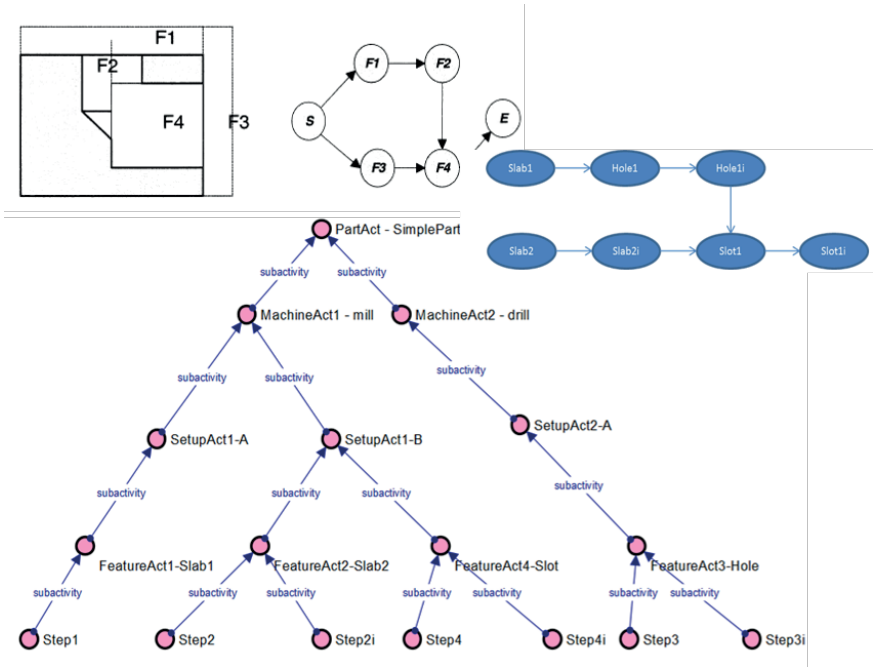

Fig. 1. Extended FPN of a simple part with four features.

whether such process is capable of satisfying any remaining specifications for the work-in-progress part.

The particular type of SPARQL query, used in this study, contains CONSTRUCT clause with one or more unknown variables. These variables are mapped by invocation of a associated service (given in additional FUNCTION clause), which may trigger another SPARQL query before returning values. Such type of augmented SPARQL is used to distribute the planning into different query engines using service based communication. As the rest of the patterns in these queries strictly follow the standard SPARQL 2.0, this particular augmentation is not discussed in detail in this paper.

The entire planning system contains many such SPARQL queries but only three of them are presented below. The first query builds the occurrence tree for the entire part, following the precedence among its features, the second query builds the sub occurrence tree for each feature, following the prescribed sequences of alternative processes, and the third query shows a sample strategy of matching specification and capability. Other SPARQL queries are mostly used for utility purposes, such as importing initial triple sets, transforming local RDF knowledge base, and updating the triple set for query answering.

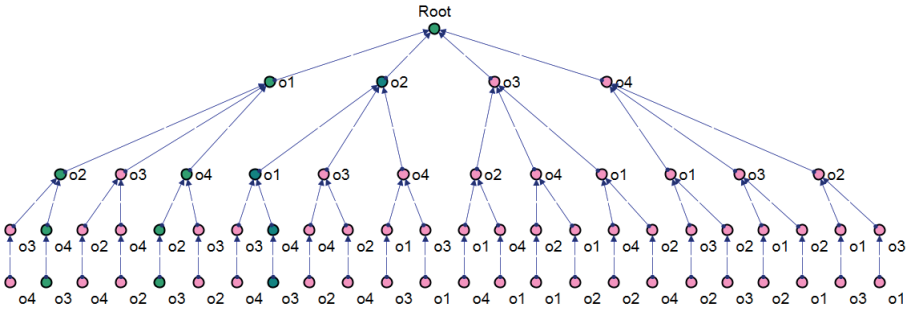

Fig. 2. Occurrence tree for the simple part shown in Figure 1.

4.1 Plan Feature by Precedence

Before the query 'plan-features-by-precedence.rq' (Figure 3) is triggered perpetually until there remains no feature to be planned, or in other words, the select query fails to return any value, the root of the occurrence tree, which is a dummy occurrence of type `plan:RootProcess`.

At each iteration, the SELECT query selects the next available set of feature specifications for each routing so far planned. Five nested SELECT queries, which forms the WHERE clause of the main query, finds all possible features which can be planned for each routing planned so far and filters them for various criteria, such as no such feature be already processed by some occurrence in the corresponding routing. Finally, the FILTER clause at line 26-27 filters only those pairs, bound in ?pCurrent (last occurrence for every routing) and ?rNext (next available feature representations to be planned), for which the count in ?frcount (number of distinct features should be processed as per feature precedence) is greater than or equal to the count in ?fpcount (number of features already processed by the routing).

This particular pattern, consisting of line 21-25, is a ubiquitous pattern, which is used in many rules to find the leaf node of a tree, starting from the root node. In this case, the pattern binds the leaf occurrences to the variable ?pCurrent. Once the leaf occurrences are identified, every possible routing can be found by traversing the path from leaf occurrence to the root occurrence. This is performed by employing the inverse property path ^plan:precedes* (zero or more), which binds all the occurrences in ?p3 for each routing, the last occurrence for which is denoted by each occurrence in ?pCurrrent.

The service is selected automatically by the query by matching the type of the feature specification instance with the input type of the service. The service selects a set of routes, each of which can process the feature completely. These routes can be represented by a occurrence tree. This occurrence tree forms a portion of the complete occurrence tree; therefore, can be called sub-occurrence tree, representing the alternaitve routes for a feature. Every 'feature planning' service returns the set of nodes, which are the direct children of the root oc-

currence of the sub-occurrence tree. On successful execution of the service, the CONSTRUCT part of the rule 'plan-features-by-precedence.rq' appends the returned list of occurrences as children (*plan:precedes*) of the current leaf processes of the current occurrence tree. The leaf occurrences are those, which are bound to ?pCurrent for the input feature specification in ?fs.

Fig. 3. Rule to select features according to precedence among them and append the sub occurrence tree planned by the service to generate the complete occurrence tree for the given part

4.2 Plan Processes for Feature

In this study, seven types of standard prismatic features, suitable for CNC machining are considered. Each type of 'feature planning' agent captures this knowledge as a rule, which reads all available process individuals for the compatible process types and assert the required order among them. The available process individuals are read from the process capability knowledge base. The structure of process capability knowledge base (A-Box) and referred ontology is not included for brevity.

The query 'plan-processes-for-feature.rq' (figure 4(a)), recursively selects applicable set of processes from the available processes, respecting the prescribed order of application among them and then tests if the capabilities of any process can satisfy the dimension or tolerance specifications of the feature. At every iteration, the processes, satisfying at least some of the specifications of the feature,

are added to the occurrence tree by creating a new occurrence for such process type. The rule keeps on triggering repetitively, until no process remains in the precedence graph or the feature specification is already satisfied completely.

However, at every iteration, this rule delegates the task of comparing capability and specification for figuring out the suitable process types to a separate matching service, named 'ask_to_select_process'.

4.3 Match Specification Capability

There can be myriad of ways, in which this comparison may be applied, depending on the type of the capability and how they are measured. In this development, most of the capability information are expressed as numerical range. Every instance of process capability is able to satisfy a specific kind of specification, which is linked to the instance of capability by predicate *cco:references*. The rule, given in Figure 4(b), simply tests whether the dimension of the corresponding specification of the feature lies within the maximum and minimum bounds of the capability by applying the FILTER in line 30. The pair of matching capability and specifications are selected by the type of the instance (?dimType) linked to the capability instance (?capa) by *cco:references*. The pattern to select the maximum and minimum bounds are similar and given in line 17-22 and line 24-29 respectively. The pattern follows the information structure of range capability, in which the maximum and minimum bound bearing entity (?maxIBE and ?minIBE) are contained by the corresponding information content entity variables ?maxICE, and ?minICE, distinguished by the maximum measurement ordinal ?maxOrd and ?minOrd, respectively.

The pattern of the query 'match-specification-capability-by-limit' (Figure 4(b)) marks the specifications whose value is contained by the range of a matching capability, as described above. For every satisfied specification, the CONSTRUCT of the rule creates a new instance (?d1) of
`cco:InformationQualityEntity`, which *cco:concretizes* that specification instance (?d). The instance of `cco:InformationQualityEntity` is a real quality, which inheres in the physical feature. As every such real quality instance is linked to the corresponding specification instance, every part produced by following the plan can be associated with the corresponding design specification to tiniest detail.

5 Experiment

This section presents the evaluations conducted to verify the efficacy and performance of this semantic process planning queries, described above, by using several different design specifications as input samples. Some of these sample designs are hand-crafted to test different type of features and associated specifications. These samples are used for testing the planning outcome for individual feature type. In the following sections, the result of planning a hole type feature is presented first. Similar experiments for other types of features, such as slot,

(b) match-specification-capability-by-limit.rq

Fig. 4. (a) Rule to generate the sub-occurrence tree for a given feature specification, (b) rule for testing whether the feature has any specification whose value is contained by the range of a matching capability

pocket, and slabs can be found in Sarkar's doctoral dissertation [33]. Then, we present the summary of the planning of a set of three complex parts in section 5.2.

5.1 Planning a hole type feature

The sample hole feature with radius 1.0 mm, depth 2.0 mm, requiring roundness tolerance 0.003, and true position 1.44E-4 mm. The planning for the sample hole feature is conducted by allowing the planner to consider every available processes, realizing `HoleMaking` functions, such as functions of types **HoleStarting**, **HoleMaking**, **HoleImproving**, and **HoleFinishing** and need to be applied in the same order. The sub-occurrence tree for the feature, created by an in-planner plot, is shown in figure 5. The occurrence tree contains every possible route, which can be applied to drill the hole. However, it can be observed that the most of output features of the leaf occurrences are colored red, indicating that those routes fail to satisfy the specifications completely, except only three leaf occurrences: `Reaming_Ir899r1`, `Reaming_I0xgnkm`, and `PrecisionBoring_Ij5f3e1`, having output features colored in green, indicating that a completely satisfied feature is produced. It is apparent from the graph that the planner continued applying the next available process, whenever certain process produced a partially satisfied feature (of type **IntermediateFormFeature**), which are marked in blue.

We analyzed the 'part-4a-plan.rdf' with the analyzer program. The program picks up three valid routes with the following sequence of occurrences, agreeing to the observation from the in-planner graph, shown in Figure 5.

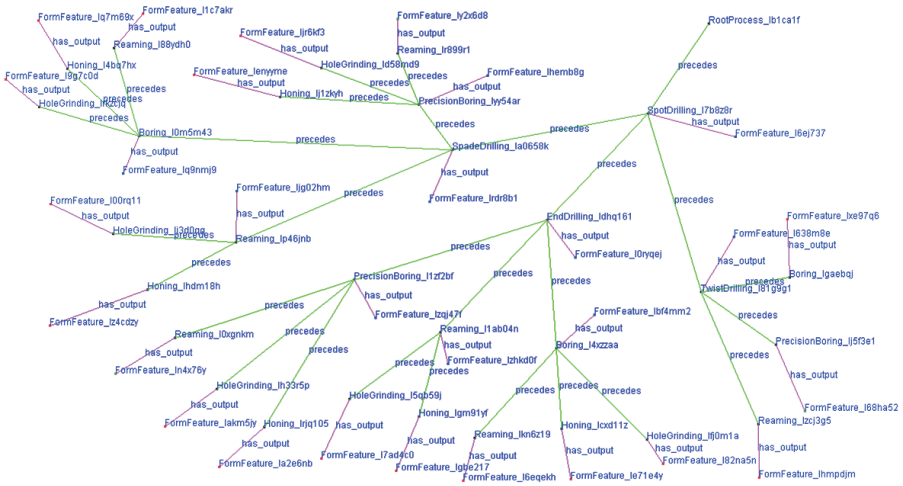

Fig. 5. Sub-occurrence tree of feature 'Test-Hole'.

  PrecisionBoring_Ij5f3e1@Test-Hole
```

5.2 Practical Design Samples

These standard part designs are originally designed in Siemens NX CAD application and then analyzed by IMPlanner application to generate the corresponding design XML file, which contains the features, associated dimension and tolerances, and machining precedence among the features (given in 6). These design XML files are transformed into RDF graph before the planning rules are triggered.

The planning for the parts are conducted by allowing the queries to consider a set of processes, which can be performed by a combination of CNC machines and tools with variable ranges of capability. These processes maintain a order in their application, which is also stored in the knowledge graph. We want to test whether the planner can find every possible way to produce the part completely. In figure 7, the given occurrence trees (in the same order of the samples in figure 6 are generated by extracting the occurrences and *precedes* relationships among them and plotting in yEd graph viewer. For Netex part, the planner generated total 24960 unique routes to process the part completely. The NIST-CTC-01

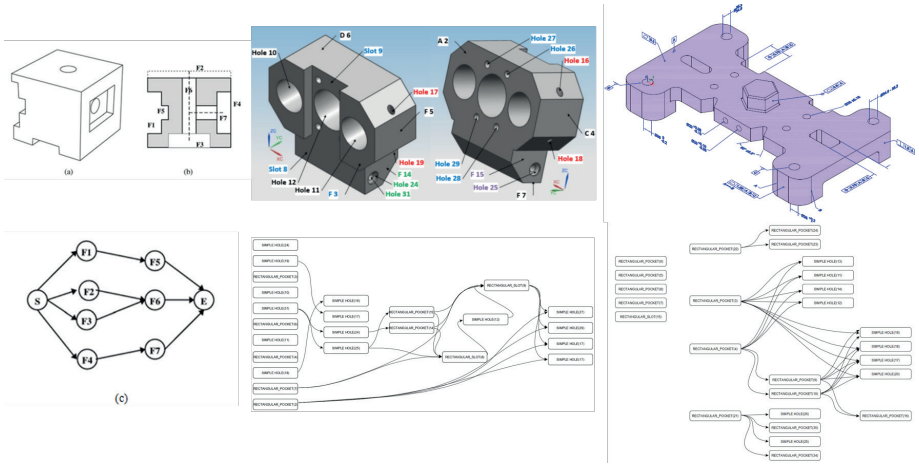

Fig. 6. Sample parts for evaluation

and the Slider part were tested with alternative completely ordered precedences among features in order to avoid longer processing time, however, the alternative processes were allowed. In figure 7, the complete occurrence tree for Netex contains alternatives generated from the partial order among the features as well as the alternative processing routes in the sub-occurrence tree for each feature. Two out of many alternative occurrence tree following various complete order precedence among features are given for Slider part. No such visualization for NIST-CTC-01 part is created because each such complete order occurrence tree itself contains 32768 alternative routes.

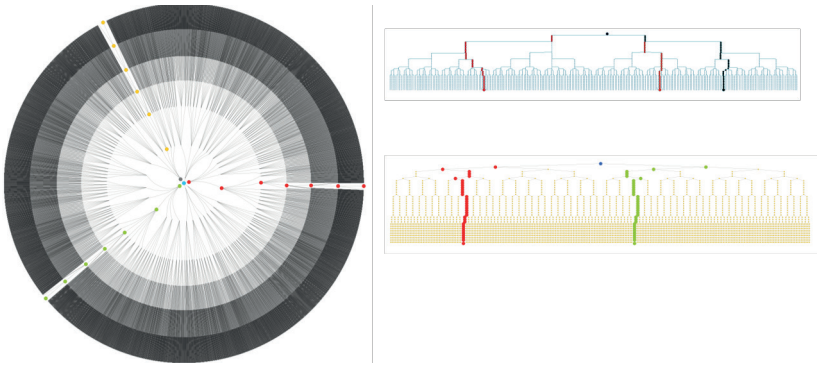

Fig. 7. Occurrence trees produced by the queries for first two sample parts in [**?**]

The colored nodes in the occurrence trees, given in 7, marks different sample routes which are validated by checking the criteria: whether every alternative

route in the occurrence tree is unique, there is at least one process dedicated for each feature in the part, and the features are processed as per the machining precedence among features.

6 Summary and Future Work

The most critical part of the ontology development is the planning ontology, which aims to capture the three dimensional information structure of manufacturing process plan, comprised of aggregation, variety, and time dimension. Except the aggregation dimension, which we do not include in this study, the axioms are heavily motivated by the concepts of process compositions and temporal relationship among occurrences, which are borrowed from PSL with some modifications to adapt to the situation of planning. The output features of the planned processes are also classified based on their conformance to the given specification. Finally, manufacturing process plan is represented as an occurrence tree, which collects every possible route for manufacturing a part completely is represented in a tree structure.

The planning queries are evaluated by a number of sample parts and by constraining it to select from a specific set of alternative processes. The accuracy of these plans is mostly guaranteed by evaluating the criteria, such as whether the plan contains some occurrence for every feature, whether the alternative routes obey the constrains of feature precedence and process precedence, and whether every feature is completely processed or if not, for what reason. Some experiments are conducted with industrial parts, usually containing numerous features, e.g. Netex, Slider, and NIST-01, in order to show the applicability of SIMPlanner in practical cases. However, a complete occurrence tree could not be generated for Slider and NIST-01 in a single run, due to the time-consuming rule in 'part planning agent'. Instead, the experiments are conducted with completely ordered feature precedence, derived from the given partial order among the features, in order to minimize the load on the rule in 3.

The fundamental cause for the increasing amount of execution time for the planner in case of larder parts are due to the fact that the search and update of occurrence at every iteration results in a large derivation tree. A search strategy needs to be implemented in order to guide queries to be executed for only the shortest possible derivation path. As observed in the experiments with a large number of features, the planner consumes an extraordinary amount of time. In a distributed manufacturing environment, this problem will be exacerbated by the sheer volume of alternative resources (machines, tools, and suppliers). A number of space-search algorithms, such as A*, may be applied with a suitable heuristic to avoid expanding some of the alternative routes further. These type of bounding algorithms need to be embedded in the queries of part planning and feature planning agents.

In order to extend the prototype, presented in this study, for handling process planning for other domains of manufacturing, such as assembly, metal stamping, forging, injection molding, and 3D printing, the domain level ontology needs to

be furnished with taxonomies of concepts from these domains. For this purpose, a detailed investigation needs to be conducted for each of these domains to gather the list of processes, functions, and capabilities of machines and tools, used in these domains. Furthermore, various domains level planning knowledge, precedence among processes, material conditions, and general best practices need to be encoded in the rules of the agents. Some of the planning related concepts in other domain may even require certain adjustments in the definitions of upper level concepts. Such an endeavor definitely coincides with the current work of Industrial Ontology Foundry in developing a global ontology for manufacturing. In the future, the proposed model of upper level manufacturing ontology is expected to converge.

Abstract. In this contribution, a novel framework for the Shop-floor Scheduling Nervousness (SN) is presented. The SN is defined as an evolving state associated to an on-going schedule domain. The approach is suitable to be instantiated within industry 4.0 manufacturing environments.

Keywords: Nervousness, Online Scheduling, Industry 4.0.

1 Introduction

Traditionally, the production scheduling problem has been addressed by means of (i) predictive approaches, (ii) robust proactive approaches, and (iii) predictive-reactive approaches. In practice and due to their intrinsic and complex dynamic nature, industrial plants constantly face unexpected events and changes on the expected performance (Novas & Henning, 2010). Thus, scheduling at real contexts needs to be addressed by means of online approaches, in order to continuously revise the agenda.

Nevertheless, even when immediate rescheduling actions are performed each time a disruption or deviation occurs in order to get a new feasible/good quality solution, this adaptation-to-change response mechanism might not be well accepted on the shop-floor. That is because repeated changes could lead to a continuous rearrange of predefined plans on the shop floor, and through all the plans linked, even up to the supply chain level. This undesired behavior is known in practice as *nervousness*. Since changes occur on plans at different areas, nervousness also exists at different levels. Nervousness happens in MRP systems and it has been studied for many years (Belmokhtar et al., 2010). This kind of nervousness has to do, mainly, with changes on the production orders plan and has been identified in the literature as *scheduling nervousness* (or its counterpart *scheduling stability*). Nervousness also occurs at the control systems level, where it has received increasing attention (Hadeli et al., 2006).

Yet, further interpretation and specification of the nervousness happening at the shop floor level, where a short-term on-going schedule drives the production agenda, is needed. The *shop-floor scheduling nervousness* (SN) exists because of the intrinsic connections among the planning and shop domain entities. Thus, the efficient control of the SN is a key issue to be handled in order to have efficient scheduling support systems. Here, advances on a novel framework to characterize the SN are presented.

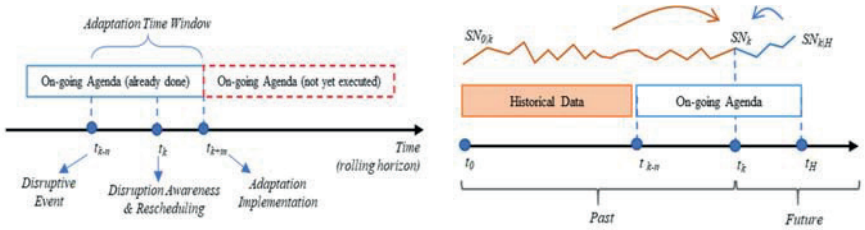
2 A Shop-Floor Scheduling Nervousness Framework

The presented framework is aimed at providing a conceptual ground over which approaches intended to identify and manage SN can be developed. In this section, some insights of the features that characterize the proposed shop-floor nervousness are identified (the complete framework is not described here because of lack of space).

The SN Scope. A definition of shop-floor scheduling nervousness is provided, with the aim of distinguishing the main aspects that characterize it. The SN is identified as a *state* of the shop schedule, which represents a latent state of inefficient behaviors, that exists at every time point along the scheduling horizon, while the shop is executing production orders, which results from (i) what has already happened in the recent past, during the already executed portion of the on-going schedule, (ii) what has occurred in past executed agendas and represented by historical data, and (iii) what is not happened yet, but either it is planned and/or can be expected based on that historical data. From the SN management it can be expected to: (i) Kip track of the past changes on the agenda. Allowing to optimize performance measures, like the cost-related ones, at any reactive activity, and at the same time, to know the deterioration of the agenda along the scheduling horizon caused by disruptions. (ii) Determines the more suitable reactive/adaptive actions to implement. For instance, some change over a given schedule entity might be forbidden if a certain nervousness threshold is overpassed. (iii) Known a nervousness trend of the global agenda, as well as for each individual domain entity (resources and jobs, mainly).

Relations among Rescheduling, Stability & Nervousness. The *reactive scheduling* or rescheduling activity is intended to update and adapt an on-going agenda. It can be carried out periodically, triggered by a disruptive event, or by a hybrid policy. A reactive scheduling task occurs at a certain time point within the schedule horizon and pursues the rearrangement of the agenda trying not to degrade the schedule performance. *Stability*, then, is a natural objective of a rescheduling task. Considering stability leads to a reactive action that tries to change as less as possible the properties of the on-going schedule. This means that the values the temporal variables have, the assignments of operations to resources, and all related planned decisions, will be maintained as much as possible.

At this point, it is possible to differentiate between nervousness and stability. While *nervousness* represents a state of the shop, the stability is an objective to reach each time a rescheduling action takes place. Nevertheless, nervousness and stability are highly related. A shop will increase its nervousness when the changes through time (as results of rescheduling tasks) have a cumulative negative impact on stability measures. A highly nervous shop arises as a consequence of the system inability to efficiently manage its stability through time.



The SN not only is related with the stability of the agenda, but to its performance too. How potential modifications on schedule entities can impact on an efficiency performance measure is also associated with the SN concept. The more related the domain variables are, the higher SN is. Historical statistical analysis can show in-

sights about the correlation among different entities/variables, which in turn can be helpful to predict a probable behavior when changes occur on those variables.

Time-related features. Having a SN characterization requires an explicit domain specification. Among other relevant domain issues, diverse types of time-points associated with different schedule knowledge are identified. Fig. 1 (a) shows some of these time points, which correct management is essential in order to effectively apply an adaptation to an on-going agenda.

As it was already stated, the SN strongly depends on time: the more unstable a manufacturing shop was in the past, the more uncertainty about its future it has, and therefore, the more nervous it is in the present.

Let's say there is an on-progress schedule at time t_k, as it is shown in Fig. 1 (b). The schedule has started its execution n periods of time before t_k and the activities will be finished at t_H, as planned. The shop nervousness value at t_k, SN_k, is influenced by historical data, from t_0 to t_{k-n}, the already executed portion of the on-going schedule data, from time point t_{k-n} to t_k, as well as for the SN predicted values from t_k to t_H.

(a) (b)

Fig. 1. (a) The proximity among the depicted time-points will depend on the automation and complexity level of the shop-floor and production agenda. (b) Schematic representation of the past data and forecasted data making impact in the current SN at t_k.

Part of the novelty of this proposed framework is the consideration of the future into the online schedule system. The past behavior of schedule entities can be analyzed and, when it is feasible, future behavior can be predicted by statistics or AI based methods. Thus, not only past events and current status impacts on SN state, but the predicted future values too.

3 A conceptual model for SN in practice

As it was stated, the SN is related with an on-going agenda, their domain entities, the historical and recent past data, and the forecasted data, considering uncertainty when it is suitable. Here and because of lack of space, just an illustrative insight of a developed conceptual model is described.

A production schedule can be acknowledged as a set of planned events that are linked to domain entities, such as the production tasks. These tasks have temporal properties, creating an agenda for the jobs and their required operations. Therefore,

shop schedule properties such as its performance, and domain entities attributes like a tardiness associated with a job, can be identified and measured.

There is also historical data associated with some of the entities, such as jobs and resources. This data can be used to know the behavior that characterizes them. From this information, features such as a probability of failure of a machine, probability of tardiness completion of a job, among another relevant knowledge, can be estimated. Likewise, the nervousness associated with an entity can be estimated.

The linkage of the shop schedule and other related plans is a fundamental part of a nervousness estimation, since it has to do with the potential impact of a given plan over other ones. This can be tackled, for instance, as part of correlation analysis.

The unexpected disruptive events have also to be incorporated as part of a SN framework. There is a set of unplanned events that cannot be predicted, but there are other many events over which a prediction can be done, in terms of their probability of occurrence. Disruptions caused by a broken machine, a new urgent job, a discontinuation of a raw material supply, among others, sometimes may have a given behavior based on a given probability of occurrence. Thus, that behavior can be estimated.

Knowing a global level of SN will allow to take more effective and efficient decisions each time the agenda needs to be adapted or changed. For instance, a shop with a low level of nervousness can take more changes to the ongoing agenda than one with a higher level of nervousness. In a high nervous system, there is small room for alterations to what is already planned. This means that not necessarily each rescheduling action requires to minimize as much as possible changes: The level of enabled changes will depend on the level of nervousness the system has at that time point.

4 Conclusions

In this work, a novel framework for the Shop-floor Scheduling Nervousness is presented. It is intended to define the SN as an evolving state associated to an on-going schedule domain. In this conceptual-based framework different features characterizing the SN are identified. The contribution describes a novel schedule revision approach, that considers not only past and current data, but future estimated data, too. Based on this framework, diverse approaches, models and metrics can be developed and tested within diverse manufacturing environments.

Abstract. Com fábricas e produtos inteligentes, mudanças ocorrerão na maneira como os produtos serão fabricados, impactando em vários setores do mercado. O PLM mantém a promessa de integrar e disponibilizar todas as informações produzidas durante as fases do ciclo de vida de um produto. A Indústria 4.0 (I4.0) propõe uma gestão eficiente de dados, disponibilidade, confiabilidade e responsividade, permitindo que decisões sejam tomadas em tempo real. Com base no portfólio obtido da revisão da literatura, uma comparação cruzada entre a I4.0 e o PLM foi conduzida sob a ótica das dimensões de maturidade e principais perspectivas de cada área, no sentido de identificar lacunas e oportunidades de pesquisa. O trabalho foi desenvolvido com o objetivo de avaliar a maturidade de uma organização do ramo de eletrodomésticos no contexto do PLM relacionados com atributos da indústria 4.0. Para tal, foi elaborado um modelo de maturidade, a partir da relação entre os principais atributos da I4.0 e as fases do ciclo de vida do produto. Com base neste modelo o diagnóstico do nível de maturidade foi realizado através do método AHP avaliando a importância relativa dos critérios que caracterizam atributos da I4.0 e dimensões do PLM. Os resultados obtidos indicam que a empresa se encontra em Nível 3 de maturidade.

Keywords: PLM, Indústria 4.0, Modelo de Maturidade, AHP.

1 Introdução

A Indústria 4.0 é um conjunto de tecnologias que proporcionam numerosos benefícios ao setor industrial. A também chamada de 4ª Revolução Industrial contribui para personalização das empresas no mercado, a gestão do conhecimento organizacional e a qualificação dos colaboradores nesta nova etapa dos processos produtivos (SCHWAB, 2016).

A Gestão do Ciclo de vida de Produto, também conhecida como PLM (*Product Lifecycle Management*), é um conceito de gestão constituída de dados relacionados aos produtos e processos, ao longo do seu ciclo de vida (SAAKSVOURI; IMMONEN, 2008, p.15; ZANCUL, 2009, p.1). Está se tornando uma parte fundamental dentro das empresas para gerar valor sustentável e concorrência, no qual os consumidores estão interessados nos impactos ambientais das mercadorias consumidas (GUELERE FILHO *et al*., 2009, p.2).

Com a integração da Indústria 4.0 e o PLM em todas as etapas de fabricação é possível obter um melhor gerenciamento do mesmo, com respostas mais rápidas e fáceis, permitindo que o aproveitamento dos dados impulsione o sistema produtivo, pois cada setor possui um desafio e uma necessidade diferente. Diante desse cenário, parâmetros de classificação quanto a maturidade das organizações para o emprego de produtos relacionados as exigências da Indústria 4.0 podem ser usados como alternativa para monitorar e garantir eficiência no emprego de projetos que exigem cada vez mais flexibilidade e performance.

Cristofari Junior *et al.* (2010), descreve a grade de maturidade como "estruturas que apresentam uma descrição qualitativa das áreas estratégicas do processo". Para os autores, o melhor modelo de maturidade a ser aplicado é aquele que aplica a grade de maturidade juntamente com modelos de capacidade. O resultado desse modelo de maturidade é o emprego de um questionário sobre as melhores práticas do processo avaliado, no qual o colaborador avaliou as práticas de acordo com uma escala variante de 0 a 4. O resultado dessa avaliação permite definir o grau de maturidade do segmento.

O presente trabalho contribui para a formalização de um modelo diagnóstico de maturidade no segmento da indústria de eletrodomésticos, de forma a suportar uma avaliação diagnóstica e decisional para o estabelecimento de um plano de diretrizes e melhorias.

A Figura 1 representa o fluxograma da pesquisa, as quais foram separadas em etapas. Para o desenvolvimento deste trabalho foi utilizada, em uma primeira etapa, uma revisão da literatura para melhor entendimento dos conceitos relacionados aos modelos de maturidade caracterizando os atributos da Indústria 4.0 e o PLM. Na segunda etapa foi elaborada uma matriz relacional com o intuito de identificar a intensidade da relação entre os atributos da I4.0 e o PLM, caracterizando-os em nula, fraca, média ou forte relação. Logo em seguida, com os atributos selecionados, foram realizadas fichas de avaliação, as quais serviram como base para elaboração da quarta etapa, que caracterizou a estruturação do método AHP e a aplicação do mesmo tendo como resultado o diagnóstico do nível de maturidade atual da empresa.

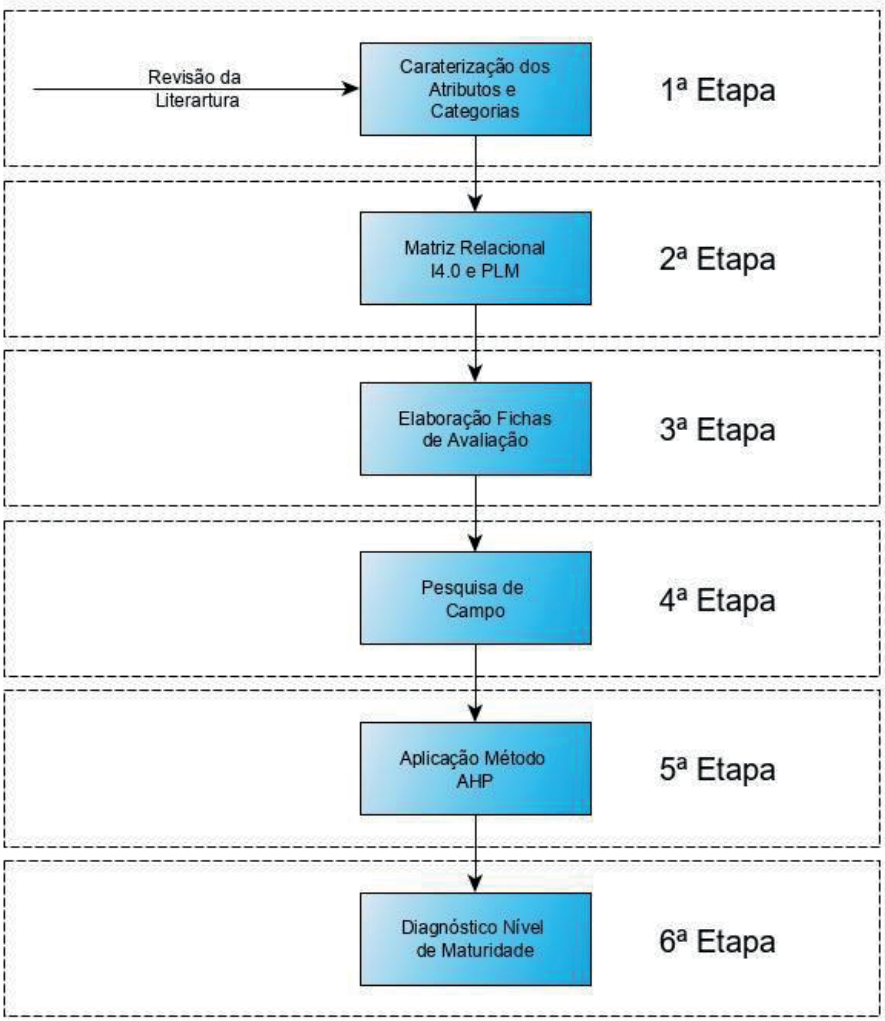

Fig. 1. Fluxograma de Pesquisa

O presente artigo é estruturado da seguinte forma. Na Seção 2, os conceitos básicos da Indústria 4.0, PLM e seus respectivos modelos de maturidade são apresentados. Na Seção 3 é aplicado o método da matriz relacional para a seleção dos atributos a serem utilizados na avaliação. Na Seção 4 é feita a análise diagnóstica através do método AHP sendo os resultados discutidos na Seção 5. As considerações finais são apresentadas na Seção 6, destacando algumas limitações deste artigo e sugestões para futuras pesquisas sobre o assunto.

2 Base conceitual

2.1 Indústria 4.0 Modelos de Maturidade

A respeito de seu surgimento, Hahn Filho (2016) afirma que o conceito de Indústria 4.0 foi exposto para o público geral em 2011, na feira de Hannover, propondo uma ruptura de paradigma na maneira como as fábricas operam. Os pilares que conceituam a indústria 4.0 já são utilizados na manufatura, porém sua integração transformará a produção, consolidando fluxos integrados, otimizados e automatizados e mudando as tradicionais relações entre fabricantes, fornecedores e clientes, bem como humanos e máquinas (RÜßMANN *et al*, 2015). De acordo com os autores, são oito os principais pilares de sustentação: a) *Big Data and Data analysis;* b) *Autonomous robots;* c) *Simulation*; d) *Internet of things*; e) *Cyber-physical systems* (CPS); f) *Cyber security;* g) *Cloud;* h) *Additive manufacturing;*

Um modelo de maturidade descreve em um espaço de tempo as capacidades específicas dentro de uma organização (HYNDS *et al*, 2014). A maturidade de uma empresa pode ser entendida como uma medida de sua excelência dentro da organização. Os modelos de maturidade descritos são alguns dos disponíveis na literatura referente a Indústria 4.0.

O Impuls-VDMA é uma ferramenta de auto avaliação criada pela Associação Alemã de Fabricação de Máquinas e Instalações Industriais (VDMA) juntamente com a fundação Impuls, que é aplicada por empresas para o conhecimento do seu nível de preparação e condições para a transformação promovida pela Indústria 4.0 (SANTOS; MARTINHO, 2018).

O I4.0 *Maturity Model*, modelo proposto por Schumacher *et al*. (2016) apresenta oito dimensões envolvendo diferentes perspectivas. 1º Dimensão – *Strategy: Implementation I40 roadmap; Available Resources for realization; Adaption of business models.* 2ª Dimensão – *Leadership: Willingness of leaders; Management competences and methods; Existence of Central coordination for I40*. 3ª Dimensão – *Customer: Utilization of customer data; Digitalization of sales/services; Customer's Digital media competence*. 4ª Dimensão – *Products: Individualization of products; Digitalization of Products; Product Information into other systems*. 5ª Dimensão – *Operations: Decentralization of processes; Modeling and simulation; Interdisciplinary; Interdepartmental*. 6ª Dimensão – *Culture: Knowledge sharing; Open-innovation and cross company collaboration; Value of ICT in company*. 7ª Dimensão – *Governance: Labour regulations for I40; Suitability of employees to new technology; Autonomy of Employees*. 8ª Dimensão – *Technology: Existence of modern ICT; Utilization of mobile devices; Utilization of machine-to-machine communication*.

O modelo proposto por Leyh *et al*. (2017), chamado de *System Integration Maturity Model Industry* 4.0 (SIMMI), é composto por quatro dimensões: *vertical Integration, horizontal integration, digital products development* e *cross technology*. A dimensão *vertical integration* diz respeito aos componentes dos níveis mais baixos da organização, em que objetos físicos, como produtos e máquinas, precisam trocar informações entre esse nível e entre níveis superiores. *Horizontal integration* trata da cadeia de valores, na qual é necessário um fluxo automatizado e integrado de informações no nível

horizontal da cadeia e fora dele, permitindo interoperabilidade entre os envolvidos na cadeia de suprimentos. A dimensão *digital products development* envolve a representação digital, na qual pelo menos um sistema deve estar integrado a uma etapa do processo. A dimensão *cross technology* é fundamentada na avaliação de quais tecnologias são adotadas nos diferentes campos da indústria 4.0

Schuh *et al*. (2017) propõem o modelo Acatech Maturity Index, composto de quatro dimensões: *resources, information systems, culture e organizational structure*. A dimensão *resources* refere-se à recursos, contemplando a força de trabalho da companhia (recurso humano), máquinas e equipamentos, ferramentas, materiais e o produto final. *Information systems* preparam, processam, armazenam e transferem dados e informações. A dimensão *culture* parte da premissa que as organizações não poderão alcançar seus objetivos e o desejo de agilidade se simplesmente introduzirem tecnologias digitais sem abordar a cultura corporativa. *Organization structure* refere-se no modelo proposto à organização interna da companhia (estrutura e processos operacionais) e sua posição quanto a cadeia de valores, estabelecendo regras que organizam a colaboração interna e externa (SCHUH *et al*, 2017).

2.2 Product Lifecycle Management e Modelos de Maturidade

Para Amann (2002) a concepção do PLM é uma abordagem estratégica para criação, gerenciamento e uso eficaz do capital intelectual corporativo, desde a concepção inicial de um produto até sua aposentadoria. Li *et al*. (2015) ponderam uma ideia básica desses processos, começando pela fase de design, na qual uma ideia é concebida em uma descrição detalhada, seguindo para a fase de produção, onde o produto final é elaborado e na fase logística é armazenado e transportado para o cliente, que pode fazer o uso de seu produto enquanto o fabricante provê serviços fundamentais. Se o produto vier a apresentar defeito, a manutenção entra em questão e caso o produto não possa mais ser usado, chega ao fim de sua vida com a reciclagem ou descarte. As fases que envolvem esses processos dividem-se basicamente em três períodos característicos: *beginning of life* (BOL), *middle of life* (MOL) e *end of life* (EOL).

De acordo com Li *et al*, 2015 os principais atributos inseridos no início de vida do produto (BOL) são: *Customer's Demands, Maintenance and failure information, Cooperative corporation information, Design specifications: Bill of material, Production Information*. Já na fase MOL são: *User manual, Production Information, Maintenance supporting information, Product status information, Usage environment information, Maintenance plan*. No EOLtemos: *Maintenance history information, Product status information, Usage environment information, Recycling part information, EOL product status information, Dismantling information.*

3 Análise relacional da I4.0 e PLM

Para a priorização dos itens com maior influência no ciclo de vida do produto em relação aos pilares da Indústria 4.0, foi aplicado uma matriz relacional, representado em parte na Figura 2, selecionando os atributos dos modelos de maturidade com cada fase do modelo de PLM. Os modelos de Maturidade da Industria 4.0 estudados foram: Impuls – VDMA, I4.0 Maturity Model, Simmi 4.0 e Index (Acatch) e os modelos de maturidade do PLM foram: Stark, Kärkkäinem, Saaksvuori, Zhang e Terzi. Na aplicação da ferramenta, foi comparado cada atributo da I4.0 com os atributos de todas as fases do PLM, a qual estava sendo avaliada e os autores efetuaram a classificação com uma nota que variou entre 0 (nula), 1 (fraca relação), 3 (média relação) e 9 (forte relação).

Fig. 2. Recorte da Matriz QFD.

Como resultado da análise relacional da I4.0 e PLM através da ferramenta matriz relacional, foram selecionados todos os atributos com nota 9, ou seja, caracterizado forte relação e entre os atributos escolhidos foram selecionados 4 para cada fase do PLM, os quais possuíam um panorama ligado a análise de dados relacionado ao cliente e informações de manutenção do produto.

Para a realização da pesquisa foi apresentado aos colaboradores fichas de avaliação (Figura 3) descrevendo os quatro níveis de maturidade, com informações sobre a fase

do PLM, descrição do atributo, proposta, ou seja, como o atributo será avaliado na dimensão proposta, indicadores de avaliação, o resultado e a diretriz a ser tomada para atingir próximo nível.

Fase do PLM	BOL
Atributo	Customers Data
Atributo Relacionado	Demanda do Cliente (Customers Demand)
Nível de Maturidade	Nível 1
Descrição do Atributo	São esperados dados do cliente relacionados à necessidade da função do produto, configurações, embalagens, custo e outras expectativas. A empresa utilizará esses dados (informações) para o processo de desenvolvimento de produto.
Proposta	Verificar como esses dados são informados pelo cliente e como a empresa irá utiliza-los.
Indicadores de Avaliação	a) Disponibilidade dos dados b) Clareza dos dados c) Compartilhamento dos dados d) Divulgação dos dados
Resultado	Não há o compartilhamento de dados dos clientes e a empresa realiza o processo de desenvolvimento de produto sem essas informações.
Diretriz	Promover um melhor compartilhamento das informações (parcial).
Alternativas para sobrepor atributo selecionado	Sugerem algumas propostas para que os dados (níveis de informações) tenham evoluções

Fase do PLM	Fase do PLM em que se encontra o atributo: BOL / MOL / EOL
Descrição do Atributo	Descrição do atributo considerando o quadrante a que pertence
Proposta	Como o atributo será avaliado na dimensão proposta
Indicadores de Avaliação	Que pontos e critérios serão avaliados na organização
Resultado	Descrição da informação do atributo relacionado ao nível de maturidade
Diretriz	Recomendação de melhores práticas
Alternativas para sobrepor atributo selecionado	Propostas de alternativas para sobrepor o atributo

Fig. 3. Exemplo ficha de avaliação.

Entrando na etapa de pesquisa de campo, esta foi aplicada para 10 colaboradores envolvendo diversos departamentos da empresa com cargos de gestão como: Diretores, engenheiros de manufatura, logística e qualidade. O questionário foi desenvolvido em duas fases, sendo a primeira com o objetivo de perceber o grau de relevância entre os atributos da Indústria 4.0 de cada fase do PLM. Para a realização desta fase foi perguntado ao colaborador qual atributo correlacionado ele identificava com maior relevância dentre as fases do PLM os dados obtidos desta fase estão descritos na Figura 4.

BOL		MOL		EOL

4 Aplicação Método AHP

O AHP é um método desenvolvido para ajudar empresas e pessoas a tomar decisões mais complexas, embasando a escolha em múltiplos critérios, podendo um parâmetro ter maior peso em relação ao outro. O objetivo da aplicação do método AHP é determinar a importância que os atributos correlacionados exercem nas alternativas, ou seja, nos níveis de maturidade. A abordagem avaliativa inspira-se no trabalho (Cestari *et al,* 2017, p. 1-37) o qual utiliza o AHP para uma avaliação de diagnóstico relacionado a comparação dos atributos para a par. Através desta avaliação também será possível especificar a relevância dos atributos correlacionados dentro de cada fase do PLM. Foi elaborado uma estrutura mais simplificada do Método AHP, conforme a Figura 10.

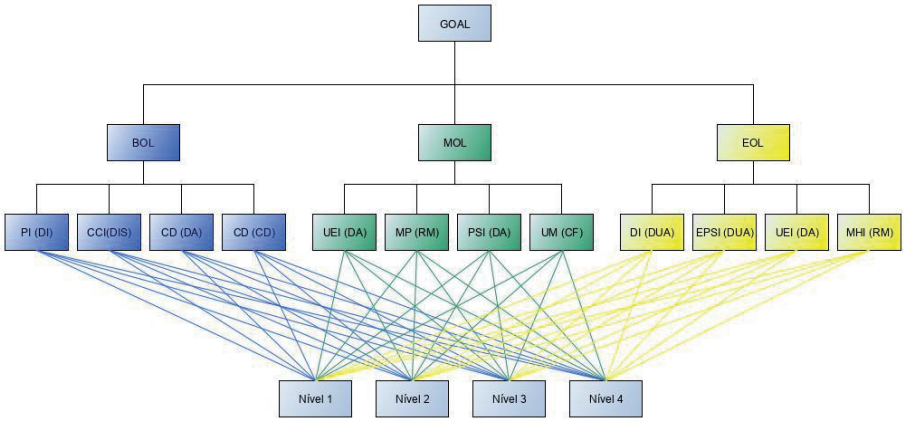

Fig. 10. Estrutura hierárquica do método AHP.

A estrutura do AHP apresentada na Figura 10, foi desenvolvida com o objetivo de proporcionar uma avaliação do PLM com conceitos da indústria 4.0, utilizando como critérios do método AHP as 3 fases do PLM (BOL, MOL e EOL) e como subcritérios os atributos associados com forte relação oriundos da matriz relacional, sendo estes: Para BOL *Production Information (Data Information) "PI(DI)"*; *Cooperative Corporation Information (Data Information Sharing) "CCI(DIS)"; Customers Demands (Data Analysis)"CD(DA)* e *Customers Demands (Customers Data) "CD(DA)"*. Para o MOL *Usage Environment Information (Data Analysis) "UEI(DA)"; Maintenance Plan (Remote Monitoring) "MP(RM)"; Product Status Information (Data Analysis) "PSI(DA)"* e *User Manual (Customer Focus) "UM(CF)"* e para o EOL *Dismantling Information (Customer Data Integration) "DI(DUA)"; EOL Product Status Information (Data Utilization and Analysis "EPSI(DUA)"; Usage Environment Information (Data Analysis) "UEI(DA)"* e *Maintenance History Information (Remote Monitoring) "MHI(RM)"*. Como alternativa estão os níveis de maturidade, os quais indicam o posicionamento da organização onde o diagnóstico definirá o nível de maturidade.

A atribuição de valores para a conversão dos critérios foi definida de acordo com as médias das respostas dos colaboradores. A primeira fase teve como objetivo determinar quanto um critério é mais importante que o outro dentro de cada fase do PLM, sendo este apontado como o de maior peso na decisão.

O modelo diagnóstico propõe uma escala de 4 níveis de maturidade e a escala AHP é composta de pesos de 1 a 9. Para o cálculo da matriz de conversão, foi dividido o grau mais alto da escala AHP pelo número de níveis do modelo diagnóstico. Os resultados obtidos foram arredondados e seus resultados encontram-se na Table 1.

O software que ofereceu suporte para a resolução dos cálculos do método foi o SuperDecisions.

Alternativa Fichas de Avaliação	Escala AHP
Nível 1	2
Nível 2	5
Nível 3	7
Nível 4	9

Table 1. Matriz de conversão.

No início do ciclo do de vida do produto (BOL) os atributos que apresentaram maior relevância foram *Customers Demands* (*Data Analysis*) e *Production Information* (*Data Information*), ambos com resultado de 37,5%, conforme apresentado na Figura 11.

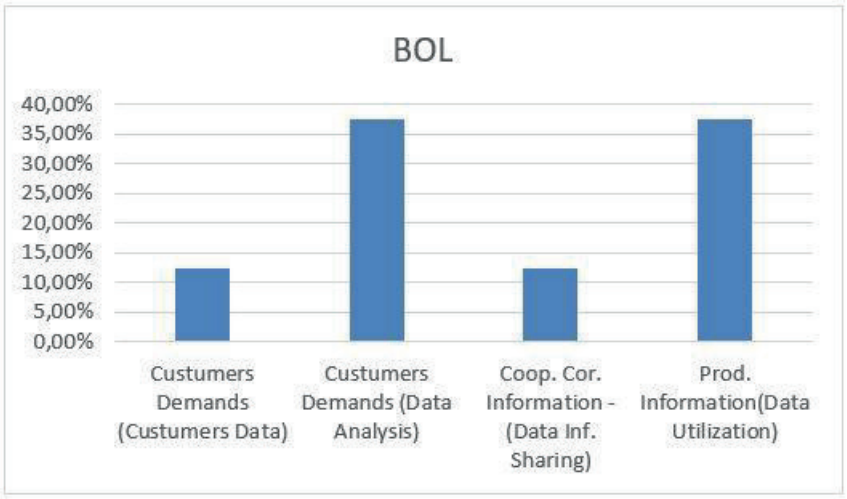

Fig. 11. Comparação gráfica atributos BOL.

Para a *Middle of Life*, a qual diz respeito a fase em que o produto é estabelecido, dentro das respostas coletadas o atributo *Maintenance Plan* (*Remote Monitoring*) tem maior relevância nessa fase, atingindo 54,16% conforme apresentado na Figura 12.

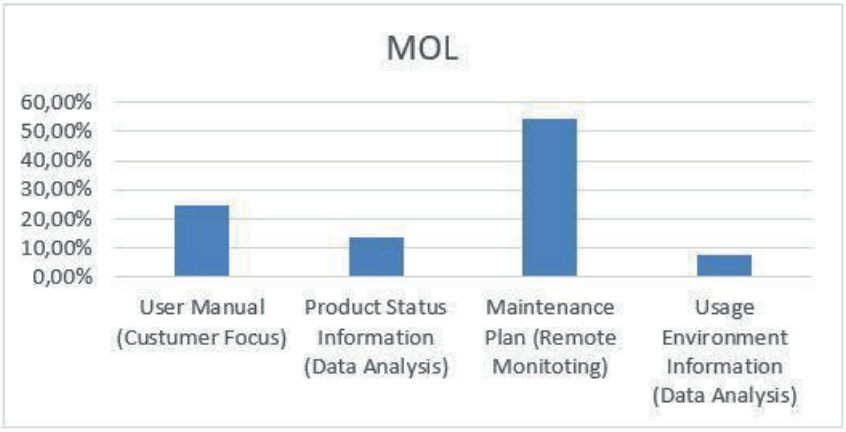

Fig. 12. Comparação gráfica atributos MOL.

A última fase do ciclo de vida (EOL) o atributo *Maintenance History Information* (*Remote Monitoring*) apresentou 44,8% de relevância, de acordo com a Figura 13.

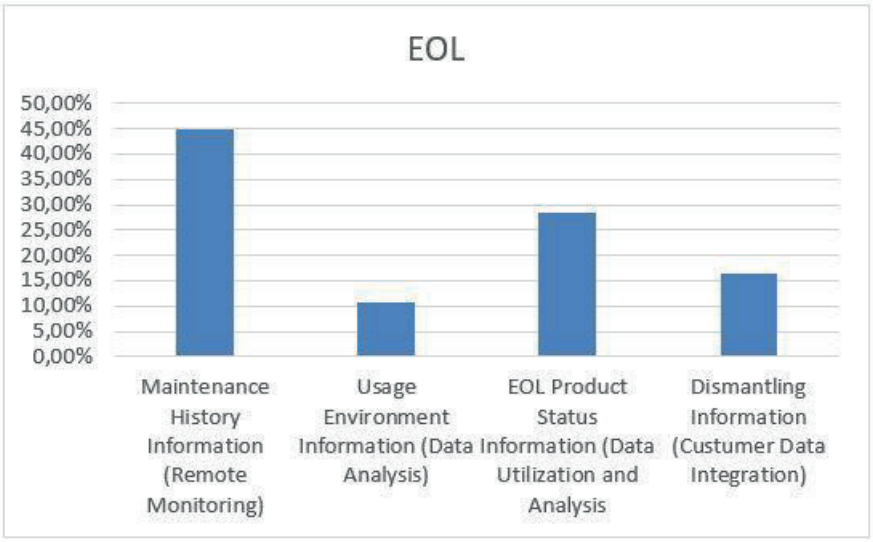

Fig. 13. Comparação gráfica atributos EOL.

A resolução do método AHP trouxe como resultado a Figura 14, classificando a empresa avaliada como nível 3, visto que a empresa se encontra com maior valor entre os níveis de maturidade.

Fig. 14. Resultado AHP (Nível de Maturidade).

Contudo, para elevar o nível de maturidade de 3 para 4, é aconselhável seguir algumas diretrizes, como otimizar no início do ciclo de vida do produto uma análise de dados relacionado à previsão de demanda de forma automatizada. Para a fase em que o produto já se encontra estabelecido, melhorar o manual do usuário, trazendo o cliente mais próximo do produto, com a utilização de uma linguagem acessível e com imagens ilustrativas ou a utilização de *QR Code* com vídeos de pessoas utilizando o produto. Para a fase final do ciclo de vida otimizar a integração com o cliente agrupando as informações desmanteladas sobre do produto e utilizar mais de 50% dos dados coletados.

5 Discussão e considerações finais

O estudo de caso revelou resultados promissores para a análise do nível de maturidade da organização através da abordagem proposta. Através do método AHP foi possível realizar comparações e diagnosticar atributos de maior relevância dentro de cada fase do ciclo de vida do produto (BOL MOL e EOL), tornando justificáveis em qual nível de maturidade do PLM com conceitos da indústria 4.0 a organização se encontra.

A empresa, sob nível 3 é caracterizada por ter um bom desenvolvimento de seu produto em todas as fases do ciclo de vida, porém pode otimizar seus resultados com maior utilização de dados obtidos. Na fase inicial do ciclo de vida do produto poderia ser trabalhada a aproximação do cliente e para as demais fases atuar agrupando as informações desmanteladas. Desta forma atende-se os seus clientes com respostas mais rápidas atuando na redução de custos sem perder a qualidade. Integrando cada vez mais o usuário com o produto é possível que a empresa consiga melhorar seu nível de maturidade.

Portanto após as melhorias sugeridas é possível que a empresa consiga ser classificada com nível 3 com tendência para o nível 4, atendendo seus clientes com respostas mais rápidas atuando na redução de custos sem perder a qualidade, aumentando sua competitividade e integrando cada vez mais o usuário com o produto.

Abstract. En este trabajo se presenta un modelo de optimización multiperíodo para el diseño de un Sistema de Gestión Integral de Envases Vacíos de Fitosanitarios. El propósito es generar un esquema para la recolección de envases dentro del Sudoeste Bonaerense (SOB) y determinar las localizaciones óptimas para la instalación de Centros de Acopio Transitorio (CAT) y de Plantas Operadoras (OPR) de envases, conociendo la tasa de generación de envases en cada partido del SOB. La formulación propuesta considera la inversión y los costos operativos (fijos y variables) de cada CAT y OPR, así como los costos de transporte incurridos en la recolección de los envases y en el traslado a las plantas de procesamiento. Además, se incorpora la alternativa de realizar Campañas Itinerantes en las que los envases se transportan en forma directa desde los partidos a las plantas operadoras. El modelo matemático resultante corresponde a un Problema Mixto Entero Lineal (MILP) donde las decisiones discretas se emplean para determinar la instalación y uso de los CAT y OPR a lo largo del tiempo. El criterio de performance utilizado es la maximización del valor presente neto del sistema completo de gestión, teniendo en cuenta diferentes costos e ingresos por la venta del producto de las OPR. Los 4 escenarios estudiados arrojan resultados prometedores con un valor presente neto superior a USD 570.000 a lo largo de un periodo de 15 años.

Keywords: Fitosanitarios·Optimización·Modelo Mixto-Entero Lineal.

1 Introducción

Argentina cuenta con más de 36 millones de hectáreas cultivadas en las que se emplean casi 230 millones de litros de herbicidas y cerca de 350 millones de litros de agroquímicos [1]. Los envases necesarios para su comercialización generan unas 13.000 toneladas de polietileno de alta densidad (PEAD) cada año [2]. Particularmente, en la provincia de Buenos Aires se generan aproximadamente 5 millones por año de envases vacíos de agroquímicos [3]. Dentro del país los envases ya utilizados y sus contenidos residuales son considerados residuos peligrosos conforme la Ley Nacional de Residuos Peligrosos 24.051 [4]. En la actualidad, el manejo de estos envases se hace de diversas formas dependiendo del usuario. Tradicionalmente, los envases de agroquímicos vacíos han sido quemados, enterrados, reutilizados como contenedores para otros productos o bien tirados en canales de riego, ríos, arroyos, zanjas o campo a cielo abierto, generando focos de contaminación al medio ambiente y representando un peligro para la salud de personas y animales [5]. Los efectos por el uso de plaguicidas y sus envases reflejados en la salud de los usuarios directos, de la población expuesta indirectamente y los daños al ambiente, plantean la necesidad de medidas preventivas que garanticen el manejo seguro de estas sustancias [6].

Recientemente se sancionó la Ley Nacional 27.279 (Resolución N.° 327/17) [7], que establece los presupuestos mínimos de protección ambiental para la gestión de los envases vacíos de fitosanitarios, en virtud de la toxicidad del producto que contuvieron, requiriendo una gestión diferenciada y condicionada. Dicha Ley específica que el sistema se articulará en tres etapas: a) del Usuario al Centro de Acopio Transitorio, b) del Centro de Acopio Transitorio al Operador, c) del Operador a la Industria. Esta ley introduce el concepto de Responsabilidad Extendida y Compartida en la gestión de envases vacíos de agroquímicos. La misma asigna responsabilidades y establece obligaciones específicas a los distintos actores de la cadena. También es importante mencionar que el Art. N°5 apartado b) especifica que el tránsito inter-jurisdiccional no podrá ser prohibido por las provincias, pero si razonablemente reglamentado.

Múltiples esfuerzos para la gestión de envases de agroquímicos se han llevado a cabo en forma aislada tanto por municipios como por organizaciones no gubernamentales, sin obtener una solución concreta para el problema real. Aun se observan grandes falencias logísticas y de implementación, procesando una mínima cantidad de envases vacíos sin trazabilidad de su limpieza.

En este contexto, el presente trabajo presenta un estudio de gestión integral sostenible para los envases vacíos de fitosanitarios en el Sudoeste de la Prov. de Bs.As. Dicha región tiene como principal actividad productiva la producción agropecuaria. Además, su lejanía con respecto a las plantas operadoras localizadas en Cnel. Brandsen y en Lanús y su gran extensión territorial, representan un verdadero desafío a la hora de diseñar un plan eficiente de gestión para la recuperación de los envases vacíos de fitosanitarios. Como herramienta para el análisis se desarrolló un modelo matemático de optimización que permite estudiar los aspectos de diseño y operación de una red logística de recolección y disposición de dichos envases vacíos, teniendo como marco la Ley Nacional 27.279.

2 Formulación del problema

Teniendo en cuenta que la sostenibilidad es un pilar esencial para la gestión exitosa de los residuos, y que a su vez la misma se basa en tres aspectos fundamentales íntimamente relacionados entre sí, tales como la economía, la ecología y los aspectos sociales, este estudio se focaliza en la problemática asociada a los productores y municipios del Sudoeste de la Provincia de Buenos Aires (SOB).

El SOB se conforma con 22 partidos, 21 de los cuales tienen como principal actividad económica la producción agropecuaria. En el SOB se concentran 8 de los 27 Centros de Acopio Transitorio (CATs) instalados en la provincia de Buenos Aires y no posee ninguna planta operadora habilitada para lavar y procesar el plástico de los bidones [8,9]. En la Tabla 1 se listan los partidos que integran el SOB y se indica la capacidad de almacenamiento de envases vacíos de aquellos que poseen un CAT habilitado. En conjunto, los CATs habilitados tienen la capacidad para almacenar 89.000 envases de 20 litros, lo que representa aproximadamente un 6% del total de envases generados anualmente en el SOB.

Tabla 1. Partidos que conforman el sudoeste bonaerense

(10) Gral. la Madrid		(21) Villarino	5.000
(11) Guaminí			

Resulta importante para el diseño de un sistema de gestión integral contar con un diagnóstico actualizado de la localización geográfica, cantidad y tipo de envases que se generan en la región en estudio. La cantidad de envases se determinó a partir del área sembrada de cada cultivo extensivo y los protocolos de siembra aplicados a cada uno. Se realizó una regionalización del SOB en función del uso de fitosanitarios de acuerdo a las condiciones de suelo y el clima de cada región (ver Fig. 1). Los protocolos de siembra se consultaron a Extensionistas de las Agencias de INTA referentes de cada región: Bahía Blanca, Coronel Suárez y Tres Arroyos. Por otra parte, a partir los datos publicados por la Dirección Nacional de Análisis Económico Agroindustrial (Dirección de Estimaciones Agrícolas) en las Campañas 2008 a 2018 [10], se obtuvieron regresiones lineales, para estimar la superficie sembrada en el área de interés en función de los años a lo largo de en un periodo de 15 años. El número de envases de 20 litros que se genera por año en promedio en cada partido del SOB se muestra en el mapa de la Figura 1. En la misma se incluye la ubicación y capacidad de los CATs instalados actualmente,

como también la localización de las dos plantas operadoras y su capacidad de procesamiento de plásticos por año.

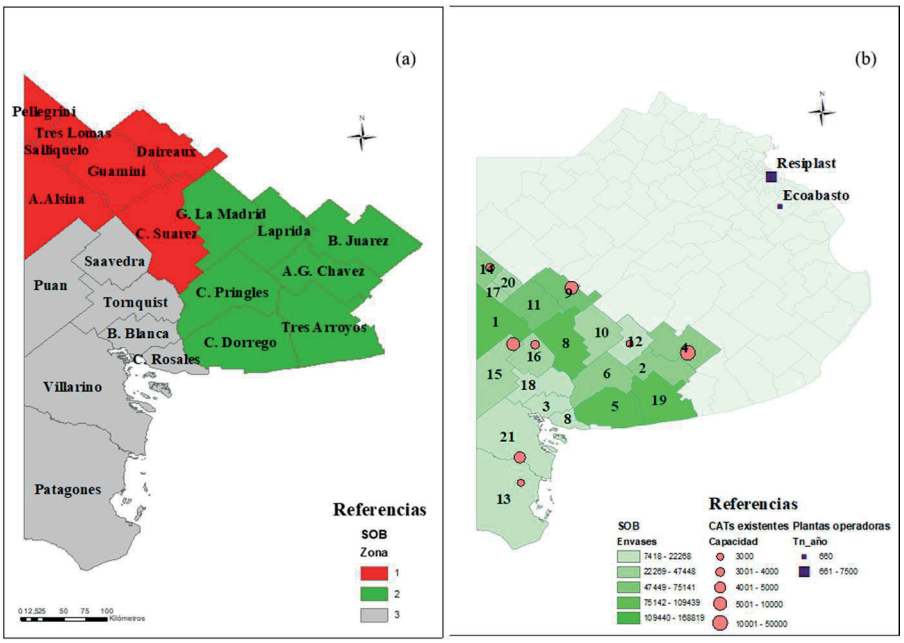

Fig. 1. Mapa del sudoeste bonaerense (SOB). (a) Regionalización del SOB por protocolo de siembra. (b) Envases generados en cada partido y ubicación de centros de acopio transitorio y plantas operadoras. Los partidos siguen la numeración provista en la Tabla 1. (Fuente: elaboración propia)

Una característica importante del SOB son las grandes distancias entre los lugares de generación del residuo y entre éstos y los centros de acopio y de tratamiento, por lo que resulta importante pensar adecuadamente los aspectos logísticos para generar un sistema integral de gestión de residuos que resulte práctico y eficiente.

3 Modelo matemático

El modelo consta de 34 ecuaciones para determinar la estructura óptima del problema de asignación de unidades de infraestructura con capacidades acotadas (CATs y OPRs), así como ecuaciones de costos fijos y operativos, en forma anual y a lo largo de un dado horizonte de tiempo.

La logística representa un costo significativo en cualquier plan de gestión de residuos, particularmente en las regiones en las que hay mucha distancia entre las áreas agrícolas y la zona de reciclaje y eliminación. Transportar envases vacíos es ineficiente, debido a la razón entre su gran volumen y su peso. Transportar los bidones enteros

consigue movilizar apenas un 20% de los kilos de plástico que pueden trasportase compactados. Los pre-tratamientos más utilizados para la disminución del volumen de los envases vacíos de fitosanitarios son la compactación y/o el triturado [11]. A diferencia del triturado de los envases, su compactado no afecta el proceso de reciclado que se lleva a cabo posteriormente en las plantas operadoras. En este trabajo se asume que la compactación solo se realiza en los CATs, donde se instalan equipos de prensado (enfardadoras), dado que es la opción que el Organismo Provincial para el Desarrollo Sostenible considera utilizar. Por lo cual, los bidones se transportan enteros desde los partidos hasta los CAT o desde los partidos hasta la planta operadora. Dentro del sistema de gestión, este último transporte constituye las campañas itinerantes de recolección de envases.

Dado que se trata de un problema de planificación a lo largo de un horizonte de tiempo, de la instalación de infraestructura necesaria para efectuar la recolección y tratamiento de los envases vacíos de fitosanitarios que se generan en el SOB, se elige como función objetivo maximizar el valor presente neto (VPN). Es necesario aclarar que, la instalación de al menos un CAT es una restricción del modelo. Esta restricción se incluye no solo por ser establecimientos definidos en el contexto de la Ley Nacional 27.279 sino también por constituir espacios que aseguran el correcto almacenamiento de los envases vacíos, desde el punto de vista de seguridad para las personas y cuidado del medio ambiente.

El modelo formulado es de tipo Mixto Entero Lineal (MILP). En la siguiente sección se presentan las definiciones de los diferentes conjuntos, parámetros (o datos) y variables enteras y continuas que definen el modelo.

3.1 Nomenclatura

Conjuntos

i	Partidos del SOB.
j	Centros de acopio transitorio (CAT).
t	Periodos del horizonte de planeación.
l	Plantas operadoras (OPR).

Parámetros

CAP	Costo del agua de proceso [USD/m^3].
CapcamC	Capacidad de carga vehículos de envases compactados [kg].
CapcamE	Capacidad de carga vehículos de envases enteros [kg].
$CAPreal_j$	Capacidad real de los CATs instalados en el SOB [envases].
CCj	Pendiente promedio de la curva de economías de escala del CAT j
CEE	Costo del MWh [USD].
CEnfar	Costo de compra de una enfardadora [USD].
CEsAP	Consumo especifico de agua en la planta operadora [m^3/t].
CEsEE	Consumo específico en la planta operadora [kWh/t].
CEsEEE	Consumo especifico de EE de la enfardadora [kWh/t].

c_{il}	Distancia entre el partido i y la planta operadora l [km].
$CMCAT_j$	Capacidad operativa máxima del CAT j ∈ J [envases/mes].
$CMOPR_l$	Capacidad operativa máxima de las OPRs l ∈ L [envases/período].
COCATfijo	Costo fijo de operación de cada CAT [USD/mes].
CT	Costo unitario de transporte de mercancías [USD/km].
CTA	Costo del tratamiento de agua [USD/m^3].
CTP	Costo unitario de transporte de residuos peligrosos [USD/km].
d_{ij}	Distancia entre el partido i y el CAT j [km].
ECOP	Costo de los equipos críticos planta operadora [USD].
Fadm	Factor costo fijo administrativo.
Fcomer	Factor costo fijo comercialización.
Fman	Factor costo fijo mantenimiento.
fr_t	Fracción de recuperación de envases en cada periodo t.
h_{it}	Envases del partido i en el período t [envases/período].
IAOP	Factor de costo de instalación y auxiliares de las OPRs [USD].
M	Valor utilizado para restricciones de tipo “Big-M”.
NC	Número máximo de CATs a instalar.
NCmin	Número mínimo de CATs a instalar.
NOP	Número máximo de plantas operadoras a instalar.
OOj	Ordenada al origen de la curva de economías de escala del CAT j.
P	Meses por periodo.
PE	Peso del envase de 20 L de HDPE [kg/envase].
Per	Cantidad de personas para operar la planta operadora.
Pr	Precio de venta de plástico HDPE [USD/t].
PTEL	Costo de la planta de tratamiento de efluentes [USD].
rec	Reciclo del agua de proceso.
r_{jl}	Distancia entre el CAT j y la planta operadora l [km].
S	Sueldo por persona [USD/periodo].
TR	Tasa de descuento de capital entre los períodos 1 y t.

Variables

Binarias

x_{jt}	Representa la operación del CAT j en el periodo t.
y_{lt}	Representa la operación de la OPR l en el periodo t.
$zCAT_j$	Representa la instalación de un CAT en j.
$zOPR_l$	Representa la instalación de una OPR en l.

Continuas

BEN_t	Beneficios netos en cada periodo t [USD/periodo].
$CICATamp_j$	Costo de ampliación de los CATs existentes [USD].
$CICAT_j$	Costo de inversión en j [USD].
$CIOPR_l$	Costo de inversión en l [USD].
$COCAT_{jt}$	Costo operativo de j en el periodo t [USD/ periodo].
$COCATtot_t$	Costo operativo de los CATs en cada periodo t [USD/ periodo].
$COOPRfijo_{lt}$	Costo fijo de la OPR l en el periodo t [USD/ periodo].
$COOPR_{lt}$	Costo operativo de l en cada periodo t [USD/ periodo].
$COOPRtot_t$	Costo operativo de las OPRs en cada periodo t [USD/ periodo].

$COOPRvar_{lt}$	Costo variable de la OPR l en el periodo t [USD/ periodo].
COP_t	Costos operativos totales en cada periodo t [USD/ periodo].
$COTRA_t$	Costo del trasporte en cada periodo t [USD/ periodo].
e_{ijt}	Envases enviados desde i al CAT j en t [envases/periodo].
f_{jlt}	Envases enviados del CAT j a la OPR l en t [envases/periodo].
g_{ilt}	Envases enviados desde i a la OPR l en t [envases/periodo].
ING_t	Ingresos totales en cada periodo t [USD/periodo].
$STCAT_{jt}$	Cantidad de envases en el CAT j en el periodo t [envases/periodo].
$STOPR_{lt}$	Cantidad de envases en la OPR l en el periodo t [envases/periodo].
$TSTCATextra_j$	Tamaño de ampliación requerida de CATs existentes [envases].
$TSTCAT_j$	Máx. N° de envases en el CAT j [envases/mes].
z	Variable objetivo.

Ecuaciones

A continuación, se presenta el modelo completo.

La Ecuación (1) es la función objetivo que maximiza el valor presente neto del problema de instalación de CATs y OPRs y de transporte de los envases. Las Ecuaciones (2) a (8) son las ecuaciones lógicas para la determinación de la localización de los CATs y OPRs. Las Ecuaciones (9) a (21) determinan el tamaño de los envíos de los partidos a los CATs, de los CATs a las OPRs y de los partidos a las OPRs. También determinan el stock por mes de cada CAT y por año de cada OPR. Las Ecuaciones (22) a (32) calculan los costos anuales de inversión, operativos y de transporte. La Ecuación (33) calcula los beneficios anuales de la venta del plástico procesado y la Ecuación (34) calcula los beneficios netos cada año.

El modelo se implementó y resolvió con el programa GAMS 24.2.3 (General Algebraic Modeling System) [12], con CPLEX 12 como programa de resolución del modelo MILP. Los resultados que se presentan en la siguiente sección se obtuvieron en una computadora con procesador Intel(R) Core (TM) i7-85500, 2,00 GHz y una memoria RAM de 16GB.

4 Resultados

El modelo matemático se aplica para la resolución de dos escenarios, cada uno con dos alternativas. El Escenario 1 es el de una situación en la que se diseña desde cero la red de CATs y OPRs, donde se determina en forma óptima la cantidad y ubicación de estas unidades, así como la asignación del envío de los envases desde los partidos a los CATs y/o OPRs, y desde los CATs a las OPRs. Además, se impone que al menos se instale un CAT. El propósito del Escenario 1 es tener una referencia y compararlo con el Escenario 2, que consiste esencialmente en el mismo problema, pero si bien se pueden ubicar unidades adicionales con su correspondiente costo de instalación y de operación, se respeta la cantidad y ubicación de los CATs y OPRs ya existentes, por lo que para ellos no se considera su costo de instalación. En total para este escenario hay 8 CATs instalados y 2 plantas operadoras ubicadas en los partidos de Brandsen y Lanús, en la Provincia de Buenos Aires, pero fuera de la región SOB (ver Figura 1).

Ambos escenarios se dividen en dos situaciones, en la primera (Escenarios 1a y 2a) se considera que el 100% de los envases que se generan en el SOB se alimentan al sistema de recuperación de envases, mientras que en la segunda situación (Escenarios 1b y 2b) esta alimentación se realiza en forma gradual desde el primer periodo hasta el último. En la Fig. 2 se muestra un esquema general del problema a resolver.

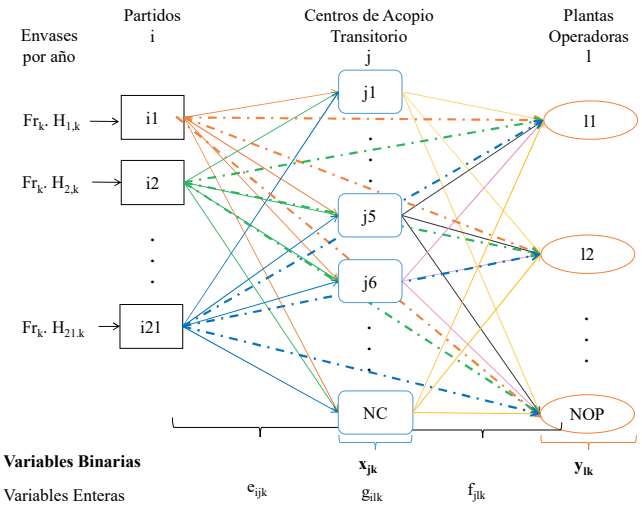

Fig. 2 Esquema general de los escenarios estudiados en este trabajo. (Fuente: elaboración propia)

Para los cuatro escenarios, el tamaño del modelo indica que se trata de un problema relativamente chico tanto en variables continuas como binarias como se observa en la Tabla 2. En la Tabla 3 se puede observar que las soluciones se alcanzan en tiempos de CPU del orden de uno a dos minutos, lo cual es razonable en relación al tamaño de los problemas. En esta tabla se observa además que el esfuerzo computacional de resolución es menor en los casos donde el porcentaje de recuperación de envases aumenta con los años (E1b y E2b). También se presentan los tiempos empleados para alcanzar el valor final de la función objetivo, que se ve son mucho menores a los tiempos necesarios para lograr el gap cero en todos los escenarios, lo que sugiere que los tiempos de cómputo podrían reducirse sustancialmente si fuera necesario, fijando un gap mayor para convergencia y sin que eso implique un deterioro de la función objetivo.

Tabla 2. Tamaño de los modelos empleados para describir los escenarios estudiados en este trabajo

Escenario	Variables binarias	Variables continuas	Ecuaciones	Desigualdades
E1 a y b	768	26053	3709	17367
E2 a y b	768	26095	3751	17367

Tabla 3. Resumen de los tiempos de cómputo de los escenarios estudiados en este trabajo y valor de la función objetivo obtenida para cada uno

	E1a	E1b	E2a	E2b
CPU GAP=0 (s)	68,734	44,703	435,406	57,922
CPU solución (s)	34,61	39	317	1,36
Función objetivo (USD)	4.337.487	771.367	3.883.426	570.295

Como puede observarse en la Tabla 3, para todos los escenarios estudiados el VPN es positivo y superior a 570.000 USD indicando que el sistema de gestión integral de envases vacíos de agroquímicos propuesto para cada caso resulta atractivo económicamente. El VPN del Escenario 2a es del orden del 90% del correspondiente al Escenario 1a, cuando el 100% de los envases forman parte del sistema de gestión; mientras que el VPN del Escenario 2b es un 75% del obtenido para el Escenario 1b. Esto sugiere que, si el sistema opera con menor cantidad de envases, lo hace más alejado del escenario de referencia óptimo. Además, para ambos escenarios, el VPN de las alternativas b es apenas el 20% de las alternativas a.

La localización óptima de los CATs y de las plantas operadoras para cada escenario se indican en las Tablas 4 a 7 , además se incluye el costo de instalación de los mismos y la cantidad máxima de envases que se reciben y procesan respectivamente. Debido a que el número de envases generados en el SOB crece a lo largo del horizonte de tiempo de estudio, la capacidad máxima de la planta operadora tiene lugar en el último período, al igual que la ocupación máxima de los CATs en los Escenarios 1b y 2b ya que la incorporación de envases al sistema es gradual y se incrementa con el tiempo. Para los Escenarios 1a y 2a, los CATs operan en su capacidad máxima desde el primer período estudiado. Además, es importante destacar que el costo de inversión de la planta operadora es el mismo para todos los escenarios, esto se debe a que la cantidad anual de envases vacíos generados en el SOB, es menor a la capacidad mínima de las tecnologías de procesamiento de plástico comúnmente empleadas para el reciclado del PEAD de estos contenedores.

Tabla 4. Resultados para el escenario 1a

Localización de los CATs	Costo de inversión (USD)	Ocupación mensual (máx. envases)
J19: Tres Arroyos	193.538	41.483
Localización de las OPRs	**Costo de inversión (USD)**	**Ocupación anual (máx. envases)**

L27: Brandsen	0	1.434.274

CATs: Centros de Acopio Transitorio, OPRs: Plantas Operadoras

Para facilitar la visualización de los resultados obtenidos, las Figuras 3 a 6 muestran el esquema óptimo de asignación de Partidos-CATs-OPRs que deben seguir los envases vacíos de fitosanitarios para cada uno de los escenarios estudiados en este trabajo. En cada figura se puede notar como se modifica el esquema a lo largo del horizonte de tiempo estudiado, las Figuras 3 a 6 (a) corresponden al primer período y las Figuras 3 a 6 (b) al último.

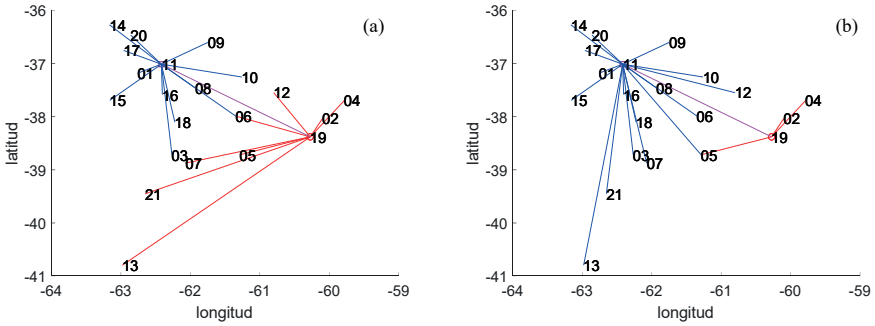

Fig. 3. Escenario 1a, (a) primer período (b) último período. Las líneas rojas indican los partidos que se asignan a las unidades de CATs seleccionados por el modelo, las magenta corresponden a las asignaciones de los CATs a las OPRs y las líneas azules indican las campañas itinerantes. Los partidos siguen la numeración provista en la Tabla 1. (Fuente: elaboración propia)

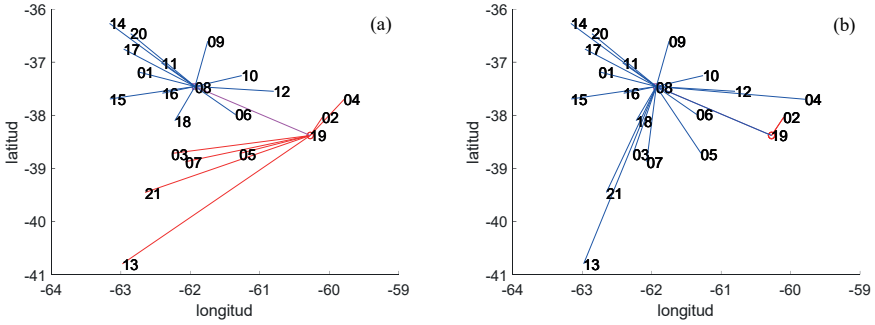

Fig. 4. Escenario 1b (a) primer período (b) último período. Las líneas rojas indican los partidos que se asignan a las unidades de CATs seleccionados por el modelo, las magenta corresponden a las asignaciones de los CATs a las OPRs y las líneas azules indican las campañas itinerantes. Los partidos siguen la numeración provista en la Tabla 1. (Fuente: elaboración propia)

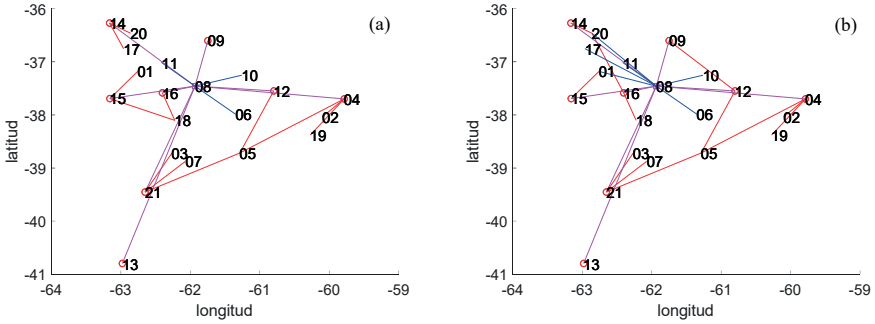

Fig. 5. Escenario 2a (a) primer período (b) último período. Las líneas rojas indican los partidos que se asignan a las unidades de CATs seleccionados por el modelo, las magenta corresponden a las asignaciones de los CATs a las OPRs y las líneas azules indican las campañas itinerantes. Los partidos siguen la numeración provista en la Tabla 1. (Fuente: elaboración propia)

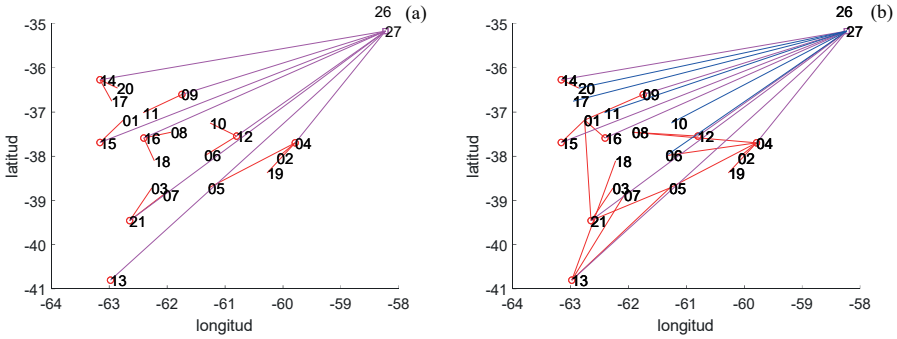

Fig. 6. Escenario 2b (a) primer período (b) último período. Las líneas rojas indican los partidos que se asignan a las unidades de CATs seleccionados por el modelo, las magenta corresponden a las asignaciones de los CATs a las OPRs y las líneas azules indican las campañas itinerantes. Los partidos siguen la numeración provista en la Tabla 1, 26 y 27 representan las plantas operadoras de Lanús y Brandsen respectivamente. (Fuente: elaboración propia)

En particular, como resultado de la optimización del escenario de referencia, es decir, sin tener en cuenta los CATs que se encuentran actualmente instalados en el SOB, el modelo sugiere instalar un CAT y una OPR en el SOB. Independientemente de la oferta de envases (escenarios a y b). En el caso en que todos los envases generados en el SOB se integren al sistema de gestión integral desde el primer año, el modelo sugiere la instalación de un único CAT con capacidad para 42.000 envases en Tres Arroyos. En el caso en el que la incorporación de los envases al sistema sea progresiva, el CAT también se instala en Tres Arroyos, pero tiene una capacidad menor, menos de la mitad. En ambos casos, alrededor de 8 partidos envían sus envases al CAT como puede observarse en la Figuras 3 y 4. A lo largo del horizonte de tiempo, como se muestra en las figuras, para ambos escenarios se incrementa el número de campañas itinerantes. La localización de la planta operadora es distinta para los dos escenarios, en el escenario 1a se instala en Guaminí mientras que en el escenario 1b se instala en Coronel Suárez. Esto se debe a la alimentación progresiva de envases en el tiempo que tiene lugar en el Escenario 1b. En esta situación, es más rentable instalar un CAT de menor capacidad en Tres Arroyos y realizar más campañas itinerantes en los años que sea necesario. En consecuencia, para reducir los costos de transporte, el modelo decide instalar la planta operadora 68 km al sudeste de Guaminí (localización de la planta operadora del E1a), en un punto central geográficamente del SOB. Este efecto puede visualizarse comparando las Figuras 3 y 4.

Por otro lado, los resultados para el escenario 2 indican que no se instalan nuevos CATs, si no que conviene ampliar los existentes. Sin embargo, la capacidad de almacenamiento total en el Escenario 2a disminuye en un 3% respecto a la capacidad instalada en la actualidad (Tabla 1), lo que sucede es que el CAT ubicado en Benito Juárez no se ocupa su totalidad. Por otro lado, en el Escenario 2b la capacidad de almacenamiento de envases vacíos se incrementa en apenas un 5%, en ambos escenarios lo que ocurre es que principalmente aumenta la capacidad relativa de los CATs que se ubican en la zona noroeste del SOB y en particular es el CAT ubicado en Pellegrini el que aumenta de forma más significativa su capacidad. Como puede observarse en la Figura

5 el número de campañas itinerantes se duplica a lo largo del tiempo para el Escenario 2a y a partir de la Figura 6 se puede notar que en el caso del Escenario 2b aparecen recién en el último período, representando apenas la mitad que en el Escenario 2a. En el escenario 2a se instala una planta operadora en el partido de Coronel Suárez, mientras que para el escenario 2b, los envases son enviados a la planta existente en Brandsen. Este resultado muestra que, mientras el factor de recuperación de envases en el SOB sea cercano al 100% es conveniente invertir en una planta operadora en lugar de utilizar la de la localidad de Coronel Brandsen, como se obtiene en el escenario 2b, donde el factor de recuperación de envases aumenta de forma gradual a lo largo del horizonte de planificación.

Una de las principales características de los problemas logísticos es la incertidumbre en los datos [13,14]. En particular en la logística de envases fitosanitarios vacíos la oferta de los mismos es uno de tales datos críticos dado que no se dispone de registros oficiales de los mismos [15,16]. Por este motivo se realizó un análisis de sensibilidad alrededor de la solución nominal (fijando las variables binarias) para los 4 escenarios, considerando una variación de ± 30% en los envases a recolectar. Los resultados indican una importante sensibilidad en este parámetro ya que una variación del 30 % en la cantidad de envases disponibles influye en un 40 % en el VPN en el escenario 1a, en un 85 % en el escenario 1b y en un 100 % en el escenario 2b. En el caso del escenario 2a, solo se realizó un análisis de sensibilidad de entre el + 10% y + 30% ya que en el caso de que la oferta disminuyera, el modelo localiza la planta en Cnel. Brandsen.

5 Conclusiones

Los resultados del trabajo indican que las alternativas estudiadas para la gestión de la recolección de envases vacíos de fitosanitarios resultan rentables con valores del VPN superiores a los 570.000 USD a 15 años.

Además, se logra cuantificar la importancia de la concientización, difusión y capacitación constante acerca del sistema de gestión integral para lograr el desarrollo de una economía circular entorno al mercado de agroquímicos en el sudoeste bonaerense, como así también, la importancia de determinar fehacientemente la cantidad de envases para que el diseño del sistema sea confiable. El VPN de los Escenarios 1b y 2b disminuye drásticamente en un 80% respecto a las alternativas 1a y 2a en las que el 100% de los envases vacíos generados en el SOB se alimentan al sistema de gestión integral.

Los resultados del modelo para los Escenarios 2 a y b que tienen en cuenta los CATs actualmente instalados, indican que se requiere la ampliación de la capacidad de almacenamiento de envases vacíos de los CATs ubicados en el noroeste del SOB para optimizar el funcionamiento del sistema de gestión integral. También se puede notar la importancia de las campañas itinerantes como herramienta para el buen desempeño del sistema de recupero de envases vacíos.

Otro aspecto interesante para destacar es que para el Escenario 2a que considera que el total de los envases generados en la región se alimentan al sistema de gestión, el modelo indica como óptima la instalación de una planta operadora en Coronel Suárez un partido muy productivo y ubicado en el centro geográfico del SOB. Si en cambio, la

incorporación de los envases es gradual, es más conveniente económicamente enviar los envases del SOB a procesar a la planta existente en Brandsen. Este aspecto también se demuestra mediante el análisis de sensibilidad. Se podría concluir que el esfuerzo conjunto de todos los actores de la cadena de comercialización de agroquímicos del SOB podría tener como resultado un importante impacto en el desarrollo de la región.

Abstract. Industry 4.0 is a modern approach where the connectivity between different stages of the production process and the consumers is enhanced. In this paper a relevant problem for both Industry 4.0 and flow shop literature is addressed: an operation skipping flow shop scheduling problem. A solution method to optimize total tardiness, which is novel to the related literature, is presented. The solution approach consists of two stages. In the first stage, a genetic algorithm is applied to obtain an efficient solution in a permutation fashion. In the second stage, the solution obtained in the previous stage is improved with a simulated annealing algorithm considering a non-permutation strategy. Results show that NPFS solutions outperform PFS solutions for this problem. Furthermore, if the percentage of skipping operations increases the impact of the NPFS approach increases too.

Keywords: Industry 4.0, Non-Permutation Flow Shop, Skipping Operations, Cyber-Physical System.

1 Introduction

The conceptual model Industry 4.0 enhances connectivity between the different components of the production systems, as well as among the components and the decision-making centers [1] [2]. This allows production planners to manage information in real time from the shop floor [3]. This communication increases the flexibility of the production system since the machines have the capacity to communicate with each other and with the decision-making centers [4], allowing designs of innovative products with increasing adaptability. Moreover, given the high level of digitalization and through IIoT (Industrial Internet of Things), it is possible to offer mass customization of products as a business strategy, i.e., the production process can be adjusted so that the final products meet the specific customer requirements. In other words, for a given product

each customer can choose among different combinations of optional features, configurations or characteristics in such a way that the final product is highly personalized [5]. However, these personalized products are translated into specific production activities in the production line. Therefore, efficient scheduling techniques that can manage this variability should be applied in the production line to meet the specifications of each customer in the Industry 4.0 production environment [6].

Currently, one of the most widespread and efficient production configurations is the manufacturing cell. The manufacturing cell represents a set of production resources or machines that are grouped by the type of products they produce and organized in sequential mode [7]. The resulting output of a machine is transformed into the input of the next machine, and this happens with each of the machines in the cell. Generally, this type of configurations is considered within the flow shop scheduling family of problems [8] [9]. Product customization powered by Industry 4.0 will have a significant impact on this type of problem [5]. Given the freedom provided to the customer when customizing a product, it is very likely that, when following the customer specifications, the operations that must be performed to produce this product imply different uses of the machines in the cell. Thus, some of the operations introduced in the cell design may not be required to achieve the specifications requested by customers [9], these are the missing or skipping operations.

In the related literature, problems of flow shop with skipping operations for many productive environments have been studied [10]. In the vast majority of these works, the problems are solved by considering only permutation solutions (PFS) [11], meaning that the works are processed by each machine in the same order. In terms of search space, this entails finding the best solution in a universe of $n!$ possible solutions, being n the number of jobs to be processed. However, this condition of permutativity is not a technological constraint of the production process, since, in general, machines can process works in any order. It is only a condition introduced for reducing the complexity of the scheduling process. Therefore, another approach to solve these problems is based on relaxing this condition of permutativity, which involves solving the problem under the non-permutation approach (NPFS) [12]. In this approach, the job sequence for each machine can be modified, increasing the search space considerably from n to $n!^m$ solutions, where m is the number of machines [13]. Since NPFS solutions include PFS solutions as a particular case, NPFS solutions are at least as efficient as PFS if not more efficient, and it has been demonstrated that PFS are usually outperformed by NPFS in regard to the objective function values [10] [13]. Despite the industrial interest in this problem, NPFS has not yet been addressed for systems that contemplate Industry 4.0 production environments [3]. This article applies metaheuristics to solve PFS and NPFS, following the aforementioned approach.

Although results in the related literature show that NPFS solutions tend to outperform PFS solutions when considering objective functions related to delivery dates [13], the NPFS with skipping operations considering such optimization criteria has not been studied until now [14]. Therefore, this work makes a contribution and aims at providing a solution approach for considering PFS and NPFS solutions in this kind of problem.

2 Problem Definition

In this section, we properly introduce the problem studied in this work. Firstly, we analyze the impact of Industry 4.0 in manufacturing cells and how this influences the exchange with the customer. Then, we define our conception of the problem, relating our approach to the scheduling literature.

2.1 Industry 4.0 Environment

Industry 4.0 proposes a digital transformation of traditional production systems [2]. This transformation is based on the implementation of cyber-physical systems (CPS), which integrate virtual and physical processes in the same system [15]. Moreover, through IoT, CPS can communicate with each other and with the Decision Support Systems, which in terms of production planning, means to allow directly linking the shop floor with the support systems for production decision making [15] [4]. On the other hand, CPS allows generating a digital twin of the physical system [16], to analyze situations and making decisions more agilely and with more information than in a traditional production system. This results in a much more flexible production system, better adapted to different scenarios [17]. This way, the manufacturing system becomes smart, being able to provide an improved service to the customer, satisfying its needs in a personalized way [1]. This allows bringing the final product closer to the true requirements of the customer, who is actively involved in the design of the product [17].

The customer expresses his/her preferences by specifying different variants of a base product belonging to a given family of products, configuring what is known as a personalized variant of the product [18]. In this way, by making the production system more flexible, and making it smart, Industry 4.0 allows to offer to the customer a much higher level of personalization than in traditional production systems [19] [20].

The problem addressed in our work responds to these conditions imposed by Industry 4.0 in manufacturing cell systems. Given that the focus when solving the problem is on providing the best possible level of service to the customer, it is appropriate to study scheduling performance metrics related to service level, such as total tardiness.

2.2 Flow shop Scheduling in Manufacturing

The problem considered in this work can be described as to schedule production for a set of products that share production resources, with the feature that all products use the same resources maintaining the same technological sequence, i.e., a flow shop scheduling problem [8]. However, considering the scenario of intensive personalization promoted by Industry 4.0 [2], each product will have its particularities, a fact that will imply a different use of resources, which is generally expressed in varying processing times. This difference in use can even imply that, directly, the product does not use one of the resources of the manufacturing cell, which means that the product skips that operation (skipping operations flow shop scheduling problem) [21]. Therefore, the objective is to schedule production in such a way that the highest service level is achieved,

complying with the delivery dates. For this, we will seek to minimize the cumulative delays in the delivery of the products.

On the other hand, this problem can be addressed by considering only permutation solutions (Permutation Flow Shop, PFS), or by considering non-permutation solutions (Non-Permutation Flow Shop, NPFS) [9] [14]. In the first case, PFS, the solution search space includes those sequences represented by the possible permutations of the n jobs, that is, a total of $n!$ feasible solutions. Whereas if the job ordering is allowed to be modified for each stage of the flow shop, i.e. NPFS, the space of solutions grows to $n!^m$, where m is the number of machines. These problems are identified in the classic notation for scheduling problems [22] as *F|prmu/missing|TTard* and *F|missing|TTard*, respectively.

Therefore, the problem to be solved is to sequence the jobs in such a way that, complying with the precedence relationships among the operations, the objective function is minimized. If π is a permutation sequence, that implies that once job j was processed before job j', then, j will precede job j' on all machines. Therefore, to minimize the objective function, the permutation version seeks that the order π of the jobs, allows the completion times of each job, C_j, to exceed as little as possible the delivery date of each job d_j. In other words, the tardiness for each job j is as small as possible. Where the tardiness for job j is: $T_j = max\{C_j - d_j, 0\}$. Then the objective function can be expressed as:

$$\min_{\pi} \sum_j T_j(\pi) \tag{1}$$

For the non-permutation case, the objective function is the same, but the order π' is considered, which allows changes of precedence relationships among jobs. For instance, for π', job j can precede job j' up to machine i, and from machine $i + 1$ onwards, j' can precede j.

3 Solution approach

To solve the problem under study two metaheuristic algorithms were used in a sequential fashion. First, a Genetic Algorithm (GA) is used to optimize this problem considering only PFS solutions. Then, the best solution obtained by the genetic algorithm is used as the initial solution for the second algorithm. This second phase is a Simulated Annealing Algorithm (SA) that aims at improving the solution by considering NPFS solutions. The main characteristics of both algorithms are presented below.

3.1 Genetic Algorithm

For solving the PFS problem introduced in Section 2, a steady state Genetic Algorithm (ssGA) is proposed. ssGA is known to be a valid choice in problems where fitness evaluation is computationally expensive [23] and, thus, in flowshop problems (see, e.g., [24]). The proposed algorithm was implemented in Java, by using JMETAL framework [25] version 4.5.2. This algorithm has the following features.

Solution representation. Solutions are encoded as a permutation of integers of length equal to the number of jobs n. Each index in the vector represents the processing order in the (first) machine and the corresponding integer value represents the job.

Initialization. The population of size $\#P$ is initialized by applying a random procedure to generate the permutations using a uniform distribution.

Genetic operators. The recombination operator is the Partially Mapped Crossover (PMX) applied over two selected individuals with probability p_c. The mutation operator is based on Swap Mutation and interchanges two elements of the permutation. The Mutation operator is applied to an individual with probability p_m. The proposed operators guarantee the feasibility of the solution.

Selection, replacement, and fitness assignment. Tournament selection is applied, with tournament size of two solution representations. The tournament criterion is based on the fitness, and if two compared individuals have the same fitness, either of the two is chosen with equal probability. The new individual replaces the worst individual in the population if it has better fitness.

Parameters setting. The parametrization was performed with a statistical analysis considering three main parameters: population size $\#P$, crossover probability p_c and mutation probability p_m. The values considered were 100 and 200 for $\#P$; 0.7, 0.8, 0.9 and 1 for p_c; and 0.05 and 1 for p_m. The maximum number of evaluations used for the parametrization was 5000. The parameter setting analysis was made using three instances of size n =15 and m = 20, different from the scenarios used for the computational experimentation of Section 5. For each instance and each parametric combination ($\#P$, p_c, and p_m), 30 independent runs where performed. Shapiro-Wilk test was applied to assess if the fitness values follow a normal distribution. Since several of the runs did not adjust to the normal distribution, the medians were analyzed and the final parametric combination that was selected was $\#P$ = 100, p_c = 0.7 and p_m = 0.05.

3.2 Simulated Annealing algorithm

In this section, the simulated annealing algorithm used to solve the problem presented previously is described.

Simulated Annealing (SA) is a local search-based method that was developed from an analogy with the phenomenon of annealing [26] to solve complex optimization problems. Local search methods look for the solution with the best value of the chosen criterion in the neighborhood of the current solution, accept it as the current solution, and repeat this step until it is not possible to improve the solution in the explored neighborhood. By systematically applying this procedure, in general, a local optimum for the problem is obtained. To avoid getting trapped at a local optimum, a diversifying mechanism should be incorporated with the aim of exploring the entire solution space. In the simulated annealing metaheuristic, the diversifying strategy allows moves, with a certain probability, toward solutions that worsen the current value of the objective function. SA has shown competitiveness in handling regular flow shop environments [13] and also NPFS with missing operations [8].

In a minimization problem, the simulated annealing algorithm evolves from one candidate solution to the next, considering the behavior of the objective function value

following to the subsequent procedure. If the newly generated candidate solution (S_C) which is in the vicinity of the current solution ($S_C \in V(S_A)$] has a smaller objective function value than the current solution, i.e., $z(S_C) \leq z(S_A)$, the candidate solution is accepted as the current solution. Conversely, if $z(S_C) > z(S_A)$, a probabilistic test known as the Metropolis criterion is used to determine the probability of accepting a relatively lower quality solution. This means, that this sequence can be accepted with a certain probability $P(A) = e^{-\Delta z/T}$. Thus, $P(A)$ decreases as the difference between the objective function values of both solutions increases. T is the control parameter that simulates the role of the temperature in the physical process of annealing. If the candidate solution is not accepted, another sequence is selected randomly and the procedure is repeated.

4 Results

The experimental evaluation was aimed at evaluating appropriately the PFS and NPFS approaches to solve the skipping operations flow shop scheduling problem. This Section presents the instances and the experimental design that were used to assess the algorithms and describes the results obtained by applying both algorithms, making a comparison between the PFS and NPFS solution approaches.

4.1 Instances and Experiment design

For generating the test instances, we have taken as reference previous works that have considered NPFS with missing operation [8] and those that considered due-date related objective functions [27] [28]. The main parameters of the instances are the processing times of each job in each machine ($p_{i,j}$). In general, $p_{i,j}$ values are simulated using a uniform distribution within the interval [1; 99]. However, since this paper considers the possibility of job skipping machines (or operations), it is necessary to incorporate the 0 within that distribution. Furthermore, since this experiment aims at testing the algorithms in instances with a significant proportion of missing operations, a pseudo-uniform distribution is implemented where the probability assigned to $p_{i,j} = 0$ is greater than the probabilities for the rest of the possible interval values. Thus, by defining different values for the probability of occurrence of $p_{i,j} = 0$ within this pseudo-uniform distribution, it is possible to generate diverse instances with different proportions of zeros [8]. In this paper we have considered two values of probability of occurrence of $p_{i,j} = 0$: 5% and 10%. Additionally, for the calculation of the objective function it is necessary to calculate the due-date of each job j (d_j). In this case, literature guidelines presented in [27] were followed, where the due-dates are calculated according to the following formula for a job j: $d_j = \sum_{i \in I} p_{i,j} \cdot (1 + random \cdot 3)$, where *random* is uniformly distributed value between 0 and 1.

To evaluate the experimental results, we have used the Relative Percentage Deviation (RPD) to measure the performance of the algorithms. The RPD is obtained using the following formula:

$$RPD = \frac{S-B}{B} \cdot 100\% \quad (2)$$

Where S is the solution to be evaluated and B is the best known solution for that instance. For the assessment of the algorithms 30 runs where performed for each instance. Thus, we will report the average and standard deviation of the RPD. These values are computed for both algorithms, ssGA and SA. Then, the indicators are identified as $Ave.RPD^{ssGA}$ and $Dev.RPD^{ssGA}$, which represent the average values of RPD and its standard deviation for the ssGA algorithm, and, $Ave.RPD^{SA}$ and $Dev.RPD^{SA}$ in the case of SA, respectively. In order to compare NPFS and PFS solutions, the average relative improvement of the NPFS solution over the PFS solution, $Ave.NPFS$, is calculated. This improvement is measured with the following formula:

$$Ave.NPFS = \frac{sol.PFS - sol.NPFS}{sol.PFS} \cdot 100\% \quad (3)$$

Where *sol.PFS* represents the best PFS solution obtained by means of ssGA, and *sol.NPFS* represents the best solution obtained by means of SA for the same problem. $Ave.NPFS$ expresses the average value of that difference for the 30 runs. In turn, the standard deviation of these differences (between *sol.PFS* and *sol.NPFS*) was also computed, which is indicated as $Dev.NPFS$.

4.2 Experiments results

The values of *Ave.RPD* and *Dev.RPD* for the ssGA and SA algorithms are presented in Tables 1 and 2, respectively. Comparing both algorithms, it can be seen that they have similar performances, both in terms of the RPD average and standard deviation. In the case of RPD and problems with 5% skipping operations, the range of values for both algorithms goes from 4%, for problems with 20 machines and 80 jobs, up to around 40%, for problems with 10 machines and 40 jobs. In regard to the instances with 10% skipping operations, the range of values for both algorithms is around 6% for instances with 20 machines and 80 jobs. In the cases of 20 machines and 40 jobs, the RPDs differ between both algorithms, being 34.7% for ssGA and 39.4% for SA.

From the data in Tables 1 and 2 it can be suggested that, at least for the instances considered in this analysis, when the number of machines is closer to the number of jobs in absolute terms (in these cases, it would be 20 machines and 40 jobs), the RPD is maximum for both algorithms and both percentages of skipping operations. Thus, these instances are more difficult to solve for the algorithms. Another supporting argument of this inference is related to standard deviations. These are larger for instances of 20 machines and 40 jobs, those problems whose matrix of processing times tends to be more square when compared to the other problem sizes (15 machines and 40 jobs, and 20 machines and 80 jobs). However, a larger experimental work is required to draw a thorough conclusion regarding this aspect.

Table 3 presents the results of the solution comparison between the PFS and NPFS approaches. In Table 3 it can be seen that in the majority of cases NPFS solutions are better than PFS, as evidenced in the "*Improvement Freq.*" columns, since this percentage is larger than 96% for all the instances. In regard to the effect of the probability of skipping operations, when it is 10%, it is evident that NPFS is superior in all the cases except for the case of 20 machines and 40 works (in which NPFS is better in 98.7% of

the time). Regarding the improvement in terms of the objective function, on average NPFS is better than PFS, since all the values of the "*Ave.NPFS*" columns are positive. These improvements range from 0.5% for 20 machines and 80 jobs and 5% of skipping operations, to 2.8% for 20 jobs and 40 machines. When considering the instances with 10% of skipping operations, it is observed that this improvement increases, since instead of the 0.5% improvement in the problem of 20 machines and 80 jobs, it goes to 0.9% improvement. For 20 machines and 40 jobs, the improvement goes from 2.8% for 5% of skipping operations, to 3.97% for 10% of skipping operations. The standard deviations of NPFS improvements over PFS ("*Dev.NPFS*" column) also increases going from 5% to 10% of skipping operation.

Table 1. Average and Deviation RPD values for ssGA.

m	*n*	*Ave. RPD*^{ssGA}		*Dev. RPD*^{ssGA}	
		5%	10%	5%	10%
15	40	20.0%	15.5%	8.6%	9.5%
20	40	38.7%	34.7%	25.4%	20.0%
	80	4.3%	6.0%	2.3%	3.2%

Table 2. Average and Deviation RPD values for SA.

m	*n*	*Ave. RPD*^{SA}		*Dev. RPD*^{SA}	
		5%	10%	5%	10%
15	40	17.9%	17.3%	10.4%	10.0%
20	40	40.2%	39.4%	25.6%	22.9%
	80	4.6%	6.4%	2.4%	3.3%

Table 3. Solution improvement of NPFS approach over PFS approach.

m	*n*	*Ave.NPFS*		*Dev.NPFS*		*Improvement Freq.*	
		5%	10%	5%	10%	5%	10%
15	40	1.83%	3.53%	1.73%	2.20%	96.7%	100%
20	40	2.80%	3.97%	3.36%	3.74%	96.0%	98,7%
	80	0.50%	0.95%	0.43%	0.50%	99.3%	100%

5 Conclusions

This work addressed a scheduling problem in Flow shop systems that arises in Industry 4.0 manufacturing environments. This is the scheduling problem with skipping operations that takes into account the increase in personalization of products to meet the specific requirements of customers. To address this problem, this work proposes an innovative way to consider NPFS solutions to find efficient production schedules, seeking to minimize the total tardiness. Two meta-heuristic algorithms are presented that

allow to tackle realistic size instances, a steady state Genetic Algorithm (ssGA) and a Simulated Annealing algorithm (SA). Both algorithms were effective in addressing the instances considered in the experimental study. Specifically, the ssGA was used to optimize the PFS approach, and SA was used to optimize the NPFS. When comparing solutions, it was observed that NPFS tends to outperform PFS solutions in the vast majority of cases. Even when considering different proportions of skipping operations, it was observed that NPFS tends to increase its dominance over PFS when increasing the percentage of skipping operations.

To continue advancing in this line of research, it is proposed to approach problems that consider other types of objective functions, for example, objective functions of the regular type (e.g. makespan), as well as multi-objective problems. Additionally, another future research avenue would be to expand the experimentation by considering instances with larger percentages of skipping operations.

Abstract. All over the world, Industry 4.0 (I4.0) and Sustainable Development (SD) have progressively gained the interest of scholars, politicians, and other parts of society. Besides beings two of the most debated topics of the last decades; they also have overlaps between their independent research fields. Some examples are reductions of environmental impacts and improvements in production technologies. This integration of technologies and sustainable advances within an industrial context can enable a set of important competitiveness forces, which results can reflect in business improvement. However, the link between I4.0, SD, and business still needs a broader understanding. Basing on this perspective, this paper proposes a systematic literature review (2015–2020) to identify the current state of research on the subject by mapping and summarising existing research efforts, as well as identifying research agendas, gaps, and opportunities for more development. Results point to that there are fourteen research opportunities, showing the potential of Industry 4.0 as an enabler of sustainable business models that changes the responsibilities of companies.

Keywords: Industry 4.0, 4th Industrial Revolution, Sustainability, Business Model, Systematic Literature Review.

1 Introduction

The overlap between Sustainable Development (SD) or Sustainability and Industry 4.0 (I4.0) or also called the fourth industrial revolution has been one of the most important industrial debates in recent years [1,2,3,4,5,6,7,8,9]. But, although the I4.0 revolution can be described as a facilitator for sustainable development, this union remains underdeveloped in many aspects [3,5,6,10,11,12,13]. One of these aspects is about Sustainable Business Models (SBM) into the I4.0 revolution [1,2,3,4,14].

The new era of smart production can provide companies with a more aggressive attitude to embrace opportunities. As pointed by Porter and Heppelmann [14], the

changing nature of products will force many companies questioning what business they doing because new products raise a new set of strategic choices related to how value is created and captured, in other words, it redefines the value chains and business models [1,6,8,10, 14,15].

Based on this observation, the study present here was structured into three questions (Q). The set of questions increase understanding about how two of the most debated topics of the last decades are being discussed now to support future research agenda (Q1); mapping the field (Q2), and, finally, showing the chronological evolution (Q3). The questions are as follows: (1) What are the opportunities for future research agenda?; (2) Where this topic is being investigated?; (3) What is the current status of this research field?.

2 Conceptions description

The study is based on three main concepts, I4.0, SD, and SBM. In this section, these concepts are presented.

2.1 The connection between Industry 4.0 and Sustainability

Sustainability does not have a unique definition [16]. Due to this, concrete implementation is considered difficult because there is a high degree of complexity regarding the depth and specifications of the fields of action [3,16]. However, the most common definition cited was presented by the Brundtland Report, which describes sustainable development as "the ability to meet the needs of the present without compromising the ability of future generations to meet their own needs" [17]. Besides this definition, another highly referenced concept is the Triple-Bottom-Line (TBL), whose objective is to operationalize sustainability through the balance between economic profitability, respect for the environment, and social responsibility [18]. The common meaning among these different approaches is the general scope to support the increase of the companies' competitive capacity [19] and improve the use of their resource productivity [20].

Likewise, I4.0 is also a paradigm whose unique definition is not possible due to its wide range of approaches [2,21,22]. Most definitions consider I4.0 as a digital technological advance to make industrial production systems more intelligent, connected, and capable of decentralizing production [2]. Some practical examples of new technologies of revolution 4.0 used in the industry are: big data and analytics, Internet of Things (Internet of Things (IoT)), augmented and virtual reality, simulation, robots and autonomous vehicles, additive manufacturing, cloud, cybersecurity, among others.

According to Kuik and Diong [23], I4.0 refers to extracting real-time data and developing new and innovative information systems (IS) through the use of computer and/or sensing devices as well as information communication tools. In the same way, Piccarozzi et al. [22] state that I4.0 is based on the horizontal and vertical integration of production systems driven by real-time data interchange and flexible manufacturing to enable customized production.

Many publications on I4.0 and sustainability are dedicated to the economic and environmental dimensions [3,21]. Although I4.0 also has enormous potential for the social dimension [6]. In the economic dimension, most of the literary contributions of I.40 to sustainability relate to the proposal of new technologies to reduce manufacturing costs through systems integration [6]. In the environmental dimension, most of the literary contributions of I.40 to sustainability are related to improving the standard of living of the society and increasing the quality of production without causing damage to the environment [6]. In the social dimension, most of the literary contributions of I.40 to sustainability are related to predicting better conditions and beneficial opportunities for workers [11].

The predictive use of production data provide by I4.0 toward more sustainable industrial value creation will change the ability to make planning production for competition between non-sustainable and sustainable products [6,8,23,24]. Therefore, is also highlights the impact of this union in business management models and firms' main components and the importance of more studies with this domain [22].

2.2 Sustainable Business Model (SBM)

A new business mindset can generate many advantages and challenges. When sustainability is added to the core of the business model concept, it can systematically change the purpose of the company [25]. In this regard, SBM offers opportunities for companies to rethink their process of value creation, product production, pro-active multi-stakeholder management, and long-term perspective [1,7,26].

At the same time, SBM can be limited by the introduction of incremental or radical innovations [1]. According to Inigo et al. [27], evolutionary approaches, based on incremental sustainability innovations, adjust the creation of value to respond gradually to market needs. On the other hand, radical innovations introducing new value propositions to address a new sustainability issue. This way can result in the creation of an unprecedented market segment.

Among diverse SBM definitions, Schaltegger et al. [28] argue that a business model for sustainability "describe, analyze, manage, and communicate (i) a company's sustainable value proposition to its customers, and all other stakeholders, (ii) how it creates and delivers this value, (iii) and how it captures economic value while maintaining or regenerating natural, social, and economic capital beyond its organizational boundaries". On the other side, it is possible to find SBM definitions based on Brundtland Report as in Garetti and Taisch [29] that describes SBM as the preservation of the environment, while continuing to improve the quality of human life. Dyllick and Hockerts [30] view SBM as the meet the needs of a firm's direct and indirect stakeholders without compromising its ability to meet the needs of the future. Similarly, Bansal and DesJardine [31] argue that SBM is the ability of firms to respond to their short-term financial needs without compromising their (or others') ability to meet their future needs.

3 Review methodology

To better identify the relationship between I4.0, SD, and SBM, a Systematic Literature Review (SLR) was implemented according to Tranfield et al. [32] procedures. A literature review is essential to strengthening the field of study [32]. As scientific inquiries, the SLR should be a transparent, valid, reliable, and replicable method for identifying, describing, evaluating, and synthesizing evidence related to a specific topic [32]. The SLR rigors ensure that the result found has scientific validity since it describing the information with the least possible distortion and errors; also, because it has the legitimacy to improve knowledge development and make decisions [33].

To secure the validity and transparent rigors of SLR, specific databases were selected: Scopus and Web of Science. These databases were used because contains a significant number of internationally renowned publications, like Springer, Elsevier, Emerald, and Taylor and Francis. The review process considered only formal literature that was: (i) written full-texts in English, (ii) published between May 2015 and May 2020; (iii) peer-review published papers. Then, a structured keyword search was conducted executed through a pairwise query, focusing on titles, abstracts, and keywords.

Table 1. Search results

	Keyword pairwise query	Scopus	Web of Science
1	TITLE-ABS-KEY ((sustainability AND business model AND industry 4.0))	8	4
2	TITLE-ABS-KEY ((sustainability AND new business model AND industry 4.0))	4	2
3	TITLE-ABS-KEY ((sustainability AND organization improvement AND industry 4.0))	1	1
4	TITLE-ABS-KEY ((sustainability AND maturity model AND industry 4.0))	1	0
5	TITLE-ABS-KEY ((sustainability AND maturity evaluation AND industry 4.0))	0	0
6	TITLE-ABS-KEY ((sustainability AND dynamic capability AND industry 4.0))	2	0
7	TITLE-ABS-KEY ((sustainability AND strateg* AND industry 4.0))	17	3
8	TITLE-ABS-KEY ((sustainability AND competitiveness AND industry 4.0))	7	1
9	TITLE-ABS-KEY ((sustainability AND competition AND industry 4.0))	9	2
10	TITLE-ABS-KEY ((sustainability AND value creation AND industry 4.0))	8	4
11	TITLE-ABS-KEY ((sustainability AND strategic planning AND industry 4.0))	0	0
12	TITLE-ABS-KEY ((sustainability AND product AND development AND process AND industry 4.0))	12	3

13	TITLE-ABS-KEY ((sustainability AND product AND development AND industry 4.0))	20	3
14	TITLE-ABS-KEY ((sustainability AND product AND industry 4.0))	33	7
15	TITLE-ABS-KEY ((sustainability AND continuous improvement AND development AND industry 4.0))	1	1
	Total in each database	123	31
	Final result	154	

In each database, 15 different search strings were used. Table 1 reports the search strings and the resulting number of papers in each database. The search found 154 papers from both databases. To refine the results further, duplicate papers were exclusion. The total numbers of articles dropped to 36 papers after reading the abstract according to the review purpose for the final review.

4 Results and analysis

This section made a descriptive analysis of the whole sample. Even at a general level, the database allowed extrapolation of interesting information. This information will be presented according to the order of the questions. Started by (Q1): What are the opportunities for future research agenda?. Not all authors present directions for future research. However, fourteen opportunities for further investigation were identified (see Table 2).

Table 2. Future research opportunities

N	%	Future research directions
1º	16,70%	Apply the study in large-scale
2º	16,70%	Analyze the different functions of the company in interaction with I4.0
3º	10,60%	TBL dimensions in the context of the I4.0
4º	9,10%	The impact of I4.0 on supply chain network design
5º	9,10%	The impact of I4.0 on managing customer channels
6º	8%	Employee quality
7º	6%	How Industry 4.0 will change the competition
8º	6%	How incorporating the I 4.0 into theory about sustainable value propositions
9º	6%	Qualitative research
10º	4,55%	Cost-benefit analysis of Industry 4.0 solutions
11º	3,03%	Policy-making efforts to I4.0
12º	1,52%	Transformations in the identity of a manufacturing company
13º	1,52%	Risk assessment to I4.0 implementation
14º	1,52%	Ensure data security

Two of these were the most mentioned: apply the studies in large-scale and analyze the different functions of the company in interaction with I4.0. The first opportunities are regard to test the empirical observations found in each paper in a large-scale study of

companies since very small to bigger ones; in the context within and across industries; applied to any business function; into new customized segments; diversified markets; between different cultures and nations; and different methodologies [21,34,35,36,37,38,39,40,41,42,43,44]. In more, could be investigated its influence on other business models types, such as product-focused and result-focused ones [37,38].

Analyze the different functions of the company in interaction with I4.0 is an option for future research to observe the shift industry boundaries and theories of the firm within a manufacturing context [1,7,34,35,45,46]. More investigations are needed to analyze how can the currently highly production-oriented developments and the data they generate be included in the entire corporate information and decision-making processes [1,46]. Additionally, future research projects should take into consideration other key variables and outcome to give a broader view on it specific characteristics and requirements that influence the implementation of I4.0, e.g., top management support, metrics of performance, environmental uncertainty, digital servitization, new technologies, absorptive capacity, and so on [6,21,26,37,38,43,45].

Investigations on TBL dimensions in the context of the I4.0 shows that there is still a lack of investigations about the interplaying and conflictive relationships between dimensions [1,6,7,13,26,37]. Furthermore, current research emphasizes the need for more studies on the social impacts of I4.0 [3,21,26,47].

Possible contributions to the impact of I4.0 on supply chain network design can analyze how it facilitates reverse logistics to reduce production waste, overproduction, and energy consumption; focusing on production planning, structure, and control of product recycling [4,6,42]. Additionally, the resource-sharing aspect of sustainable business models [49].

Future research about the impact of I4.0 on managing customer channels should try to describe it in the creation of sustainable awareness of customers, customer loyalty, and satisfaction for sustainable I4.0 products/services [4,7,45].

More detailed investigations should observed work quality between humans and machines regarding which job profiles emerge and which diminish because of the I4.0 [13,21,49]. This opportunity for future research is linked to social dimension issues. But, here further research is needed on the issue of accidents involving hazardous chemicals, new tools, and techniques by developing technologies I4.0; and, professional training [6,42].

A research agenda is also needed to explain how I4.0 will change the competition, especially, between non-sustainable and sustainable products [4]. Is also necessary to verify how it improves the competitiveness of the company over time, i.e., in the long-term [47]. As well as the role of dynamic capabilities in resource reconfiguration and processes it changes require [45]. Moreover, future research should examine how I4.0 transforms bargaining power in different sections of manufacturers [45].

How incorporating the I4.0 into an organizational theory about shape new sustainable value propositions is a gap to further studies close [4,48]. As well how can organizations integrate, analyze, and exploit data to generate sustainable value-propositions [48]. Novel insights are needed to explore how manufacturers shift their value creation and capture from product-centric to service-centric, and further to data-centric [1,21,45].

Quantitative research is another future possibility to check results presented in articles [34,36,50], more specific to measure social and ecological impacts [3]. Valuable contributions are needed regarding the cost-benefit analysis of Industry 4.0 solutions to supported sustainable products [4,45]. In this cost, the transaction should be analyzed downstream and upstream interactions [45].

Literature has lacked studies, since the debate on this theme is recent, on policy-making efforts to foster the development of I4.0 by national and local governments. Potential studies can explore the regulation of political, financial, and fiscal aspects, as well as the provision of infrastructures, services, knowledge, and a skilled workforce [26,51]. Moreover, based on the scarcity of results of the SLR, there is a need to urgently investigate how I4.0 transforms the identity of a manufacturing company [45]. In the same line, must be better understood the risk assessment to I4.0 implementation, depending on short, medium, and long-term management, different corporate and environmental contexts [50]. Finally, although ensure data security is a point commonly debated in studies about I4.0, few articles in the sample of this SLR highlighted the need to further investigations of it by a sustainable business model perspective; how it would be developed, and what companies think about it [26,34,46].

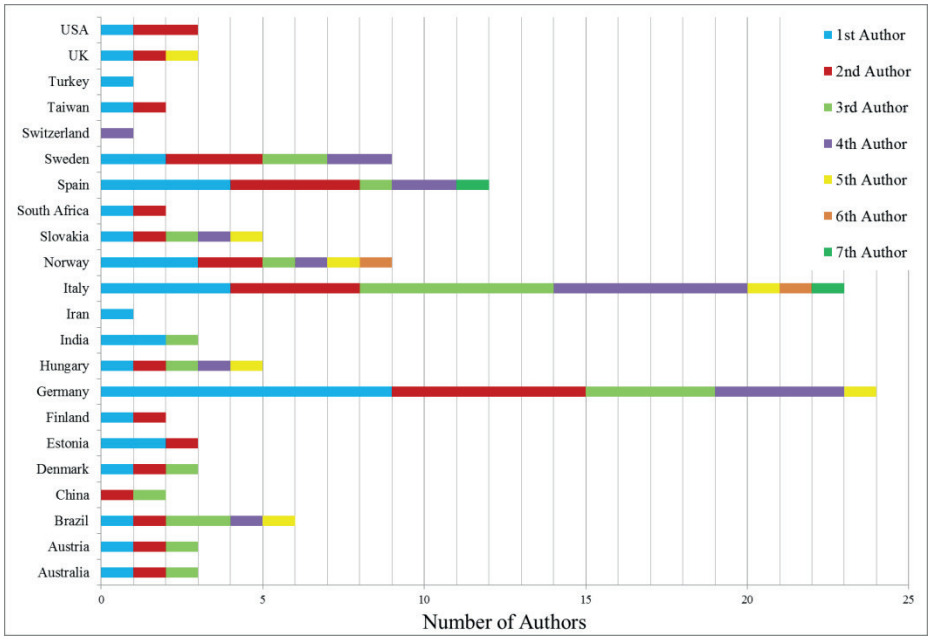

Fig. 1. Authors' affiliations countries.

Data to (Q2) Where this topic is being investigated?, considering the authors' affiliations, reveals that there is a strong predominance of German (19,2%) and Italian (18,4%) authors, as shown in Figure 1. The next predominance countries perceptual contributions are Spain (9,6%), Sweden (7,2 %), and Norway (7,2 %). The other 17 countries' contributions accounted for about 38,4% of the total number of works

published. This shows that the major research contributions are coming from countries with few authors. This means that, despite the dominance of German and Italian authors, this field of research is of interest to several countries.

The detail of figure 1 also showed that the greatest number of first authors is from Germany, Italy, and Spain. This result is equal to the second authors. Most of the third and fourth authors are form Italy and Germany. Fifth authors predominate with the diversity of countries: Slovakia, Norway, United Kingdom (UK), Italy, Hungary, Germany, and Brazil. Sixth and seventh authors are from Norway and Italy, Spain, and Italy, respectively.

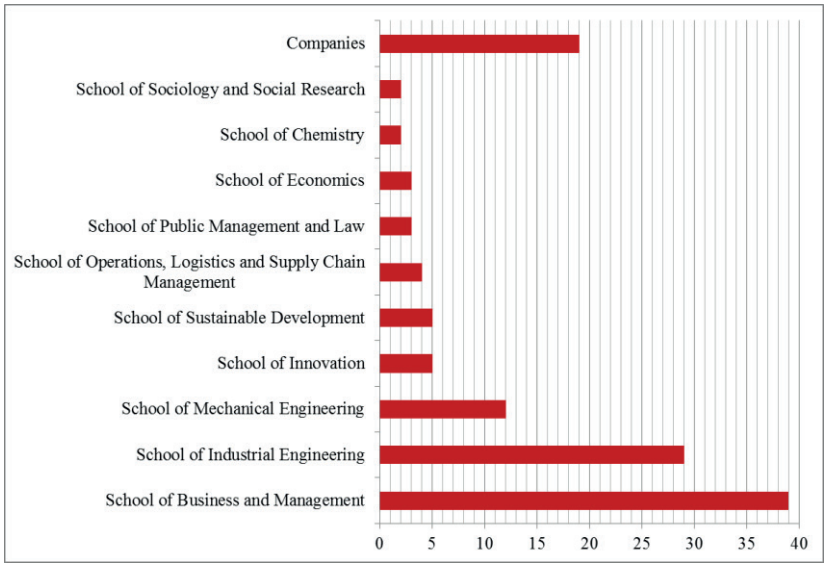

Fig. 2. Authors' affiliations school.

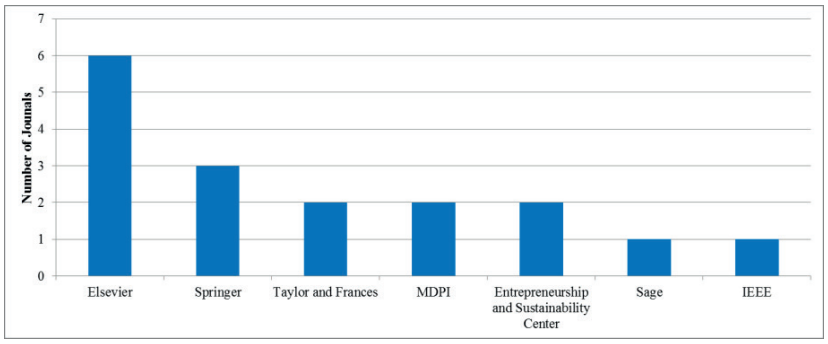

Fig. 3. Publisher list.

According to the authors' affiliations, figure 2 shows from what school each author is. Most of them are researchers in business and management (31,7%), then engineering (23,5%) and mechanical engineering (9,75). Authors' affiliations from companies

represent 15,44% in the sample. Most of them work in automotive companies, production systems advisory, financial, and innovation consultancies.

Going into contributions by publishers, figure 3 reveals that Elsevier has the highest number of scientific journal titles, with six journals, followed by Springer with three scientific journals title. However, the journal with the highest contribution (number of papers published) is Sustainability from MDPI Publisher (see Fig. 4).

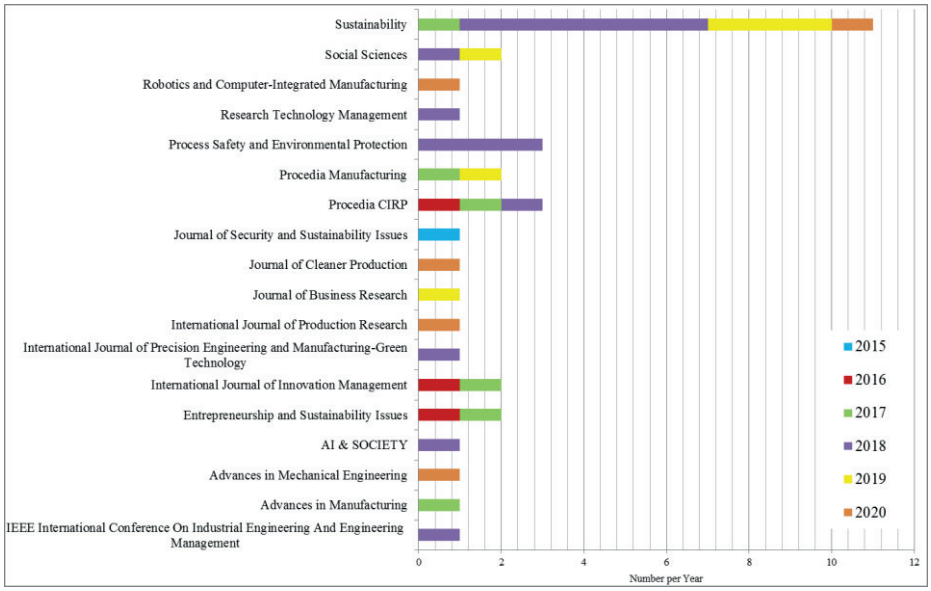

Fig. 4. Journal titles list.

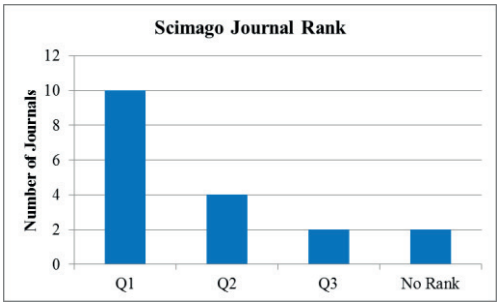

Fig. 5. Journal rankings by Scimago.

Regarding the quality of these scientific journals, their classification in Scimago was verified to analyze their impact factors. As shown in figure 5, most journals have a great impact factor, being classified in Q1 (the best rating). Looking at how many contributions each journal had, the result pointed out that most articles are from journals with a Q2 classification. Besides, it was possible to identify the main topics of each journal according to the description of Scimago (see Fig. 6). The close link between business, I4.0, and engineering proved to be relevant because the most cited subjects were

engineering and business, management and accounting; following the three dimensions of the TBL: environmental science, finance, and social sciences. In particular, this emerging link can also be verified by looking at journal titles. One-third of the entire sample deals specifically with the topic of sustainability, but not the other two (Sustainability, Entrepreneurship and Sustainability Issues, Journal of Security and Sustainability Issues, Process Safety and Environmental Protection, Journal of Cleaner Production, International Journal of Precision Engineering and Manufacturing – Green Technology).

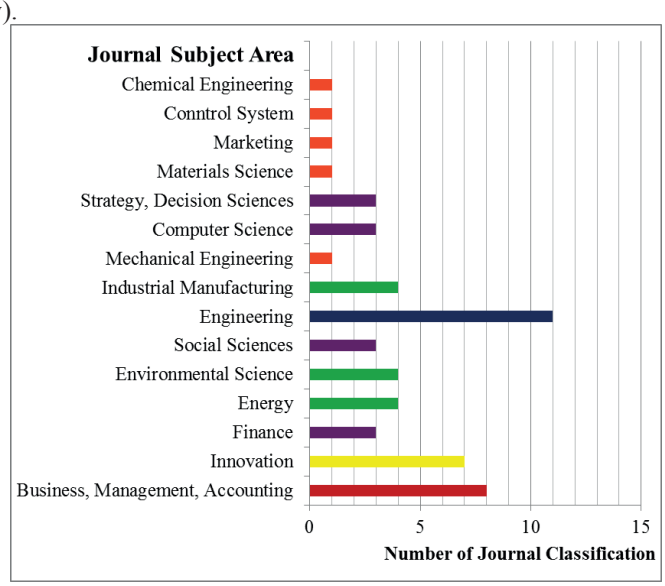

Fig. 6. Journal Subject Area list.

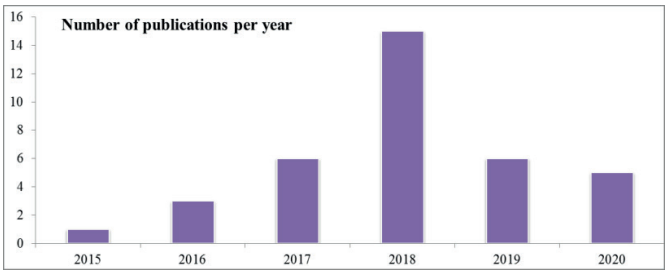

Fig. 7. Chronology of article publications.

The chronologic data to answer Q(3) What is the current status of this research field?. revels that there was an upward trend observed from the year 2015 to 2018 (see fig. 7). However, the number of papers published from 2019 onward has decreased drastically. It is observed that 69,44% of total papers were published in the year 2015–2018. In contrast, 2019 revealed little attention devoted to these topics by the authors. Papers' date to 2020 was published only in April and March. This outcome highlights the need for more studies covering this important link between business model, sustainability, and I4.0.

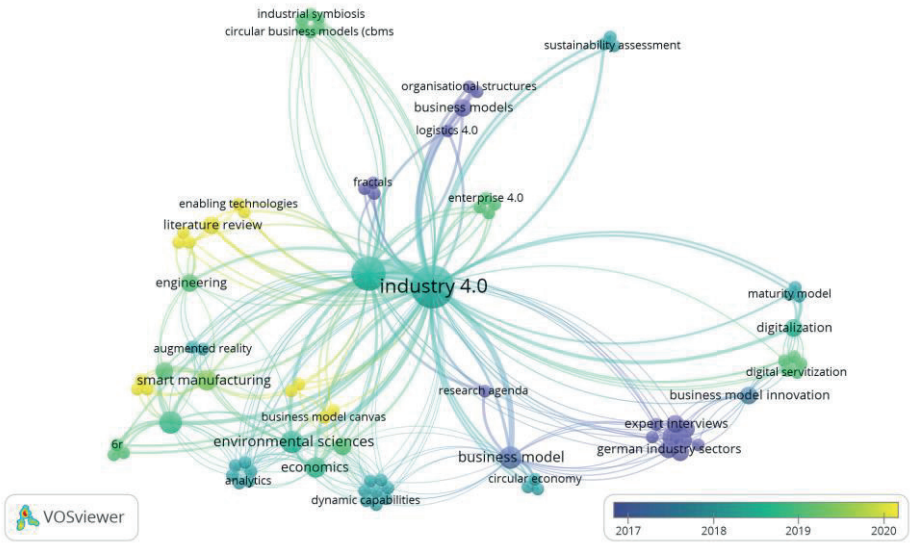

Fig. 8. Chronology of article publications by keywords.

Another way to observe how is the theme currently is looking at keywords statistics (see Fig. 8). Here, were extracted the most commonly used keywords in all selected papers using the VOSviewer tool [52]. The most frequent keywords used until 2017 were: business model, research agenda, expert interviews, German industry sectors, logistics 4.0, and organizational structures. The most frequently keywords used in 2020 were business model canvas, smart manufacturing, literature review, and enabling technologies.

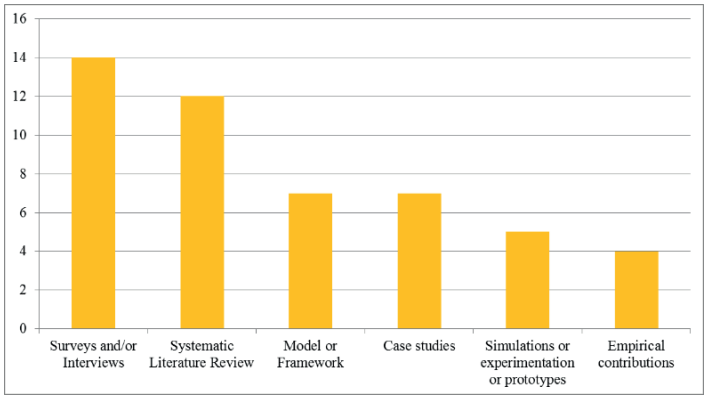

Fig. 9. Chronology of article publications by methodologies.

Finally, fig. 9 shows the distribution of the selected 36 papers by methodology. The sample is mostly made of surveys and/or interviews (28,5%). Then, systematic literature review (24,4%), model or framework (14,2%), case studies (14,2%), simulations

or experimentation or prototypes (10,2%), and empirical contributions (8,16%). One important observation about papers' type of research was the change of type year by year. In the initial years 2015 until 2017, most of the articles were surveys or interviews, case studies, and simulations, experimentation, or prototypes. From 2018 until 2020, the main papers' type of research was a systematic literature review and model or framework. Based on this, it can be said that this recent topic was initially studied from a practical and expert point of view, while in more recent years conceptual and theoretical research has become more frequent.

5 Conclusion

This study aimed to investigate, through a multidisciplinary lens, the current state of research on the theme I4.0, SD, and SBM performing an SLR. 36 articles were analyzed for this purpose. Based on the limited number of articles analyzed and the initial proposal, this study was not intended to use statistical analysis or to provide a more in-depth analysis of specific topics. However, this review was successful in demonstrating the potential of introducing I4.0 into SBM. We conclude that I4.0 is an enabler for sustainable business models that changes the responsibilities of companies, making them responsible for their entire consumption system, and not only for the production and sale of consumable goods. This crossing of borders introduced a competitive advantage of high technology that initially approached a vision of technocentric evolution for a holistic view. Nevertheless, our results have some limitations due to its qualitative nature. Selected keywords and databases may be one of the limitations of this article, as there may be articles relevant to the scope of the study outside these criteria that were not considered. Finally, the result highlighted the need for further research. A research agenda for the development of sustainable business models were presented in the results section. Future work can also extend the analysis made by this SLR and focus on how the union of the observed themes reflects in the science of business and management, such as company theory, strategic planning, and so on.

Acknowledgments. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

Abstract. The growing significance of innovation ecosystems and the need for collaboration projects, as well as Open Innovation (OI) practices, has been shaping the way as universities produce Research and Development (R&D), impacting Product Lifecycles Management (PLM) directly. The collaboration between different actors enrolled in the development of new products and services is a growing trend, indicating more challenging innovation processes. It is possible to find in literature and empirical knowledge that R&D and OI, even separately, can be complicated and more extensive than expected. Innovation process complexity can be more demanding, especially when its crucial to consider the context of new technologies, sustainable and user-centric and other approaches and more recently, new crises such as pandemics restrictions. This paper aims to realise a literature review in qualified databases, to find the best practices that universities have been carrying out in recent years in Open Innovation concerning Research and Development. Primarily, the goal of this study is to find the literature contributions in OI and R&D in universities and its respective characteristics and further, try to obtain information about the elements that can be related to as development methods, product lifecycles, results and particularly R&D impact. The central purpose of this paper was to find relevant information for innovation management in universities and industries, and through the data gathered from the literature, to generate inputs to foster future R&D and OI research projects, closing the gap between university and industry and promoting greater outcomes.

Keywords: Open Innovation, Research and Development, Higher Education, Universities Best Practices, Product Lifecycles Management.

1 Introduction

1.1 Context

The efforts to obtain original sources of innovation are increasing daily in organizations of every industry. As the main point of competitivity or for different purposes, innovation has been the theme in the priorities agendas of every company which aims to survive. Some concepts, theories, practices of innovation have been raised in several approaches, but it is not more acceptable that one only one company can answer all facets demanded by innovation. In response to this urgency of contemplating different stakeholders or actors with their needs and expectations, raised the Open Innovation (OI) concept [1]. Open innovation is a process which combines internal and external ideas

in overture with the market to develop new ideas and technologies – such as systems or architectures. The authors of the concept understand that Open Innovation changes Research & Development perspective, treating it as an open system since the flows of ideas are able to come inside and outside the organization able to be applied or commercialized inside or outside this organization. [2] Since then, OI applications have been evolving according to the context, always in order to obtain broader and more successful results for innovation.

It can be observed that to deal with the evolution of research, development and innovation, the universities have been changing their approach. To foster Research and Development in openness with other organisations and to be market-oriented, the different initiatives have been emerging, giving an expanded vision for the so-called university-industry collaboration.

For this reason, universities have been engaging or creating their own innovation ecosystems have several approaches and programs to seed entrepreneurship, incubation and acceleration programs, technology transfer offices, which means that articles, patents, software, products, start-ups and more innovation outcomes are presented in different stages of Product Lifecycle requiring new approaches for its management.

The authors of this paper have been studying the purpose of the university in the face of the challenges of sustainability and innovation and its role as the protagonist of change management troughs its outputs: high-quality professional education, knowledge provider, science, research and development and more [3]. It is from this context that the present work aims to search in the literature, best practices of universities have been carrying out in recent years connecting the themes of Open Innovation concerning Research and Development and Product Lifecycle Management.

1.2 Background

The purpose of open innovation is to reorganise innovation processes leading flows of knowledge beyond organisational boundaries [4], which means that more opened sources of external knowledge have been proven to facilitate better outputs for innovation [4]. It is based in this concept that all sort of enterprises has been working close to universities, government, suppliers, customers to gather brand-new and unexpected knowledge to develop more innovative products, services and processes. In other words, the OI practices can be extended to innovation management research and practice and with its interactions with business ecosystems [5].

The model of the Triple Helix proposes interactions between university-industry-government as innovation pillar. [5] The interactions between these three actors are organised in the Triple Helix model in order to understand the role and contributions of each institution for innovation as well as the variables and quality of these relations as institutional and functional arrangements and its ability to foster innovation outcomes. [6]

Additionally, it is necessary to understand the concept of Product Lifecycle Management (PLM), which summarily means the activity where organisations manage their products considering all the stages of the complete lifecycle: since the idea conception, including production, distribution and including product post-use until the disposal. [7]

Three macro-phases are the pillar of the Product Lifecycle: a) beginning of life (BOL) which contemplates phases such as product planning, design and production and distribution; c) Middle-of-life (MOL) which includes phases such as utilisation, service and maintenance and finally; c) End-of-life (EOL) that contains the phases or reverse logistics, disposal, reuse, recycling. [8]

Considering the context of Fourth Industrial Revolution, sustainability challenges, there is a large field of opportunities to apply Research & Development in different stages of Product Lifecycle and Open Innovation seems to be a useful and effective approach to support the innovation specially the innovation developed by universities, which are the main interest of this study.

Universities play an essential action in the OI contribution since they are a significant knowledge provider for Research and Development (R&D) [10]. The practices of OI now becoming more present in innovation activities in university-industry-government, which has been shaping the new approaches as universities produce Research and Development (R&D) impacting Product Lifecycles Management (PLM) directly.

Thriving entrepreneurial ecosystems count with an excellent capacity to transform inventions into innovations and in to commercialise knowledge. For this reason, universities are considered as key actors within the entrepreneurial ecosystems to perform knowledge commercialisation through academic spin-offs and technological development [10]. The university function is perceived as an essential motor of product development – independently of which stage of the lifecycle it is, and always supported by research and development.

Furthermore, there are significant contribution for product lifecycle in stages such as: stakeholder engagement, proposition of new ideas; validation and evaluation of product concepts; creative approaches and product launch [11]. Moreover, PLM moves beyond engineering's incorporating manufacturing and marketing, and it is to become product-centric, crossing organisational boundaries, observing its supply chain and contemplating all the phases of the product's life: create, build, use and disposal [12, 13].

2 Method

2.1 Literature Review

2.1.1 Data search

This paper aims to conduct a structured literature review [14, 15, 28, 29], in qualified databases, to find the best practices that universities have been carrying out in recent years in Open Innovation concerning Research and Development and its best practices and the relations of Open Innovation.

The search for articles to fulfil the proposed goal, included the terms: Open Innovation (OI) and Research and Development (R&D). Additionally, a complimentary search was done to obtain extra data regarded to Open Innovation (OI) and Product Lifecycle (PLM). In both cases, the searches were combined with the word University as the exposed following (Fig. 1).

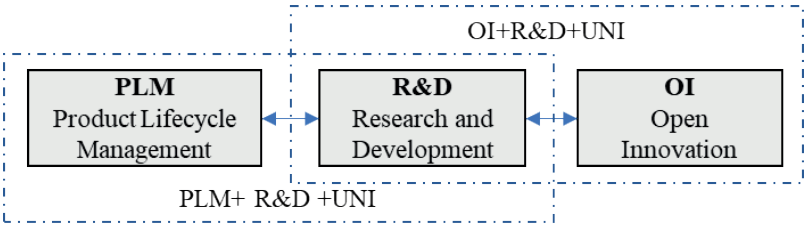

Fig. 1. Keywords relation.

Scopus and Web of Science were the databases chosen for the search; both are internationally known by the widely quality of content, large metadata availability and usability to conduct the queries. The combination of keywords for this universe search is illustrated below (Fig. 2). Additionally, as the first criterion of inclusion, the search included exclusively articles published in English and 2009-2020 as time coverage.

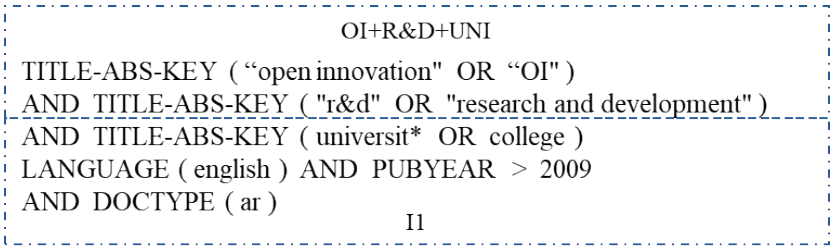

Fig. 2. Query example.

The literature review contemplated eight steps, separated in three groups of activities: 1) Databases search of the keywords combined, as the example in figure 2; 2) Database organisation: removal of duplicated articles and exclusion of articles that are not related to the scope of the study. 3) Inclusion criteria: quality, language and reading of articles metadata.

The queries keyword in databases search resulted in 542 articles, with the removal of duplicated files and the out of scope, the total base contemplated 488 articles to be read. Only the papers published in the first quartile (Q1) according to *Scimago Journal Ranking* – 2018 were selected to the next phase, resulting in 186 sources. Finally, the articles selected to this work are which presented all the studied words (Open Innovation, Research and Development, Product Lifecycle Management and University) in all fields (title, keywords, abstract). After that, all the metadata of the articles were read, resulting in 12 final articles selected to full content analysis.

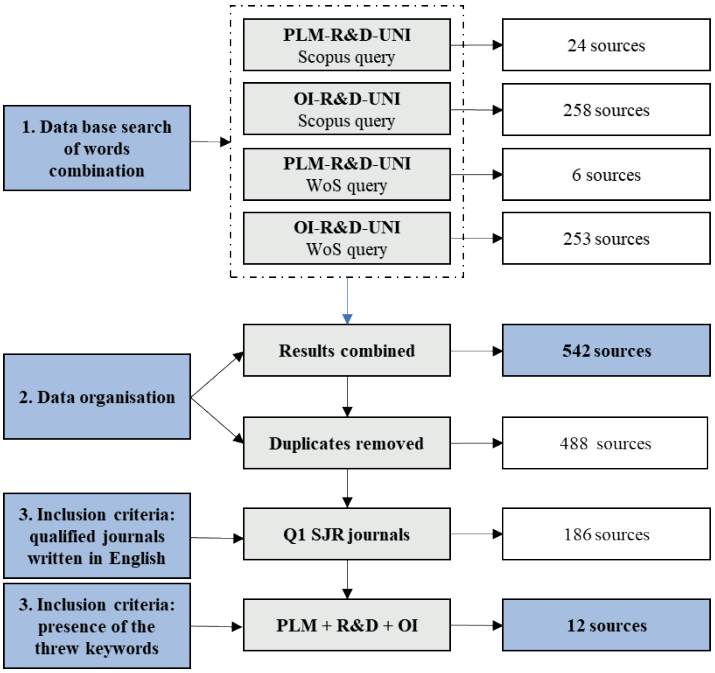

Fig. 3. Literature review steps.

2.2. Content analysis

The content analysis of the articles was conduct in two steps. Firstly, the authors analysed the general contributions of each paper, and secondly, the specific practices or contributions of the university regarding OI, R&D and PLM were interpreted. Table 1 presents the contributions, limitations and applications of each article. The works are presented by year of publication, in order to facilitate the theme's evolution through a timeline.

Table 1. Literature review findings.

Author(s)	Contributions	Limitations	Applications
Ebener, Liemiester, Krcmar (2009) [16]	Crowdsourcing for open innovation by multiple actors sustained by a system.	Gaps of concepts, tools and methods to support the innovation process.	Challenges and organisation structures for product development innovation.
Spithoven, Frantzen & Clarysse (2010) [17]	The impact of intensity of research on the innovative product to increases revenue.	Belgium contexts, self-reported data, quantitative analysis and few qualitative reflections.	Alignment for R&D expectations in short-term and long-term for managers.
Petroni, Venturini & Verbano (2012) [18]	How the OI has changed the organizational structures of R&D and the managing methods.	Four companies with very different profiles.	Best people management for open innovation in universities and companies, including roles beyond research.

Author(s)	Contributions	Limitations	Applications
López *et al.* (2014) [19]	Profiles of companies which collaborate with universities to R&D and country influence.	European countries and focus on small or medium enterprises.	Innovation actions to foster to non-technologies companies.
Bianchi *et al.* (2014) [20]	The benefits of the integration OI and R&D to PLM, focusing in internal and external paths.	Spanish context, solely manufactory companies and unappropriated dataset.	Inputs for successful new product development and licensing for tech companies.
Gesing *et al.* (2015) [21]	How the open innovation is impacted by governance models, collaboration partners, intern R&D to product development.	German context.	Insights about the level of formality and open innovation – R&D processes.
Oguguo, *et al.* (2015) [22]	The institutional context and the effect of national policies to foster innovation and R&D.	Firms benefited by 7TH Framework Program for Research and Technological Development.	Public policies advocacy.
Bianchi *et al.* (2016) [23]	OI and R&D to foster technological development.	Spanish context; Time scope (1999-2007). Quantitative approach lack of qualitative. Aggregation bias.	Insights about external technological.
Rubera, Chandrasekaran & Ordanini (2016) [24]	Open innovation applied to PLM: impact in product innovation and firm performance.	Focused on inbound open innovation.	OI applied for product lifecycle.
Naqshbandi (2016) [26]	The importance of management for effective open innovation results.	Study of management influences in a general approach, without specificities.	The function of management to across the boundaries in all OI actors.
Greco, Locatelli and Lisi (2017) [26]	Collection of pieces of evidence and factors which motivates companies to innovate.	Energy sector and British context.	The purpose of academia to support OI and the need for policies.
Triguero & Fernandez (2018) [27]	Geographic influences on Open Innovation, R&D and the actors' interactions related to product development.	SLR time scope (2003-2013); Spanish context.	Fostering regional ecosystem by technology domain.

The last ten year has shown the contribution of the university for open innovation. Even the search was conducted under some specific and combined terms, the study found the following contributions. Most of the articles have focus in the of Open Innovation for university-industry-government, but with general approaches privileging themes such as innovation management, internal organization and culture, and approaches [25, 21], companies' profiles and motivations [26], public policies [22], and methods for generation of innovation [16], There were some essays about firms' size; innovation programs appear more frequently than the university profiles.

Under the analysis of Research and Development as the central theme; the object of the study of the articles are mostly in concentered in subjects related to the impact [23],

intensity [17], revenue, structures and management for innovation in R&D [18]. Also, there are two studies which consider regional factors as influencers of innovation outcomes [17, 27].

Finally, by the perspective of Product Lifecycle Management, just two works presented a clear connection with the other studied themes. One study highlights the benefits of the integration of OI and R&D to PLM, including internal and external overviews [20]. Moreover, the second study that observes how OI applied to PLM impacts product innovation and firm [24].

As limitations, most of the article concentrates in regional contexts of countries or continents. Commonly, the approaches are qualitative or quantitative, and the authors agree that for each case, there is a complementary analysis missing to advance the studies. Also, there is not possible to find patterns of firm's profiles or uniform universities actions, firstly because of the nature of the innovation activity and secondly because it was not the scope of this study.

All the articles generated insights for future applications. These data are organized into two categories. The first category contemplates different approaches to foster innovation in different levels: inside the companies [16, 17], and universities [26], regional initiatives [19, 27], public policies [22]. The second category presented articles related of many interfaces of management for innovation: people management [25] [18], culture management [21] external scenarios, [23]. Relevant considerations of methods to work with innovation such as PLM applied to OI [21, 24].

To find the best practices of universities, regarded to open innovation, research and development and product lifecycle, the second part of content analysis evaluated the articles, in the same sequence presented before. This second part aims to identify how the studies about OI, R&D and PLM considers the importance and interactions with universities as presented in Table 2.

Table 2. Universities best practices.

Author(s)	Universities best practices
Ebener, Liemiester & Krcmar (2009) [16].	• Interface between company – universities – educational institutions. • Challenges of open innovation including all different actor to generate innovation for products and software development.
Spithoven, Frantzen & Clarysse (2010) [17].	• Universities are required to perform complex research. • Interorganisational collaboration with universities produces positive impacts in R&D. • Efficiency and opened R&D processes deliver successful innovation products and revenue.
Petroni, Venturini & Verbano (2012) [18].	• Growing number of contracts between enterprises and universities. • The interest of researchers in collaboration with highly specialised research firms. • Decentralisation of R&D structures allowing more and specialised collaboration with universities. • Development of R&D centres/laboratories inside companies to train universities students to be hired by this firms.
López *et al.* (2014) [19].	• Innovative firms and high-tech firms tend to be more opened to collaborations with universities. • Country factors may affect the collaborations university-industry.

Author(s)	Universities best practices
	• Non high-tech firms have interest in collaboration focusing in organisational and commercial innovation.
Bianchi *et al.* (2014) [20].	• Collaborations between firms and external organisations, such as universities and other actors, can result in better results in transforming technological resources in new products for different industries.
Gesing *et al.* (2015) [21].	• Partnerships with universities provides access to unique technological knowledge. • Technological breakthroughs and long-term commercial opportunities origined by applied and basic research. • Universities face few opportunities to commercialise intellectual property. • Contractual and formal governance tend to be more effective in science-focused collaboration than informal.
Oguguo, Bodas & Genet. Al (2015) [22].	• Evaluation of risks of cost, schedule, knowledge leakage in collaboration university-industry. • University as open knowledge provider. • Co-publication authored by firm-industry benefits and risks.
Bianchi *et al.* (2016) [23].	• Outsourcing of R&D from universities as knowledge and technology acquisition.
Rubera, Chandrasekaran & Ordanini (2016) [24].	• Universities as a source (between other sources) of Open innovation to development and commercialisation.
Naqshbandi (2016) [25].	• University-industry ties for OI may occur by management interactions. • Universities as knowledge and resources providers and influencers of OI.
Greco, Locatelli and Lisi (2017) [26].	• Universities as main influencers of OI to energy innovation. • Development of technologies. • Support firms in funding programs. • Universities as partners to develop environmental innovations. • Public policies and its influence in university industry collaboration. • The recent simplification of process for joint collaborations as well as intellectual property and start-ups spin-off management. • Ways to eliminate the cultural barrier to collaborations with university.
Triguero & Fernandez (2018) [27].	• Vital contribution of universities for specific science-based industries. • Universities as an attractive option for firms with less capacity of investment in innovation. • OI strategies which includes universities are increases the chances of success of innovation of new products and processes. • The higher knowledge, the higher innovation results.

The analyse of universities' best practices found some theoretical convergences about the university as a robust knowledge producer, innovation partner and as a protagonist of innovation. From the perspective of open innovation, most of the articles agree that university, at least theoretically, it is a protagonist regarding the initiative related to open innovation. Since there are many facets and outcomes offered by the university, the more are the match opportunities for societies´ demands.

Additionally, for the point of view of research and development, some studies point the university as a good solver of complexes problems, as a source of precise knowledge, and for hard sciences research and development.

Furthermore, the universities receive more deference of its work when the capability of research and development it is considered. The robust solutions offered by universities regard science - basic or applied, including high technologies, developed inbound or outbound, it is when it receives the higher levels of partners appreciation and reliability.

Other analysis of the content of this study contemplated the presence of Open innovation according to the Triple Helix context. The articles had its content analysed, and except by two works, all of them highlight the role and contribution of University, Industry and Government to innovation development separately as well as the interdependency and the balance between the interactions of these three actors to promote better environment and conditions for innovation. Table 3 shows the almost full presence of the Triple Helix actors discussed in the studied articles.

Table 3. Triple Helix mentions.

Author(s)	University	Industry	Government
Ebener, Liemiester & Krcmar (2009) [16]	Yes	Yes	
Spithoven, Frantzen & Clarysse (2010) [17]	Yes	Yes	Yes
Petroni, Venturini & Verbano (2012) [18]	Yes	Yes	Yes
López *et al.* (2014) [19]	Yes	Yes	Yes
Bianchi *et al.* (2014) [20]	Yes	Yes	
Gesing *et al.* (2015) [21]	Yes	Yes	Yes
Oguguo, Bodas & Genet. Al (2015) [22]	Yes	Yes	Yes
Bianchi *et al.* (2016) [23]	Yes	Yes	Yes
Rubera, Chandrasekaran & Ordanini (2016) [24]	Yes	Yes	Yes
Naqshbandi (2016) [25]	Yes	Yes	Yes
Greco, Locatelli and Lisi (2017) [26]	Yes	Yes	Yes
Triguero & Fernandez (2018) [27]	Yes	Yes	Yes

Even that almost all articles contemplate the relations university-industry-government; naturally, some of them give more attention to determining themes according to the scope of this study. However, it is convenient organise the articles which show more contribution to innovation when considered which one of the three Triple Helix actors. Independently of these different approaches, all of them cope with different management perspectives and levels.

All author of the following papers realises the benefits and outcomes of the collaboration of university-industry. There substantial importance of straight collaboration between research with firms and universities or public research organisations. (Spithoven). Firms which works with innovative activities and product innovation, tend to be more interested in collaborating with universities. Moreover, there are some

differences between the non-high-tech and high-tech firms. The second one shows more interest and opportunities to collaborate with universities than the other type. (Lopez)

Although the collaboration is imminent, the way that the firms manage these interactions internal and externally can be different and influenced by many variables. Furthermore, most of the studied articles highlighted how to manage human factors in detriment of methodologies by itself, such as described by the following authors. Firms should collaborate with external subjects to enhance the effectiveness and efficiency of internal research & development investments [26]. Just a consistent base of technical knowledge can guarantee the shift from the inter-functional integration of technology required for Open Innovation practices. This implementation requires a policy that supports all changes in managing scientific personnel [18]. The use of other companies as sources of information is an essential determinant of R&D intensity and, indirectly, of innovative output and revenue growth. Additionally, it seems that managerial ties with managers of other firms, universities/research institutions and government officials facilitate Open Innovation, and that can be realised by absorptive capacity. (Naqshbandi) Informal governance mechanisms such as relational trust, interfirm socialisation, and partnership reputation affect employees' attitudes toward external knowledge positively [21].

Finally, there are some studies which emphasises the understanding and management of information, structure profiles, internal and external policies, regional characteristics which support Open Innovation processes as described by these following authors. The interaction structures of such innovation communities require a deeper understanding of the antecedents, the structural elements, design parameters and the outcomes of idea competitions [16]. The nature of the determined markets and its learning curve demands the intervention of policymakers in order to make the innovations feasible. [26]. There are technological spill overs for R&D product innovation in the same sector, induced by geographical proximity [27].

Firms tend to develop capabilities to engage in networks of partners to access resources and inputs to advance their technology and product development in countries where firms are more exposed to institutional and economic incentives for organising innovation activities [22].

The last part of content analysis privileged the study of Product Lifecycle Management approaches. Even that the PLM keyword was present in all twelve selected articles, and an amount of them are clearly related to product development, the texts did not clearly mention the PLM approach in any of its phases. The developing of innovation regarding the PLM stage as Beginning of life, Middle of Life or End of Life was not considered or described. The articles presented mentions to research and development and innovation just as a general development perspective.

Conclusion

This paper mapped the universities best practices to deal with Open Innovation. Some authors are transparent in identifying factors that still impede the collaboration between the university and other actors. The complexity of relations, cultural barriers,

complexes solutions only, or hard sciences - high technologies profile, formalities and contract affairs, affect the way that potential partners con-sider universities for potential collaborations.

More than bureaucratic affairs, there is a challenging scenario which considers internal and external factor and the healthy relationship between then to move this big motor called Open Innovation. The complexity of the relationship surpasses laboratory capacity, enterprise investments or public policies. A considerable volume of pieces of information details enterprise architecture and human factors which con-verges in a proper culture for innovation should be the agenda for the leaders who want to implement or improve Open Innovation practices.

Many of the studied papers also indicate the university as a source of open innovation, but not only. It is growing the articles which consider suppliers, laboratories, research institutes, governments, consumers, as sources for open innovation. These initiatives that try to include as many as actors as possible in OI processes, to complementary results or even replacing universities roles. In these cases, R&D institutes, laboratories and other functions by its technical expertise or by other factors such as time-to-market orientation, or even less bureaucracy are replacing universities for similar collaborations.

When the analysis of these articles is made by the optical of Product Lifecycle, the relations university-industry are not clear. In general, the studied papers show the importance of the university in open innovation, indicating some interactions in product development; nevertheless, specifics or detailed contributions for PLM were not found. This factor indicates the opportunities for future studies, to understand Open Innovation considering university can cope with a PLM approach, observing characteristics that can better suit the innovation proposal for different stages. Mainly because of the scientific research and development which flourish within universities is composed of very high quality, however, very specialised solutions. There are opportunities to develop more comprehensive and combined approaches inducing more overtures as sometimes one university is not able to develop solutions for a whole product lifecycle.

The Open Innovation best practices considering universities as the protagonist of the innovation ecosystem found by this study are many: some methodologies, approaches, management styles, organizational architecture, and more. In summary, this study sought to identify the best practices of Open Innovation, finding gaps in the literature as well as in practice, and based on this finding, propose future studies to encourage Open Innovation in universities and their partners.

Abstract. With the advent of Industry 4.0 and all the technologies and concepts linked to it, a new reflection on the methodologies and concepts already established in the scientific scope and their usability with the insertion of these new technologies and concepts in the manufacturing environments is necessary. Industry 4.0 brings with it concepts of Distributed Manufacturing that work from information returns from the entire production chain and allow the production lines to act flexibly. The degree of flexibility of a manufacturing process is precisely one of the main variables of the Product-Process Matrix, a concept of a two-dimensional matrix created by Robert H. Hayes and Steven C. Wheelwright in the late 1970s in order to facilitate the understanding of options strategic aspects of an organization, particularly with regard to its manufacturing function. This work explores the impact of current industrial environment contrasted with a classic late 70s matrixial tool, highlighting its substantial differences, mainly regarding the flexibilisation of modern production lines. That way, it might be possible to comprehend how the product-process matrix, which is still used so far, behaves in relation to recent and future scenarios, also measuring its practical value.

Keywords: Product-Process Matrix, Distributed Manufacturing, Flexibilisation.

1 Introduction

The need for coordination between marketing strategy and manufacturing strategy has long been emphasized in the literature. A study by Woodward [1] emphasized the need for such coordination, although the focus of the study was on the classification of manufacturing companies. Skinner [2] emphasized the need to align manufacturing policy with corporate strategy so that the strength of manufacturing can be exploited to obtain a competitive advantage in the market. Subsequently, a relationship between the product life cycle and process innovation was proposed by Abernathy and Townsend [3] and Utterback and Abernathy [4]. The product life cycle has been studied in a wide range of organizational configurations. It focuses on the marketing implications of life cycle patterns, and this implies that other aspects of the business and industry environment move in concert with the market life cycle.

Later, based on these studies, Hayes and Wheelwright [5] brought the product-process matrix, which evolves from a fluid process - one that is highly flexible, but not very cost efficient - and continues to increase standardisation, mechanisation and automation.

Currently, the technologies of Industry 4.0 allow the achievement of higher levels of performance in quality, productivity, time and cost savings, with implications that directly impact the structure of the product-process matrix and advances that support greater industrial product flexibility through automation. Therefore, it is feasible to explore these paradigms brought by disruptive technologies, in an analysis of the applicability of the product-process matrix to current and future manufacturing scenarios. In this way, we will investigate the impact of Industry 4.0 technologies on the structure of the product and process matrix.

This work is structured as follows: Section 2 presents the main concepts to be addressed in the paper, namely the product-process matrix and distributed manufacturing. Section 3 introduces flexibility as the mediating effect for the realignment of the product-process matrix according to distributed manufacturing characteristics, and Section 4 further explores the mediating role of flexibility to revise the product-process matrix. Finally, Section 5 presents the conclusion of the work and some final remarks.

2 Theorical Background

To achieve a coherent conceptual framework, the revision of the Theoretical Foundations of the existing literature must be carried out. The basic terminology and theoretical foundations for this research are detailed in the following subsections.

2.1 Product-Process Matrix

The product-process matrix was proposed by Hayes and Wheelwright [5][6] to correlate the structures of the production processes with different product structures, as shown in Fig 1. In practice, the matrix helps to identify the types of production processes and their alignment with a company's products. A striking visual feature of the product-process matrix is that, when the production system analyzed is positioned diagonally across the matrix, this represents that a superior competitive performance has been achieved. In other words, it is assumed that there is an optimal combination of product and process.

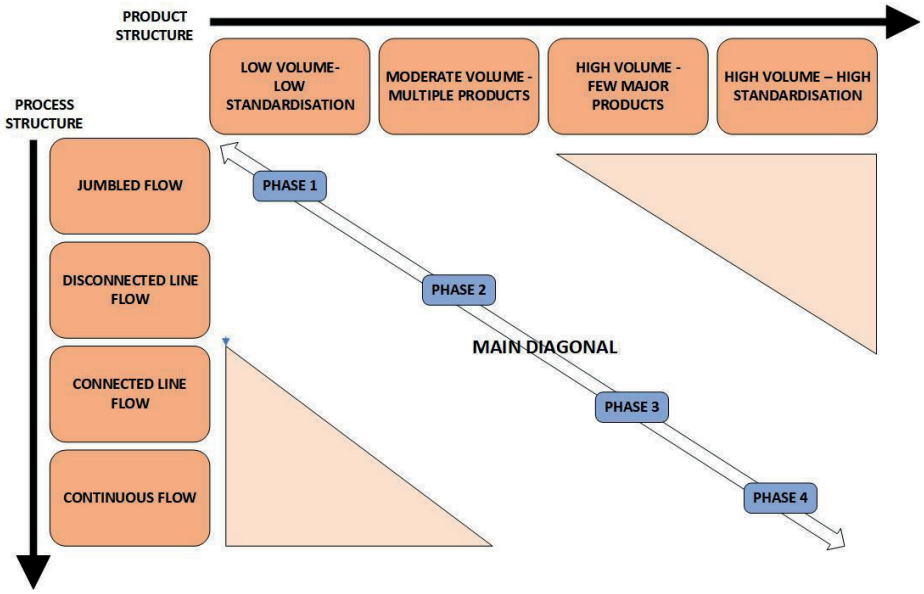

Fig. 1. The product-process matrix adopted by Hayes and Wheelwright [5].

The product-process matrix proposes four basic types of processes: job-based production, i.e., job shop; batch production; mass production, i.e., assembly lines; and continuous process production. A company can be characterized as occupying a certain region of the matrix, according to its product life cycle and its production process for that product. The product process matrix can be represented in 4 phases:

- *Phase 1:* When the company is positioned in the upper left corner of the product process matrix, it is characterized by having a unique product with a low manufacturing volume, with an undefined/confused manufacturing process. Another characteristic of this analysis suggests that the company has a low equipment occupancy rate, employees that multitask during the process and high production time.
- *Phase 2:* Following the matrix's main diagonal, slightly more to the right and to the bottom, the manufacturer usually chooses a production structure characterized as a "disconnected line flow" process. The company chooses to offer several products with basic characteristics, but with high variability. This allows the manufacture to go from a "Job Shop", to be considered a low volume assembly line.
- *Phase 3:* Even further down and diagonally to the right, it is a production model characterized by automobile manufacturers or large household appliances. Thus, the company opts for a relatively mechanized and connected production process. It is also characterized by a standardized and automated process to satisfy the product's life cycle and the company's savings.
- *Phase 4:* Finally, in the right corner of the matrix, we find examples of industries such as sugar or petroleum refineries, where the product is a commodity and the process is continuous. Its operations are characterized by being

inflexible and capital intensive, however their disadvantages are offset by the low variable costs resulting from a high volume that goes through a standardized process. At the time the original model was created, operationalization was well aligned with contemporary literature on organizational technologies. Therefore, the layout of the value adding process was a relevant contingency variable in the organization's design [8].

Notwithstanding, process technologies have changed significantly over the past three decades, and therefore the model must be updated to accommodate the flexibility of modern manufacturing technologies.

2.2 Distributed Manufacturing

With recent advances in Industry 4.0, production and infrastructure technologies allow manufacturing on a smaller scale with much greater proximity between the end user and the product, referred to as Distributed Manufacturing (DM). The concept of DM is not restricted to only fundamental manufacturing concepts, such as digitalisation and intelligent machines, but also to decentralisation of Manufacturing, where there is participation of the end user from the beginning of the project to production [9].

In a process of constant evolution analogous to digital transformation, the DM paradigm is characterized by new business models operating in "distributed economies" (Johansson et al., 2005). Those economies, whose small-scale flexible networks have a more local dimension, use materials and other resources that are also local, offering environmental benefits and leading to more sustainable forms of production. Thus, such sustainability directly impacts energy efficiency and resource-saving manufacturing systems [9],[10],[12].

The work of Srai [9] compares other manufacturing paradigms (Virtual Enterprise, Industry 4.0, Grid Manufacturing, Concurrent Engineering, Smart Manufacturing and Cloud based Manufacturing), recognizing five main characteristics of DM: (i) digitalization, (ii) personalization; (iii) location; (iv) new manufacturing technologies; and (v) multiuser participation. The scope of this research focuses on three characteristics of DM, not addressing 'location' and 'multiuser participation' as they are not directly related to the product-process matrix, being irrelevant by analyzing these characteristics from the perspective addressed.

3 Flexibility and its mediating effect

In the future, long-established paradigms of production will still have to continue to change to meet the demand for even more individuality, customer-specific product variants and shortest delivery times within the meaning of the term "production on demand" [12]. Skinner [2] claimed that there is a tradeoff among multiple manufacturing competitive performances in his landmark paper on manufacturing strategy; therefore, firms have to focus on some type of performance such as quality, dependability, and cost, which are critical for the attainment of the strategic objective [5], provided the product–process matrix to emphasize the importance of the cooperation of

manufacturing (processes) and marketing (products) to achieve the unified goals based on Skinner's tradeoff theory [33]. Gunasekaran *et al.* [34] defend that to a greater extent, the investigation of the product-process interplay in technology-enabled manufacturing paradigms offers tailored quality management practices and fulfill the expectations of global customers. Despite that, Ariss and Zhang [33] defends that environments have dramatically changed, and recently, some studies have empirically verified that a firm can achieve multiple competitive performances simultaneously. Thess studies especially illustrate how the high flexible process capability that a firm possesses greatly enlarges the feasible zones and reduces the constrained zones in the product–process matrix.

In today's highly competitive global business landscape, customers demand personalized products and responsive distribution systems, hence fueling the concept of Distributed Manufacturing (DM) as a paradigm that suggests the geographical distribution of manufacturing systems adjacent to the markets enable 'production on demand' [5]. This study's objective is to make a theoretical comparison of the main concepts of DM and the product-process matrix by the lens of a common denominator – flexibility – and understands how the new technologies of DM and Industry 4.0 will change the way that relationships between product and processes are seen.

3.1 The flexibility concept

According to *Oxford Dictionaries, s.v.* "flexible," accessed August 12, 2020, https://www.lexico.com/definition/flexible; means capable of bending easily without breaking - and more specifically, in context with the proposed question - able to be easily modified to respond to altered circumstances.

A manufacture which can be easily modified will improve a firm's abilities to react in timely manner to customer demands and to increase production system productivity, without incurring excessive costs and expending an excessive amount of resources. Ultimately, market and industry trends favor a higher product mix and fast responsiveness to demand changes and static business models are no longer able to keep pace with such change, forcing business processes to become more dynamic, requiring more flexibility [29] + [30]. In an interview research, [31] highlights the need for companies to see process improvement as one of its main drivers, expecting that it leads to quality and output improvement as well as time-savings and a higher adaptability of production**.**

Nonetheless, one difficulty in designing flexible production lines in the age of Industry 4.0, is the huge amount of product mix and existing production systems. In the past, companies in process industry sold single products in standard size and packaging. Today, companies are advertising a higher variety of products and selling them in different packaging sizes [29]. By automating, standardizing and globally sourcing processes, organizations can become more agile, more responsive to changes in demand, and better able to increase and sustain profitability [32]. In the context of the product-process matrix, Increasing the product mix challenges the ability of production systems to maintain high productivity.

The process life cycle was presented by Hayes and Wheelright in late seventies to be compared with the product life cycle and form the bidimensional matrix that is well known nowadays as the product-process matrix. Just as a product and market pass through a series of major stages, so does the production process used in the manufacture of that product. The process evolution typically begins with a "fluid" process—one that is highly flexible, but not very cost efficient—and proceeds toward increasing standardization, mechanization, and automation. This evolution culminates in a "systemic process" [5]. The main characteristics of this concept is that it becomes less flexible at each level.

However, accordingly to Ariss & Zhang [33] flexible manufacturing systems have allowed some assembly/continuous flow shops to achieve customisation in mass quantities. Moreover, some batch shops use similar methods to produce standardized products in moderate to high volumes. Therefore, flexible capability changes the feasible region of the product–process matrix from the solid line to the dotted line, as seen in Fig. 2.

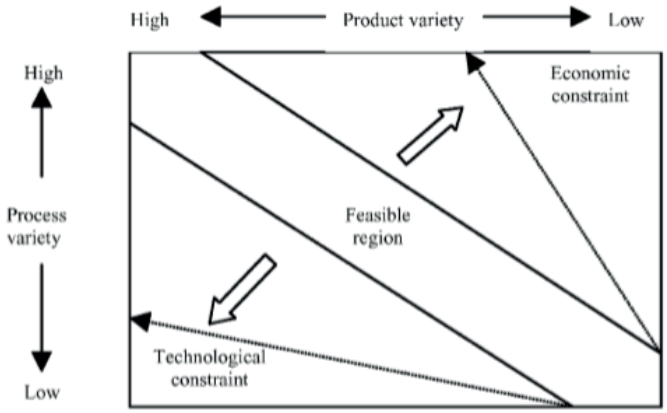

Fig. 2. The effect of flexible capability on the product-process matrix (based on Ariss & Zhang [33]).

Weraerfelt [35] presents the concept of flexible process capability, which changes the feasible region in product–process matrix, and argues that strategic analysis should shift its attention from industry forces and product market positioning to developing and exploiting the unique set of resources (such as technical and organizational skills) upon which a firm's long-term profitability depends.

Distributed Manufacturing is particularly characterized by technological developments in engineering and computing that bring new capabilities to manufacturing in terms of automation, complexity, efficiency, and most of all, flexibility. Following Kohtala [10], DM takes the perspective of production planning for networked or "virtual" enterprises aiming for flexibility, agility and greater customer orientation in manufacturing and mass customization.

The concept of Distributed Manufacturing enhances flexibility in modern industries with help of its three main characteristics, as explained in the next section.

3.2 Key characteristics of Distributed Manufacturing and their relationship to flexibility

The components of this DM characteristics (see Fig. 3) as seen in Kumar [7] are levels that enable its applicability and are defined below:

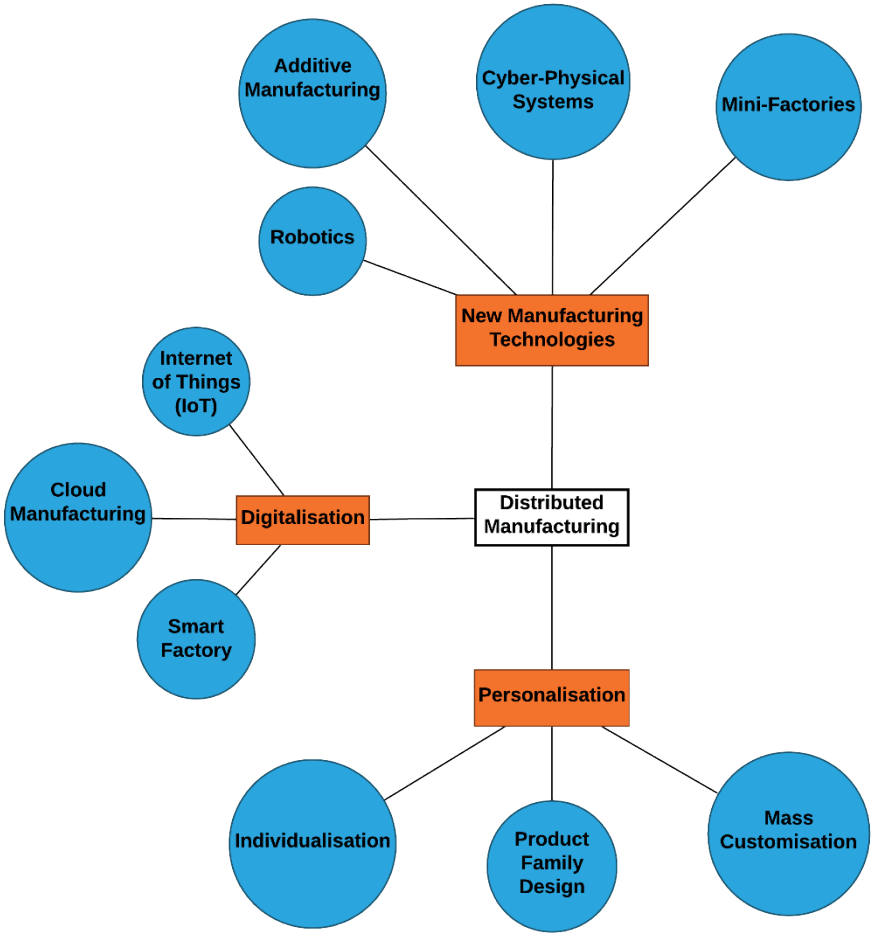

Fig. 3. Mind map of the concepts of DM, its components in blue, and characteristics in orange (based on Kumar [7]).

Digitalisation. Digitalisation of manufacturing implies the integration of information and knowledge between production and planning levels, further expanding to customers and suppliers [13]. The definition of its components is seen next.

- *Internet of Things (IoT).* IoT in manufacturing, from a technical perspective, envisions to connect every element of a manufacturing system to the Internet and provide, from a practical viewpoint, context-sensitive information to the

right people at the right time to propel the related decision-making process [14].

- *Cloud Manufacturing.* The Cloud Manufacturing or Cloud Computing aims at integrating autonomous agents, multiple clients, and various suppliers on a single cloud platform to optimize manufacturing operations [15].
- *Smart Factory.* Smart Factory comprises a set of smart machinery and conveyers that can communicate with each other to reconfigure dynamically for enabling the flexible production of multiple product types [16].

Personalisation. Direct consequences of digitalisation, which facilitates the modification, both subtle and extensive, of physical products [9].

- *Individualisation.* The Individualisation strategies aim to satisfy each customer as an individual with implicit needs so that the final product, as well as the basic design and product structure, are changeable, adaptable, configurable, and consequently less predictable [20].
- *Product Family Design.* Product Family Design aims for sufficient external product variants combined with manageable internal variety to obtain economies-of-scale at the component level and to reduce complexity in the development and manufacturing capabilities [21].
- *Mass Customisation.* Mass Customisation aims to fulfil individual customer needs at a cost level that satisfies a large share of the market [22].

New Manufacturing Technologies. Enable product variety at multiple scales of production, and as they mature, promise resource efficiency and improved environmental sustainability [9].

- *Robotics.* Robotics or robot technology could be described as intelligent artificial beings, typically made of metal, capable of executing intellectually demanding human tasks [36].
- *Additive Manufacturing.* Additive manufacturing, widely referred to as 3D printing, suggests that a technical design, generated using a three-dimensional computer aided design system, can be fabricated directly without the need for process planning [37].
- *Cyber-Physical Systems.* Cyber-Physical Systems are defined as the systems where the physical and software components are intertwined, operate on different spatial and temporal scales, exhibit multiple and distinct behavioral modalities, and interact in a myriad of ways that alter with context [38].
- *Mini-Factories.* Mini-Factories are flexible and rapidly reconfigurable small-scale factories for the geographically distributed manufacturing of products ensuring both product and quantity flexibility [12].

4 Realigning the product-process matrix to distributed manufacturing concepts

Is it possible that the Distributed Manufacturing concepts will allow the feasible region of the product-process matrix, early kept only in the main diagonal of the matrix, to expand and encompass all the model quadrants? The answer seems to be yes. Hayes & Wheelright [5] deduced that the process evolution typically begins with a natural process — one that is highly flexible, but not very cost efficient— and proceeds toward increasing standardization, mechanization, and automation. This evolution culminates in a "systemic process" that is very efficient but much more capital intensive, interrelated, and hence less flexible than the original, more natural process. For example, the key competitive advantage of a jumbled flow operation is its flexibility to both product and volume changes. As one moves toward more standardised processes, the competitive emphasis generally shifts from flexibility and quality (measured in terms of product specialisation) to reliability, predictability, and cost [5]. The authors of the product-process matrix would say that the corners of the matrix are void of industries and companies because, for the upper right the process are not economical, end for the lower left the process are too inflexible, therefore Ariss & Zhang [33] make two assumptions: (1) within a given technology, manufacturing is able to do everything; and (2) manufacturing's contribution concerns the achievement of efficiency rather than the effective support of market needs.

Taking these assumptions into consideration, perhaps the concepts and characteristics of distributed manufacturing could help improve the feasible zone with flexible characteristics and yet establish a sustainable competitive advantage. Considering that the flexible capability changes the feasible region of the product–process matrix from the solid line to the dotted line as proved by Ariss & Zhang [33] (see Fig. 2), it's possible to use the concepts of Digitalisation and Personalisation to improve the feasible zone, while the new technologies will serve as a base to development, as seen in Fig 4.

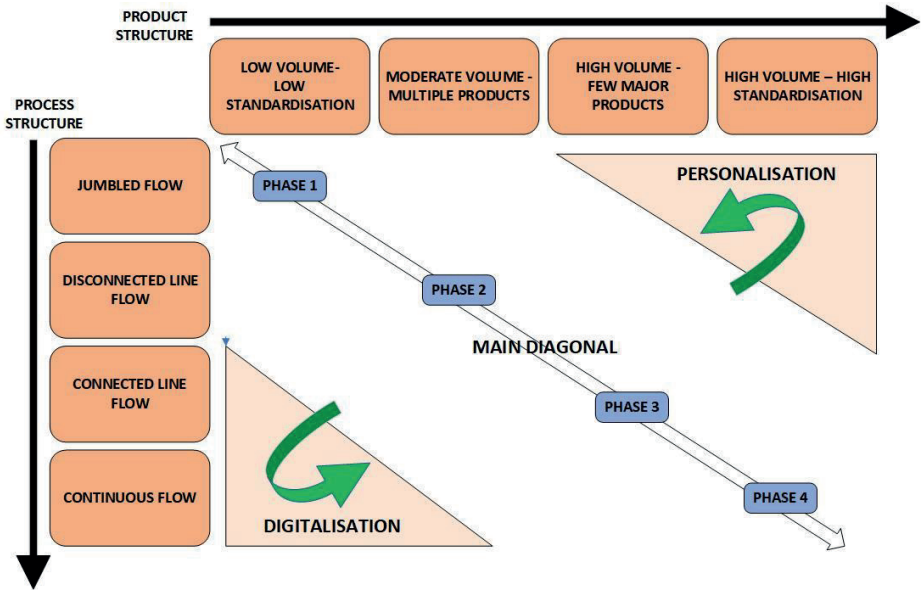

Fig. 4. Personalisation and digitalisation in product-process matrix.

In this situation, it is possible to dismantle the concepts of digitalisation and personalisation into its main characteristics and easily identify which of these characteristics could help improve each space of the matrix, looking from the process lens. Fig. 5 shows the first phase of process life cycle stage aligned with these concepts, where individualisation can help improve the link between the first phase with product phase 2, mass customization linking with product phase 3 and product family design with product phase 4.

	Low volume - low standardization, one of a kind	Multiple products - low volume	Few major products - higher volume	High volume - high standardization, commodities
Jumbled Flow		Individualisation	Mass customisation	Product family design

Fig. 5. First stage of the matrix with personalization concepts.

Using the same criteria, it is possible to link phase 2 and 3 of the process axis with upper diagonal correspondent phases of product axis, as shown in Fig. 6 and Fig 7. In these cases, its already possible to identify the lower diagonal as well. For these spaces, the main characteristics of the digitalisation concepts are used, following the same idea of Fig. 5.

	Low volume - low standardization, one of a kind	Multiple products - low volume	Few major products - higher volume	High volume - high standardization, commodities
Disconnected line flow (batch)	Smart factory		Mass customisation	Product family design

Fig. 6. Second stage of the matrix process axis with personalisation and digitalisation concepts.

	Low volume - low standardization, one of a kind	Multiple products - low volume	Few major products - higher volume	High volume - high standardization, commodities
Connected line flow (assembly line)	Smart factory	Cloud manufacturing		Product family design

Fig. 7. third stage of the matrix process axis with personalisation and digitalisation concepts.

At last, in the final phase of the process axis of the matrix is linked at each phase of the product axis by all the main characteristics of the digitalisation concept, as shown in Fig. 8

	Low volume - low standardization, one of a kind	Multiple products - low volume	Few major products - higher volume	High volume - high standardization, commodities
Continuous flow	Smart factory	Cloud manufacturing	Internet of things (IoT)	

Fig. 8. Fourth stage of the matrix process axis with digitalisation concepts.

The final assembly of the matrix aligned with distributed manufacturing concepts can be seen in Fig 9.

	Low volume - low standardization, one of a kind	Multiple products - low volume	Few major products - higher volume	High volume - high standardization, commodities
Jumbled Flow		Individualisation	Mass customisation	Product family design
Disconnected line flow (batch)	Smart factory		Mass customisation	Product family design
Connected line flow (assembly line)	Smart factory	Cloud manufacturing		Product family design
Continuous flow	Smart factory	Cloud manufacturing	Internet of things (IoT)	

Fig. 9. Full aligned product-process matrix.

5 Conclusions and Final Remarks

As one of the great standards of strategic operations management, it is impressive how the product-process matrix managed to stay as the main model of production relations, but it seems that the brand new concepts and technologies of industry 4.0 can help evolve the vision presented by Hayes and Wheelright in a great manner, increasing the feasible zone of the matrix and helping stakeholders all around the world to keep the production strategy up to date and better able to increase and sustain profitability.

This revisited Product-process matrix can help researches to discover possibilities of technological implementations that better suits into company strategy, taking into account the company size and its manufacturing proportions, as well defined by the matrix, and correlate the structures of the production processes with different product structures. The defined concepts of distributed manufacturing can help mapping the opportunities of any phases of production and connect it to this new concept trends and show to the stakeholders a holistic view of the implementation roadmap.

For future studies, the conceptualisation of a possible framework could be an advance to help keeping the matrix up to date, or even reconfigured for a present perspective. Industry 4.0 technologies may guide further research and encourages practitioners to consider them in their current and future activities.

Abstract. Production and maintenance planning are interconnected problems, so that their joint solution can enhance system performance. This paper develops a systematic review on the integrated production and maintenance planning on manufacturing systems. The content analysis included sixty-nine papers, embracing aspects of production system modelling, optimization mechanism, practical applications and research directions. The findings indicate the predominance of theoretical studies, the use of genetic algorithm for the optimization engine, in which costs and makespan are the variables of the objective function. Future research directions point to applications for real scenarios, predictive maintenance and models with increasing complexity.

Keywords: Production planning and control, Maintenance scheduling and production planning, Maintenance models and services, Modelling and decision making in complex systems, Modelling of manufacturing operations, Production scheduling, Meta-heuristics.

1 Introduction

In production environments, machines are not always available as they are subject to periods of downtime due to planned and unplanned shutdowns [1-2]. Considering the dynamic and stochastic nature of failure occurrence, production planners and managers have complex decisions to deal with on a daily basis [3-4]. Aiming to speed up production, recommended maintenance intervals are often poorly planned [1].

Production and maintenance scheduling have attracted great practical and academic interest, however those problems are commonly treated as independent [5-6]. Notwithstanding, literature has shown that developing the production planning and control integrated with the maintenance planning can benefit several production performance indicators [7-8]. Indeed, manufacturing systems generally show a natural in-

terdependence between production and maintenance activities, which raises the question of how to optimize them jointly to avoid conflicts and improve system performance [9].

A large number of studies about production and maintenance were carried out, however, almost all of them considered these as two independent problems. Only a few studies tried to combine the two issues to solve them simultaneously [7]. In addition, the criticality of resources may change depending on the production planning being conducted. Therefore, there is a need to coordinate production and maintenance planning tasks, which incorporate potential cost minimization [9].

The objective of this article is to perform a systematic review of the literature regarding the current models that integrate production planning and control with maintenance planning. This systematic review can allow the acknowledgment of existing studies in the field and, the identification of research gaps, helping to prevent the production of duplicate works [10]. Besides, it can provide several insights from the state-of-the-art literature, including common practices and research directions.

The systematic review intends to answer three research questions about the subject: (i) how did the studies on integrated production planning model the production system and the optimization process? (ii) which studies modelled real scenarios for integrated production and maintenance planning? (iii) what are the main directions for future research?

The remaining of this paper is structured as follows. Section 2 shows the research method of the systematic review and bibliometric analysis. Section 3 shows a brief bibliometric analysis, followed by the systematic review in Section 4, which is divided accordingly to the research questions. Finally, section 5 presents the discussion and proposals for further research.

2 Research Method

The conducted systematic literature review followed the Preferred Reporting Items for Systematic review and Meta-Analysis (PRISMA) approach, which is proposed by [11] and is the most commonly used for reporting literature review [12]. It was first applied in health care studies but is also suitable for many areas, including industrial engineering [13-14].

The paper selection step used the following search logic: (TITLE-ABS-KEY(("Produ* plann*" AND maint*) OR ("Produ* Sched*" AND maint*) OR ("Manufac* plann*" AND maint*) OR ("Maint* plann*" AND (Produ* OR manufacture*)) OR ("Maint* Sched*" AND (produ* OR manufacture*))). The search was performed in two databases: Scopus (www.scopus.com) and Web of Science (www.webofknowledge.com).

The process for selecting papers is shown in Figure 1. After the identification of the papers, duplicates were removed. The criteria for inclusion and exclusion of papers are presented in Table 1, following the ones used by [15], and were applied by reading titles, abstracts and keywords only. The remaining papers in the last stage were eligible for the content analysis, i.e. the qualitative synthesis.

Table 1. Inclusion and exclusion criteria.

x	Criteria	Criteria explanation
Inclusion	Closely related (CR)	Time period: prior to April 2020; Articles that were published until 2014 were included only with more than 5 citations according to Bibliometrix.
Exclusion	Search engine reason (SER)	The article has only the title, abstract and keywords in English, but not the full text in English.
	Without full-text (WF)	The full-text of the article is not available.
	Non-related (NR)	NR1: It is not an academic article; NR2: It is not aligned with "integrated production planning model with maintenance".
	Loosely related (LR)	The article does not focus on discussing the development of an integrated production planning model with maintenance. More specifically: LR1: It is used only as an example; LR2: It is used only as part of its future research direction; LR3: It is used only as a quoted expression; LR4: It is used only in keywords or references; LR5: The research that does not address the context.

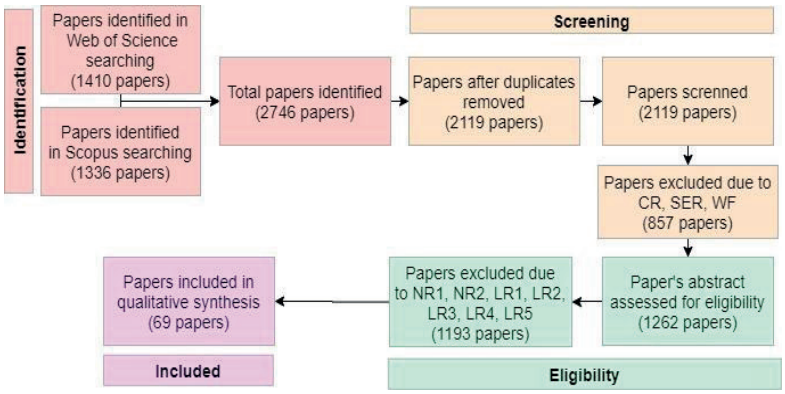

Fig. 1. Systematic review process.

From the articles included in the content analysis, we performed a brief bibliometric analysis pursuing to better understand the scientific activity through time and among different journals and research groups. Such analysis was aided by the Bibliometrix package developed in R programming language [16], more specifically using the Biblioshiny interface and the RStudio© integrated development environment.

3 Bibliometric Analysis

From the analysis of the bibliometric data, Figure 2 shows the temporal evolution of the publication of the articles included in the analysis of this research. The first article was published in 2000, and starting in 2010, there is a tendency of publication volume increase. Although the largest number of publications are in the last decade, the number of published articles has fluctuated between 1 and 11 per year. It is also noteworthy that the year 2020 is incomplete because of the date when the search was performed.

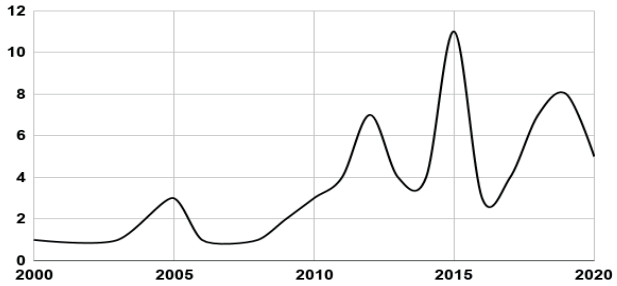

Fig. 2. Increase in publication quantity per year.

Most of the selected papers were published in the International Journal of Production Research with 9 occurrences [17-25], in sequence, International Journal of Advanced Manufacturing Technology with 5 papers [26-30]. The paper [31] has the highest number of citations (135) in other studies. The second with the highest number (90) of citations [32] is by the same author. Both are articles about potential studies for the topic presented here. Considering the scientific production by countries, we can highlight that China is ahead with 21 published papers, next we have Canada with 11 and France with 8.

4 Systematic Literature Review

This section addresses the research questions: (i) how did the studies on integrated production planning model the production system and the optimization process? (ii) which studies modelled real scenarios for integrated production and maintenance planning? (iii) what are the main directions for future research?

4.1 How did the studies on integrated production planning model the production system and the optimization mechanism?

Integrated production and maintenance planning have been treated as an optimization problem, having been addressed by several solution methods. Table 2 shows the quantity and types of methods that were used to solve the models in the literature.

Table 2. Resolution methods.

Resolution Method	Paper
Branched exploration algorithm	[33]
Genetic algorithm of approximate non-dominant classification II	[39]
Best fit descending algorithm	[40]
Optimization based on biogeography	[46]
Optimization of hybrid genetic algorithm	[5], [61]
Hybrid ant colony optimization	[5]
Mixed integer linear programming	[17], [50]
Differential evolution method	[47]
Annealing simulation method	[47]
Randomized research method	[47-48]
Experiences project	[48]
Artificial immune algorithm	[70]
Simulated annealing algorithm	[38], [65]
Harmony search algorithm	[50]
Vibration damping optimization algorithm	[50]
Pseudo-polynomial programming algorithms	[71]
Evolutionary genetic algorithms multiobjective	[74]
Non-dominated genetic classification algorithm II	[20-21], [27], [74]
Algorithm based on multi-objective optimization of ant colonies	[72]
Pareto ant colony optimization	[27], [72]
Stepwise optimization method	[52-53]
Policy improvement algorithm	[19]
Dynamic programming	[25]
Dantzig-Wolfe decomposition technique	[54]
Continuous resource task network	[55], [80]
Chaotic particle filling optimization algorithm	[77]
Clonal immune selection algorithm	[59]
Mixed linear model	[24], [37], [64], [67-68]
Hybrid particle swarm optimization	[27]
Pareto force evolutionary algorithm II	[20], [27]
Linear quadratic model	[18]
Branch and limit algorithm	[21], [31]
Optimization-based simulation	[46]
Genetic algorithm	[1], [22-23], [34-35], [41], [46], [49], [51], [57], [69], [73], [75-76], [78-79]
Other heuristics	[7], [9], [19], [26], [28-29], [32], [36], [38], [42-45], [56], [58], [60], [63], [66]

There is a predominance (18,1%) in the use of genetic algorithms (GA), which also appears in approaches combined with other heuristics. These studies that applied the use of a genetic algorithm conceptually validate their application, since they achieved good results, but still need better development, according to the authors. The use of heuristics (other heuristics) created by the authors themselves is also relevant, with 22,9% of the total. The literature is quite comprehensive and there are several methods of resolution, all with different characteristics and applicability. Comparing methods present in the literature can be a good question to find the best result. We can also analyze that in some papers, more than one method was used

The desired objective in each approach present in the literature also varies. Cost-related indicators were used as key performance indicator (KPI) for optimization in 71% of all articles. The use of cost as a KPI in the optimization method facilitates the aggregation of different variables in the composition of the best solution, such as cost of maintenance, production and delivery delay to the customer. Among them, few articles address the cost of quality, delay and stock in addition to the production and maintenance costs. The second most used KPI was makespan (29%), and system availability is considered in four papers.

In some articles, in order to model the useful life behavior of machines and production systems, or their deterioration process, different forms of representation are used. In Figure 3 we analyzed the articles that included machine deterioration processes (55% of the total). The predominance was of criteria adopted and elaborated by the authors themselves. Another one with greater use was the use of Weibull Distribution and its combination with Gamma Distribution.

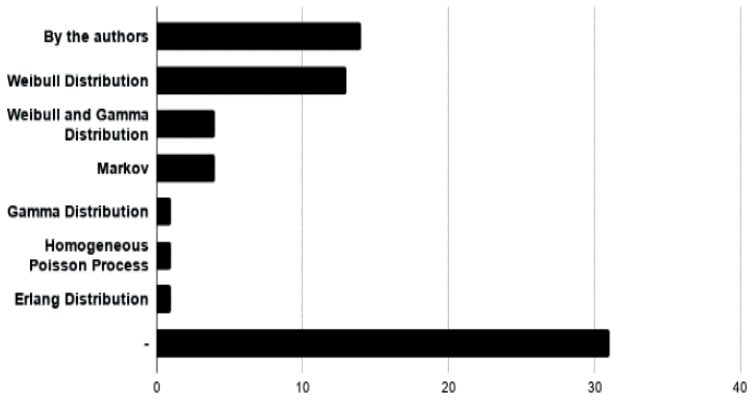

Fig. 3. Number of papers in relation to the deterioration method.

In Figure 4, the articles were classified according to the type of productive system modeled. The predominance of single machine models is evident. Nowadays, with all the technological advances, the production processes become more complex every day and with significant machine interaction.

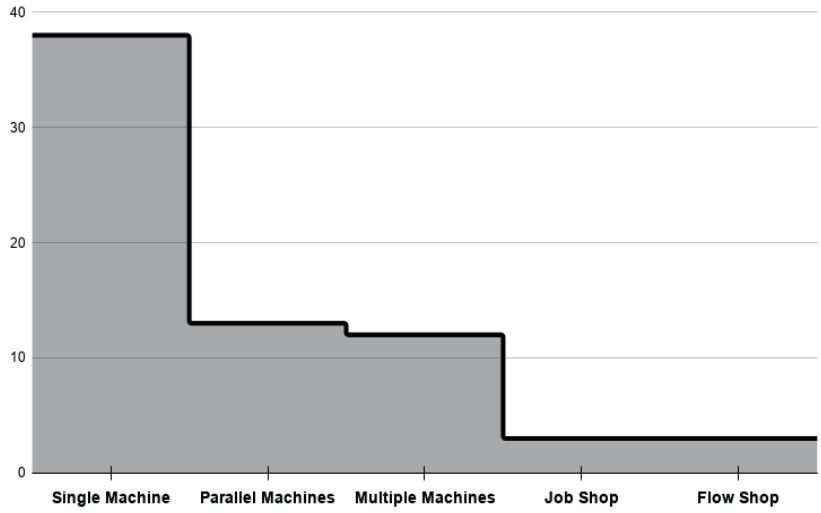

Fig. 4. Number of articles in relation to the type of production of the model.

4.2 Which studies modelled real scenarios for integrated production and maintenance planning?

Only the papers [7, 17, 28, 33-38] developed and applied a model considering a practical case of application, i.e. 13%. The rest of the papers (87%) did not apply in a real production scenario [1, 5, 9, 19-27, 39-80]. The same authors who applied in real scenarios, reinforce the need for this type of application in order to validate the efficiency of the method, so that it can be replicated by other industries and start to be better improved.

Among these studies applied in real production systems, the models [34-35] used the genetic algorithm as a resolution method, while the rest used other heuristic methods of resolution. Moreover, these authors still point out the need for an approach that uses methods able to adapt to different scenarios. These applied cases brought relevant KPI's improvements. In Table 3, we can see the main gains of the models applied in a real scenario.

Table 3. Gains from applying the method.

Reference	Results
[7]	Reduction in general production costs, because rescheduling efforts, rework and scrap, as well as inventory were reduced.
[17]	Costs reduced by up to 63.5% compared to the company's schedule.
[28]	Information for the managers to be able to make decisions, the paper did not bring an exact result.
[33]	Charts to show that, by applying the method, costs can be minimized and production maximized.
[34]	Limited their study in an injection company related to the maintenance of these molds, obtaining a 44.9% reduction of the production delay
[35]	The results obtained validate the efficiency of the new heuristic method.
[36]	Minimization of operating costs and maximization of the company's profit.
[37]	It allows you to decide which products need to be produced and the exact amount of production in each period and the best date for maintenance can be set. Production quantities were also influenced by the cost of inventory and the cost of back orders for different products.
[38]	80% savings. The numerical example indicates that an integrated model proposal performs better than stand-alone models.

4.3 What are the main directions for future research?

52 out of the 69 papers present future proposals for research to be developed. Many authors refer to the need for future research to focus on real cases for practical validation [5, 31, 41, 43, 47, 53, 61, 63, 71, 77, 79].

Also, many papers point to the demand for applications in more complex production scenarios, e.g. with different behavior patterns and production systems that use more than one machine [1, 20, 29, 32-33, 35, 37-41, 50, 63, 66, 68, 74-75]. Such demand was also observed in our systematic review, as explored in the first research question of this work. In [5, 63] the model developed is limited to a scenario with deterministic behavior; thus, the authors report the need for extension in unplanned and planned environments with stochastic situations.

For [9, 20, 22-23, 33, 37, 39, 44, 50, 66, 78] a strategic predictive maintenance policy needs to be better used in models so that it can allow the prediction of equipment deterioration in an environment with complexity to optimize machine availability. In [7, 21, 26, 43, 67-68] the authors state that methods of predicting maintenance failures should be better considered in new models.

For [17, 29, 49, 66], there is a necessity to improve the procedures for choosing and applying heuristics, since different choices may bring different results for a same model. In [20, 27, 45, 64, 73] the authors indicate meta-heuristics investigation for solving their models because it has potential for effective gain. In article [46] the use

of optimization-based simulation approach has had good results and has a potential for application in other contexts.

The study by [72] highlights the importance of developing other methods that evaluate the application of genetic algorithm hybridization, since it presents potential to efficiently solve these problems. In [58, 74], the authors encourage the study of more complex methods such as multi-objective optimization of ant colonies to solve new models as well as perform a comparison with Pareto Ant Colony Optimization, in [22, 24], they intend in future research to solve problems with greater complexity using the relaxation method and hybrid considerations. In the same way, the genetic algorithm has potential for new research because it presents good results in initial tests. In summary, we can see in Figure 5 a summary of the main directions of future research reported here in this section.

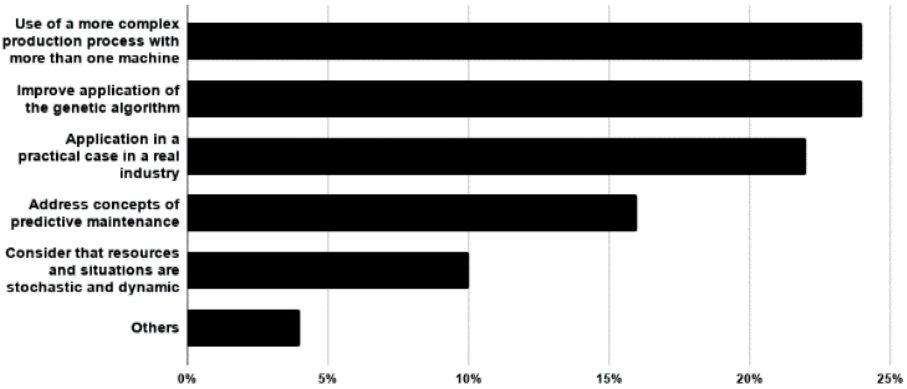

Fig. 5. Percentage of the main future researches reported by the authors.

5 Discussion

The conducted systematic review addressed the research questions and contributed to a better understanding of the field, considering modelling aspects, applications and research directions.

In summary, by analyzing the directions indicated by the papers in the portfolio and the trend of the papers over time, it is possible to identify some opportunities. Despite the predominance of the use of preventive maintenance for the integration of production and maintenance planning, the development of predictive approaches has increased.

There is extensive use of different heuristics in the optimization problem. The use of hybrid approaches appears as an opportunity to be further developed in this topic. As for the study environment, research that considers the production systems as a whole (most research considers only a single machine), and the application in real environments can still be better developed and only one paper was found that used an optimization-based simulation approach.

Analyzing other aspects and selecting other keywords to apply the literature review methodology of the proposed subject may be a good way, trying to seek other results. The interest in seeking the development of a model that integrates production planning and control with maintenance in a way that can be replicated in various contexts of the productive environment ends up being a challenge for future models.

In a next study by the authors of this paper, the application of these final analyzes in a conceptual and practical context is motivated, aligning these two requirements and being able to bring through the application positive results that may contribute to the subject.

Abstract. The concept called Industry 4.0 has a very complex technological architecture based on Cyber-Physical Systems (CPS), which represents one of the main concerns in the start-up stage at an industrial level. The effective implementation of Industry 4.0 technologies continues to be a research topic. Some works propose maturity models for the implementation of these technologies, while others focus on the study of their impact on industrial performance. However, there is a lack of studies that provide evidence on the way in which these technologies are implemented in manufacturing companies in general. This fact leads to the following question: What are the current implementation patterns (degree of implementation – maturity stage) of Industry 4.0 technologies in companies? To answer this question, this work proposes the development of a tool for maturity assessment which allows understanding what is required to carry out an effective analysis of implementation of Industry 4.0 technologies in manufacturing companies by studying the degree of implementation – maturity stage in companies from different sectors.

Keywords: Industry 4.0, Maturity Assessment Tool, Maturity Model.

1 Introduction

The Fourth Industrial Revolution – also named as Industry 4.0 – is characterized by a fusion of advanced technologies that is disrupting almost every industry in every economy [1].

Industry 4.0 is a German strategic initiative whose main objective has been to create smart factories, where manufacturing technologies are updated and transformed through Cyber-Physical Systems (CPS), Internet of things (IoT) and Cloud Computing [2, 3, 4].

The fundamental idea of Industry 4.0 is based on integrating manufacturing systems of different smart factories along a value chain, or a value network, in the form of CPS so that data and information can be obtained in real time throughout the value chain, allowing time and precise decision making [5]. Moreover, the CPS are defined as transformative technologies to manage interconnected systems among their physical assets and their computational capabilities [6]. The competitive nature of today's industry

forces more factories to implement high-tech methodologies through recent developments that have resulted in greater availability and affordability of sensors, data acquisition systems, and computer networks [6, 7].

Industry 4.0 comes from the need to improve the means of production in a context of high emergence of new technologies in the field of information technology. It corresponds to a strategic program with the objective of developing production systems, thus improving the efficiency of the industry [2].

An important part of this program fits with the concept of Smart Manufacturing, which corresponds to a great flexibility of the production lines that can adapt to any change in products or conditions, ensuring an increase in quality and productivity [8].

Another part of the program focuses on Smart Working, i.e., the role of human workers that needs to evolve with the help of robots, which could fulfill difficult tasks and also make decisions through communication networks among them [9].

The exchange of information also represents a challenge for this new industry. Whether it is with customers, suppliers or other companies, this concept of Smart Supply Chain allows reducing delivery time and possible falsification of information. Furthermore, communication with other companies contributes to the targeting of their resources on the subject of innovation, working together to limit false leads and accelerate the development of technologies [10].

The last part of the program is given by integrated-embedded technologies which are called Smart Products, whose information is fed back from the final products, with the aim of improving and detecting possible production defects, developing new products and solutions to the customer [11].

Industry 4.0 technologies can be separated into the following layers [12]:

A) Front-end technologies of Industry 4.0 which considers the transformation of manufacturing activities based on emerging technologies (Smart Manufacturing) and the way in which products are offered (Smart Products) [8]. The way in which raw materials and the products are delivered (Smart Supply Chain), as well as the new ways in which workers carry out their activities based on the support of emerging technologies (Smart Working), are also contemplated.

B) Base technologies which comprise technologies that provide connectivity and intelligence for Front-end technologies. This layer makes the Industry 4.0 concept feasible, differentiating it from previous industrial stages.

This work presents the development of a Preliminary Maturity Assessment Tool (PMAT) that is used to identify technologies related to Industry 4.0, and to verify their degree of implementation – maturity stage in companies from different sectors.

This approach is considered as the first step for future research works, and consists of a Questionnaire that includes three types of questions: A) Basic; B) About technologies; and C) Open. The first and second types are closed questions and include a 5-point scale: 1) Non-existent; 2) Low; 3) Medium; 4) High; and 5) Very High. This scale indicates the level and degree of implementation – maturity stage.

The PMAT – Questionnaire is based on two propositions – hypotheses which are presented in Section 3 and guide to establish the points of interest and to develop more concrete and clear questions.

Section 2 depicts the research methodology which consists of multiple–case studies, and the propositions – hypotheses (PHs) constitute the units of analysis (UAs). Section 4 shows the analysis of the results, while Section 5 presents a discussion by including a comparative analysis of different maturity models of Industry 4.0. Finally, Section 6 develops the conclusions.

2 Methodology (Multiple – Case Study)

Based on the methodology of multiple – case studies with many units of analysis (UAs) [13], this methodology is proposed as a part of the first phase of a research project that aims to study the implementation of technologies related to Industry 4.0 in the region under analysis. For this purpose, four case studies have been selected representing different industrial sectors (see Fig. 1).

For each case study three units of analysis are considered, in which two of them are directly connected to the propositions - hypotheses (PHs) that are described in Section 3.

The choice of a qualitative methodology allows us to analyze in greater detail certain characteristics related to Industry 4.0 that are being implemented in the region, as well as to give us the first approach for future studies using other types of qualitative or quantitative methodologies.

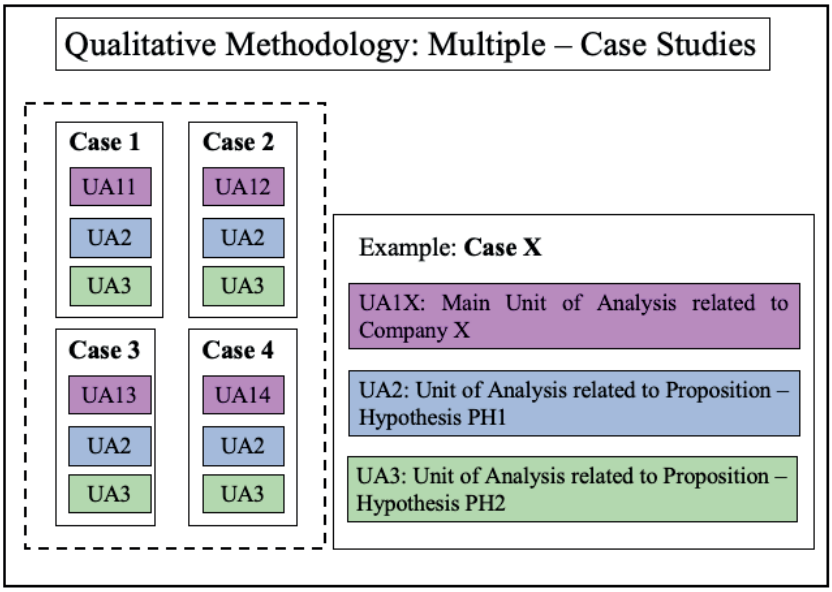

Fig. 1. Methodology of multiple – case studies with many units of analysis (UAs).

2.1 The Companies

In the current phase of the research project focused on Industry 4.0 in the Santa Fe region, fifteen companies were analyzed to apply the methodological process.

After studying several characteristics, such as size and clusters, four companies were finally selected with which it was possible to complete an exhaustive questionnaire that is described later.

Tables 1 and 2 show the clusters and the size, respectively.

Table 1. Industrial clusters of the companies under study.

Cluster	Percentage
Textile	25
Equipment manufacturing	25
Software and technology	50

Table 2. Size of the companies under study.

Size	Percentage
SME (<100 employees)	75
Large (>100 employees)	25

Thus, the research group has had the opportunity to study companies that had totally different activities and sizes from each other.

In this way, it was also possible to classify them according to the type of activities and form three "clusters" that helps to exploit the results.

In addition, the research group chose several characteristics describing the companies that make up the clusters that allow to explain several differences in the results that can be observed in Section 4 (analysis of results).

2.2 The Characteristics

The selected characteristics are detailed below.

Direct and indirect consumption. The terms direct and indirect consumption of a product indicate, in the case of direct consumption, the direct use of the product by the customer. In other words, the product has no other purposes than those for which it was produced. (Examples: Food, clothes). On the contrary, an indirect consumption of a product means that the product has been produced to be used for another purpose (Examples: Laboratory equipment, packaging).

Long life time. It is considered that a life span is long when it exceeds one year. Food or drinks, for example, do not fall into this category.

Maintenance. A product needs maintenance when an expert must visit the product to check its proper operation. Thus, the product is constantly monitored until the end of its life cycle. (Examples: Mechanical lifts, cars).

Remote modification. A modification is considered remote when a company can make it on a product from its offices, without requiring the intervention of an expert. (Examples: Websites or Software).

The products of each cluster and their characteristics are detailed in Table 3.

Table 3. Main characteristics of the Clusters.

Cluster characteristics	Textile	Equipment manufacturing	Software and technology
Direct consumption	X	-	-
Indirect consumption	-	X	X
Long life time	X	X	X
Maintenance	-	X	-
Remote Modification	-	-	X

3 The Propositions – Hypotheses and Questionnaire

3.1 The Propositions – Hypotheses

The first proposition – hypothesis (PH1) is proposed to establish the link among the presence of technologies related to the concept of Smart Manufacturing, Smart Product, Smart Working and Smart Supply Chain in a company under study, and the degree of implementation – maturity stage of the Industry 4.0 concept in this company. Indeed, all these technologies fit the concept of Industry 4.0; thus, they are essential to reach a high degree of implementation – maturity stage.

The second proposition – hypothesis (PH2) surges as the certain importance of the technologies linked to the term Smart Manufacturing. The other technologies are equally important; however, those related to the term Smart Manufacturing have a special value due to the characterization of the concept of Smart Manufacturing as the heart of Industry 4.0.

Therefore, it can be sustained the fact that a company with many technologies connected to the term Smart Manufacturing has a high degree of implementation – maturity stage of Industry 4.0.

These propositions – hypotheses have guided to establish the points of interest and in this way, to develop more concrete and clear questions, as it is depicted in Fig. 2.

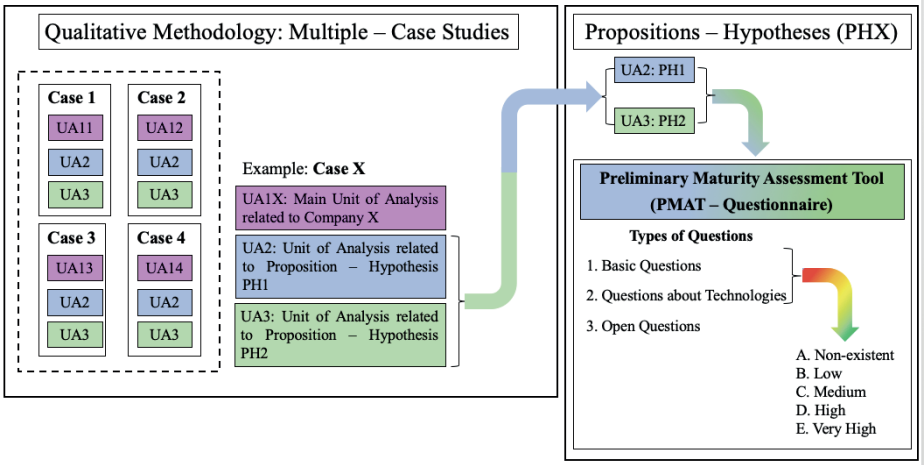

Fig. 2. The relationship between the qualitative methodology and the Preliminary Maturity Assessment Tool (PMAT – Questionnaire).

3.2 Characteristics of the Questionnaire

The objective of the questionnaire is to verify the degree of implementation – maturity stage of Industry 4.0, i.e., for each technology determine whether its implementation is basic or advanced, as well as the use of the new paradigms. Thus, most of the questions refer to estimate the degree of implementation – maturity stage of the technologies and paradigms related to Industry 4.0. Three types of questions are proposed:

- Basic questions.
- Questions about technologies.
- Open questions.

Basic questions provide information about the company, such as its name, focus, and size. These questions help to clearly define what type of company you are dealing with, whether it is large, medium or small; if it produces in series or it develops projects.

The answers make it possible to classify the different companies in a way that is then easier to take advantage of the results.

The questions that refer to technologies help to estimate their degree of implementation – maturity stage in the Industry 4.0 concept. These questions are closed and a 5-point scale has been used to specify the level – stage of knowledge of each employee regarding every technology, since this level – stage is directly related to the actual degree of implementation – maturity stage. The 5 points are as follows:

A) Non-existent.
B) Low.
C) Medium.
D) High.
E) Very High.

Some questions asked whether the company had particular computer systems or it had the previous versions of these systems.

On the other hand, other questions referred to if the employees thought if a technology was feasible (to be able to verify its implementation in the company in another way). Thus, several different questions were available, although they focused only on technologies.

At the end of the questionnaire, the open questions appeared with the objective of explaining the differences in the degree of implementation – maturity stage of different technologies:

- One of these questions concerned measures taken in the past to achieve compliance with the principles of Industry 4.0. The completed responses helped to understand the current situation of the company, and thus, it was possible to verify if these measures were efficient.
- The other one refers to the belief in the efficiency of Industry 4.0 and the need to trace the production system to it. This question was necessary since it indicated the opinion of the employees on this matter, an opinion that is revealed to be important since the employees are who allow the good functioning of the company, and if they do not believe in Industry 4.0, they cannot adapt to use it.

The following section analyzes the responses of the companies and shows if the established clusters are related to each other through common characteristics.

4 Analysis of Results

4.1 Closed Questions

Table 5 represents the implementation of advanced technologies in Industry 4.0 through the use of colors whose meanings are coded in Table 4.

The companies are divided into the clusters chosen above and the results were averaged for each company.

Table 4. Meaning of the color coding.

Meaning	Colors
High implementation	
Medium implementation	
Low implementation	
No implementation	
Not known	

It has been chosen to use colors to describe the degree of implementation – maturity stage of the technologies, so that the differences among the clusters are more visible.

Table 5. Results of the closed questions (Types 1 and 2).

Cluster			Textile	Software and technologies	Equipment manufacturing
Smart Manufacturing	Vertical integration	Sensors and Actuators			
		ERP			
		MES			
		SCADA			
	Virtualization	3D Representation			
		Artificial Intelligence			
	Autonomous robots	Robots along the production chain			
		Communication networks among them			
	Traceability of products				
	Flexibility	3D Printing			
		Adaptation of production lines			
		Monitoring about energy consumption			
Smart Working	Remote control of production				
	Augmented reality	Augmented reality during manufacturing			
		Augmented reality during training of workers			
Smart Supply Chain	Digital platforms company-clients-suppliers				
	Digital platforms among companies				
Smart Product	Interconnectivity of products				
	Supervision and control of final products				
	Data return				
Cybersecurity					

Table 5 shows that the cluster related to the textile sector fits globally with the principles of Industry 4.0. Indeed, with the exception of 3D printing, all advanced technologies are implemented and particularly those that relate to the term Smart Manufacturing, a fact that, according to the propositions – hypotheses previously described, shows a high degree of implementation – maturity stage of Industry 4.0.

The cluster related to Software and Technologies companies presents a medium degree of implementation – maturity stage of Industry 4.0, due to the diversity of degree of implementation – maturity stage of each technology. This grade is high for some technologies contained in Smart Manufacturing and low for others. Therefore, this cluster can be assimilated to an intermediate cluster respecting the principles of Industry 4.0.

The cluster that includes Equipment Manufacturing companies shows a low degree of implementation – maturity stage of Industry 4.0. Indeed, very few current technologies are known in these companies, with the exception of the technology that refers to the rapid adaptation of production lines.

Thus, the three clusters describe three implementation states of Industry 4.0 in the region under study: high, medium and low. In this way, it was possible to validate the choice made previously about the distribution of the companies in the three clusters and to analyze the reasons for the differences among them, thanks to the open questions that were proposed in the questionnaire.

From now on, it is called Cluster 1, the cluster associated to the Textile sector; Cluster 2, the one related to Software and Technologies, and Cluster 3, the one linked to Equipment Manufacturing.

4.2 Open Questions

The question related to the measures taken in the past regarding the integration of the principles of Industry 4.0 indicates that Clusters 1 and 2 took many measures with the aim of integrating these principles, unlike Cluster 3, which did not take any measure.

The question that refers to the opinion of the company regarding the need for Industry 4.0 shows a lack of knowledge of the companies in the Cluster 3. Indeed, the companies do not seem to know about the existence of this Industry, but they seem inclined to be interested to this concept. On the other hand, Clusters 1 and 2 are both convinced of the importance of matching it.

4.3 Analysis of the Results Based on the Characteristics Studied

According to the results obtained, it can be seen that the two characteristics of the final products of a company that induce a high degree of implementation – maturity stage of Industry 4.0 are direct consumption combined with a long-life span. These two characteristics are those of the products produced by the companies of the Cluster 1 and caused industrial needs that resulted in an efficient implementation of the advanced technologies of Industry 4.0.

On the other hand, it was found that indirect consumption induces a good degree of implementation – maturity stage, only if it is combined with a possibility of remote modification (Cluster 2) and not with a need for maintenance (Cluster 3).

These conclusions are clear, but one should be cautious about their implications, due to the limits of the study that are described as follows.

4.4 Limits of the Study

The number of companies that answered the questionnaire is the main limit of this study. For the study to be more precise, more responses should have been received, therefore, a better description of the situation could have been guaranteed, adapting or even generating other clusters with other characteristics.

In addition, it has been considered throughout the study that all the technologies of Industry 4.0 were adaptable to each company and all of them were important, whatever the industrial sector. However, there are sectors that do not need certain technologies because they are incompatible with the way companies operate.

For instance, a software company does not need 3D printing to produce its services. Thus, this technology is not going to be raised or considered by the directors of this company, and the absence of this technology does not mean that the company is lacking a way to square with Industry 4.0.

5 Discussion

5.1 Comparative Analysis

This section proposes a comparative analysis by considering different *maturity models* of Industry 4.0.

Mittal et al. [14] propose a critical comprehensive review of smart manufacturing and Industry 4.0 *maturity models*, and their implications for small and medium-sized enterprises (SMEs), by analyzing their fit and recognizing the specific requirements of SMEs. This work presents features that are characteristic for SMEs and identify research gaps needed to be addressed to successfully support manufacturing SMEs in their progress towards Industry 4.0.

The work of [14] develops an exhaustive analysis by comparing different methodologies, such as *framework*, *maturity model*, *readiness assessment*, and *gap analysis*, which are used to discuss the enterprise journey towards smart manufacturing (SM) and Industry 4.0.

An important observation from the study of [14] is that researchers have different perspectives towards the understanding of *dimensions* ([15], [16], [17], [18], [19]). For instance, Schuh et al. [15] mentioned resources, information systems, organization structure and organization culture as the *dimensions*. While Schumacher et al. [18] noted strategy, leadership, culture, people, and governance.

Moreover, Mittal et al. [14] indicate that only [20] and [21] mentioned the prerequisites of Industry 4.0 in the form of technologies, toolbox and building blocks. In this group, the work of Frank et al. [12] can be included.

Frank et al. [12] propose a structure of Industry 4.0 technology layers that shows levels of adoption of these technologies and their consequences for the implementation of the Industry 4.0 concept. This structure is synthetized as a *final framework* which represents a *maturity pattern* of the Industry 4.0 implementation. This framework of Industry 4.0 technologies suggests two *layers of adoption*: 1) front-end technologies, and 2) base technologies.

The first layer includes four *dimensions* of Industry 4.0: Smart Manufacturing, Smart Products, Smart Supply Chain and Smart Working. The second layer considers technologies that provide connectivity and intelligence to the front-end technologies. In order to understand the connections among the technologies, as well as to define patterns of adoption of the two layers, a cluster analysis in relation to the companies under study is applied.

According to Schuh et al. [15], the Acatech Industrie 4.0 Maturity Index divides the structure of a company into four structural areas or *dimensions* (Industry 4.0 capabilities): 1. Resources 2. Information systems 3. Organizational structure 4. Culture. Each dimension is defined by two principles that are identified along with the capabilities required for each structural area. The capabilities are geared towards the achievement of the various stages of development and provide manufacturing companies with the foundation to transform into agile organizations. The Acatech Industrie 4.0 Maturity Index has six *maturity stages*: 1. Computerization 2. Connectivity 3. Visibility 4. Transparency 5. Predictive capability 6. Adaptability.

Schumacher et al. [18] propose five *maturity stages*: Likert-scale reaching from 1 (not distinct) to 5 (very distinct). Nine company *dimensions*: 1. Strategy; 2. Leadership; 3. Customers; 4. Products; 5. Operations; 6. Culture; 7. People; 8. Governance; 9. Technology.

Leyh et al. [22] describe the model called SIMMI 4.0, which has five *maturity stages*: 1. Basic digitization level. 2. Cross-departmental digitization. 3. Horizontal and vertical digitization. 4. Full digitization 5. Optimized full digitization. The model SIMMI 4.0 includes four *dimensions*: 1. Vertical integration. 2. Horizontal integration. 3. Digital product development. 4. Cross-sectional technology criteria.

Lichtblau et at. [23] present an Industry 4.0 *maturity model* (IMPULS) which consists of six *stages*: 0. Outsider. 1. Beginner. 2. Intermediate. 3. Experienced. 4. Expert. 5. Top performer. Moreover, [23] depict six *dimensions* which are further (detailed into 18 fields): 1. Strategy and organization. 2. Smart factory. 3. Smart operations. 4. Smart products. 5. Data-driven services. 6. Employees.

Colli et al. [24] propose a digital *maturity model* which takes into consideration a number of existing digital *maturity models* ([15], [18], [22], [23]).

This maturity model of Colli et al. [24], it is suggested to assess the level of digitization of an organization, and it is composed by six sequential digital *maturity stages*: None, Basic, Transparent, Aware, Autonomous, Integrated.

In order to map the digital capabilities of the organization, these stages are grouped into five areas which are called digital *dimensions*: Governance, Technology, Connectivity, Value creation, Competences.

As an extension of [24], Colli et al. [25] present a contribution that consists of raising the need for contextualization in relation to digital maturity assessments by proposing a novel assessment approach to address this need.

In addition, [25] provide a reference model which is based on the Acatech maturity model [15], chosen for its focus on data and connectivity, which relates *maturity stages* and *dimensions* for mapping the information collected during the assessment process, as well as a more detailed description of the proposed assessment procedure, testing it in three cases and discussing its contextualization capabilities and the key contextual

factors that emerged. The proposed approach is intended as a learning tool, based on PBL (Problem Based Learning), to assist professionals in providing company-specific guidelines as a result of a digital *maturity assessment*, and academics in their study of the transition through *digital maturity stages* in many contexts.

Finally, this work has proposed the development of a Preliminary Maturity Assessment Tool (PMAT) which is used to identify technologies related to Industry 4.0, and to verify their *degree of implementation – maturity stages* in companies from different sectors.

The PMAT is based on two propositions – hypotheses which are connected to two *dimensions* of Industry 4.0, related to front-end-technologies: 1. Smart Manufacturing. 2. Smart Products. 3. Smart Supply Chain. 4. Smart Working.

The PMAT consists of a Questionnaire with three types of questions. The first and second types include a 5-point scale: 1. Non-existent. 2. Low. 3. Medium. 4. High. 5. Very High. This scale indicates five *degree of implementation – maturity stages.*

5.2 Possible Future Work

A possible future work could be an improvement of the PMAT, i.e. the SMART (Skilled–Maturity Assessment Research Tool) by means of increasing the propositions – hypotheses, thus, to achieve an enrichment of the number of *dimensions* related to Industry 4.0 front-end-technologies, as well as their base technologies.

Moreover, the SMART with an improved Questionnaire with other types of questions could be proposed. Therefore, a discussion with each company could be established with the aim of adapting the questions to the language of the company and the type of products it provides so that employees can answer the questions more precisely and exhaustively. In order to indicate five *degree of implementation – maturity stages*, the 5-point scale (1. Non-existent. 2. Low. 3. Medium. 4. High. 5. Very High) could also be included.

Finally, in a new study it is possible to investigate in depth, what are the current patterns of adoption of technologies related to Industry 4.0 that are implemented in the companies of the region under study.

6 Conclusions

This work developed a Preliminary Maturity Assessment Tool (PMAT). The PMAT founds on two propositions – hypotheses and consists of a questionnaire that is based on three types of questions, where the two first types include a 5-point scale.

The PMAT is used to identify technologies related to Industry 4.0, as well as to verify their degree of implementation – maturity stages in companies from different sectors.

What stands out from this study is the willingness of companies to adopt Industry 4.0 as a production paradigm. Even companies that did not know the term or the concept showed willingness to take an interest in the matter and adopt it in the near future.

The proposed questionnaire (PMAT) made it possible to investigate the degree of implementation - maturity stages of the technologies involved in different companies, and in this way, to have a point of reference on the current state of knowledge and the measures adopted by the companies.

Therefore, this first study was very encouraging for future research projects related to the patterns of implementation of Industry 4.0 technologies in companies in the region under study.

Resumo. Com a crescente evolução industrial e tecnológica, o setor produtivo está passando por mudanças profundas em sua estrutura e operações, o que está sendo entendido como a Quarta Revolução Industrial, ou Indústria 4.0 (I4.0). Este termo retrata a digitalização e a interoperabilidade no setor industrial global, despertando interesses nos setores público e privado. O presente trabalho caracteriza este paradigma industrial abordando seus conceitos, princípios e pilares tecnológicos para, posteriormente, realizar um estudo multicasos, discutindo usos de tecnologias relacionadas à I4.0 no setor eletroeletrônico brasileiro, com objetivo de retratar os avanços das organizações brasileiras neste contexto. Realizou-se uma revisão sistemática da literatura, construindo dois portfólios bibliográficos: um para a etapa teórica, de caracterização; e outro para a etapa de casos. Em seguida, realizou-se análise bibliométrica e análise de conteúdo dos documentos do portfólio teórico, de modo a identificar as categorias de análise pertinentes à realização da etapa subsequente, de estudo de casos múltiplos. Essa etapa envolveu a análise de cinco casos selecionados, apresentando aplicações de tecnologias da I4.0 nas áreas de fabricação de máquinas, operação e monitoramento de usinas hidrelétricas, educação e regulação do setor elétrico. A partir deste estudo, pode-se compreender "como" e "em quê" os benefícios e tecnologias da I4.0 são utilizados em diferentes aplicações ou segmentos industriais do setor eletroeletrônico. Os aspectos presentes de forma predominante em todos os casos foram os princípios de intercoexão e virtualização; os benefícios de flexibilidade e integração das informações; e as tecnologias IIoT e computação em nuvem. Pesquisas futuras poderão utilizar a mesma estrutura teórica para conduzir estudos de casos empíricos, retrospectivos ou longitudinais, sobre a migração, adoção, uso ou desenvolvimento de tecnologias da I4.0 em contextos específicos, visando retratar a situação real das empresas e organizações sobre "o quê" e "como" utilizam ou se inserem no conceito de I4.0.

Palavras-chaves: Indústria 4.0, manufatura avançada, setor eletroeletrônico, estudo multicasos.

1 Introdução

A Indústria 4.0, ou I4.0, é caracterizada pelo aprimoramento das tecnologias da Terceira Revolução Industrial e da disseminação de inovações tecnológicas incorporadas no chão-de-fábrica, virtualizando a automação ao longo da cadeia de produção e permitindo a fusão do mundo físico ao digital [1].

Esta nova revolução industrial "transformará a fabricação, operação, *design* e serviço de produtos e sistemas de produção", por meio da "conectividade e interação entre peças, máquinas e seres humanos", elevando a eficiência dos sistemas de produção em 25% e acelerando a produtividade em 30% [2]. Máquinas e sistemas se comunicarão entre si por sistemas ciber-físicos (CPS - *Cyber-Physical Systems*) através da Internet das Coisas (IoT - *Internet of Things*), operando a produção de forma autônoma e auxiliando o ser humano, simultaneamente.

Conforme indica [3], o setor industrial brasileiro é o 9º maior do mundo, representando, atualmente, cerca de 10% do PIB nacional, valor três vezes menor ao que representava na década de 80. O Brasil está na 41ª posição em estrutura de produção e na 47ª posição nos vetores de produção da indústria internacional. O país possui potencial para melhorar sua situação na nova economia, investindo na integração de tecnologias emergentes e capacitação em áreas da engenharia, integração de sistemas, comunicação digital, análise de dados e trabalho multidisciplinar, entre outras.

Assim, este trabalho visa caracterizar a I4.0, definindo as principais tecnologias que compõem esse novo padrão industrial, bem como apontando e descrevendo aplicações de tais tecnologias no âmbito industrial eletroeletrônico brasileiro.

Pelo fato da Indústria 4.0 já estar sendo desenvolvida e aplicada especialmente em países como Estados Unidos e Alemanha, se vê a necessidade de compreender esta nova revolução, para que países emergentes, como o Brasil, se aprofundem no assunto tanto no contexto acadêmico quanto, a partir disso, no setor industrial.

Dessa forma, pretende-se contribuir com a literatura discutindo conceitos, características e tecnologias da I4.0 através de uma Revisão Sistemática de Literatura (RSL); com a prática industrial brasileira e de outros países emergentes, a partir da análise de casos brasileiros de migração para a I4.0; e também com o setor eletroeletrônico brasileiro, estabelecendo alguns marcos para a adoção das práticas e tecnologias da nova revolução industrial.

2 A Indústria 4.0 e seus princípios básicos

A Indústria 4.0 surgiu nos últimos anos para retratar a digitalização e a interoperabilidade no setor industrial global [4]. O termo Indústria 4.0 (I4.0) é relacionado à Quarta Revolução Industrial, e foi utilizado pela primeira vez na Feira de Hannover em 2011, na Alemanha, a partir das iniciativas dos setores governamentais, acadêmicos e privados, para denominar uma iniciativa do governo alemão que visa o fortalecimento do poder competitivo do país na área da manufatura, através da implantação de fábricas inteligentes [5].

Nessa nova transformação industrial, máquinas, sensores e sistemas de TI se interconectam ao longo do chão de fábrica das indústrias [2]. Todos esses sistemas interagem através de protocolos baseados na internet, fazendo leituras e análises de dados

em tempo real, se adaptando a mudanças e prognosticando falhas, convertendo indústrias convencionais em fábricas inteligentes, conforme indica [6].

[1] e [7] apontam os princípios básicos para uma implantação eficaz da I4.0.

2.1 Interconexão. A interconexão, também nominada como interoperabilidade, é relacionada à troca e compartilhamento de informações entre sistemas de uma organização inteligente [8]. Tem como característica o intercâmbio de dados e acesso a sistemas por meio de uma rede industrial, fornecendo três tipos de conexões: homem-homem, homem-máquina e máquina-máquina, através da Internet das Coisas (IoT).

2.2 Virtualização (ou transparência informal). A partir da interconexão de pessoas e dispositivos, os sistemas organizacionais são capazes de criar um modelo virtual do ambiente real através de dados de dispositivos e sensores pertencentes ao mundo físico, fazendo uma cópia do mundo físico no ambiente digital [8].

2.3 Decisões descentralizadas. Com a maior automatização e individualização da produção, a dificuldade em manter um sistema de controle centralizado aumenta. Na I4.0, a descentralização se torna uma solução para descomplexificar tais problemas [1]. As decisões descentralizadas se baseiam na interconexão de pessoas e dispositivos inteligentes, que podem monitorar e executar tarefas com maior autonomia, capazes de tomar decisões por conta própria, permitidas pelos sistemas ciber-físicos (CPS), do que decorre uma produção eficiente e sincronizada. Em situações especiais, como no caso de conflito de metas, as decisões passam a ser delegadas a um nível superior [7] [8] [9].

2.4 Assistência Técnica. Através da interconexão e descentralização, máquinas e robôs passam a executar funções operacionais básicas e repetitivas, garantindo maior segurança e eficiência na produção. Ademais, podem atuar no suporte físico de outras tarefas envolvendo homem e máquina, interagindo, robôs e trabalhadores capacitados, para esse tipo de serviço colaborativo, de modo seguro e aceitável para ambos [7].

2.5 Capacidade de resposta em tempo real. A capacidade de resposta em tempo real tem a competência de coletar, analisar e fornecer os dados necessários para atender decisões instantaneamente. Os dados provenientes dos sistemas inteligentes são extraídos e analisados, com o intuito de ter respostas em tempo real para poder certificar que o sistema seja competente caso necessite de uma reação instantânea, por motivo de alteração de demanda ou mesmo por problemas operacionais [1] [8].

2.6 Modularidade. Na I4.0 a produção passa a possuir vários módulos, os quais podem se adequar e se ajustar de acordo com as necessidades do cliente, permitindo assim uma grande flexibilidade nos sistemas de manufatura. Esses sistemas modulares podem ser introduzidos em organizações industriais convencionais, fornecendo suas funções pela rede industrial através de protocolos padrões de comunicação [1] [8].

De forma complementar aos princípios de implantação, outro conceito central para a compreensão da I4.0 é o que se chama de Sistemas Ciber-Físicos (CPS). [10] definem os CPS como um "conjunto de sistemas nos quais sistemas naturais e feitos pelo homem (espaço físico) são fortemente integrados aos sistemas de computação, comunicação e controle (espaço cibernético)", tendo a descentralização e os processos de produção autônomos como principais colaboradores.

Os CPS são chaves para a criação de fábricas inteligentes, incluindo a constante troca de informação entre máquinas e dispositivos permitindo o controle autônomo, envolvendo sistemas, máquinas, produtos, clientes, estoques e serviços terceirizados [11].

3. Tecnologias-chaves associadas à Indústria 4.0

Há nove tecnologias emergentes que estão em evidência na transformação dos processsos de produção, sendo consideradas como os pilares da I4.0. Em linhas gerais, a fusão entre os mundos físico, digital e biológico é viabilizada através dessas tecnologias.

3.1 Internet Industrial das Coisas (IIoT). [12] e [13] definem a IoT através da conexão entre qualquer objeto físico, sistemas e pessoas por meio da internet. Quando referida especificamente às indústrias, a chamada Internet Industrial das Coisas (IIoT), incorpora softwares, sensores, objetos físicos, dispositivos, máquinas e demais "coisas" presentes nas indústrias, permitindo a comunicação, a coleta e a troca de dados através de sensores inteligentes, de modo que tais objetos podem se tornar participantes ativos dos processos de negócios. [4] [5] [14] [15] [16].

3.2 *Big Data Analytics.* O *Big Data Analytics*, ou simplesmente *Big Data*, representa o conjunto de tecnologias envolvidas na coleta, processamento e análise de grandes volumes de dados provenientes da IoT, sejam eles armazenados ou coletados em tempo real. [17] e [18] apontam suas três principais características: Volume – relacionado à quantidade de dados disponíveis, aumentando a capacidade analítica; velocidade – relacionada com a agilidade na geração dos dados; e variedade – relacionada à diversidade de dados gerados.

3.3 Computação em Nuvem. Os dados gerados por da IoT e *Big Data* são manipulados pela computação em nuvem, armazenando informações em banco de dados de alta capacidade. Essa tecnologia permite que clientes e trabalhadores tenham acesso aos dados ao mesmo tempo, possibilitando analisar o fluxo de dados em tempo real [6] [8] [11] [19], dispensando grandes investimentos em *softwares* e infraestruturas [20] [21].

3.4 Cibersegurança. Refere-se à proteção de dados de TI por meio de procedimentos que proporcionam segurança digital contra roubos ou danos de dados [22]. Esta tecnologia é essencial para as tendências da manufatura, visto que a I4.0 é fundamentada na digitalização e nos serviços baseados em dados, garantindo privacidade e segurança em todos os processos de produção [8]. As vulnerabilidades são comumente relacionadas a dispositivos virtuais que possuem conexão com os sistemas da nuvem [23] [24] [25].

3.5 Manufatura aditiva. A manufatura aditiva converte um desenho computacional 3D em um objeto real através da impressão em camadas. Esta tecnologia vem sendo utilizada atualmente na fabricação de produtos inteiros, personalizados de acordo com as exigências de cada cliente [26] [27], possuindo a vantagem de trabalhar com estoques reduzidos, barateando a produção e diminuindo o tempo de espera de um produto [2].

3.6 Realidade Aumentada. A realidade aumentada (RA) aprimora a visualização do ambiente físico industrial, sobrepondo em tempo real informações virtuais à realidade, gerando funcionalidades inteligentes de fabricação [2] [6], elevando os padrões da manufatura através da inserção de sons, gráficos, imagens em 3D e feedback de toque ao mundo real [6]. [28] aponta aplicações de RA nas indústrias em termos de operações,

manutenção e assistência remota, treinamento, controle de qualidade, gerenciamento de segurança, design e visualização, e logística.

3.7 Simulação. A simulação é uma tecnologia utilizada para prever comportamentos de um sistema real, utilizando modelos físicos ou matemáticos para criar e projetar sistemas reais ou ilusórios. Nos processos de produção da I4.0, a aplicação da simulação atua na redução de falhas, agilizando a tomada de decisões e reduzindo o tempo de inatividade de máquinas e dispositivos [2], rumo a retratar o mundo físico em um modelo digital, incluindo máquinas, seres humanos e produtos [2] [29]. A realização de testes virtuais de diversas configurações de procedimentos, permitirá previsões, melhorias ou alterações nos processos já utilizados [29] [30].

3.8 Robôs Autônomos. A implantação de robôs no chão de fábrica permitiu a realização de atividades que não podiam ser resolvidas facilmente pelo homem. Com a I4.0, os robôs se tornam mais flexíveis e autônomos, interagindo entre si, cooperando e aprendendo com humanos. Eles incorporarão novas capacidades, automatizando a linha de produção por conta própria e dispensando supervisionamento, coordenando ações e tarefas que são inseguras ou desagradáveis para os operários [2] [6] [31]. Os *Cobots*, ou robôs colaborativos, são pensados para trabalho cooperativo em espaço compartilhado com humanos, garantindo a segurança necessária [32].

3.9 Sistemas de Integração Horizontal e Vertical. Na I4.0, as indústrias se associarão com os recursos e funções variadas devido à integração de dados e dispositivos (CPS) com o chão de fábrica, proporcionando uma cadeia de valores realmente automatizada [2] [4]. A integração horizontal digitaliza toda a linha de processos industriais, realizando o intercâmbio de informações em toda a cadeia de valor com clientes e fornecedores, integrando diversos sistemas, recursos e processos dentro das fábricas como também com outras fábricas. Por outro lado, a integração vertical relaciona a integração de tais elementos presentes nas fábricas em diferentes níveis hierárquicos internos de produção, desde o chão de fábrica até os executivos e diretores [2] [33].

4 Metodologia

Este trabalho adotou por método a pesquisa bibliográfica, desenvolvida na forma de uma Revisão Sistemática de Literatura (RSL) [34], seguida por um estudo multicasos [35].

A pesquisa bibliográfica consistiu na análise de artigos científicos publicados em periódicos indexados ou conferências, relatórios organizacionais e acervo legal ou regulatório nacional. Uma RSL foi realizada para a seleção das bibliografias, passando pela seleção de portfólio e realização das análises bibliométrica e de conteúdo, enfocando as tecnologias no âmbito da Indústria 4.0. Foi definido um portfolio bibliográfico teórico, sobre aspectos da I4.0; e, na sequência, outro portfolio de artigos abordando aplicações de tecnologias emergens no setor eletroeletrônico brasileiro. As etapas da pesquisa seguiram a estrutura detalhada a seguir.

Etapa 1: Planejamento da Pesquisa. A primeira etapa do trabalho consistiu em uma busca horizontal da literatura, com o objetivo de levantar informações e questionamentos para um melhor alinhamento de ideias, como também para delimitar a pesquisa e orientar seu design metodológico. Nesta busca, foram acessados artigos de periódicos

e congressos internacionais, dissertações e teses, *sites* da instituições industriais e governamentais, e relatórios institucionais.

Etapa 2: Seleção de Portfólio Bibliográfico Teórico e de Casos. Para a seleção do portfolio teórico procedeu-se a partir dos seguintes passos:

a) Escolha das bases de busca, elegendo-se as bases *Scopus, Web of Science* e *IEEEXplore*, por conterem vasto acervo de documentos e serem as principais no ramo do conhecimento cie*ntífico.*

b) Definição dos eixos de pesquisa e palavras-chaves, adotando-se os eixos e palavras-chaves conforme exposto na Tabela 1

Tabela 1. Eixos e palavras-chaves empregados na pesquisa

Eixo 1 – I4.0	Eixo 2 – Tecnologias
Industry 4.0	Cyberphysical System
Factory 4.0	Big Data Analytics
Company 4.0	Augmented Reality
Enterprise 4.0	Additive Manufacturing
Advanced Manufacturing	Cloud
	Cybersecurity
	Industrial Internet of Things
	Horizontal / Vertical System Integration
	Simulation
	Autonomous Robots

c) Coleta de dados para compor o portfólio. Aassociações de palavras-chaves foram feitas utilizando operadores booleanos, gerando 50 combinações que foram inseridas nas bases de busca, aplicando-se um filtro para retornar artigos apenas no período de 2011 a 2019. Os artigos selecionados foram importados para gerenciamento e catalogação bibliográfica por software, para melhor manipulação e seleção dos artigos.

d) Exclusão de duplicados e filtragem. A importação resultou num total de 14.941 artigos. A partir disso, foram feitas filtragens seguindo critérios baseados nos objetivos da pesquisa, começando pela eliminação de duplicações, restando 9.934 artigos. Em seguida, foram lidos os títulos (ficam 1.494 documentos), seguido dos resumos (reduz para 118). Então, se fez uma leitura preliminar de cada artigo, restando 21 referências.

e) Processo de repescagem e definição do portfólio teórico final. Após o processo de leitura preliminar, fez-se um levantamento para verificar a ocorrência de outros trabalhos dos autores dos 21 artigos dentre os descartados na etapa de leitura dos resumos. Na identificação dessas ocorrências, a mesma entraria para uma lista de repescagem. Para avaliar qual referência da lista de repescagem poderia ser reintegrada ao portfólio, se fez a leitura na íntegra dos trabalhos, para certificar o alinhamento do conteúdo às ideias e objetivos estabelecidos. Com isso, 2 referências foram resgatadas. As 23 referências totais foram lidas integralmente para avaliar se estavam seguindo o critério da pesquisa, resultando em um portfólio teórico final de 18 documentos.

Na seleção de artigos para compor o portfólio de casos, fez-se uma nova pesquisa com os mesmos procedimentos expressos nos itens de *a)* a *d)* anteriores, adicionando dois novos eixos de pesquisa: Setor Eletroeletrônico e Brasil. Também fora adicionada

a base de busca brasileira, SciELO, para garantir uma melhor aderência à pesquisa de casos brasileiros. A palavra-chave *Simulation* foi retirada nesta etapa de busca referir-se a uma gama de aplicação muito ampla em comparação aos objetivos da pesquisa, desvirtuando os resultados.

A consulta às bases com os eixos e palavras-chaves definidos resultou em 2.094 referências, tendo a base IEEEXplore 74,7% de representatividade. Após as etapas de filtragem, obteve-se o total de 13 artigos, que foram lidos integralmente. Após a leitura completa, dentre os 13 artigos, 5 atendiam aos requisitos da pesquisa da etapa de seleção dos casos, a saber: pertencer ao setor eletroeletrônico brasileiro; e utilizar tecnologias referentes à Indústria 4.0. Estes 5 artigos foram selecionados para compor o portfólio de casos, tornando possível o desenvolvimento do estudo multicasos.

Etapa 3: Análise Bibliométrica e de conteúdo do Portfólio Teórico. Esta etapa investiga a composição do conhecimento científico relacionado com o tema em questão, através de um conjunto de métodos para avaliar a relevância do conteúdo da pesquisa, verificando o alinhamento com seus objetivos [36] [37].

A análise bibliométrica indicou através de gráficos e tabelas, dados quantitativos do portfólio teórico. Os indicadores utilizados nesta análise foram: o reconhecimento científico dos artigos (citações), a relevância de autores no portfolio, a relevância dos veículos de publicação; e incidência de palavras-chaves, cujos resultados estão expostos na seção 5. Neste processo foi utilizado o *Google Scholar* para verificar quantas citações possuía cada artigo até a consulta, datada em 14 de abril de 2019.

Posteriormente, a análise de conteúdo foi centrada na extração e vinculação de informações relevantes do portfolio de casos, adotando-se as seguintes categorias *a priori* de análise, todas relativas à I4.0: princípios de implantação; benefícios percebidos ou esperados; principais tecnologias.

Etapa 4: Estudo Multicasos. A etapa do estudo multicasos adota abordagem qualitativa, enfocando a ampliação de conhecimento do tema I4.0 no setor eletroeletrônico brasileiro. A escolha pelo estudo de casos múltiplos visa a comparação entre os casos, investigando semelhanças, distinções e correlações entre eles, corroborando com a pesquisa e seus métodos aqui empregados [35].

Para a seleção dos casos, utilizou-se como critério de filtragem o enfoque descritivo acerca dos elementos abordados nas seções 2 e 3 deste trabalho: os princípios de implantação da I4.0, seus benefícios e as tecnologias consideradas como pilares. Tais elementos são resgatados da análise de conteúdo do portfolio teórico.

Na análise dos 5 casos selecionados, descritos como A, B, C, D e E, são detalhadas aplicações de tecnologias 4.0 em diferentes segmentos ou finalidade específicas do setor eletroeletrônico brasileiro, permitindo acompanhar iniciativas da revolução 4.0 em diversas áreas deste setor no Brasil.

5 Portfólio teórico, análise bibliométrica e análise de conteúdo

A presente seção apresenta os resultados da seleção do portfólio teórico, bem como sua análise bibliométrica e de conteúdo.

A Tabela 2 apresenta o portfólio teórico selecionado, relacionando o número de citações dos artigos. Este levantamento serve para visualizar, em um contexto geral, o nível de reconhecimento científico de cada artigo.

Tabela 2. Identificação e citações do portfolio teórico

5.1 Análise Bibliométrica. Quatro análises foram conduzidas nesta etapa da pesquisa. Fez-se o levantamento de reconhecimento científico dos artigos, por meio do número de citações dos documentos pertencentes ao portfólio teórico; e análise de relevância dos autores e dos veículos de publicação no tema. Por fim, apresenta-se uma bibliometria de incidência de palavras-chaves nos artigos do portfolio.

No que se refere à relevância científica dos artigos, o maior destaque é o trabalho A4 [7], apresentando 1054 citações. Deve ser considerando, no entanto, que este trabalho data de 2016, dispondo de mais tempo para ser citado do que maioria dos demais o que, num tema emeregente como I4.0, é relevante. Juntos, os artigos A4, A6, A14 e A18 correspondem a 86,4% do total de citações do portfólio teórico, constituindo-se em base importante para as futuras discussões qualitativas.

No que concerne à recorrência de autores, verifica-se que apenas um autor dentre os 62 existentes assina mais de um artigo incluso no portfólio, o que sinaliza na direção de que ainda não há uma concentração de pesquisa sobre o tema. Já no que tange à relevância dos veículos de publicação, embora o periódico Procedia Manufacturing seja o único com 2 artigos no portfolio, a diferença é muito sutil frente aos demais, com um artigo. Dado que o tema é emergente, a dinâmica desse indicador tente a ser grande.

Por fim, o resultado do levantamento da incidência das palavras-chaves dos artigos do portfólio é mostrado na Figura 1.

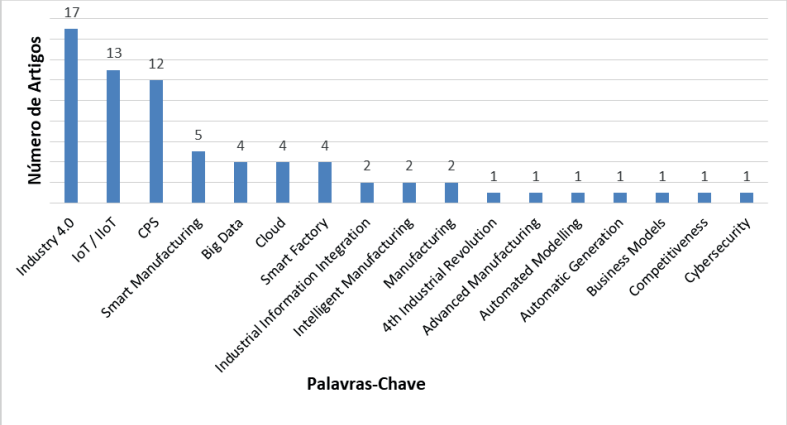

Fig. 1. Ocorrência de palavras-chaves no portfolio teórico

5.2 Análise de Conteúdo. A análise de conteúdo aqui apresentada descreve os conteúdos provenientes dos documentos do portfólio teórico utilizados para a elaboração das seções 2 e 3 deste trabalho. Essa análise auxilia na reinterpretação do que já fora abordado, oferecendo ao leitor uma compreensão mais acessível dos conteúdos em um nível superior se comparado com uma simples leitura [41].

Para facilitar a compreensão, as informações dos documentos do portfólio teórico foram reunidas em dois quadros para melhor visualização e comparação das informações de cada elemento, como pode ser visto na Tabela 3 e Tabela 4. Estas tabelas são utilizadas posteriormente para comparar os casos de estudo, confrontando os relatos de casos empíricos às informações provenientes da literatura teórica.

Tabela 3. Análise de conteúdo sobre os princípios e benefícios da I 4.0

Dimensão	Elemento	Descrição	Códigos
Princípios	Interconexão	Conexão entre sistemas industriais, com troca e processamento de informações	A3, A4, A8, A13
	Virtualização / Transparência Informacional	Criação de um modelo virtual da situação real a partir de dados, permitindo monitoramento e tomada de decisão em sistemas	A4, A8
	Decisões Descentralizadas	Capacidade dos sistemas tomarem decisões sozinhos através da interconexão, executando trabalhos com mais autonomia	A4, A8
	Assistência Técnica	Assistência ao homem em diversas tarefas pelos sistemas	A4, A10
	Cap. de resposta em Tempo Real	Agilidade dos sistemas em coletar e conceder decisões instantaneamente	A8
	Modularidade	Alta flexibilidade na alteração repentina de tarefas da linha de produção	A8
Benefícios	Demanda Personalizada / Customização	Capacidade de realizar alterações específicas em qualquer etapa da produção	A3, A8, A10, A11, A14, A15
	Flexibilidade Produtiva	Agilidade em atender diversas demandas customizadas, permitindo uma tomada de decisões mais inteligente e responsável	A3, A8, A10, A13, A14, A15, A18
	Info. Compart. / Integração das Operações	Aumento na eficiência através de integrações entre sistemas	A3, A4, A8, A10, A15, A18
	Produtividade de Recursos Melhorada	Gerenciamento de recursos e energia mais automatizado	A3, A8, A10, A11, A14, A15, A17

Tabela 4. Análise de conteúdo sobre as tecnologias da I 4.0

Tecnologias	Descrição	Códigos
Sistemas Ciber-Físicos	Conjunto de sistemas capaz de integrar o mundo físico com o virtual, monitorando dispositivos e máquinas	A1, A2, A3, A4, A5, A8, A10, A11, A14, A15, A17, A18
IIoT	Tecnologia capaz de conectar dispositivos e máquinas através do mesmo protocolo de internet	A1, A3, A4, A5, A8, A10, A11, A13, A14, A15, A18
Tecnologias	Descrição	Códigos

Big Data Analytics	Conjunto de tecnologias capaz de armazenar, distribuir, gerenciar e analisar grandes volumes de dados	A2, A3, A8, A10, A14, A15, A17, A18
Computação em Nuvem	Armazena os dados provenientes do *Big Data* em um servidor na internet	A3, A8, A10, A15, A17, A18
Cibersegurança	Garante segurança digital nas organizações contra ataques virtuais	A7
Manufatura Aditiva	Tecnologia que permite criar qualquer objeto através de impressões 3D	A8, A15
Realidade Aumentada	Visualização do ambiente real junto a dados e opções virtuais por dispositivos	A10, A15
Simulação	Prevê comportamentos desejados e não desejados de sistemas reais através da projeção em ambiente virtual	A10, A12, A15, A16
Robôs Autônomos	Robôs que interagem entre si, aprendendo com humanos e também uns com os outros	A10, A14, A15
Sistemas de Integração Horiz. e Vert.	Sistemas que integram toda a linha de chão de fábrica em nível horizontal, integrando elementos verticalmente em nível hierárquico	A11, A15

Na Tabela 3 pode-se notar que os benefícios da I4.0 são bastante abordados em documentos para retratar o "patamar 4.0", juntamente com as definições e características dessa nova revolução. Por outro lado, ao observar a Tabela 4, nota-se que as tecnologias mais citadas nos artigos são os CPS, IIoT, *Big Data* e Computação em nuvem, pelo fato de serem praticamente essenciais para a implantação da I4.0 nos ambientes fabris, atuando diretamente na interconexão entre dispositivos e pessoas.

6 Análise dos casos

O setor eletroeletrônico no Brasil é organizado em diversas áreas industriais, como informática, automação industrial, componentes eletrônicos, telecomunicações, geração e distribuição de energia, entre outras e está essencialmente relacionado com a I4.0, pois implementará mudanças nas empresas para se atingir o novo paradigma industrial por meio dos pilares tecnológicos, cujas tecnologias são provenientes do setor eletroeletrônico.

Na seleção de artigos para compor o portfólio de casos, fez-se nova pesquisa com a mesma metodologia do portólio de caracterização, adicionando dois novos eixos de pesquisa: Setor Eletroeletrônico e Brasil. O eixo Simulation foi retirado nesta etapa de busca por possuir uma gama de aplicação muito ampla em comparação aos objetivos da pesquisa. Nas etapas de filtragem, foram eliminados artigos duplicados e feita a leitura dos títulos e dos resumos, restando-se 13 artigos, que foram lidos na íntegra.

Após a leitura completa, dentre os 13 artigos, 5 atendiam aos requisitos da pesquisa da etapa de seleção dos casos: pertencer ao setor eletroeletrônico brasileiro e utilizar tecnologias referentes à Indústria 4.0. Estes 5 artigos foram selecionados para compor o portfólio de casos, tornando possível o desenvolvimento do estudo multicasos. São eles:

Caso A - Monitoramento em uma empresa de fabricação de máquinas [42].

Caso B - Sistema de manutenção e operação em uma usina hidrelétrica [43].

Caso C - Monitoramento de segurança de barragem em uma usina hidrelétrica [44].

Caso D - Medição sem fio do consumo de energia elétrica em uma linha de produção industrial avançada [45].

Caso E - Sistema de análise de dados para o setor elétrico brasileiro [46].

Embora tenha sido realizada análise individual dos casos, neste trabalho não é descrito esse detalhamento. Será enfocado o resultado do estudo comparativo entre os casos, por trazerem maior contribuição, de forma consolidada.

Para realizar a análise multicasos, as Tabelas 3 e 4 da seção 5.2 (análise de conteúdo) são rearranjados para confrontar os casos, resultando nas Tabelas 5 e 6, construídas a partir das informações disponíveis nos documentos de cada caso. Como leganda, adota-se a cor branca para representar que não há informações sólidas sobre o uso ou não dos elementos nos casos; a cor vermelha quando é especificado que não há uso algum de determinado elemento; a cor cinza para indicar que há pouco ou algum tipo de utilização de elementos; e a cor verde para indicar uso moderado ou expressivo dos elementos.

Tabela 5. Indicação de princípios e benefícios da I4.0

Dim.	Elemento	Caso A	Caso B	Caso C	Caso D	Caso E
Princípios	Interconexão					
	Virtualização / Transparência Info.					
	Decisões Descentralizadas				-	-
	Assistência Técnica				-	-
	Capacidade de Resposta em Tempo Real					-
	Modularidade			-		-
Benefícios	Demanda Personalizada / Customização	-	-			
	Flexibilidade Produtiva					-
	Info. Compart. / Integração das Operações					
	Produtividade de Recursos Melhorada		-			

Analisando a Tabela 5, pode-se notar o elemento Interconexão presente em todos os casos, bem como os demais elementos aplicados em quase todos, corroborando com a caracterização da Indústria 4.0, que relaciona tais elementos diretamente com suas características de implantação. O elemento Demanda Personalizada / Customização em Massa é uma exceção neste sentido, pois dentre os cinco casos abordados, apenas o Caso D indica sua aplicação, o qual apresenta uma linha de produção completa, desde o início de fabricação até a expedição.

Tabela 6. Ocorrência de aplicações das tecnologias da I4.0

Dim.	Elemento	Caso A	Caso B	Caso C	Caso D	Caso E
Tecnologias	Sistemas Ciber-Físicos	-		-	-	-
	IIoT	RFID		Protoc. XMPP	RFID	
	Big Data Analytics		-			
	Computação em Nuvem					
	Cibersegurança	-	-			-
	Manufatura Aditiva	-	-			
	Realidade Aumentada	-	-	-	*QR Code*	
	Simulação	-	-	-	*Digital Twin*	-
	Robôs Autônomos	-	-		*Cobots*	
	Sistemas de Integração Horizontal e Vertical				-	
	Outros	-	Manut Preditiva	-	-	-

Analisando a Tabela 6, fica evidente o uso da tecnologia IIoT em todos os casos, assim como o *Big Data* e Computação em Nuvem, pois estas tecnologias são essenciais para a comunicação, coleta de dados e armazenamento entre dispositivos, máquinas e pessoas, sendo o ponto principal deste novo conceito de manufatura.

O elemento Sistemas Ciber-Físicos não é citado diretamente entre os casos, porém, pode-se afirmar, indiretamente, que os dispositivos/maquinários utilizados nos casos são sistemas ciber-físicos, pois podem se comunicar, realizar trocas de dados e interagir entre si, unindo o ambiente físico ao ambiente virtual através da Internet das Coisas.

Outro destaque importante está no Caso D, que emprega diversas tecnologias e apresenta vários benefícios de I4.0 em uma linha de produção utilizada para realizar medições de consumo de energia elétrica remotamente, podendo analisar na prática o real uso de tais elementos em um ambiente fabril, sendo este o único caso de estudo que envolve I4.0 em uma linha de produção.

7 Conclusões

O presente trabalho teve por objetivo caracterizar a Indústria 4.0, bem como seus conceitos, princípios e tecnologias-chaves, buscando evidenciar, à luz da literatura, casos de uso de tecnologias 4.0 no setor eletroeletrônico brasileiro através de um estudo multicasos.

As informações oriundas da definição do portfólio bibliográfico teórico e da análise bibliométrica e de conteúdo foram importantes para posteriormente realizar a pesquisa da etapa de casos e definir o segundo portfólio do trabalho, buscando casos de estudo que envolvem os elementos abordados na análise de conteúdo.

Os casos utilizados para análise foram selecionados com base em duas premissas: pertencer ao setor eletroeletrônico brasileiro e utilizar tecnologias associadas à I4.0. Portanto, 5 casos foram selecionados, abrangendo as áreas de fabricação de máquinas,

operação e monitoramento de usinas hidrelétricas, educação e regulação do setor elétrico. Os casos foram desenvolvidos tanto por empresas privadas como órgãos públicos, concluindo que o interesse pelo tema desta pesquisa é de ambos os setores do país, privado e público.

Cada segmento industrial abordado neste estudo apresenta suas próprias aplicações e singularidades, o que enaltece a importância e versatilidade da I4.0 no futuro para garantir a competitividade de indústrias e organizações.

A pesquisa traz contribuição teórica em termos do levantamento e sistematização da literatura sobre o tema, propondo uma estrutura conceitual para análise de casos. Em termos de contribuição prática, agrupa e evidencia casos específicos de aplicação de tecnologias relacionadas à I4.0 no setor eletroeletrônico, permitindo, além de melhor conhecer a realidade desse setor na adoção dos princípios e tecnologias I4.0, comparar os benefícios percebidos por essas organizações nessas iniciativas.

Algumas limitações de pesquisa podem ser especificadas. Pelo fato do tema em questão ser muito recente, algumas abordagens não apresentavam uma teoria sólida sobre os assuntos estudados. Também por essa razão, foram encontrados poucos casos para análise, sendo alguns destes pouco detalhados em relação ao desenvolvimento do uso das tecnologias e como foram utilizadas realmente.

Abstract. With the rise of Industry 4.0 an era of real-time global connectivity between customers and the processes that transform consumer goods is imminent. Faced with the need to satisfy the current dynamic demand, the Japanese technology industry has developed an innovative production system called Seru, which is distinguished by its satisfactory results in economic and environmental terms. This study poses a production planning problem in a Seru production system considering heterogeneous workers and the energy consumption of production. To solve it, a multi-objective mathematical model is proposed in order to balance the production time between workers (intra-Seru) and between serus (inter-Seru) and minimize the total energy consumption. For larger instances, a metaheuristic algorithm is developed based on the evolutionary algorithm NSGA-II. Finally, the effectiveness of the proposed genetic algorithm is evaluated by comparing the area under the curve obtained with the solutions of the pareto frontier that it generates and the area under the curve from the pareto frontier of the multi-objective linear optimization model created via ε - constraint.

Keywords: Seru Production System, Production Planning, Line Balancing, Heterogeneity, Energy Consumption, CO_2 Emissions

1 Introduction

The Seru production system (SPS) is recognized for its economic and environmental benefits (double E) [2]. Due to the growing concern about environmental problems, studies related to sustainable production systems have acquired greater relevance. However, the SPS has not been widely studied in this area. According to [2], only those companies that lead a transformation towards environmental efficiency will be competitive. On the contrary, those that do not modify their traditional production processes will incur in high costs for waste, fines for violation of environmental legislation and high costs for energy consumption.

According to a 2020 report by UNEP (United Nations Environment Program), the record for global concentrations of carbon dioxide has been reached despite the COVID-19 crisis. Through the drilling of an ice core it was determined that in the last 800,000 years the current concentration of CO_2 in the atmosphere had never been reached, 416.21 ppm. According to the World Energy Outlook in 2018 industrial activities generated 24 % of global CO_2 emissions.

Anticipating the growing need to develop manufacturing techniques to stay competitive, technology company Sony implemented SPS in 1992. Later, other companies in the technology industry such as Canon adapted this production system [4]. Both companies experienced economic and environmental benefits that have caught the attention of academics, regulators and companies [2]. Among the benefits there is a decrease in assembly time, in the number of workers required, in the space used for production, in the cost of machinery, in energy consumption and CO_2 emissions. [7]

To ensure the effective implementation of SPS. [5] proposed three problems that should be studied: 1) determine the correct moment to implement this new production system, 2) determine a suitable allocation plan of workers and products and 3) develop a practical production planning system. This study focuses on the production planning in a SPS through the assignment of workers-serus, batches-Serus and workers-tasks. The problem considers heterogeneous workers, that is, they are trained to perform a specific set of tasks. Additionally, it considers the proficiency of each worker to perform a particular task. According to[5] the aforementioned allocation problem can be associated with a traditional allocation problem with two levels, the first level being the allocation of workers to Serus and the second level being the allocation of products to Serus. These levels generate an additional worker-task assignment problem.

The characteristics of the SPS allow it to respond quickly to the fluctuating demand of Industry 4.0. This is defined as a type of manufacturing cell differentiated by two main characteristics, it is reconfigurable and includes additional operations to the production of the product such as packaging and quality processes. Its use is justified by three global advantages: increased productivity, quality and flexibility. Additionally, this system provides a *trade off* between efficiency (lean manufacturing) and responsiveness (agile manufacturing). [4].

In recent years, multiple investigations have been carried out on the Seru production system given its results in real cases of the Japanese technology industry. [2] proposed a bi-objective mathematical to minimize CO_2 emissions from production considering the energy consumption to produce a unit of a product and decrease the makespan. Additionally, they create a NSGA-II based algorithm to solve larger instances. On the other hand, [10] simultaneously addressed minimizing the total cost of production and energy consumption in an assembly line. Additionally, it considered the skills set of each of the workers to make a more efficient assignment. For small instances, they presented the mathematical formulation in order to generate an optimal pareto frontier through the ε contraint method. They also design three metaheuristic solutions using an NSGA-II, MOSA (multi-objective simulated annealing) and a PT-EC SFR

(processing time and energy consumption sorted-first rule).
Additionally, because this Japanese production system recognizes workforce as the main resource [8], researchers have shown interest in the heterogeneity of workers to carry out the allocation problem. [1] proposed a mathematical model that balances the production time between Serus (inter-Seru) and between workers (intra-Seru) considering the heterogeneity and proficiency of each worker. Using the weighted sum method, they give equal weight to both objective functions of the exact model. For larger instances they used a NSGA-II based algorithm. [11] have investigated the problem of assigning and training workers. To do this, they proposed a multi-objective mathematical model that aims to minimize the total cost composed of the cost of training and the cost of balancing the processing times of the workers of the same Seru. Additionally, they design a two-phase heuristic called the SAIG algorithm, based on the concepts of the SA (simulated annealing) metaheuristics and the IG (iterated greedy) algorithms. [12] investigated the same problem and presented the same objective functions, under a scenario where an assembly line is reconfigured into multiple Serus. To solve the assignment problems between task-worker and worker-Seru, they developed a three-stage heuristic algorithm. [13], proposed a bi-objective mathematical model that minimizes the makespan and the workload imbalance considering workers transfering between Serus. Additionally, created a NSGA-II based algorithm given the non-polynomial (NP-hard) nature of the worker assignment problem.

2 Problem Description

The production planning problem is established in a Seru production system considering heterogeneous workers. To generate a solution, the batches size must be determined for each type of product, the allocation of batches and workers to the serus and the assignment of tasks to workers according to their skills and proficiency. To carry out the assignment, it must be considered that each worker is trained to carry out a set of tasks $subS \subseteq S$. Additionally, each worker has a proficiency that determines their ability to perform a specific task. Each of the products has a deterministic demand that must be satisfied. To do so, it is possible to distribute the demand of a specific product in as many batches as serus exist, allowing a flexible allocation.

3 Mathematical formulation

3.1 Model assumptions

As assumptions of the model, we have: **1.** The demand for the products is known and deterministic. **2.** The available time of each worker is known. **3.** All products can be produced in any seru. **4.** The upper bound of workers in a seru is known. **5.** The task processing time of each product is known and deterministic. **6.** Workers can only perform tasks of their skills set. **7.** The workers' proficiency

is constant. The learning curve is not considered. **8.** workers transfer between serus is not allowed. **9.** Batch transfer between serus is not allowed. **10.** Only one worker can be assigned to perform a batch's task. **11.** Each worker of a Seru must perform at least one task from each batch assigned to the same seru. **12.** The travel time of workers between one workstation to another is negligible. **13.** The reconfiguration cost of the serus is negligible. **13.** The electrical power $[kW]$ of the machines used to perform the tasks is constant and known.

3.2 Notation

To solve small instances, the following mathematical formulation is presented. The formulation presented by [1] was taken as a basis to solve the production planning problem. They proposed a bi-objective model that aims to balance production time between workers and between serus. In the formulation presented in its model, the batches size of each type of product is known, unlike the mathematical formulation of this study where a variable is modeled to determine the batches size in order to allow a better balance of production time. Additionally, the product demand as allowed to be produced in all the available serus. Additionally, the model presented by [2] was considered to model the calculation of energy consumption depending on the machine used for each task and the time of use of this.

Sets The following sets are defined: C: set of serus $\{1, ..., n_C\}$, B: set of batches $\{1, ..., n_B\}$, S: set of tasks $\{1, ..., n_S\}$, textbf P: set of products $\{1, ..., n_P\}$, W: set of workers $\{1, ..., n_W\}$.

Parameters To model the proficiency of each worker w to perform a task s, the parameter $f_{w,s}$ is considered. Being $t_{p,s}$ the time required to carry out a task s of a type of product p in minutes, those workers with a proficiency lower than 1 finish the task in less time with respect to the standard time $t_{p,s}$. On the contrary, if the proficiency of a worker is greater than 1, it indicates that he is slower to perform the task, taking a longer time with respect to the standard time $t_{p,s}$.

To calculate the energy consumption of performing a task s of a product p by a worker w, the parameters pot_s, $t_{p,s}$ are required and $f_{w,s}$. The first parameter (pot_s) refers to the electrical power in kilowatts [kW] of the machine with which the task s is carried out. The multiplication of the standard time required to perform a task $t_{p,s}$, the proficiency of the worker who performs the task $f_{w,s}$ and the electrical power of the machine used to perform it pot_s, allows to obtain the energy consumption of performing the task s in kilowatts per minute $[kW * min]$. Additionally, the parameter ζ indicates the CO_2 emission factor $[gCO_2/kWmin]$. This allows determining the CO_2 emissions generated in production from energy consumption.

d_p, M, N, G, E are also defined. The first refers to the demand of a product p, the second and third, represent the upper bound of workers assigned to a

seru and of tasks assigned to a worker in a batch. Additionally, the parameter G represents the total available time of each worker in minutes and the parameter E is the upper bound of grams of CO_2 generated in production.

Finally, three binary parameters are defined. $x_{b,p}$ indicates whether batch b belongs to product p; $y_{p,s}$ represents if the task s is required by the product p; finally, the parameter $e_{w,s}$ indicates whether the worker w is trained to do the task s.

Decision variables The binary variable $l_{b,c}$ is defined, which indicates whether the batch b is assigned to the seru c. The binary variable $a_{w,c}$ takes the value of 1 if worker w is assigned to seru c. The binary variable $z_{w,b,s}$, represents whether the worker w performs the task s of batch b. Additionally, the binary variable ex_b indicates whether batch b is used or not in production. Finally, the variable q_b represents the batch size of b.

The proposed optimization model has two objective functions. The first objective function (FO_1) aims to balance the production times between workers and between serus. The second objective function (FO_2) aims to minimize the total energy consumption of production. The first objective function is composed of two parts: the inter-Seru balance (between Serus) and the intra-Seru balance (between workers). Equations (1) and (2) represent the variances of the production times of serus and workers, respectively. The FO_1 is formulated as the sum of these variances (3). Next, the mathematical formulation of the model is presented.

$$WO_1 = \frac{1}{C}\sum_{c=1}^{C}\left[\sum_{w=1}^{W}\sum_{b=1}^{B}\sum_{p=1}^{P}\sum_{s=1}^{S} x_{b,p}y_{p,s}e_{w,c}l_{b,c}a_{w,c}z_{w,b,s}q_b t_{p,s}f_{w,s} - \frac{1}{C}\sum_{c=1}^{C}\sum_{w=1}^{W}\sum_{b=1}^{B}\sum_{p=1}^{P}\sum_{s=1}^{S} x_{b,p}y_{p,s}e_{w,c}l_{b,c}a_{w,c}z_{w,b,s}q_b t_{p,s}f_{w,s}\right]^2 \quad (1)$$

$$WO_2 = \frac{1}{W}\sum_{W=1}^{w}\left[\sum_{c=1}^{C}\sum_{b=1}^{B}\sum_{p=1}^{P}\sum_{s=1}^{S} x_{b,p}y_{p,s}e_{w,c}l_{b,c}a_{w,c}z_{w,b,s}q_b t_{p,s}f_{w,s} - \frac{1}{W}\sum_{w=1}^{W}\sum_{c=1}^{C}\sum_{b=1}^{B}\sum_{p=1}^{P}\sum_{s=1}^{S} x_{b,p}y_{p,s}e_{w,c}l_{b,c}a_{w,c}z_{w,b,s}q_b t_{p,s}f_{w,s}\right]^2 \quad (2)$$

Minimize

$$FO_1 = WO_1 + WO_2 \quad (3)$$

$$FO_2 = \sum_{c=1}^{C}\sum_{b=1}^{B}\sum_{p=1}^{P}\sum_{s=1}^{S}\sum_{w=1}^{W} x_{b,p}y_{p,s}e_{w,c}l_{b,c}a_{w,c}z_{w,b,s}q_b t_{p,s}f_{w,s}pot_s \quad (4)$$

Subject to,

$$\sum_{c=1}^{C} l_{b,c} = ex_b \quad \forall \quad b \in B \tag{5}$$

$$\sum_{c=1}^{C} a_{w,c} = 1 \quad \forall \quad w \in W \tag{6}$$

$$z_{w,b,s} \leq e_{w,s} \quad \forall \quad w \in W, b \in B, s \in S \tag{7}$$

$$\sum_{w=1}^{W} z_{w,b,s} = \sum_{p=1}^{P} x_{b,p} y_{p,s} ex_b \quad \forall \quad b \in B, s \in S \tag{8}$$

$$\sum_{c=1}^{C} a_{w,c} \leq N \quad \forall \quad c \in C \tag{9}$$

$$\sum_{s=1}^{S} z_{w,b,s} \leq M \quad \forall \quad b \in B, w \in W \tag{10}$$

$$\sum_{w=1}^{W} a_{w,c} e_{w,c} \geq \sum_{p=1}^{P} l_{b,c} x_{b,p} y_{p,s} \quad \forall \quad c \in C, s \in S, b \in B \tag{11}$$

$$z_{w,b,s} \leq \sum_{c=1}^{C} l_{b,c} a_{w,c} \quad \forall \quad w \in W, b \in B, s \in S \tag{12}$$

$$\sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} z_{w,b,s} \geq \sum_{c=1}^{C} l_{b,c} a_{w,c} \quad \forall \quad b \in B, w \in W \tag{13}$$

$$\sum_{b=1}^{B} q_b x_{b,p} \geq d_p \quad \forall \quad p \in P \tag{14}$$

$$ex_b \sum_{p=1}^{P} d_p x_{b,p} \geq q_b \quad \forall \quad b \in B \tag{15}$$

$$ex_b \leq q_b \quad \forall \quad b \in B \tag{16}$$

$$\sum_{c=1}^{C} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} e_{w,c} l_{b,c} a_{w,c} z_{w,b,s} q_b t_{p,s} f_{w,s} \leq G \quad \forall \quad w \in W \tag{17}$$

$$\sum_{c=1}^{C} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} \sum_{w=1}^{W} x_{b,p} y_{p,s} e_{w,c} l_{b,c} a_{w,c} z_{w,b,s} q_b t_{p,s} f_{w,s} pot_s \zeta \leq E \tag{18}$$

$$\begin{gathered} l_{b,c}, a_{w,c}, z_{w,b,s} \in \{0,1\}, \\ q_b \in z^+ \end{gathered} \tag{19}$$

As mentioned before, from equations (1) and (2) the FO_1 is modeled as the sum of the variances of the production times of the serus and of the workers (3). It should be clarified that the model assumes that a product cannot be processed in the next workstation until it is completely processed in the immediately preceding workstation. With respect to the FO_2, the total energy consumption in production is obtained from the product between the total time required to perform a task and the power in kilowatts of the machine used to carry out that task (4). The result of this objective function is the energy consumption measured in $kilowatts * minute$.

The model restrictions are found in equations (5) - (19). The first restriction (5) ensures that each batch is assigned to a single seru. Similarly, constraint (6) ensures that each worker is assigned to only one seru. The third restriction guarantees that a task is performed only by workers that are trained to perform the task (7). Constraint (8) ensures that each task in each batch can only be performed by one worker, as long as the batch size is greater than zero. Restriction (9) limits the number of workers in each seru to N and restriction (10) limits the number of tasks assigned to a worker in a batch to M. Restriction (11) guarantees that for each task in a batch assigned to a seru there is at least one worker trained to carry out that task in the same seru. Restriction (12) prohibits a task from being performed by a worker that is not in the same seru as the batch that requires that task. Restrictions (11) and (12) prevent movement of batches and workers between serus. Restriction (13) ensures that all workers perform at least one task from each batch assigned to the same seru. Constraint (14) ensures that the demand for each product is satisfied. Constraints (15) and (16) model the relationship between the variables ex_b and q_b. The restriction (17) ensures that the total time used by a worker in production does not exceed its available time and the restriction (18) guarantees that the upper bound of grams of CO_2 generated in production is not exceeded.

The model presented is not linear given that there are multiplication of variables in the restrictions and in the objective functions. To obtain a linear model, the auxiliary variables $D_{c,b,w} = l_{b,c} \cdot a_{w,c}$, $H_{c,b,w,s} = D_{c,b,w} \cdot z_{w,b,s}$ and $R_{c,b,w,s} = H_{c,b,w} \cdot q_b$ are created. $D_{c,b,w}$ and $H_{c,b,w,s}$ are binary variables since they result from the multiplication of binary variables. The variable $R_{c,b,w,s}$ belongs to the set of positive integers including zero. To model these auxiliary variables the following restrictions are added to the model:

$D_{c,b,w}$ linearization:

$$D_{c,b,w} \leq l_{b,c} \forall c, b, w \tag{20}$$

$$D_{c,b,w} \leq a_{w,c} \forall c, b, w \tag{21}$$

$$D_{c,b,w} \geq l_{b,c} + a_{w,c} - 1 \forall c, b, w \tag{22}$$

$H_{c,b,w,s}$ linearization:

$$H_{c,b,w,s} \leq D_{c,b,w} \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{23}$$

$$H_{c,b,w,s} \leq z_{w,b,s} \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{24}$$

$$H_{c,b,w,s} \geq D_{c,b,w} + z_{w,b,s} - 1 \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{25}$$

$R_{c,b,w,s}$ linearization:

$$R_{c,b,w,s} \geq q_b - (1 - H_{c,b,w,s}) \sum_{p=1}^{P} d_p x_{b,p} \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{26}$$

$$R_{c,b,w,s} \leq q_b \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{27}$$

$$R_{c,b,w,s} \leq H_{c,b,w,s} \sum_{p=1}^{P} d_p x_{b,p} \quad \forall \quad c \in C, b \in B, w \in W, s \in S \tag{28}$$

The above restrictions are added to the model and the auxiliary variables are replaced in equations (12), (13), (17) and (18). To linearize the model, it must also be considered that FO_1 has quadratic terms. According to [6] the minimization of the sum of squares contained in the variance of production times between serus and between workers, can approximate the difference between the maximum and the minimum time of production of serus and workers, respectively. However, the maximum and minimum functions are not linear. To linearize them, four additional variables are created each with an associated restriction that forces them to take the maximum or minimum value of the inter-seru or intra-seru production time. In equations (29 - 32) the new variables of the model are defined. These constraints and auxiliary variables must also be added to the model. All these new auxiliar variables are continuous and non-negative.

$$I \geq \sum_{w=1}^{W} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} e_{w,c} R_{c,b,w,s} t_{p,s} f_{w,s} \quad \forall \quad c \in C \tag{29}$$

$$J \leq \sum_{w=1}^{W} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} e_{w,c} R_{c,b,w,s} t_{p,s} f_{w,s} \quad \forall \quad c \in C \tag{30}$$

$$K \geq \sum_{c=1}^{C} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} e_{w,c} R_{c,b,w,s} t_{p,s} f_{w,s} \quad \forall \quad w \in W \tag{31}$$

$$U \leq \sum_{c=1}^{C} \sum_{b=1}^{B} \sum_{p=1}^{P} \sum_{s=1}^{S} x_{b,p} y_{p,s} e_{w,c} R_{c,b,w,s} t_{p,s} f_{w,s} \quad \forall \quad w \in W \tag{32}$$

Replacing the new variables I, J, K and U in the equations WO_1 and WO_2 we get:

$$WO_1 = \frac{1}{C}(I - J) \qquad (33) \qquad\qquad WO_2 = \frac{1}{W}(K - U) \qquad (34)$$

4 NSGA-II based algorithm

The following is the NSGA-II based genetic algorithm developed to solve large instances of the production planning problem. To create the structure of the chromosomes, the encoding presented by [1] was taken from the layers whose alleles represent the decision variables $l_{b,c}$, $a_{w,c}$ and $z_{w,b,s}$, this means, the second and third layer.

4.1 Encoding

Each chromosome is made up of three layers. Said layers are made up of alleles that represent the values of the decision variables presented in the mathematical formulation of the problem. The alleles in the first layer represent the value of the decision variable q_b. Let n_C be the number of serus available in production, n_P the number of types of product demanded and n_B the number of batches available, the length of the first layer is $L_1 = n_C * n_P = n_B$. This structure allows each product to be distributed in as many batches as Serus are available. The parameter $x_{b,p}$ defined above, determines the type of product for each batch. In order to guarantee compliance with the demand for each type of product, the sum of the batch sizes of a type of product must be equal to the value of its demand. The batch size is allowed to be zero, therefore, the binary decision variable ex_b will also take this value.

The second layer of the chromosome determines the assignment of batches and workers to the serus. The alleles of this layer can take values that are within the set of serus ($C = 1, \ldots, n_C$). Consequently, alleles allow setting the values of the decision variables $l_{b,c}$ and $a_{w,c}$. This layer is made up of two lists. The length of the first list is n_B and the length of the second list is n_W, that is, the number of available workers. Thus, the second layer has a length $L_2 = n_B + n_W$. The positions of the genes in each list make it possible to identify which batch or worker is being referred to and the allele value of each gene determines the seru to which the corresponding batch or worker was assigned. In the case in which a batch is assigned a value of zero units in the first layer ($q_b = 0$), the position of that batch in the first list of the second layer will have an allele with the value 'None'. In order to generate better solutions, it is guaranteed that each seru has at least one worker and one assigned batch. This is achieved by assigning each allele with each Seru to a gene on the first and second lists of the second layer of the chromosome. Batches and workers that have not been assigned are randomly assigned to any Seru.

The last layer of the chromosome allows to determine the value of the decision variable $z_{w,b,s}$. This layer is made up of as many lists as batches. Each of the lists represent a batch ($B = 1, \ldots, n_B$). A list has as many genes as tasks required by the corresponding batch. Thus, with S_b being the number of tasks in a batch b,

the length of the third layer is $\sum_{b=1}^{B} S_b$. The position of each gene within a list represents a task from that batch. The allele of each gene determines the worker ($W = \{1, \ldots, n_W\}$) who will perform the task. In the case in which a batch is assigned a value of zero units in the first layer of the chromosome ($q_b = 0$), the list corresponding to that batch will be empty in the third layer. For the worker-task assignment, it must be ensured that if a worker is to perform the task of a batch, they must be trained to perform it. Additionally, it must be in the same seru of the batch with the task that was assigned to it.

4.2 Feasibility correction

Once the initial population is created, infeasible chromosomes may appear that violate some of the constraints of the linear model. One of the infeasibility may be due to some tasks not being assigned. This infeasibility refers to the alleles of the third layer that take values of 'None'. This happens when there is no competent worker to perform a specific task in a seru. To correct this infeasibility, two scenarios are considered. In the first scenario, the infeasible batch is the only one in the seru. In this case, workers from other serus skilled to perform the problematic task and if they are not the only workers from their Serus , should be selected. When one is randomly selected the second and third layer are modified. In the second case, the infeasible task does not belong to the only batch in the seru. In this scenario, the infeasibility is resolved by sending the problematic batch to another Seru where the assigned workers can execute the task.
Another infeasibility is that the maximum limit of workers per seru is exceeded. Again, two particular cases are conceived to correct this infeasibility. In the first case, the Seru that exceeds the maximum number of workers has a worker who is not assigned to any task in the seru. In this case, the serus that could receive an additional worker without becoming infeasible must be identified and the worker assigned to one of them randomly. The second case considers redundant workers that could be sent to another Seru without affecting the third layer. Redundant workers are those workers whose useful skills in the Seru are contained in the skills of the other workers of the same Seru. Once a redundant worker is sent to a Seru that can receive an additional worker, the second and third layers must be updated.
Additionally, it is not allowed for a worker to be assigned more than M tasks from the same batch. This infeasibility is prevented in the creation of the third layer of the chromosome when, when identifying the competent workers to perform a specific task, the number of times that the alleles of the batch have taken the value of that worker in the third layer is counted. If the worker is trained to do the task but has already been assigned M times to tasks of that batch, it is not taken into account to be assigned to more tasks of the same batch.
Finally, it may be occur that a worker assigned to a Seru is not assigned to any task from each batch of the Seru. To avoid this infeasibility, the creation of the third layer seeks to balance the load of workers so that if several workers are competent to carry out a task, the one who has assigned, so far, the least amount of tasks in the batch is selected. . Even with this balancing, it is possible to obtain

chromosomes that present this infeasibility. This is corrected by assigning the infeasible worker a task of another worker from the same Seru in which he is competent, provided that this is not the other worker's only task.

4.3 Fitness y penalty function

Fitness is calculated from the objective functions presented in the mathematical formulation and two penalty functions. The first step to obtain fitness is to determine the values of the decision variables according to the values that the alleles of the chromosome have taken in each layer. Subsequently, it is possible to obtain the value of the objective functions.

Now, there are still some infeasible chromosomes even after correcting the infeasibilities mentioned above. This is because the mathematical formulation contains two complex constraints that involve the relationship between all the decision variables. These correspond to the restriction that establishes the maximum working time per worker, and the restriction that limits the CO_2 emissions generated in production. Those chromosomes that violate any of these restrictions will be subjected to both penalty functions. This prevents the illegal chromosomes from being selected to pass to the next generation, therefore, it is also not possible that they have intercrossing for the generation of descendants. The penalty functions used for the fitness calculation are created from the penalty function proposed by [14]. and adapted by [1]. Given a chromosome i of the population P_t we have:

Δv_1(i) = constraint violation value (17) for chromosome i.
Δv_2(i) = constraint violation value (18) for chromosome i.
k = parameter that determines the severity of the penalty function.
G = maximum time available per worker.
ε = positive number tending to zero.
E = maximum CO_2 emissions allowed in total production.
Δv_1max = value of the maximum violation of constraint (17) in P_t.
Δv_2max = value of the maximum violation of the constraint (18) in P_t.

From the previous parameters it is possible to construct the penalty functions associated with the restriction (17) and (18) respectively:

$$penalFit1(i) = 1 + \left(\frac{\Delta v_1(i)}{\Delta v_1 max}\right)^k$$
$$\Delta v_1(i) = max\{0,\ g(i) - G\}$$
$$\Delta v_1 max = max\{\varepsilon,\ \Delta v_1(i) \mid i \in P_t\}$$

$$penalFit2(i) = 1 + \left(\frac{\Delta v_2(i)}{\Delta v_2 max}\right)^k$$
$$\Delta v_2(i) = max\{0,\ e(i) - E\}$$
$$\Delta v_2 max = max\{\varepsilon,\ \Delta v_2(i) \mid i \in P_t\}$$

The term $\Delta v_1(i)$ of the penalty function associated with restriction (17) must be calculated as $max\{0, g(i)-G\}$, where $g(i)$ is the total violation of chromosome

i, calculated as the sum of the chromosome workers violation times. Similarly, the term $e(i)$ of the penalty function associated with restriction (18) determines the CO_2 emissions of chromosome i in addition to those allowed (E).

Finally, we obtain the objective functions adjusted by the penalty functions. In order to prevent an illegal chromosome from being part of the pareto frontier, each objective function is multiplied by both penalty functions. Thus, if a chromosome violates the maximum time available per worker but does not exceed the maximum CO_2 emissions, both target functions will be penalized.

$$FO_1Pen(i) = FO_1 * penalFit1(i) * penalFit2(i)$$
$$FO_2Pen(i) = FO_2 * penalFit1(i) * penalFit2(i)$$

4.4 Crossover

To generate the crossover, only the first layer of the chromosome is considered. The above, taking into account that successive layers are built from this layer. For the interbreeding, the parents who have had a better performance in the selection tournament are selected. To generate the crossover, a random number must be selected among the types of product demanded ($P = 1, \ldots, n_P$). Subsequently, the batches of the randomly selected product must be exchanged between the parents. In this way, the distribution of the batches of the other products is maintained. Finally, the second and third layers of the descendants are generated from the result of the first layer.

4.5 Mutation

The mutation only applies to the first layer of the chromosome. A random number must be selected among the types of product demanded ($P = 1, \ldots, n_P$). Subsequently, the batch size of the selected product type must be recalculated. Once the mutation is made, the second and third layers are updated and the infeasibilities that occur in the chromosome are corrected. The mutation rate (p_m) must be very low in order to maintain elitism in the solutions.

4.6 Replacement

Once the genetic operators have been defined, the iterations of the metaheuristics begin. The first iteration differs from the following and must start with the random creation of a starting population $P(0)$ of desired size $nPob$. Population initiation is carried out as previously described. Then, the selection tournament is carried out among the individuals of the initial population, obtaining the non-dominance rank and the distance to the crowd of each chromosome. This allows you to sort individuals according to their fitness and the density of nearby solutions. In this first iteration, all the individuals of the initial population go to the next generation $P(t + 1)$. To double the size of the population, the chromosomes arranged according to the selection tournament are crossed, giving rise to two descendants, in this way a population of descendants of size $nPob$ called

$Q(t)$ is created. The individuals of this last set are subjected to mutation with a probability p_m. Finally, a population of size $2nPob$ is obtained by the union $P(t) + Q(t)$.

For the following iterations, the procedure shown in algorithm is followed. The population $R(t)$ of size $2nPob$ is submitted to the selection tournament, obtaining 1) the non-dominance ranges and 2) the distance from the crowd of each individual. The individuals are selected according to the selection tournament to pass to the next generation P(t+1) of size $nPob$. This is done by prioritizing chromosomes with a lower non-dominance rank. If when adding all the individuals of a particular front the size $nPob$ is exceeded, priority is given to the chromosomes of the front that have a greater distance from the crowd. This population $P(t + 1)$ is crossed to obtain the population $Q(t)$ of size $nPob$. The population $Q(t)$ is mutated to add variability. Finally, the population $R(t)$ of size $2nPob$ is obtained and it is iterated again until the maximum number of generations is reached.

5 Analysis of results

In order to calculate the efficiency of the proposed metaheuristic algorithm, a small instance is solved with the exact method and the NSGA-II, thus obtaining two comparable pareto frontiers. For the creation of the instance, the following specifications are taken into account:**1.** The number of serus and number of workers is 2. **2.** The number of batches is 4. **3.** The number of tasks / skills is 5. **4.** The demand for each of the products follows a distribution $U(10, 70)$. **5.** The processing time of the tasks follows a $U(10, 70)$ distribution. **6.** The proficiency obeys a distribution $U(0.90, 1.10)$ **7.** The maximum number of workers per seru and tasks per worker is 3. **8 .** The size of the skill set per worker is a random integer between [3,5].

Figure 1 shows the solutions found through the NSGA-II. Additionally, it is possible to determine each one of the fronts obtained in the final generation. The approximate pareto frontier is the one generated by the solutions of the first non-dominated front, that is, those solutions that have a non-dominance rank equal to zero. To run the NSGA-II, the following parameters were taken into account: **1.** Mutation rate $(p_m) = 0.025$ **2.** Population size $(nPob) = 60$ **3.** Maximum generation $(maxGen) = 90$ textbf 4. Penalty coefficient $(k) = 2$.

Through the ε - constraint method proposed by [9], the pareto frontier of the multi-objective linear optimization model is generated. Next is presented the optimal pareto frontier obtained through the multi-objective linear optimization model and the approximate pareto frontier obtained when selecting the solutions of the first non-dominated frontier of the maximum generation of the NSGA-II. Finally, to obtain a notion of the efficiency of the metaheuristic and the proposed encoding, the comparison of both borders is made by calculating the areas under the curve of each of the borders, setting the minimum and maximum value on the x axis (dotted lines). With the results of the areas, the proportion of the

area of each method is calculated by making 15 runs of the algorithm to obtain more reliable measurements. An average gap value of 2,773 % is determined.

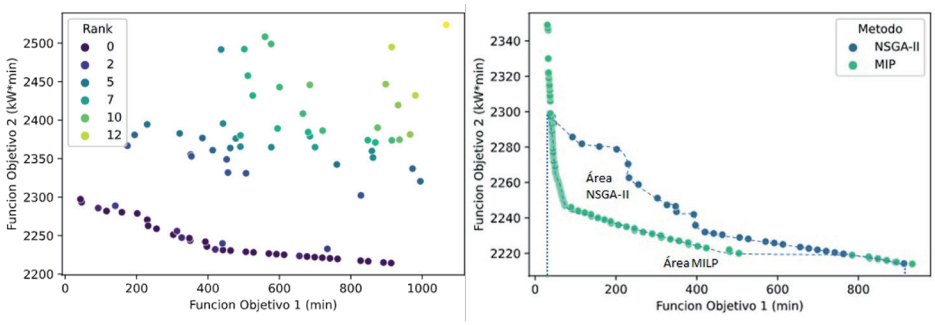

Fig. 1. Comparación frontera NSGA-II y MILP

6 Conclusions and future work

With the accelerated increase in CO_2 emissions into the atmosphere and global connectivity that boosts demand, the seru production system could be the answer to maintain competitiveness given its economic and environmental benefits and its flexibility in the face of unexpected changes in demand. The concept of heterogeneous workers makes it easy to reconfigure the system in the face of unexpected changes in the production environment.

It is evident that the variables q_b and ex_b of the exact model allow greater flexibility to carry out the assignment of batches, workers and tasks since it is possible to produce a fraction of the demand for a type of product in each of the available serus. The algorithm based on NSGA-II demonstrates a good solution regarding the optimal boundary generated with the MILP, allowing to find good solutions to the production planning problem in a reasonable computational time.

For future studies, it is proposed to identify in which other industries, apart from the tech inustry, the seru production system could be adapted and simulate it in a real case of the to quantify its benefits. Additionally, a more accurate study of the production time of a batch must be carried out, considering the WIP. On the other hand, given that the seru production system focuses on workforce, it is proposed to introduce qualitative measures such as the learning curve, teamwork and autonomy to determine how the performance of the system could be improved and what configurations of seru should be used in specific production environments.

Abstract. En toda planta de producción, un aspecto clave que debe ser considerado es el análisis integral de las máquinas, ya que estas tienen un impacto en la producción. Además, es sabido que existe una demanda creciente de los productos y un constante avance tecnológico del sector industrial. En este contexto, se pretende contribuir con una metodología que facilite la planificación del mantenimiento de las máquinas, a fin de mejorar la producción. Así, el objetivo principal del trabajo es la priorización de máquinas que componen una línea de envasado de latas de cerveza, considerando sus atributos, un registro de fallas y el cálculo de producción que se ha perdido. Se ha realizado una recolección de datos basado en las fallas de las máquinas, para luego realizar una investigación descriptiva, de naturaleza empírica y documental, sustentada en fuentes primarias y secundarias donde se estudiaron casos de eventos de seguridad y calidad, que han ocurrido en plantas similares de la misma empresa. Los resultados obtenidos muestran que es posible definir un listado de priorización de máquinas en función a una evaluación en el que se ha utilizado múltiples criterios, mediante la herramienta de decisión denominada Proceso Analítico Jerárquico (AHP). Asimismo, se han realizado simulaciones de fallas no programadas de las máquinas y finalmente, un análisis de sensibilidad de las decisiones tomadas, de tal manera a observar la robustez de los mismos. Con esto, se buscar brindar una herramienta de decisión con el fin de mejorar la gestión de mantenimiento de la empresa.

Keywords: Máquinas, Línea de Producción, Proceso Analítico Jerárquico (AHP), Toma de decisión, Criterios de evaluación.

1 Introducción

En Paraguay, las quince actividades económicas principales del sector industrial absorben el 79,1% del total de ingresos y concentran el 22,5% del total de unidades económicas. La actividad económica con mayores ingresos por el suministro de bie-

nes y servicios, es la dedicada a la generación, transmisión y distribución de energía eléctrica con el 25,8% del total de ingresos de las unidades económicas del país, seguida del procesamiento y conservación de carne con el 15,3%, luego la elaboración de productos del tabaco con el 5,0%, posteriormente la elaboración de otros productos alimenticios con el 4,2%, y finalmente, en el ranking de las cinco primeras actividades económicas, se encuentra la elaboración de bebidas alcohólicas con el 3,2% [1].

En este contexto, en cuanto a la industria cervecera del país, la compañía Cervecería Paraguaya S.A. (CERVEPAR), es una de las más representativas, la misma sigue apostando al desarrollo de la industria local, a través de inversiones que tendrían un alto impacto en la economía local. Esto no sólo sería en beneficio de la cadena de valor de la industria, sino en la percepción de los demás actores económicos [2]. Cabe resaltar que, en los últimos 5 años, Cervepar realizó inversiones por más de USD 175 millones en el país. El aporte tributario de la compañía en los últimos 5 años alcanza la suma de USD 320 millones. La comercialización de los productos de la compañía genera un movimiento comercial de USD 591 millones, esto representa el 1,6% sobre el PIB, y el 5% del sector terciario [3].

Por lo tanto, mencionada la importancia de dicha compañía para el país, el presente trabajo se ha enfocado a la industria cervecera, donde se ha analizado el sector de envasado de cervezas de dicha compañía. Ésta investigación tiene como principal misión brindar una herramienta de toma de decisión a los ingenieros encargados de la planificación del mantenimiento de la línea de producción, buscando una mayor confiabilidad en los planes de mantenimiento de las distintas máquinas que componen una línea de envasado. Con esto, se pretende mejorar las funciones del personal de la línea, y tener un adecuado control de la producción, considerando la priorización de las máquinas y con esto, realizar intervenciones estratégicas.

Para llevar a cabo el trabajo, se han realizado simulaciones de paradas no programadas, éste utiliza un esquema automatizado de la línea de producción, de tal forma a extraer del mismo, informaciones de producción (tiempo de paradas, motivos y cálculo de producción perdida). Dichas informaciones fueron registradas en una bitácora de eventos, donde los datos y registros de producción fueron utilizados para el análisis de la priorización de las máquinas. Además, han sido analizados datos estadísticos relevantes de las máquinas como, por ejemplo: datos de eventos de seguridad y calidad ocurridos en plantas de producción similares, en los últimos dos años.

2 Proceso de toma de decisión

En el área de toma de decisiones, la toma de decisión multicriterio es tal vez, una de las técnicas más utilizadas, la misma se denomina *Analytic Hierarchy Process* (AHP). El Proceso Analítico Jerárquico fue desarrollado durante los años setenta, por el matemático Thomas Saaty, buscando el desarrollo de una herramienta sistemática para la determinación de un ranking de alternativas que tenga un fundamento matemático sólido y que sea simple en su aplicación [4]. Esta metodología es utilizada para resolver problemas complejos que utilizan múltiples criterios de evaluación, donde es necesario que quien analiza el problema otorgue un nivel de preferencia subjetiva res-

pecto a la importancia de cada criterio y que posteriormente especifique una preferencia de cada alternativa en función a cada criterio, utilizando una escala.

El AHP ayuda a determinar escalas relativas utilizando una ponderación de datos de una escala estandarizada, realizando una operación aritmética posterior en tales escalas. Por lo tanto, las ponderaciones se dan en forma de comparaciones por pares. Para ello, se asume de que existen varios criterios, cuyos pesos son respectivamente conocidos. En el proceso se determina una matriz de relación por pares, cuyas filas dan las relaciones de pesos de cada criterio con respecto a todos los demás.

Primeramente, es necesario conformar un árbol jerárquico de decisión, para ello es necesario conocer el objetivo del problema abordado, para luego establecer los criterios a ser evaluados y las alternativas a ser consideradas como comparables en el proceso de toma de decisión. La distribución de dicho árbol puede tener tantos niveles como sea necesario, en el nivel superior se encuentra el objetivo principal a lograr, en los niveles intermedios se encuentran los criterios de evaluación y en los niveles inferiores se localizan las alternativas a ser consideradas como comparables [5].

El segundo paso consiste en la ponderación obtenida de la comparación por pares. Los elementos del segundo nivel están dispuestos en una matriz y las ponderaciones de los criterios, son realizadas con relación al objetivo principal. Generalmente, la metodología utiliza una ponderación con valores de una escala, de 1 al 9, como se describe en [4]. Luego de conformar la matriz de comparaciones pareadas de los criterios, se puede obtener el vector resultante de dichas ponderaciones. Este vector se estima a través del autovector de la matriz.

El tercer paso consiste en la comparación por pares de los elementos en el nivel más bajo, es decir, las alternativas son comparadas con respecto a cada criterio de evaluación. En esta parte se evalúan las ponderaciones de cada alternativa con respecto a cada criterio, según [6]. Finalmente, se multiplica la matriz resultante de la ponderación de cada criterio por el vector resultante de la ponderación de cada alternativa en función de cada criterio, y este producto da como resultado un vector columna que representa la ponderación global de las distintas alternativas, en función de todos los criterios analizados.

La herramienta de decisión AHP ha sido utilizada en diferentes casos de estudio, con el objetivo de resolver diversos tipos de problemas, algunos de ellos son: [7] – [16]. Por lo tanto, el AHP es una metodología que permite evaluar las alternativas que se plantean a la hora de tomar una decisión.

3 Metodología propuesta

3.1 Contexto actual de Cervepar

Actualmente, la compañía CERVEPAR, fundada en el año 1910, se ha convertido en la mayor planta industrial de bebidas del Paraguay. La misma cuenta con seis líneas de producción en el sector de envasado, dotando a la planta de una capacidad de envasado de 1.000.000 de litros de cerveza por día. Sin embargo, con el paso del tiempo y el avance tecnológico, es de esperarse que surjan nuevos problemas que deben ser solucionados. Se ha evidenciado la necesidad de automatizar procesos en el área de

envasado, para de esta manera mejorar el nivel de productividad de las líneas. Considerando esta situación, en una de las líneas de producción dedicada al envasado de latas, se ha comprobado que, al momento de producirse una parada no programada, la recolección de datos del evento ocurrido representa un problema importante, ya que, al producirse la parada, un operador necesariamente debe recorrer toda la línea para identificar el problema, y en base a observaciones directas, determinar el motivo de la parada y el tiempo de duración. Este procedimiento posibilita la existencia de errores humanos, lo que genera inconvenientes a la hora de realizar un análisis post-falla, aumentando la dificultad de tener una visibilidad clara acerca de la eficiencia productiva de cada máquina.

En ese sentido, el presente trabajo tiene por objeto proponer una metodología de decisión, el cual implica un esquema de automatización y simulación para el proceso de recolección de datos de paradas no programadas. Con esto, sería posible tener una mayor confiabilidad en el cálculo de la eficiencia de producción, sin intervención manual en el registro. La aplicación de conocimientos de automatización de procesos ayudaría a ahorrar tiempo en el momento de categorizar las distintas máquinas y a evidenciar los problemas que puedan surgir, al ocurrir cualquier tipo de evento. Asimismo, la aplicación de este esquema permitiría cuantificar el volumen de producción que se ha perdido al ocurrir una falla, teniendo en cuenta el tiempo de parada de la máquina y finalmente, traducir esos datos en términos de costos. Con esto, se pretende dar una visibilidad diferente a los problemas analizados y permitir al equipo de trabajo enfocarse en los puntos críticos, buscando mejorar el uso de recursos necesarios para el mantenimiento de la línea.

3.2 Criterios de evaluación

El AHP es una metodología utilizada para resolver problemas de decisión, en el que se consideran indicadores cuantitativos y cualitativos. Para dicha resolución se utilizan múltiples criterios de evaluación, donde es necesario que el tomador de decisiones otorgue un peso o preferencia al momento de realizar las comparaciones pareadas. Esta decisión debe ser subjetiva y se basa en una escala de preferencias, esta escala se denomina escala de Saaty [4]. El proceso de decisión se ha realizado dándole un peso a cada alternativa (máquina), en función a tres criterios de evaluación definidos, estos se han determinado de acuerdo a la experiencia de los decisores, para finalmente conformar una matriz de priorización de máquinas. En la Fig. 1, se puede ver el árbol jerárquico de decisión utilizado en el proceso de toma de decisión. Posteriormente, se describen los criterios de evaluación utilizados en el análisis.

Impacto Económico: para este criterio se evalúa el impacto de una parada de máquina, para ello se realizaron simulaciones de paradas habituales en cada una de las máquinas que componen la línea de envasado, con el fin de cuantificar el volumen perdido de producción en cada parada. Una vez cuantificado y obtenido los datos del volumen perdido, el mismo es valorizado según históricos de costos de producción [15], para luego utilizarlo como dato de entrada al modelo de toma de decisión, y así obtener el vector propio de este criterio.

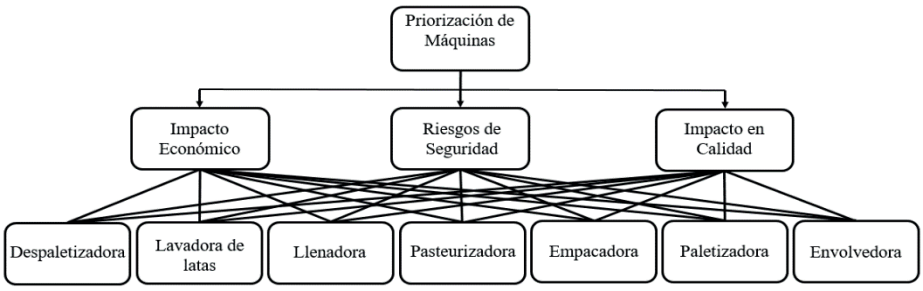

Fig. 1. Árbol jerárquico de decisión (Fuente: Elaboración propia)

Riesgos de Seguridad: para este criterio se tuvo en cuenta la seguridad, considerando qué tan crítica es una intervención de mantenimiento en cada una de las máquinas de la línea. Para ello, se han utilizado como datos de entrada al modelo de decisión, la base de datos de antecedentes históricos de eventos ocurridos en plantas similares; dichos eventos ocurrieron en el periodo 2016 - 2018 [17], [18]. Finalmente, con esto se pudo calcular el vector propio de este criterio.

Impacto en Calidad: para este criterio se consideró el impacto de la calidad del producto terminado, considerando la falla que se tuvo en el proceso de los productos. Para esto, se ha considerado como datos para el modelo de decisión, la cantidad de incidentes de calidad relacionados a las fallas de cada una de las máquinas durante el periodo 2016 - 2018 [17], [18]. Así, con esto se pudo hallar el vector propio de este criterio.

3.3 Alternativas

Las alternativas consideradas comparables para el análisis de este trabajo se pueden observar en el último nivel de la Fig. 1, dichas alternativas son máquinas que se encuentran en operación en una línea de envasado de latas de la compañía Cervepar. Las alternativas analizadas son las siguientes máquinas: Despaletizadora, Lavadora de latas, Llenadora, Pasteurizadora, Empacadora, Paletizadora y Envolvedora.

4 Caso de estudio

4.1 Simulaciones

Para llevar a cabo las simulaciones de la línea de envasado, se ha recurrido al lenguaje de programación © Python, además, como software de simulación se ha utilizado VirtualBox de © 2020 Oracle, ambos programas en sus versiones gratuitas.

La línea de envasado de latas utilizada como caso de estudio pertenece a una línea de producción de la empresa Cervepar, ésta consta básicamente de siete partes llamadas islas automáticas, unidas entre sí por medio de cintas transportadoras. Cada isla es controlada por un PLC, el cual mediante una programación almacenada dentro del mismo realiza procesos de maniobra, control, señalización, temporización, etc.

La función de conteo es realizada a través de sensores de cada máquina, donde se van adquiriendo datos de los conteos de producción y el estado propio de la máquina. Los datos de los sensores se parametrizan como entradas digitales dentro del PLC de las máquinas. Las siete islas automáticas ya fueron mencionadas, ellas son: Despaletizadora, Lavadora de latas, Llenadora, Pasteurizadora, Empacadora, Paletizadora y Envolvedora.

El simulador es una herramienta de gestión que facilita al operador la interpretación de los datos referente a la producción obtenida en un periodo de 24 horas. Facilita la observación de los eventos que pudieran darse relacionados a la eficiencia de la máquina, con el fin de generar soluciones en tiempo real, adecuadas a situaciones específicas en el caso de fallas, lo cual posibilita mejorar la producción y el trabajo del personal. En la Fig. 2 se puede observar una visualización general del simulador de línea.

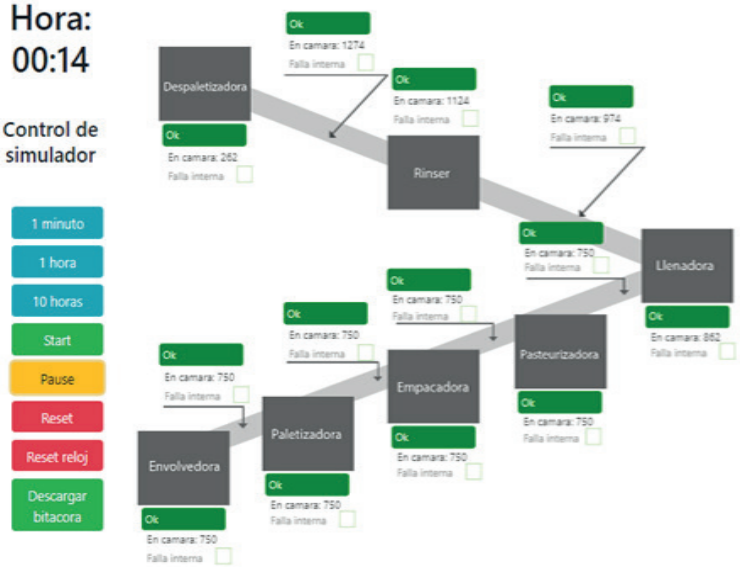

Fig. 2. Simulador de línea de envasado (Fuente: Elaboración propia)

Cada máquina tiene programada una cantidad de modos de falla. Cabe resaltar que existe un modo de falla común, tanto para las cintas transportadores como para las máquinas, llamada falta de alimentación. Esta falla se da cuando se tiene faltante de producto o acumulación del mismo. Cada máquina posee una interfaz del simulador, que contempla un botón llamado falla interna. Dicha opción ofrece la posibilidad de acceder al informe de las fallas, la cual es visualizada a través de una bitácora de eventos, y ésta contempla la cantidad de latas no producidas durante la parada.

4.2 Descripción de las funciones del simulador

El simulador desarrollado cuenta con las siguientes funcionalidades:
- Permite tener un control del tiempo de simulación de la producción en un periodo de 24 horas, de modo a tener un registro de los eventos ocurridos.

- Cuenta con un panel de botones de comando, donde el operador puede iniciar la simulación, pausarla, resetearla o adelantarla.
- Cuenta con una representación en forma de bloques de la línea de producción, donde se detalla el estado de cada máquina y transportes que componen la misma, pudiéndose ver el status de cada máquina.
- Despliega una lista de fallas típicas de cada máquina.
- Dispone de una bitácora de eventos donde se registran las paradas.

4.3 Concepto de ¨V¨ de línea

Se ha considerado este concepto para la realización de las simulaciones, el mismo se basa en el balance de línea. Dicho balance se considera al funcionamiento adecuado de cada una de las máquinas que conforman la línea, vinculada directamente a la configuración de las velocidades y ubicación de cada una de ellas. El balance es indispensable para asegurar el funcionamiento ideal de la línea de producción, lo cual asegura la producción adecuada de la misma, teniendo en cuenta la configuración previamente establecida. En el caso de la línea de latas, la misma está compuesta por siete máquinas que poseen ciertos parámetros de velocidad (dichos parámetros son configurados en consenso con el encargado del diseño del proyecto y el proveedor de la línea).

Este concepto, básicamente expresa que el balance de línea debe darse con distintas velocidades, dependiendo de la ubicación y función que tenga la máquina en la línea de producción. Sin este concepto, el diseño de una línea de producción no puede llevarse a cabo. En este caso, las máquinas presentan las siguientes velocidades:

- Despaletizadora: 135% de la velocidad nominal
- Lavadora de latas: 125% de la velocidad nominal
- Llenadora: 100% de la velocidad nominal
- Pasteurizadora: 115% de la velocidad nominal
- Empacadora: 120% de la velocidad nominal
- Paletizadora: 125% de la velocidad nominal
- Envolvedora: 135% de la velocidad nominal

Por concepto, la máquina que define la velocidad nominal de una línea, es la Llenadora, ya que es la encargada de llenar con cerveza el recipiente y es directamente cuantificable como producto terminado cuando pasa por la misma. Es así, como cada máquina debe ser ajustada para que el balance de línea ocurra. Como se ha dicho, las máquinas que anteceden y suceden a la Llenadora son más veloces, debido a que, por la separación de las cintas transportadoras, ellas deben de compensar esa separación con velocidad superior, de modo a no tener paradas por alimentación o acumulación del producto. Por último, el espacio entre máquinas representa a las cintas transportadoras en una línea de producción. Si bien no tienen una velocidad propia, son dependientes de las velocidades y rendimientos en régimen normal de las máquinas que le suceden o anteceden. Las mismas actúan de “pulmones”, debido a que pueden contener una cierta cantidad de producto y en el caso de que alguna máquina sufra una falla o parada menor, la eficiencia y rendimiento de la línea de producción no se ve afectada, siendo el ejemplo ideal de la aplicación del concepto de “V” de línea.

4.4 Aplicación de la técnica del AHP

Esta investigación analiza un caso de estudio que supone las alternativas anteriormente mencionadas, bajo los criterios de evaluación citados, estructurados de forma fundamental en el árbol jerárquico. El objetivo principal del trabajo es el de determinar la priorización de las máquinas que componen una línea de envasado. Para ello, es utilizado la metodología Proceso Analítico Jerárquico (AHP).

4.5 Resultados de los Criterios de evaluación vs Alternativas

Impacto Económico: con el fin de cuantificar este criterio, se han realizado simulaciones de parada de máquinas, de manera a responder a la pregunta: ¿Cuál es el valor de la producción que se ha perdido en una parada de una hora de duración? Una vez conocidos los valores de producción perdido, a cada máquina se le asigna un peso según la escala de Saaty. En este trabajo se han considerado paradas de una hora para todas las máquinas, obteniéndose los siguientes resultados de la Tabla 1.

Tabla 1. Latas no llenadas por máquina.

Alternativas	Latas no llenadas	Precio unitario	Total Gs.
Despaletizadora	43500	1240	53.929.444
Lavadora de latas	42250	1240	54.859.262
Llenadora	45000	1240	55.789.080
Pasteurizadora	39000	1240	48.350.536
Empacadora	18750	1240	23.245.450
Paletizadora	12750	1240	15.806.906
Envolvedora	12000	1240	14.877.088

Teniendo en cuenta datos históricos, el costo de producción promedio de una lata se puede valorar en Gs. 1.240 (Guaraní: Gs., moneda de curso legal del Paraguay). Con esta información es posible calcular el valor del producto no llenado, multiplicando el precio unitario por la cantidad de latas no llenadas, obteniendo así los resultados de la Tabla 1.

Para comparar todas las alternativas con respecto a cada uno de los criterios de evaluación, es necesario ponderar cada alternativa con un peso según la escala de Saaty. Para esta parte del proceso de decisión, se estableció un rango de pérdidas al que se le asignó una valoración de 1 al 5. Dichos rangos fueron calculados dividiendo en cinco partes iguales, el rango de montos definidos por el valor máximo y el valor mínimo obtenidos en las simulaciones, según se puede observar en la Tabla 2.

Tabla 2. Escala de ponderación de valores.

Valor mínimo	Valor máximo	Pesos para el AHP
14.877.088	23.059.486	1
23.059.486	31.241.885	2

31.241.885	39.424.283	3
39.424.283	47.606.682	4
47.606.682	55.789.080	5

Considerando dichos rangos de valores, a cada máquina se le asigna un puntaje en función a la producción que se ha perdido, esta valoración se puede ver en la Tabla 3.

Tabla 3. Valorización de la producción no llenada.

Alternativas	Latas no llenadas	Precio unitario	Total Gs.	Pesos para el AHP
Despaletizadora	43500	1240	53.929.444	5
Lavadora de latas	42250	1240	54.859.262	5
Llenadora	45000	1240	55.789.080	5
Pasteurizadora	39000	1240	48.350.536	5
Empacadora	18750	1240	23.245.450	2
Paletizadora	12750	1240	15.806.906	1
Envolvedora	12000	1240	14.877.088	1

Con estos resultados, se puede observar que se tienen cuatro máquinas con paradas extremadamente críticas desde el punto de vista económico. Dichas máquinas son las siguientes: i) Despaletizadora, ii) Lavadora de latas, iii) Llenadora y, iv) Pasteurizadora. Para este análisis, la Llenadora resulta ser la más crítica, esto resulta lógico ya que una parada en la misma representa automáticamente un producto no llenado.

Riesgos de Seguridad: para cuantificar este criterio, se han considerado los datos históricos de eventos de seguridad ocurridos en líneas de producción de envasado de latas en plantas similares a Cervepar, considerando eventos de seguridad durante el periodo 2016 - 2018. Por lo tanto, considerando dicho periodo y la cantidad de eventos relacionados a la seguridad, se pudo elaborar la siguiente Tabla 4. Asimismo, para poder comparar el impacto económico con el impacto de seguridad, es necesario llevar ambos datos a una misma unidad de medida, considerando la escala de Saaty definida anteriormente. Estos rangos de valores fueron calculados dividiendo en cinco partes iguales, el rango formado por el valor máximo y el valor mínimo de la cantidad de eventos de seguridad ocurridos. Considerando dichos eventos, cada máquina tiene un puntaje según se puede observar en la Tabla 4.

Tabla 4. Eventos de seguridad ocurridos.

Alternativas	Total de eventos	Pesos para el AHP
Despaletizadora	22	2
Lavadora de latas	5	1
Llenadora	79	5

Pasteurizadora	38	3
Empacadora	10	1
Paletizadora	44	3
Envolvedora	22	2

Con este resultado parcial, se puede notar que, desde el punto de vista de seguridad, se puede identificar una máquina como extremadamente crítica y dos máquinas como medianamente críticas, como sigue: i) Llenadora, ii) Pasteurizadora y, iii) Paletizadora.

Impacto en Calidad: para el análisis y cuantificación de este criterio, se ha considerado la cantidad de incidentes de calidad relacionados a las fallas de cada una de las máquinas, durante el periodo 2016 - 2018. Es importante tener en cuenta que, se define como incidente de calidad a todo evento de producción que genera un producto no conforme con su calidad y debe ser retenido para su posterior inspección. El resultado de esta inspección puede derivar en la liberación del producto o derrame del mismo, en caso de que no cumpla con los parámetros de calidad establecidos. Por lo tanto, para dicho periodo, los incidentes de calidad relacionados a las fallas en las máquinas son los que se observan en la Tabla 5.

Tabla 5. Número de incidentes de calidad.

Alternativas	Incidentes	Pesos para el AHP
Despaletizadora	10	1
Lavadora de latas	50	4
Llenadora	66	5
Pasteurizadora	28	5
Empacadora	28	2
Paletizadora	25	2
Envolvedora	10	1

De manera análoga, considerando la cantidad de eventos de calidad registrados y unificando las unidades de medida con relación a los otros dos criterios de evaluación, se tienen los puntajes para cada máquina, ver Tabla 5. De igual manera al criterio anterior, fueron calculados rangos de valores, dividiéndolos en cinco partes iguales, conformando así el valor máximo y el valor mínimo de la cantidad de incidentes de calidad. Luego, se puede observar que, desde el punto de vista de la calidad, se identificaron una máquina extremadamente crítica y otra crítica, ellas son: i) Llenadora y, ii) Pasteurizadora. Para este análisis, la Llenadora resulta ser la más crítica, ya que una falla en la misma compromete directamente la calidad del líquido envasado.

4.6 Resultados de los Criterios vs Criterios

Antes de poder definir cuál de las máquinas es la más crítica, en función a todos los criterios de evaluación, es necesario hacerse la pregunta: ¿son todos los criterios igualmente importantes? Para este trabajo se ha decidido dar un peso relativo a cada

criterio, partiendo de la base que siempre la seguridad del personal y la calidad del producto terminado deben ser más importantes (mayor preferencia del decisor), que una posible pérdida económica. Por lo tanto, se ha asignado un peso a cada criterio, donde los mismos fueron evaluados de par en par, siendo el resultado el de la Tabla 6.

Tabla 6. Comparación pareada de criterios.

	Económico	Seguridad	Calidad	Vector propio
Económico	1	1/5	1/2	0,13
Seguridad	5	1	2	0,59
Calidad	2	1/2	1	0,28
Total	8	1,7	3,5	1

Como se puede apreciar, cada criterio comparado contra otro tiene un peso diferente, por ejemplo, el criterio de seguridad es extremadamente preferente con relación al criterio económico, ya que la seguridad del personal debe prevalecer siempre, por lo que, en la casilla correspondiente, se pondera con 5. Dicha ponderación, directamente en su forma recíproca, da una valoración de 1/5, cuando se compara el criterio económico con el de seguridad.

Posteriormente, para poder definir cuál de los tres criterios es más importante es necesario normalizar la matriz y hallar el promedio ponderado. Para realizar la normalización de la matriz primeramente debemos obtener la suma de cada columna para así conocer el puntaje acumulado de cada criterio. Además, se ha calculado el promedio ponderado de cada fila, el resultado de esta operación indica el nivel de preferencia de cada criterio. Como se puede ver en la Tabla 6, el criterio con mayor preferencia es el de Seguridad, seguido de la Calidad y, por último, el criterio Económico.

5 RESULTADOS

Finalmente, los resultados de los pesos previos obtenidos son agrupados para conformar la matriz de ponderaciones de alternativas respecto a cada uno de los criterios de evaluación; esta matriz es multiplicada por la matriz de ponderaciones de los criterios en función al objetivo principal. El producto de ambas matrices nos da como resultado la matriz de ponderación global de todas las máquinas en función de todos los criterios y las alternativas analizadas. El resultado de dicha multiplicación matricial puede observarse en la Fig. 3.

$$\begin{bmatrix} 5 & 2 & 1 \\ 5 & 1 & 4 \\ 5 & 5 & 5 \\ 5 & 3 & 5 \\ 2 & 1 & 2 \\ 1 & 3 & 2 \\ 1 & 2 & 1 \end{bmatrix} \times \begin{bmatrix} 0{,}13 \\ 0{,}59 \\ 0{,}28 \end{bmatrix} = \begin{bmatrix} 2{,}11 \\ 2{,}34 \\ 5{,}00 \\ 3{,}81 \\ 1{,}41 \\ 2{,}47 \\ 1{,}59 \end{bmatrix}$$

Fig. 3. Ponderación global de las máquinas (Fuente: Elaboración propia)

Para este caso de estudio, según la figura anterior, las máquinas más críticas son como sigue: i) Llenadora, ii) Pasteurizadora, iii) Paletizadora y, por último, iv) Empaquetadora, con el menor nivel crítico. Por su parte, con relación a los criterios de evaluación, el más importante es el criterio vinculado a la seguridad de los empleados, ya que estos intervienen en las paradas de mantenimiento de las máquinas. En segundo lugar, se encuentra el criterio relacionado a la calidad del producto terminado. Finalmente, en último lugar se encuentra el criterio vinculado a las pérdidas económicas.

5.1 Análisis de sensibilidad

Este análisis se lleva a cabo con el fin de examinar el grado de sensibilidad de los resultados obtenidos al variar el peso de los criterios de evaluación. El objetivo de este análisis es el de confirmar que los resultados obtenidos son robustos y no son frutos del azar. Este proceso consiste en variar el peso de un solo criterio de evaluación con respecto a los otros. Además, se varía el peso de dos criterios de evaluación con respecto a los otros. Para realizar el análisis de sensibilidad se ha dado ponderaciones diferentes a los criterios con respecto a su estado inicial, de esta manera se busca responder a la pregunta de, ¿qué pasa sí? por ejemplo, para el caso del criterio Impacto Económico se le asigna un mayor peso con relación a los demás criterios.

Primeramente, para este análisis en particular, se ha asignado el mismo peso a todos los criterios de evaluación. Los resultados de priorización de las máquinas se pueden ver en la siguiente Tabla 7.

Tabla 7. Priorización de máquinas con pesos iguales de todos los criterios.

Alternativas	Priorización (%)
Despaletizadora	12,53
Lavadora de latas	15,57
Llenadora	25,08
Pasteurizadora	21,16
Empacadora	8,07
Paletizadora	10,60
Envolvedora	6,98
Total	100

En la tabla anterior se puede observar que la alternativa con mayor peso corresponde a la Llenadora. Luego, se realiza la variación de peso del criterio Impacto Económico (con asignación de peso con valor 3), con relación a los otros dos criterios. Los resultados de priorización se pueden observar en la siguiente Tabla 8.

Tabla 8. Priorización de máquinas con mayor peso del criterio Impacto Económico.

Alternativas	Priorización (%)
Despaletizadora	15,85

Lavadora de latas	17,68
Llenadora	23,38
Pasteurizadora	21,03
Empacadora	8,18
Paletizadora	8,03
Envolvedora	5,85
Total	100

En la tabla anterior se puede observar que la alternativa con mayor peso también corresponde a la Llenadora. Posteriormente, se realiza la variación del peso del criterio Riesgos de Seguridad (con asignación de peso con valor 3), dejando fijo los otros dos criterios. Los resultados de priorización se pueden ver en la siguiente Tabla 9.

Tabla 9. Priorización de máquinas con mayor peso del criterio Riesgos de Seguridad.

Alternativas	Priorización (%)
Despaletizadora	12,23
Lavadora de latas	11,70
Llenadora	26,81
Pasteurizadora	19,75
Empacadora	7,20
Paletizadora	13,42
Envolvedora	8,89
Total	100

En la tabla anterior se puede observar que la alternativa con mayor peso sigue siendo la Llenadora. Por último, para esta parte del análisis, se realiza la variación del peso del criterio Impacto en Calidad (con asignación de peso 3), con respecto a los otros dos criterios. Los resultados de priorización de máquinas, para esta variación, se pueden ver en la siguiente Tabla 10.

Tabla 10. Priorización de máquinas con mayor peso del criterio Impacto en Calidad.

Alternativas	Priorización (%)
Despaletizadora	9,52
Lavadora de latas	17,34
Llenadora	25,05
Pasteurizadora	22,70
Empacadora	8,84
Paletizadora	10,36
Envolvedora	6,19

Total	100

De igual manera que las dos variaciones anteriores, en la tabla anterior se puede notar que la alternativa que presenta mayor peso es el de la Llenadora.

Finalmente, se puede decir que los resultados obtenidos de este análisis de sensibilidad dan como alternativa prioritaria a la Llenadora, lo cual demuestra que no varía con respecto al análisis inicial de la metodología propuesta. Se puede dar una mejor apreciación a lo dicho anteriormente, en la Fig. 4, donde la Llenadora, en color verde, permanece con el mayor peso, seguido de la Pasteurizadora y la Paletizadora.

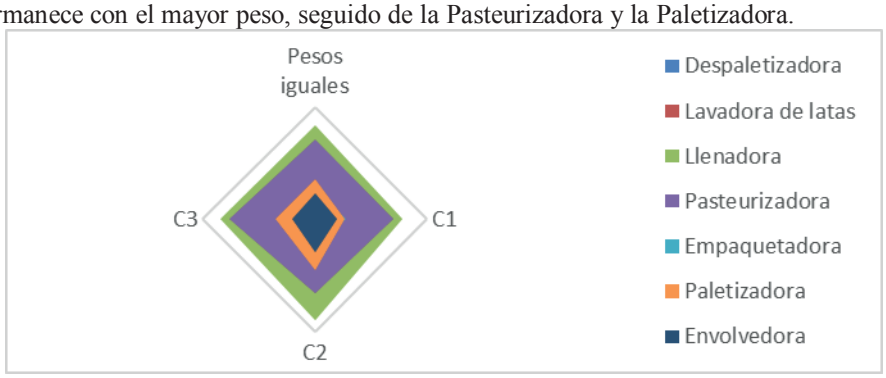

Fig. 4. Análisis de sensibilidad con variación de un criterio (Fuente: Elaboración propia)

Por último, cabe destacar que, realizando el mismo procedimiento en el marco del análisis de sensibilidad, pero con la variación de dos criterios de evaluación, se obtiene el siguiente comportamiento, demostrado por la Fig. 5, donde, de igual manera, el ranking de máquinas finalmente queda establecido por la Llenadora, Pasteurizadora y Paletizadora.

Fig. 5. Análisis de sensibilidad con variación de dos criterios (Fuente: Elaboración propia)

5.2 Conclusiones

La propuesta metodológica brinda una herramienta que primeramente obtiene información instantánea e histórica de producción de la línea, además identifica en cada etapa del proceso la velocidad de producción, la eficiencia y las fallas que ocasionan las paradas de máquinas indicando la causa.

El sistema detalla la estructura del sector de envasado de bebidas y permite conocer la ubicación y la descripción de las fallas en cada una de las islas, mediante los cuales, la solución y el seguimiento de los mismos se hacen más simples, para prevenir detenciones y mejorar el proceso de producción.

Al automatizarse la recolección de los datos de producción de la línea, se define un esquema de funcionamiento de controladores lógicos programables que permiten a los operadores evitar realizar los registros manualmente, pudiendo ellos dedicarse a otras tareas inherentes a la industria como la calibración, mantenimiento preventivo, entre otros.

La herramienta de simulación planteada es útil para categorizar a las máquinas en función a múltiples criterios, de manera a tener un mejor análisis y que sirva de información para el mantenimiento de las máquinas, la seguridad de los colaboradores y la calidad del producto terminado, creando una planificación estratégica para las inversiones e intervenciones futuras. Finalmente, se recomienda la adaptación de la presente propuesta metodológica a otras líneas de envasado.

Abstract. This article presents a proposal for the characterization of strategies that have the purpose of increasing the flexibility of production systems (and therefore their adaptability), this in the context of industry 4.0. For this, a bibliometric analysis was carried out (specifically a study of co-occurrences), from which the categories included in the proposal are defined, this seeks to provide a framework for the evaluation and analysis of flexibility strategies of productive systems within in industry 4.0. After executing the bibliometric analysis, the proposed categories are: flexibility objective, level in the process engineering, level in the manufacturing process, required technologies and links in the supply chain involved. Associated with these categories, also as a product of the bibliographic analysis, possible levels are proposed for the categories.

Keywords: Industry 4.0, flexibility, adaptability, strategies categorization, production systems

Resumen. Este artículo presenta una propuesta para la caracterización de estrategias que tienen el propósito de incrementar la flexibilidad de los sistemas productivos (y por ende su capacidad de adaptación), esto en el contexto de la industria 4.0. Para ello, se realizó un análisis bibliométrico (concretamente un estudio de coocurrencias), a partir del cual se definen las categorías que se incluyen en la propuesta la cual busca proporcionar un marco para la evaluación y análisis de estrategias de flexibilidad de los sistemas productivos dentro en la industria 4.0. Tras ejecutar el análisis bibliométrico, las categorías propuestas fueron: objetivo de flexibilidad, nivel en la ingeniería de procesos, nivel en el proceso de fabricación, tecnologías requeridas y eslabones de la cadena de suministro involucrados. Asociados a estas categorías, y también como producto del análisis bibliográfico, se plantean posibles niveles para las categorías.

Palabras clave: Industria 4.0, flexibilidad, adaptabilidad, estrategia de categorización, sistemas de producción.

1 Introducción

Las operaciones globales de fabricación actuales exigen requisitos cada vez más estrictos, tales como plazos más precisos, niveles de inventarios competitivos, gestión de demanda incierta, estandarización de procesos y diversidad de productos [1]. Esto redunda en constantes y nuevos desafíos para los sistemas de manufactura, pues se les imponen el mantenerse a la vanguardia en estrategias de gestión que articulen eficientemente en su quehacer los recientes desarrollos tecnológicos.

La Industria 4.0, en adelante I4.0, representa un cambio hacia procesos de fabricación interconectados donde las entidades individuales dentro de la cadena de suministro se comunican entre sí con el fin de lograr tanto, una mayor adaptabilidad y capacidad de respuesta en la fabricación, como una fabricación más eficiente en términos de reducción en el costo de producción [1].

Es relevante contar con referentes, que en el marco de la Industria 4.0, contribuyan a las organizaciones en la evaluación y selección de estrategias para mejorar la capacidad su adaptación; un insumo fundamental para los procesos de evaluación y selección es la caracterización. Este artículo busca, a partir de una revisión de la bibliografía, proponer un referente de caracterización de estrategias propuestas para incrementar la flexibilidad de los sistemas productivos en la I4.0

Para ello, iniciamos con el planteamiento de los referentes que dan soporte a la acción de caracterizar, posteriormente se describe y desarrolla la propuesta metodológica, se presentan los resultados (la propuesta de caracterización), y se da cierre con las conclusiones derivadas del proceso llevado a cabo.

2 Referentes

El objetivo de esta sección es brindar un marco para la caracterización de estrategias a partir de criterios (categorías), de clasificación; se define la teoría de la clasificación como los principios que rigen la organización de objetos en grupos según sus similitudes y diferencias o su relación con un conjunto de criterios [2]. En el transcurso de este apartado se presentan las bases que soportaron la elección de los criterios usados para caracterizar las estrategias que en el entorno de la I4.0 se plantean para favorecer la capacidad de respuesta de los sistemas de producción. En términos generales, los referentes considerados abarcan aspectos relacionados con los componentes de la I4.0, sus principios de diseño, las estrategias para incrementar la capacidad de respuesta de los sistemas de producción en la I4.0, y las relaciones entre la I4.0 con los sistemas de apoyo a lo toma de decisiones.

2.1 Componentes y principios de diseño de la Industria 4.0

En los últimos años se ha presentado un auge en el estudio de las posibilidades que ofrece para el sector de la manufactura la cuarta revolución industrial. Existen estudios del estado del arte [3–7], propuestas de modelos de gestión [8–13], así como estudios en los que se analiza la flexibilización de la manufactura a través de elementos de la industria 4.0 [3, 14–16]. Han surgido múltiples estrategias para llevar a la manufactura a un nivel superior en términos de su adaptabilidad y productividad; se menciona también la necesidad de la selección de las estrategias apropiadas para la transición a la industria 4.0 desde una perspectiva multidisciplinaria [17]. Este interés sostenido e incremental por este campo se ha venido consolidando desde principios de esta década, cuando en la feria de Hannover (Alemania) (salón de la tecnología), fue incursionado el término, tomando mayor relevancia desde 2013 cuando se presentó un informe oficial y detallado del concepto y sus perspectivas (para la industria alemana) [18], también en la feria de Hannover.

La principal diferencia de la industria 4.0, respecto a sus predecesoras es la interacción de agentes autónomos en estructuras descentralizadas que se conectan entre sí con centros de decisión [19]. Dentro de las tecnologías provistas por la I4.0 más relevantes a los procesos de toma de decisiones están: la computación en la nube (*Cloud Computing*); el internet de las cosas, IoT por sus siglas en inglés (*Internet of Things*); *Big Data* y conexiones RFID (*Radio-frequency identification*) [19–21]

Los Sistemas Ciber-Físicos (CPS, *Cyber-Physical Systems*) [1], entendidos como sistemas de entidades computacionales colaboradoras que están en conexión intensiva con el entorno físico circundante y sus procesos en curso [22], y que cuentan con capacidad autónoma de intercambiar información, desencadenar acciones y controlarse entre sí de forma independiente [18], han allanado el camino a la transición del control centralizado a las arquitecturas de control descentralizado en la fabricación [23].

Los Sistemas de Producción Ciber-Físicos (CPPS, *Cyber-Physical Production Systems*) hacen parte de los sistemas sobre los que se plantea el aprovechamiento de la industria 4.0 en el ámbito de los procesos de fabricación. Monostori [24] define los CPPS como un conjunto autónomo de elementos y subsistemas cooperantes interconectados de tal manera que se cubren todas las etapas del proceso de producción, desde la planta de manufactura hasta las redes logísticas.

Sobre los principios de diseño en la I4.0 se toma como referente en trabajo realizado por Hermann, M. Pentek, T., & Otto B., [25], los cuales fueron sintetizados la Fig. 1.

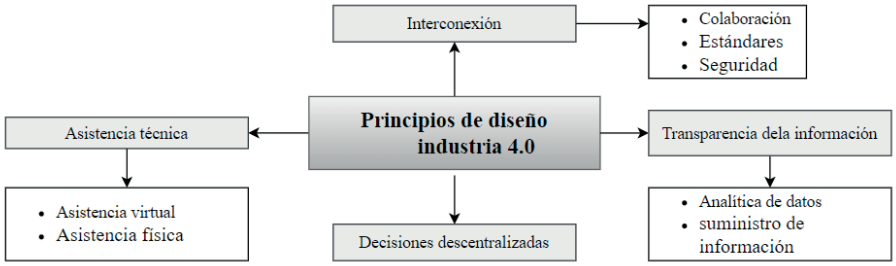

Fig. 1 Principios de diseño de la industria 4.0. Fuente: [25]

En el siguiente apartado se profundiza sobre la flexibilidad (que para el caso presenta un alto grado de sinonimia con el concepto de adaptabilidad y capacidad de respuesta), en el marco de la I4.0.

2.2 Flexibilidad de los sistemas de manufactura en la industria 4.0

En el diccionario de Cambridge se define flexibilidad como la capacidad de cambiar o ser cambiado fácilmente según la situación [26]; dentro de sus sinónimos se encuentran adaptabilidad y modificabilidad. El termino adaptabilidad está definido como la capacidad o la voluntad de cambiar para adaptarse a diferentes condiciones [27].

La necesidad que tienen los sistemas de producción de adaptarse a los requerimientos de mercados sin incurrir en costos excesivos ni gastar una cantidad excesiva de recursos [15], ha dado continua e incremental relevancia a aquellas estrategias que bajo conceptos y principios como flexibilidad, adaptabilidad, reconfigurabilidad, evolución de la arquitectura de control y toma de decisiones ágiles, propenden por mejorar en los sistemas de manufactura la capacidad de adaptación.

Se han estudiado aspectos como el balance entre la flexibilidad y la eficiencia y la importancia de tener entendimiento común en la I4.0 (grado semántico) entre las partes que intervienen [28]; se han investigado y evaluado diferentes formas de flexibilidad [15, 16, 29–31], se ha estudiado la adaptabilidad desde componentes o elementos de la I4.0 como el Cloud Computing, el IoT, Smart Factory [20, 32, 33].

2.3 Relaciones entre los sistemas de apoyo a la toma de decisiones y la industria 4.0

Los Sistemas de Soporte de Toma de Decisiones, DSS (*Decision Support Systems*), son modelos y aplicaciones informáticos para facilitar la toma de decisiones de negocio en la gestión, operaciones y planificación de las organizaciones [30] [34]. Uno de los beneficios de los CPPS, es la posibilidad de conectar directamente sensores y actuadores en la planta de producción con un sistema de toma de decisiones de alto nivel [19]. Esto permite proveer datos en tiempo real al DSS que permiten al sistema productivo reaccionar rápidamente ante eventos imprevistos [19].

Los desarrollos actuales y las tendencias futuras en DSS para la gestión de la manufactura y la cadena de abastecimiento se basan en los CPS [35, 36]. El rápido aumento de la analítica empresarial brinda oportunidades para la investigación de operaciones para resolver tanto problemas de optimización de alta complejidad y gran escala y / o incertidumbre y naturaleza estocástica, como problemas emergentes en la cadena de suministro y la gestión de operaciones [35].

3 Propuesta y desarrollo metodológico

Se llevó a cabo una revisión sistemática de la literatura con el objetivo de consolidar y analizar (desde el punto de vista bibliométrico), documentos presentes en la literatura científica (en general artículos y memorias de congresos), en los que se estudian, analizan o proponen estrategias para aprovechar las tecnologías de la I4.0 en la mejora de la adaptabilidad en los sistemas de fabricación. Lo anterior para proponer las categorías y los niveles bajo las que se podrían clasificar tales estrategias. Esto sirve como punto de partida para su posterior evaluación y favorecimiento de la toma de decisiones.
En este estudio primero se hace un análisis de coocurrencias, a partir del cual se identifican documentos relevantes en la literatura para el establecimiento de categorías a proponer.

3.1 Análisis bibliométrico

El análisis bibliométrico se desarrolló siguiendo las etapas sintetizadas en la Fig. 2, para esto se tomó como base lo presentado en la sección de referentes donde se encontraron algunos elementos comunes que dan insumos para esta revisión.

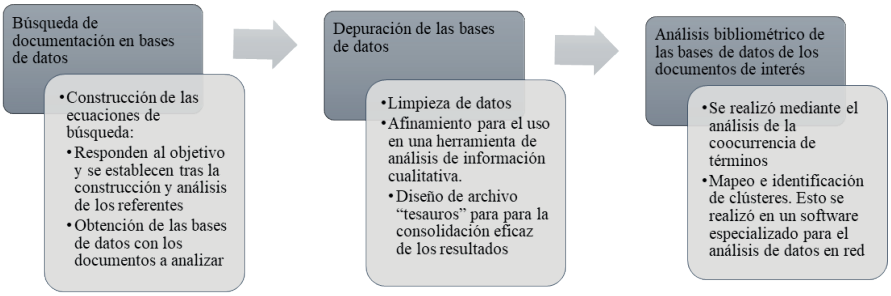

Fig. 2 Etapas del análisis bibliométrico

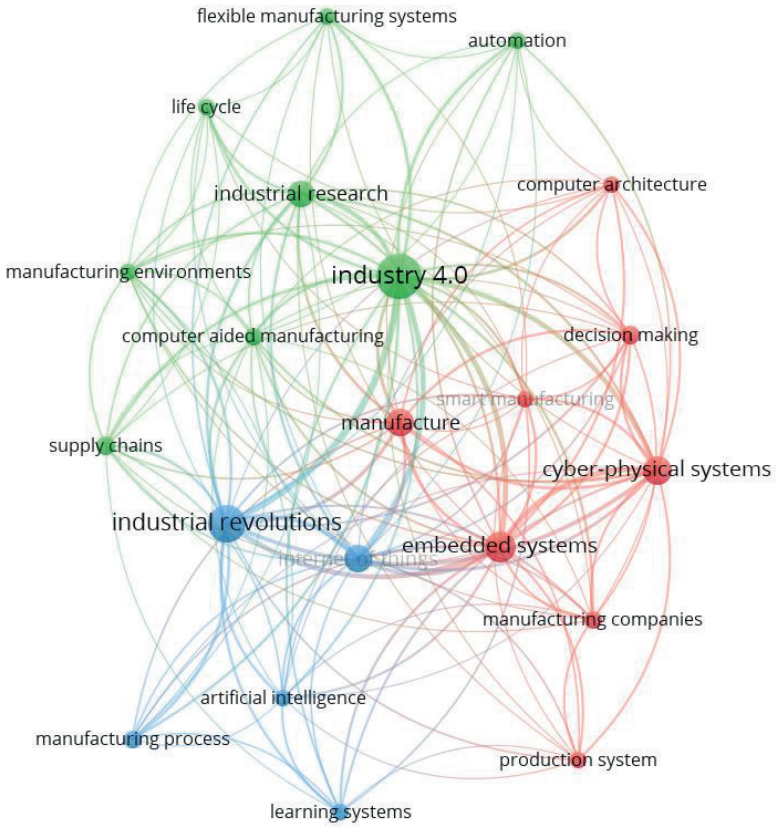
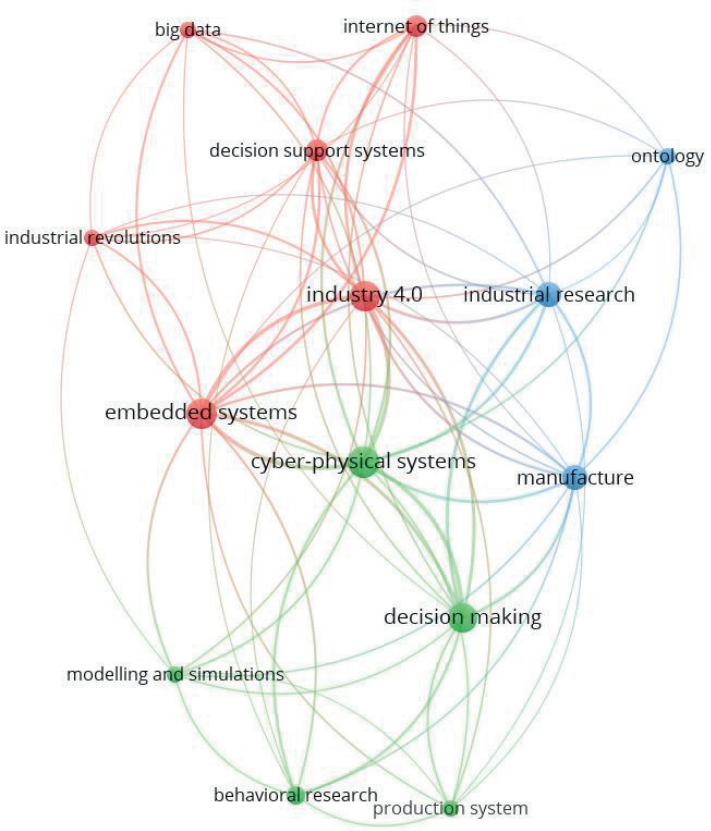


Búsqueda y depuración de documentos en bases de datos. La búsqueda se hizo en la base de datos SCOPUS. En la Tabla 1 se indican algunas de las ecuaciones de búsqueda usadas, en las observaciones se señalan los campos de búsqueda y cantidad de documentos obtenidos tras la depuración la información. Se presentan las ecuaciones

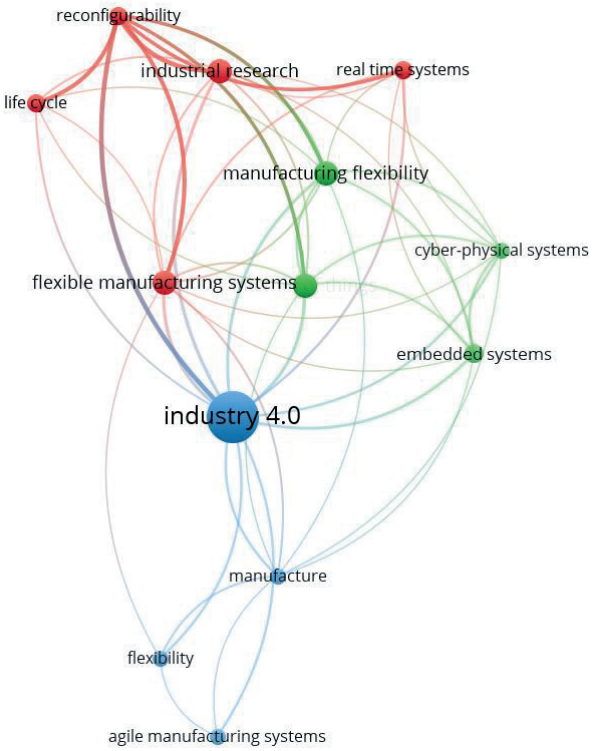
usadas más representativas tras un proceso de tamizaje y para la cuales se presentará el análisis de coocurrencias.

Tabla 1. Ecuaciones de búsqueda



No.	Ecuación de búsqueda	Observaciones
1.	(adaptability OR flexibility OR adaptive AND manufacturing OR reconfigurability OR reconfigurable) AND (manufacturing AND systems OR production AND systems) AND (industry 4.0 OR forth AND industrial AND revolution OR industrie 4.0)	Campos de búsqueda: título, resumen y palabras clave. Documentos encontrados 75
2.	(cyber-physical AND systems OR cyber-physical AND production AND systems) AND (manufacturing AND systems OR production AND systems) AND (industry 4.0 OR forth AND industrial AND revolution OR industrie 4.0) AND (decision AND support AND systems)	Campos de búsqueda: título y palabras clave Documentos encontrados 21
3.	(Industry 4.0 OR Industrie 4.0) AND (manufacturing systems OR Production systems) AND (adaptability OR flexibility OR Reconfigurability OR agility)	Campos de búsqueda: título y palabras clave Documentos encontrados 19

Análisis bibliométrico (análisis de coocurrencias). Se ejecutó un análisis de coocurrencia de términos en VOSViwer, mediante la generación de mapas (redes) de datos (palabras clave), con coocurrencia para los documentos analizados. Los resultados obtenidos se muestran en las figuras Fig. 3 a Fig. 5. En el pie de cada figura se indican los parámetros para la generación del mapa y la cantidad de enlaces resultantes.



Parámetros para la generación del mapa
Palabras clave: de autor ☐ de indexación ☐ todas ☒
Mínimo de coocurrencias: 5
Enlaces resultantes: 150

Fig. 3 Mapa de coocurrencias, ecuación de búsqueda 1

Parámetros para la generación del mapa
Palabras clave: de autor ☐ de indexación ☐ todas ☒
Mínimo de coocurrencias: 4
Enlaces resultantes: 71

Fig. 4 Mapa de coocurrencias, ecuación de búsqueda 2

Parámetros para la generación del mapa
Palabras clave: de autor ☐ de indexación ☐ todas ☒
Mínimo de coocurrencias: 3
Enlaces resultantes: 103

Fig. 5 Mapa de coocurrencias, ecuación de búsqueda 3

En síntesis, el análisis de coocurrencias nos da evidencias de las interrelaciones que existen entre los términos de búsqueda y la frecuencia con la que aparecen (en cada mapa el tamaño de los nodos está directamente relacionado con la cantidad de documentos que contienen en término en los campos de búsqueda indicados), los arcos se generan a partir del "mínimo de coocurrencias" que fue parametrizado, los colores ilustran la existencia de clústeres de documentos.

Análisis de documentos relevantes para el establecimiento de categorías. Tras revisar aquellos artículos en los que la coocurrencia de términos resultó más relevante para el cumplimiento de nuestro objetivo, y que nos permitieran establecer las categorías y niveles por proponer, se genera el resultado mostrada en la Tabla 2, donde se sintetizan las categorías propuestas y los niveles que podrían tomar acorde con la revisión bibliométrica realizada, en la columna de referente se indican las fuentes que soportan lo propuesto y que también sirven de referente para profundizar sobre los niveles planteados en cada categoría.

Tabla 2. Categorías propuestas y sus referentes

Categoría	Posibles niveles	Ref.
Objetivo de flexibilidad	Incrementar la agilidad	[18],[15]
	Compensar variabilidades temporales	[18]
	Hacer frente a riesgos de interrupción	[16]
	Hacer frente a riesgos de efecto dominó	[16], [39]
	Mejorar la sostenibilidad	[16], [38]
	Integrar proveedores	[16]
Nivel en la ingeniería del proceso	Diseño del producto	[18],[41]
	Planeación de la producción	[18],[42],[43]
	Planeación del servicio	[18]
Nivel en el proceso de manufactura	Gestión de manufactura	[50],[51],[52]
	Control de procesos	[48],[35],[43]
	Control de producción	[42],[48],[23],[49]
	Piso de planta	[44],[45],[46],[3],[47]
Tecnologías requeridas	IoT	[18],[21]
	IA	[18],[51],[54]
	Cloud Computing	[47],[8],[21], [54]
	RFID	[35],[21]
	Blockchain	[51],[35]
Eslabones de la cadena de abastecimiento involucrados	Proveedores	[39],[37]
	Fábrica	[39],[55],[56]
	Distribuidores	[39]
	Minoristas	[39]

A manera de ejemplo, la estrategia a seguir para definir la denominación de la categoría "objetivo de flexibilidad" así como sus niveles, fue el análisis de aquellos documentos en los que términos clave como "flexibilidad" se presentaban con mayor frecuencia, documentos que a su vez presentaban alta coocurrencia de términos con otros aspectos incluidos en la categorización (como tecnologías requeridas o eslabones de la cadena de abastecimiento involucrados). En particular para esta categoría (objetivo de flexibilidad) el estudio realizado por Ivanov, D., Das A., Choi T-M. [16], sobre los nuevos impulsores de flexibilidad para las operaciones de fabricación, cadena de suministro y servicios, tuvo especial relevancia. En este se mencionan los siguientes aspectos de interés para implementar estrategias de flexibilización: 1) riesgos de interrupción, resiliencia, redundancia y efecto dominó en la cadena de suministro, 2) digitalización, operaciones inteligentes y cadenas de suministro electrónicas, 3) sostenibilidad y capacidad de respuesta, y 4) integración de proveedores y flexibilidad de comportamiento [16]; igualmente plantean que dentro de los tópicos trabajados en los artículos que consideraron dentro de su estudio, están los siguientes: 1) flexibilidad de operaciones con la ayuda de nuevas tecnologías de la información, 2) cadenas de suministro y sistemas de fabricación reconfigurables, 3) flexibilidad de operacio-

nes y análisis de negocios, 4) flexibilidad de operaciones y fabricación aditiva 5) flexibilidad de operaciones y gestión esbelta 5) flexibilidad de operaciones y abastecimiento estratégico 7) flexibilidad, resiliencia y gestión de riesgos 8) flexibilidad en el servicio 9) flexibilidad de la cadena de suministro. Características que sirvieron de referentes para lo propuesto, de manera equivalente se fundamentan las otras categorías y niveles presentados en la en la Tabla 2, en la que como indicamos previamente se señalan los referentes considerados.

4 Conclusión

Partiendo de una revisión bibliométrica fue posible identificar un conjunto de categorías relacionadas con las estrategias que usando elementos de la industria 4.0, propender por mejorar la flexibilidad de los sistemas de producción, con lo que subsecuentemente se favorece el análisis, configuración y elección de estas en concordancia con los objetivos y recursos de una organización.

Abstract. El creciente desarrollo tecnológico y su uso constante a nivel mundial en todos los procesos industriales, ha permitido a las compañías mejorar en gran medida su eficiencia en todos sus procesos de producción. El mantenimiento industrial está involucrado directamente en estos cambios y debe responder con efectividad a los requerimientos que surgen en la implementación de la Industria 4.0 en las empresas. El mantenimiento puede aportar en gran medida a mejorar la eficiencia de la producción de las empresas, si se planifica y ejecuta aprovechando todos los beneficios de la tecnología en la actual era digital. La industria colombiana está en camino a ser más competitiva en varios sectores económicos. Por lo anterior es necesario identificar los factores más relevantes al momento de adoptar tecnologías de la industria 4.0 usadas en la gestión del mantenimiento que contribuyen en la mejora continua de los procesos industriales del país haciéndolos más eficientes. Esta investigación se centró en el estudio de la adaptación de estas tecnologías y se llevó a cabo mediante un estudio de carácter cualitativo que empleo un muestreo discriminado. Los datos objeto de análisis fueron adquiridos por medio de entrevistas semiestructuradas realizadas a expertos con gran experiencia en la gestión del mantenimiento en Colombia. Los resultados obtenidos destacan la importancia del talento humano y la cultura organizacional en la gestión del cambio en las empresas y como las tecnologías de la Industria 4.0 benefician la ejecución de las tareas de mantenimiento.

Keywords: Gestión del mantenimiento, Industria 4.0, Eficiencia organizacional, Toma de decisiones, cultura organizacional.

1 Introducción

El creciente desarrollo tecnológico y su uso constante a nivel mundial en todos los procesos industriales, ha permitido a las compañías mejorar en gran medida su eficiencia

en todos sus procesos de producción [1]. Esta eficiencia se genera gracias a los tiempos cortos de respuesta a la demanda que generan las actuales economías aceleradas del mundo [2]. El mantenimiento industrial está involucrado directamente en estos cambios y debe responder con efectividad los a requerimientos que surgen en la implementación de la Industria 4.0 en las empresas [3].

La Industria 4.0 encuentra su aplicación en mantenimiento en el diseño de sistemas de autoaprendizaje inteligentes que ayudan a predecir fallos, diagnosticar y activar los programas de mantenimiento [4]. Para extraer información específica y relevante, estos sistemas inteligentes son muy demandados por el acceso a los datos, por su calidad y también por el uso de múltiples fuentes de datos [5]. La Industria 4.0 promueve la conexión de elementos físicos como sensores, computadoras, dispositivos móviles entre otro por medio de Internet [6]. En el marco de la evolución industrial el mantenimiento ha dado respuesta a las necesidades que la producción masiva con altos estándares de calidad ha generado a lo largo del tiempo. Es por esto que frente a cada revolución que ha existido, el mantenimiento ha tenido las siguientes características que lo definieron [7] (ver fig. 1).

Para que un país como Colombia pueda seguir siendo competitivo frente a otros países latinoamericanos, es necesario identificar los factores más relevantes al momento de adoptar tecnologías de la industria 4.0 usadas en la gestión del mantenimiento que contribuyan en la mejora continua de los procesos industriales del país haciéndolos más eficientes. El mantenimiento puede aportar en gran medida a mejorar la eficiencia de la producción de las empresas, si se planifica y ejecuta aprovechando todos los beneficios de la tecnología en la actual era digital. El mantenimiento es de gran importancia en la industria, ya que es el encargado de mantener los activos de una empresa cumpliendo la función para la que fueron diseñados [8]. En Colombia la productividad de la industria se ve afectada en un 8.1% por la gestión del mantenimiento y las paradas no programadas [9].

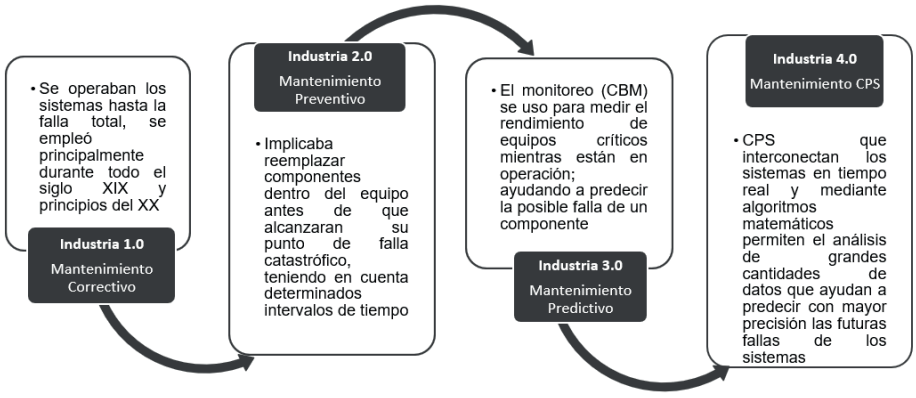

Fig. 1. Evolución del Mantenimiento en la Industria [7].

2 Tecnologías de la Industria 4.0 en el mantenimiento

Adaptar la Industria 4.0 en la gestión de mantenimiento lleva implícito el avance hacia la transformación digital, mediante el uso de las nuevas Tecnologías de la Información y la Comunicación (TIC) [10]. Esta adaptación permite la integración de los sistemas físicos con los virtuales, tales como: Internet de las Cosas (IoT), Big Data, Inteligencia Artificial (AI), Sistemas Ciber Físicos (CPS), ciberseguridad, entre otros [11]. La adaptación unida de estos sistemas contribuyen a la revolución del mantenimiento, pasando de una ejecución de mantenimientos correctivos [12] y preventivos [13], hacia la ejecución de un mantenimiento predictivo, a través de algoritmos diseñados que permiten autodiagnósticos y las auto reparaciones, basados en la información recopilada por medio de sensores en tiempo real, en escenarios que permiten almacenamiento masivo de datos para su análisis exhaustivo, permitiendo de esta manera predecir las futuras fallas en los sistemas.

2.1 Tecnologías de la Industria 4.0 en Colombia

Los empresarios colombianos cada vez más están adoptando estrategias para migrar sus negocios de un modelo tradicional a modelos fundamentalmente digitales y eso se evidencia en la cantidad de empresas que conocen que es la Industria 4.0. Para el año 2019 88,2 % de empresas en Colombia ya conocían la Industria 4.0, en comparación al 2016 donde tan solo el 43,7 % de las empresas tenían conocimiento sobre este tema (ver fig. 2) [14].

El mantenimiento representado en las paradas no programadas ocupa el cuarto lugar en la pérdida de productividad en la industria colombiana (ver fig.3) [5].

Las tecnologías asociadas la Industria 4.0 usadas en el mantenimiento, como los son el Internet de las cosas (IoT) han tenido un alto crecimiento, por lo anterior es necesario tomar decisiones en corto tiempo sobre la adaptación de estas tecnologías en el país. Para tomar decisiones primero se debe identificar en que escenarios de desarrollo se encuentra Colombia con respecto a estas tecnologías (ver fig. 4) [15].

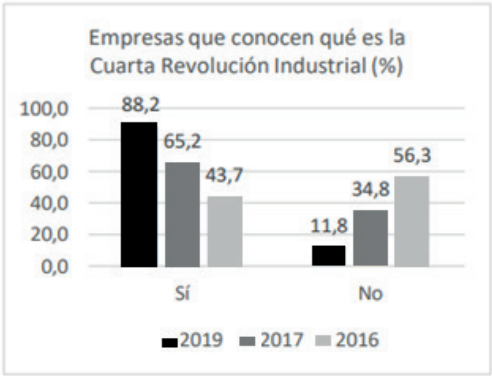

Fig. 2. Empresas que conocen qué es en la cuarta revolución industrial en Colombia [14].

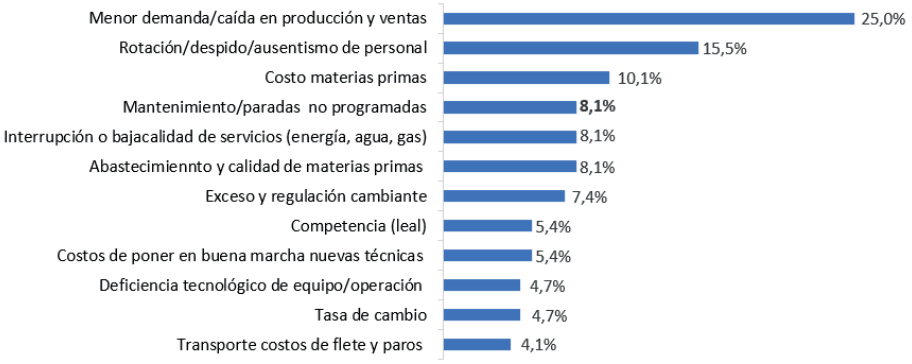

Fig. 3. Factores que han afectado negativamente la productividad en Colombia [5].

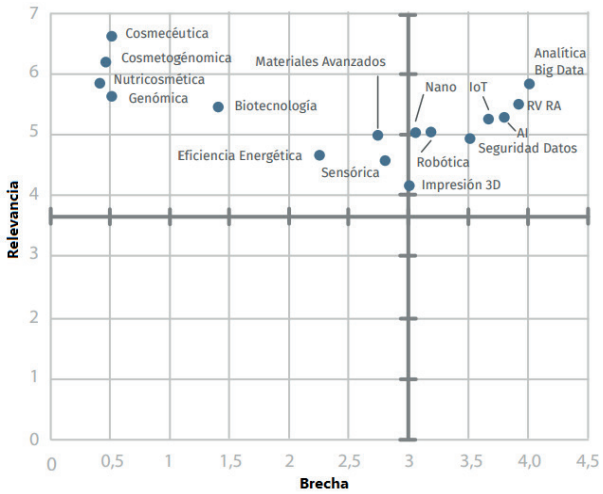

Fig. 4. Matriz de brecha frente a relevancia de las tecnologías en Colombia [15].

3 Metodología de Investigación.

Hay una carencia significativa de procesos de investigación empírica en el campo del mantenimiento. Así lo evidenciaron (Fraser, K. & *et al.* 2015) en [16] cuando revisaron la literatura y encontraron que, de varios miles de artículos sobre los conceptos de mantenimiento más comunes, una pequeña cantidad mostraban evidencia empírica del mundo real [3]. A pesar de ello existen algunas investigaciones empíricas de mantenimiento muy representativas, tales como (McKone, K. E., & *et al.*) en [17] que definieron un marco teórico de Mantenimiento Productivo Total (TPM). Y (Jonsson, P., 2000) en [18] teorizó sobre la importancia de la prevención, la integración del mantenimiento duro y la integración del mantenimiento blando, seguido de la vinculación de taxonomías empíricas de plantas con factores contextuales y diferenciales de rendimiento, por mencionar algunas.

El proceso de investigación del presente trabajo se diseñó como un estudio cualitativo. Este estudio puede ser definido como cualquier tipo de investigación que produce hallazgos a los que no se llega por medio de procedimientos estadísticos u otros medios de cuantificación. Bajo este enfoque pueden tratarse investigaciones sobre funcionamiento organizacional, movimientos sociales, fenómenos culturales o interacciones entre naciones. Tal es el caso del mantenimiento, como un proceso importante dentro de las industrias. En el desarrollo de esta investigación se reunieron datos por medio de entrevistas y observaciones con el propósito de descubrir conceptos y relaciones en los datos brutos y luego organizarlos en un esquema explicativo teórico [19].

Así mismo se hizo un muestreo de acontecimientos o sucesos representativos de conceptos teóricos pertinentes mediante entrevistas semi estructuradas. Luego estas entrevistas fueron comparadas en la búsqueda de propiedades y dimensiones, siempre considerando como un factor principal el rango o variación en la dimensión. Las personas y herramientas tecnológicas utilizadas en este proceso, proporcionaron los medios para obtener estos datos.

Esta investigación se centró en un muestreo discriminado que incluyo 20 sesiones con 8 investigadores y siete (7) entrevistas con expertos industriales que representaban a 6 empresas diferentes. Toda esta investigación se desarrolló en el marco de las medidas de distanciamiento social y el confinamiento en los hogares. Estas medidas han modificado las formas tradicionales que usamos para interactuar con nuestros semejantes, lo cual nos llevó a aprender a realizar nuestro trabajo bajo una autonomía caracterizada por la distancia y la virtualidad, lo anterior debido a la emergencia sanitaria generada por el COVID-19. En este tipo de investigaciones cualitativas, la interacción personal en la etapa de adquisición de datos es de gran importancia, pero el uso de Internet en todas las facetas de nuestra vida nos llevó a comprender que estamos frente una nueva era investigativa [20]. Este trabajo utilizó herramientas digitales y las TIC, bajo con rigurosidad que permitió continuar con la calidad en los procesos de la investigación durante todas las etapas de este.

Por lo anterior se hizo énfasis en la información brindada por los entrevistados en las sesiones virtuales mediante las cuales se realizaron las entrevistas semi estructuradas en las que se mantuvieron encendidas las cámaras de todos los participantes. Los entrevistados nos compartieron presentaciones digitales, nos mostraron softwares usados en la gestión del mantenimiento de sus empresas y las estrategias tecnológicas que emplean en sus labores como expertos en mantenimiento. La entrevista consto de 10 preguntas de base y estuvieron orientadas a identificar las tecnologías de la Industria 4.0 usadas en los procesos de la gestión del mantenimiento en las empresas colombianas. Los 7 expertos en mantenimiento industrial entrevistados tenían más de 10 años de experiencia en la industria, son ingenieros que trabajan en empresas de sectores tales como el alimenticio, educativo, abastecimiento, avícola, tecnológico y petrolero. Las personas que fueron entrevistadas son personas de alto rango dentro de las empresas y son los tomadores de decisiones asociadas al uso de tecnologías en los procesos de mantenimiento.

4 Resultados

4.1 Estructura de datos.

Los datos se estructuraron mediante una codificación selectiva a través de un muestreo discriminado dirigido por la lógica, para este muestreo es importante un cierto grado de consistencia en el sentido de que las comparaciones se realizaron sistemáticamente en cada categoría, sin perder la flexibilidad que puede requerirse en casos inesperados como el COVID-19 que sucedió en el marco del desarrollo de esta investigación. La recolección de datos es guiada por el análisis de la información y este análisis es realizado en paralelo con el muestreo de datos. El propósito de la codificación selectiva fue integrar las categorías de acuerdo con las dimensiones y de esta manera obtener una teoría.

4.2 Muestreo discriminado

Durante el desarrollo del muestreo discriminado, se escogió la plataforma Microsoft Teams como medio virtual para realizar las entrevistas y se seleccionaron 7 expertos en mantenimiento con poder en la toma de decisiones asociadas al uso de tecnologías en los procesos de mantenimiento y se seleccionaron los estudios nacionales asociados al desarrollo tecnológico del país para realizar el análisis comparativo. Lo que guío la recolección de datos durante el muestreo discriminado fueron las preguntas analíticas y las comparaciones sistemáticas. Las preguntas de las entrevistas se basaron en conceptos derivados de la literatura, de la experiencia y trabajo de campo realizado previamente por los investigadores en el desarrollo de visitas técnicas a empresas industriales como parte del proceso formativo. Las entrevistas se realizaron bajo un enfoque menos estructurado, pero tuvo una guía general bajo 10 preguntas rectoras que dieron a los entrevistados más espacio para contestar en términos de lo que es importante para ellos. Se compararon las respuestas que dieron los diferentes entrevistados a esas preguntas.

4.3 Validación de los datos

La validación se realizó simultáneamente en cada paso del análisis y del muestreo, mediante la comparación constante de los resultados del análisis de los datos recolectados en las entrevistas y los datos reales, realizando modificaciones o adiciones a medida que llegan los datos a la investigación, de esta manera se validaban o negaban las interpretaciones realizadas. Sólo los conceptos que cumplen todos los requisitos de este proceso constante y riguroso de comparaciones entran a ser parte de la teoría. El muestreo finalizo al saturar las categorías que surgieron de los datos analizados.

4.4 Categorías

Después de un gran volumen de conceptos recopilados en el muestreo discriminado realizado en el proceso de investigación, se establecieron las siguientes categorías que

definen los factores más relevantes al momento de adoptar tecnologías de la industria 4.0 en la gestión del mantenimiento, que pueden contribuir mejorar los procesos industriales de Colombia haciéndolos más eficientes:

Talento humano

La categoría central que permeo las demás categorías dentro de los factores más relevantes al momento de adoptar las tecnologías 4.0, fue la categoría de talento humano. Esto corroboró la importancia que en la gestión del mantenimiento ha tenido el factor humano para lograr la eficiencia en sus procesos [21]. Uno de los expertos expreso: "Las tecnologías emergentes de la Industria 4.0 son muy buenas y nos podrían beneficiar mucho, pero dentro de la mayoría de las empresas industriales del país, no hay personas calificadas para emplear estas tecnologías en la gestión del mantenimiento". La verdadera fuente de competitividad industrial es el Talento Humano comprometido, que encamina sus esfuerzos en resolver las necesidades de las empresas para alcanzar los objetivos estratégicos [22]. Otro de los expertos describió en este sentido: "El éxito de la gestión de mantenimiento, es un equipo de trabajo que este motivado por sus líderes y que se encuentre en constante capacitación sobre las innovaciones y avances técnicos del mantenimiento y de esta forma mejorar las competencias del personal en los procesos y en este caso, en el uso de estas nuevas tecnologías para mejorar estos procesos y ser más eficientes en las labores que se realizan". Las deficiencias en el sistema de formación del talento humano de una empresa impacta de forma directa en la pérdida de competitividad en la economía, debido a que no se puede aprovechar el potencial económico y técnico de las nuevas tecnologías, si en primer lugar no se realizan los cambios el sistema de capacitación y educación [23], al respecto uno de los expertos expreso: "En Colombia es necesario que las empresas brinden facilidades a sus empleados para seguir mejorando su perfil profesional a través de estudios formales como especializaciones y estudios de educación continua o cursos para certificaciones técnicas". Durante la comparación rigurosa de los datos se definió que el factor más relevante en la adopción de las tecnologías 4.0 en los procesos de mantenimiento en Colombia es el factor humano y es el primero que deberían estudiar y organizar las empresas antes de implementar tecnologías en sus procesos.

Cultura Organizacional

Otro factor relevante en la transformación tecnológica del proceso de mantenimiento en las empresas colombianas; es la cultura organizacional, teniendo en cuenta que para el uso de estas tecnologías 4.0 es necesario realizar cambios a nivel tecnológico y fundamentalmente se necesita realizar cambios en la cultura organizacional que procuren el aprovechamiento de estas herramientas tecnológicas y la vinculación de las mismas a las nuevas estrategias de las organizaciones [24]. Al respecto uno de los expertos afirmo que: "En Colombia no existe una cultura dentro de las empresas que migre de forma rápida de procesos industriales tradicionales a procesos industriales tecnológicos o digitales, en mantenimiento se utilizan ciertas técnicas predictivas que involucran algunas herramientas tecnológicas, pero en su mayoría las tareas de mantenimiento son hechas por colaboradores que culturalmente no están familiarizados con la tecnología

de la industria 4.0". Las empresas tienen grandes desafíos que exigen una cultura del cambio, para poder transformar muchos procesos de gestión como la comunicación, la gestión de la información y procedimientos técnicos con el fin de lograr que los trabajadores puedan manejar la complejidad de los procesos y se conviertan en miembros activos de la innovación y del cambio cultural [22]. Uno de los expertos describió alrededor de este tema que: "Modernizar los procesos de mantenimiento con nuevas tecnologías, no solo se trata de comprar nuevos equipos o softwares, si no de cambiar las formas como se han hecho las tareas de mantenimiento por años. Adicionalmente es enseñar de nuevo a los técnicos, como deben hacer sus labores ahora que serán apoyadas con la tecnología". Las empresas deben definir una nueva estructura y darle la importancia al área digital en la estrategia corporativa [25]. En este sentido uno de los expertos concluyó: "Si los empresarios colombianos que estamos en el área de mantenimiento queremos seguir siendo competitivos, debemos transformar nuestras empresas e ingresar en la era digital, pues es evidente que es en esos escenarios digitales en donde se desarrollaran las tareas más complejas e importantes de nuestra función de mantenedores de activos". Podemos afirmar que en Colombia la gestión de mantenimiento no solo depende de las estrategias de transformación digital que tenga una empresa. Depende fundamentalmente de la cultura organizacional que tienen estas compañías y su resiliencia frente a la gestión del cambio.

Toma de decisiones basada en datos

El uso de tecnología avanzada en mantenimiento permite análisis predictivos y sugiere soluciones factibles, con aplicación principal en la Industria 4.0 y especialmente en aquellos aspectos del mantenimiento que se ocupan de la recolección de datos, su análisis, visualización y la toma de decisiones sobre los activos [26]. Uno de los expertos mencionó al respecto: "Para mejorar la confiabilidad de nuestros sistemas en la empresa hemos diseñado un modelo multi estrategia que permite recopilar datos de varias dependencias de la empresa por medio de una plataforma virtual diseñada para tal fin, que en el departamento de mantenimiento aprovechamos al máximo y así contar con más información para tomar decisiones más asertivas. En la gestión de activos, la extracción de grandes cantidades de datos puede ayudar a descubrir conocimientos en la identificación de nuevas tendencias y fallas, además de identificar por anticipado las situaciones no visibles. El enfoque en grandes volúmenes de datos permite combinar la información contextual en los sistemas de apoyo a las decisiones de mantenimiento [27]. Uno de los expertos expuso: "La revolución de la Industria 4.0, es la revolución del dato y lo que hacemos los mantenedores en Colombia es tomar decisiones con datos que nos dan los mantenimientos predictivos o las inspecciones visuales. Es importante aprovechar estas nuevas tecnologías en la gestión del mantenimiento para seguir en una mejora continua del proceso y ser más eficientes a lo largo del tiempo". Para apoyar un proceso eficaz de adopción de decisiones en materia de mantenimiento se necesita un sistema de apoyo a las decisiones basado en la adquisición de datos que permita la gestión de estos [4]. Uno de los expertos concluyó al respecto: "En nuestra empresa fue necesario transformar la forma de gestionar los datos en menor tiempo, hacerlo en la medida de lo posible en tiempo real, cuando migramos a una plataforma digital, pudimos visualizar nuestros datos de mantenimiento en menos tiempo y en mayor cantidad,

de esta manera adaptamos nuestros planes de mantenimiento de acuerdo con la evidencia encontrada y en muy poco tiempo nuestros indicadores de gestión mejoraron considerablemente". De los anterior podemos concluir que en la gestión del mantenimiento la toma de decisiones basada en datos es algo que ha evolucionado a lo largo del tiempo y que el avance tecnológico permite tomar decisiones apoyadas en más datos, aumentando de esta manera el nivel de confiablidad de estas decisiones.

Tecnologías 4.0 en el mantenimiento

Una técnica tradicional de mantenimiento es observar los datos proporcionados por uno, o una serie de sensores, el Machine Learning dota a los equipos de mantenimiento de herramientas de aprendizaje de máquina capaces de adaptarse a las condiciones de funcionamiento, incluso aquellas que cambian rápidamente [28]. Uno de los expertos explicó: "El Machine Learning es una de las tecnologías de la Industria 4.0 que más impacta al mantenimiento permitiéndole ser más eficiente en sus procesos para el diseño de planes de mantenimiento efectivo, los algoritmos que podemos diseñar nos permiten analizar más variables para tomar las decisiones de intervención de los activos de la empresa". La tecnología del Big Data potencializa la recopilación de datos e información de diferentes fuentes y la recolección de datos, para analizarlos a fin de extraer información y conocimiento; y la extracción y visualización de información, para apoyar la decisión de mantenimiento [4]. Uno de los expertos menciono que: "Empleamos el Big Data en nuestros procesos y lo hicimos debido al gran volumen de datos que captamod en nuestras maquinas, esto permitió que pudiéramos ver la información prácticamente en tiempo real, detectando fallas en los equipos y hemos realizado intervenciones a tiempo, antes de que ocurriera una falla que nos retrasara de alguna manera la producción". La computación en la nube es un modelo que ayuda a mantener y almacenar grandes depósitos de datos en un almacén central y proporciona al usuario una interfaz para llevar a cabo una herramienta de análisis poderosa y robusta simplemente por su capacidad de integrar varios insumos de mantenimiento, disposición, condiciones, clima, inventario, entre otras [4]. Uno de los expertos aseguro que: "La computación en la nube fue la herramienta que empleamos en la plataforma de análisis de mantenimiento que diseñamos como un desarrollo propio adaptado a las necesidades de nuestra empresa para almacenar y analizar los datos que obtenemos de los procesos de mantenimiento, esta herramienta se diseñó para que su uso fuera intuitivo y fácil para nuestros técnicos, que no cuentan con mucha experiencia en el uso de herramientas informáticas para el reporte de sus actividades". Después de un análisis exhaustivo de la información recopilada en la investigación realizada, las tecnologías que más beneficios han brindado al mantenimiento industrial en Colombia son el Machine Learning, el Big Data y la Computación en la nube

5 Conclusiones

Realizar un estudio cualitativo alrededor de la gestión de mantenimiento y la industria 4.0 y su uso en Colombia nos ha permitido ver y dimensionar un amplio panorama de desarrollo del país alrededor de estos temas, en donde la oportunidad de innovar en el

desarrollo e implementación de las tecnologías asociadas a la Industria 4.0 son de gran importancia en el desarrollo económico y competitivo del país. La investigación mostro que los cambios que se requieren hacer dentro de las organizaciones para adoptar estas tecnologías, no solo implican un nivel tecnológico, sino que es fundamental en primera medida adaptar el talento humano de las empresas colombianas.

Se determinó que la gestión del mantenimiento es una de las áreas de las empresas que puede implementar en sus procesos las tecnologías emergentes asociadas a la industria 4.0 y encontrar beneficios sustanciales que se pueden traducir en eficiencias presupuestales, brindado a las empresas que utilizan estas tecnologías seguir siendo competitivas en el mercado. Se definió que la toma de decisiones es el proceso que más impacto tiene con el uso de estas tecnologías en el mantenimiento, ya que estas decisiones pueden tomarse con un mayor nivel de confiabilidad y contribuir a lograr los objetivos de las estrategias organizacionales de la industria en Colombia.

De los datos analizados en la presente investigación se encontró que, aunque en Colombia se conocen estas tecnologías y sus beneficios al emplearlas en los procesos de mantenimiento, la mayoría de las empresas no cuenta con personal capacitado para el uso de estas tecnologías y aun no son empleadas en sus procesos de producción incluyendo la gestión del mantenimiento. El panorama futuro que se vislumbra en la industria colombiana es uno en el que las empresas lideren estos procesos de cambio, tanto cultural como de talento humano dentro de sus compañías, adaptando a sus necesidades de capacidad humana y tecnológica el uso de herramientas como el Big Data, Machine Learning, computación en la nube entre otras, que beneficien sus procesos y los hagan eficientes permitiéndoles seguir siendo competitivos en este nuevo mundo digital.

Se proponen futuras investigaciones en torno alrededor de este tema que permitan caracterizar las tecnologías de la industria 4.0 desde sus beneficios técnicos y desde la monetización que estos beneficios representan para las empresas que tienen una estrategia de transformación digital en sus procesos de producción.

Resumen. En este trabajo se describe el desarrollo de una herramienta de asistencia a la toma de decisiones para la operación de la planta de jugos concentrados de manzana y pera de la empresa Jugos S.A. El objetivo de la herramienta es generar un programa detallado de los lotes de jugo clarificado a producir en las próximas semanas a partir de pronósticos de ingreso de fruta, compromisos comerciales y restricciones de infraestructura. La herramienta se basa en dos módulos interactivos, PLANNER y SIMOPT con propósitos diferentes y complementarios. Cada módulo está basado en modelos mixto-enteros con interfaces para ingreso de datos y visualización de resultados. PLANNER a su vez consiste de tres submódulos. SIMOPT proporciona la condición operativa de la planta junto con el cálculo de costos específicos. Esta información es a su vez empleada por PLANNER para evaluar las correspondientes funciones objetivo económicas. Además de proveer condiciones operativas óptimas para la planta y programas de producción factibles, las herramientas desarrolladas permiten generar guías para la producción futura y realizar estudios de escenario.

1 Introducción

La Cadena de Suministro de la Industria de la Fruta (CSIF) de pepita es un sistema complejo que involucra varios actores: chacras de producción de peras y manzanas, galpones de empaque, plantas de elaboración de jugo concentrado, cámaras frigoríficas y empresas de transporte. Todo el sistema está impulsado por la disponibilidad de fruta en cada temporada con el objetivo de producir una enorme cantidad de productos: manzanas y peras frescas en diferentes empaques y jugo concentrado de manzana y pera de variada acidez en una amplia variedad de envases. Una cualidad distintiva de este sistema y que torna la toma de decisiones una actividad sumamente desafiante es la

significativa incertidumbre existente en ambos extremos de la cadena: disponibilidad de fruta en chacras y precios y demandas internacionales de los productos. Aunque la mayoría de las empresas de la CSIF en la Argentina incorporaron mucha innovación tecnológica en los últimos veinte años (equipamiento, automatización, monitoreo y control) para competir a estándares internacionales, la toma de decisiones permanece aún como una actividad predominantemente artesanal, basada en la experiencia e intuición de los gerentes y asistida, como mucho, con planillas de cálculo. No obstante, el sistema frutícola nacional ha sido sumamente estudiado a nivel académico en la última década. Por ejemplo, la CSIF de pepita ha sido a modelada en [1, 2 y 3] con foco en la optimización del planeamiento de la producción desde el punto de vista de una compañía que opera varios nodos a lo largo de la cadena. Además, modelos de planeamiento específicos fueron propuestos para la mayoría de los segmentos más importantes: chacras de frutales [4], galpones de empaque [5] y plantas de jugo [6].

Este proyecto de enfoca en el nodo de producción de jugo concentrado de la cadena. Las plantas de jugo en Argentina producen jugo clarificado a 70°Brix, la mayoría del cual se destina al mercado internacional. Argentina posee el 5% del mercado internacional de jugos concentrados. Jugos S.A. es el mayor productor de jugo concentrado de manzana y pera en Argentina con aproximadamente el 60% de la producción nacional, de la cual el 70% se exporta y el resto se consume localmente. En el año 2013 la gerencia de la empresa Jugos S.A. decidió emprender el desarrollo de herramientas de apoyo a la toma de decisiones basadas en modelos matemáticos para asistir a los ingenieros de la planta en el proceso de toma de decisiones tácticas y operativas, reconociendo el valor de contar con herramientas automáticas para realizar análisis de costos, el planeamiento de la producción y generar estudios de escenario. En este artículo comentamos los aspectos más relevantes de este proyecto.

2 Proceso de Producción de Jugo Concentrado

El jugo clarificado de pera/manzana se comercializa típicamente como concentrado de 70-75 °Brix siendo un producto muy estable que puede ser almacenado y transportado de manera segura y económica. El parámetro característico del jugo concentrado es la acidez total expresada como porcentaje de ácido málico, que fluctúa típicamente entre 1.0 y 3.0 % para jugo de manzana y entre 1.0 y 2.0% para jugo de pera.

En la Fig. 1 se muestra un esquema general del proceso de producción de jugo clarificado. La producción de jugo semielaborado involucra las siguientes etapas: lavado, molienda, extracción por prensado, separación pulpa-orujo, maceración y concentración. La producción de jugo clarificado involucra adicionalmente, dilución (si se reprocesa jugo semielaborado), filtración, concentración final, empaque y almacenamiento refrigerado. Para una descripción detallada del proceso consultar [7]. Las plantas modernas también cuentan con varias líneas de producción paralelas, cada una de las cuales se puede dedicar a un tipo de jugo particular. Esto permite el procesamiento de un solo tipo de fruta a gran capacidad (pera o manzana) o ambas simultáneamente, cada una en alguna de las líneas disponibles.

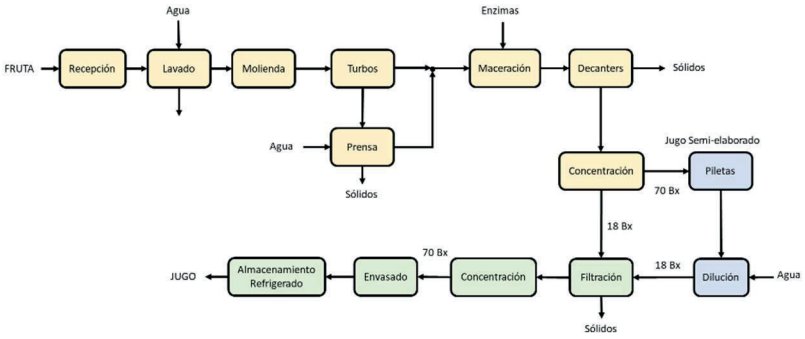

Fig. 1. Proceso típico de producción de jugo de fruta.

3 Proceso y Operación en Jugos S.A.

Jugos S.A. posee una planta de producción de jugos concentrado en Villa Regina, Río Negro, Argentina. La Fig. 2 ilustra el diagrama de flujo principal del proceso. A grandes rasgos, existen dos líneas de procesamiento en la planta: la primera (parte superior del diagrama) está destinada a la producción de jugo clarificado, mientras que la otra (parte inferior del diagrama) produce jugo semielaborado para ser almacenado en piletas. La primera parte del proceso es una playa de recepción abierta donde la fruta se almacena en bines, con dispositivos hidráulicos (lagares) para alimentar a los molinos. Luego de lavar y moler la fruta, la pulpa es separada en una serie de filtros centrífugos (turbos) y prensas.

A continuación, la pulpa es tratada con enzimas para extraer el jugo remanente en la membrana celular. Luego se realiza una separación adicional de líquido y sólidos en una serie de equipos llamados *decanters*. El jugo obtenido se concentra luego con evaporadores multi-efecto. En la línea de jugo semielaborado el jugo se concentra hasta 70° Brix y se almacena en piletas grandes para su posterior reprocesamiento. En la línea de jugo clarificado se realiza una preconcentración (18°Brix) antes de que el jugo se pase por una etapa de ultrafiltración. Finalmente, el jugo se concentra hasta (70°Brix) previo a su envasado y almacenamiento en frío. Cuando es necesario se toma jugo semielaborado desde las piletas de almacenamiento y se diluye con agua antes de ser reprocesado (ultrafiltración, concentración, empaque y almacenamiento).

La planta posee varias calderas para suministrar vapor a los evaporadores multi-efecto y cubrir otros requisitos de calentamiento. El agua extraída del jugo en la etapa de concentración es recolectada y utilizada en otros sectores del proceso (hidratación, lavado de la fruta). También se emplea agua de pozo, previo ablandamiento en una planta de ósmosis para su uso en la producción de vapor en las calderas y para refrigeración en condensadores y otros intercambiadores de calor. El agua que se emplea para transportar la fruta en los lagares se somete a un tratamiento biológico en piletas para ajustar la DBO y otros parámetros de calidad antes de su disposición final [8].

La planta utiliza grandes cantidades de gas natural en las calderas y de energía eléctrica para los equipos de bombeo, separación y refrigeración.

Los sólidos extraídos en las diferentes etapas de separación (turbos, prensas, *decanters* y filtros) son recolectados y destinados a la elaboración de compost.

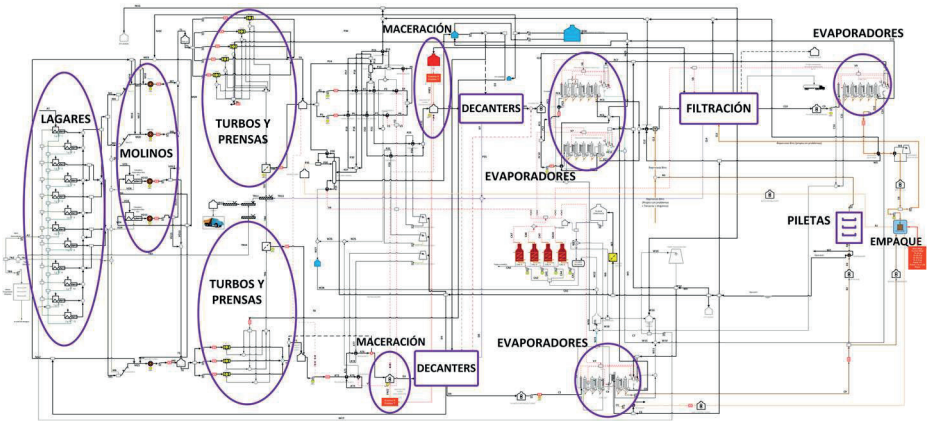

Fig. 2. Diagrama de flujo de la planta de Jugos S.A.

La planta es bastante flexible y, si es necesario, permite compartir equipos entre las líneas de producción previa limpieza y desinfección. De hecho, existen varias interconexiones entre las líneas en varios puntos a lo largo del proceso, lo que permite incrementar la capacidad de producción de una línea con recursos de la otra si es necesario. Se dispone de sistemas *Clean-in-Place* (CIP) para acondicionar los equipos cada vez que se producen estas maniobras.

Aunque muchos de los subprocesos son en realidad operaciones *batch*, la planta puede operarse prácticamente como un sistema continuo durante periodos prolongados. Las diferentes variedades de fruta almacenada en la playa de recepción se vuelcan de los bines a los lagares mediante auto-elevadores. Si bien ésta es claramente una operación *batch*, la gran cantidad de material que puede acumularse en los lagares hace que la alimentación a los molinos resulte virtualmente continua. Adicionalmente, la etapa de maceración requiere el contacto de la pulpa con enzimas durante un cierto periodo, operación que tiene lugar en tanques de grandes dimensiones. Con el objetivo de operar de manera continua, existen varios tanques dedicados a esta operación, tal que uno de ellos siempre está alimentando al proceso, mientras los restantes están siendo llenados o realizando la maceración. De manera similar, la ultrafiltración también es un proceso discontinuo dado que las membranas se van ensuciando y los filtros deben ser sacados de operación con alguna frecuencia para proceder a su limpieza [8]. Por esta razón, la ultrafiltración se realiza en varios filtros paralelos tal que algunos se encuentran funcionando mientras otros se limpian para recuperar eficiencia. Varios tanques *buffer* a lo largo de todo el proceso aseguran la operación continua de equipos como turbos, prensas, *decanters* y evaporadores por periodos extensos. En conclusión, aunque muchos equipos y subprocesos son *batch*, para muchos propósitos operativos (y de modelado matemático), la planta puede ser considerada como un proceso continuo.

Cabe aclarar que existen especificaciones de calidad muy estrictas para los jugos de manzana y pera. En particular, todos los equipos deben ser cuidadosamente lavados por

el sistema CIP con cierta frecuencia y cada vez que hay un cambio en el tipo de fruta en la línea de producción. Estas operaciones de limpieza requieren mano de obra intensiva y demoran varias horas durante las cuales la línea no está operativa.

Adicionalmente, un recurso logístico muy importante del proceso es el sistema de piletas de jugo semielaborado. La planta posee varias piletas de grandes dimensiones especialmente acondicionadas para el almacenamiento de jugo no clarificado. Este jugo puede ser bombeado desde el proceso a las piletas o desde las piletas al proceso cuando resulte necesario. Cada pileta almacena un tipo específico de jugo, pera o manzana, en rangos específicos de acidez. Se debe realizar una limpieza cada vez que una pileta se vacía y se llena con jugo de la otra fruta. Además de almacenar jugos de las diferentes especies, las piletas también cumplen la función de preservar jugos de cierta especificación. Por ejemplo, típicamente, el jugo de manzanas ácidas no se mezcla con jugos de manzanas poco ácidas. De esta manera la acidez se preserva y puede ser utilizada para ajustar la especificación de lotes futuros.

La operación final es el envasado, proceso en el cual recipientes de cierto tipo se llenan de manera secuencial. Los envases más comúnmente utilizados son bines con bolsas de polietileno y tambores plásticos o metálicos. El jugo envasado se almacena en cámaras frigoríficas antes de ser despachado. La planta posee una cámara de gran dimensión, pero si es necesario la empresa puede contratar capacidad de frío de terceros proveedores.

Respecto de la mano de obra, la planta posee un turno de personal estable para realizar actividades de producción y mantenimiento. En periodos de ingresos de fruta elevados o de grandes volúmenes de jugo semielaborado, se trabaja en tres turnos para lo que se requiere la contratación de personal adicional. Finalmente, aparte de las fluctuantes disponibilidad de fruta y demanda de jugo, el proceso/negocio está sujeto a otras restricciones. Típicamente suele haber restricciones de disponibilidad de gas natural durante los meses fríos y de energía eléctrica en verano. En estos periodos la empresa debe optar por interrumpir la producción o enfrentar penalidad en los precios de estos servicios. En la Tabla 1 se presenta un detalle de los principales parámetros de la planta para dar un panorama de la magnitud del proceso.

Tabla 1. Datos de la Planta.

Capacidad de producción (gal/año)	6 000 000
Capacidad de molienda (ton/día)	1 800
Capacidad de almacenamiento en frío (gal)	1 800 000
Superficie del *site* (m^2)	6 700
Laguna de tratamiento de efluentes (hectáreas)	6
Empleados (máxima capacidad)	175

A grandes rasgos se puede decir que la producción esta dictada por las órdenes de compra que realizan los clientes a lo largo del año de los diferentes tipos de jugos, las cuales difieren básicamente en volúmenes, acidez y tipos de envase. Durante la temporada de cosecha (febrero a abril) la fruta que ingresa típicamente sobrepasa la cantidad necesaria para elaborar las órdenes existentes. En este caso se produce y almacena jugo

semielaborado. En paralelo, con el objetivo de evitar una acumulación excesiva de fruta en la playa de recepción, también se elaboran y almacenan en frío lotes de jugo clarificado de calidades estándar, ya sea para atender directamente ordenes futuras o para reprocesar para elaborar nuevas órdenes. El problema de planeamiento de la producción básicamente requiere definir el tipo de fruta a procesar cada día en cada línea para satisfacer en tiempo y forma las órdenes de los clientes, operando dentro de las capacidades de producción y almacenamiento disponibles.

Cabe mencionar que la empresa Jugos S.A. posee las siguientes certificaciones de producción: FSSC 22000 (ISO 22000, ISO/TS 22002-1 y adicionales), producción orgánica, programas NOP-Canadá, Arg.-UE, IFOAM, MAFF, Kosher, miembro "B" de SEDEX.

4 Organización del Proyecto

En este contexto de gran incertidumbre, el desafío reside en decidir qué productos elaborar cada día del horizonte de planeamiento con el fin de maximizar el beneficio de la empresa a lo largo del ciclo comercial. Para automatizar este complejo y artesanal problema de toma de decisiones, los ingenieros de procesos de la compañía junto con nuestro grupo de investigación conformamos un equipo para desarrollar un Sistema de Soporte a las Decisiones (SSD) basado en modelos matemáticos. El proyecto se organizó en un esquema de cuatro etapas:

1. Recopilación de datos del proceso
2. Desarrollo del módulo de simulación/optimización
3. Desarrollo del módulo de planeamiento de la producción
4. Período de mantenimiento

La Etapa 1 consistió en reunir una gran cantidad de información sobre el proceso, equipos y negocio la cual estaba distribuida en varios sectores de la empresa y en el conocimiento experto de diferentes personas. Esta etapa se extendió en cierta medida, durante todo el proyecto debido a la gran cantidad de detalles involucrados en prácticamente todos los sectores del proceso/negocio.

En la Etapa 2 se desarrolló un modelo de simulación/optimización del proceso operativo, que consiste en balances de masa y energía detallados en cada nodo del diagrama de flujo de la Fig. 2. En esta etapa se requirió conocer en detalle la planta para modelar cada equipo, con el objetivo de monitorear los principales componentes de cada corriente a lo largo del proceso y estimar, con suficiente precisión, las variables importantes de cada una de las operaciones. Para varios sectores/equipos especialmente complicados (*decanters*, evaporadores, filtros), se desarrollaron modelos detallados utilizando primeros principios y se ajustaron luego con información de planta. Dichos modelos se utilizaron para obtener correlaciones que fueron luego integradas al modelo de simulación/optimización. Una actividad particularmente desafiante en el desarrollo de este módulo fue la de conciliar el modo de operación continua de la planta con las operaciones por lotes que tienen lugar en este proceso. Además de un seguimiento

completo de caudales, composiciones y temperaturas a lo largo de todo el proceso, este modelo permite el cálculo detallado de muchos índices de producción (KPI) de gran interés para los gerentes de planta. Se proporcionan más detalles en la siguiente sección.

En la Etapa 3 se desarrolló un módulo de planeamiento de la producción. Este módulo permite programar cada pedido de jugo a lo largo del horizonte de planeamiento de modo que se produzca y empaque a tiempo para que esté disponible para su envío en la fecha pactada. Este modelo requirió una comprensión completa del proceso de producción y de la logística involucrada.

La Etapa 4 consistió en el uso intensivo (diario) del sistema para detectar errores en los modelos e interfaces, e identificar posibilidades de mejora de las herramientas desarrolladas.

Una decisión estratégica importante, tomada al comienzo del proyecto, fue la selección de la plataforma de desarrollo. Siguiendo las recomendaciones del grupo de investigación, la compañía adoptó la plataforma de optimización GAMS con interfaces en Excel para la entrada de datos, la operación del modelo y la visualización de resultados. Este esquema resultó práctico ya que el personal de la compañía en todos los niveles está familiarizado con el software Excel y mucha información del proceso ya está en formato de hoja de cálculo, lo que permite su uso directo. Además, los modelos implementados en GAMS se pueden ejecutar, de manera transparente para el usuario, desde Excel incluso automáticamente.

Dado que la empresa/planta está ubicada en la ciudad de Villa Regina (provincia de Río Negro) y nuestro grupo de investigación está establecido en la ciudad de Bahía Blanca (provincia de Buenos Aires), a 450 km de distancia, se realizaron varias visitas de los miembros del grupo de investigación a la planta así como también visitas de los ingenieros de planta a Bahía Blanca a lo largo de la duración del proyecto para discutir los diferentes aspectos del proceso de producción y del negocio del jugo concentrado. Estas reuniones se complementaron con videoconferencias periódicas y numerosos correos electrónicos por mes.

Además, más de diez estudiantes universitarios de las carreras de Ingeniería Química e Ingeniería de Alimentos de la UNS se involucraron en el proyecto como PPS (Prácticas profesionales supervisadas) y/o pasantes. El resultado fue una experiencia enriquecedora para los estudiantes que se involucraron en un entorno industrial a través de un proyecto de modelamiento y también muchos de los resultados y conclusiones alcanzados por los alumnos contribuyeron al desarrollo de las herramientas. Esta interacción se convirtió en un resultado inesperado y positivo del proyecto. Desde el aspecto formal el proyecto se desarrolló en el marco de un convenio Conicet - Jugos S.A., y se registró como Proyecto de Desarrollo Tecnológico y Social (PDTS).

5 Sistema de Soporte a las Decisiones Basado en Modelos

Como se mencionó anteriormente, el SSD basado en modelos ideado para la planta de jugo concentrado de Jugos S.A. posee dos componentes principales: un modelo de simulación/optimización (SIMOPT) y un modelo de planeamiento de la producción

(PLANNER). El flujo de información entre ambos se muestra en la Fig. 3. El módulo SIMOPT realiza, básicamente, una optimización del proceso proporcionando información muy detallada del punto óptimo de operación de la planta junto a la estructura de costos desagregada, la cual es uno de los principales intereses para los gerentes de planta. Este módulo puede emplearse también para efectuar simulaciones específicas. El módulo PLANNER, que consta de tres modelos interactivos, realiza el programa de los lotes de los diferentes tipos de jugos que se elaborarán en el futuro cercano, considerando, esencialmente, compromisos (órdenes de compra), disponibilidad de fruta y pronósticos de ingresos de fruta.

Desde un punto de vista operativo, el sistema está diseñado para ejecutarse de forma modular o integrada cada vez que ingresa nueva información al sistema o se desea investigar un nuevo escenario. En particular, se supone que el planeamiento de la producción se ejecute diariamente, frecuencia típica de actualización del pronóstico de fruta entrante y la colocación de nuevos pedidos.

Cabe señalar que los modelos mencionados son determinísticos, es decir, todos los parámetros del modelo son fijos y conocidos. Tales datos se recopilan de varias bases de datos utilizadas habitualmente por los diferentes departamentos de la empresa y constituye la información más confiable disponible para la toma de decisiones en un entorno tan incierto. Se ha hecho un esfuerzo para que los modelos sean lo más sencillos posible para permitir realizar optimizaciones rápidas a medida que se recibe información actualizada, como una forma práctica e intuitiva de lidiar con la incertidumbre inherente a este complejo sistema.

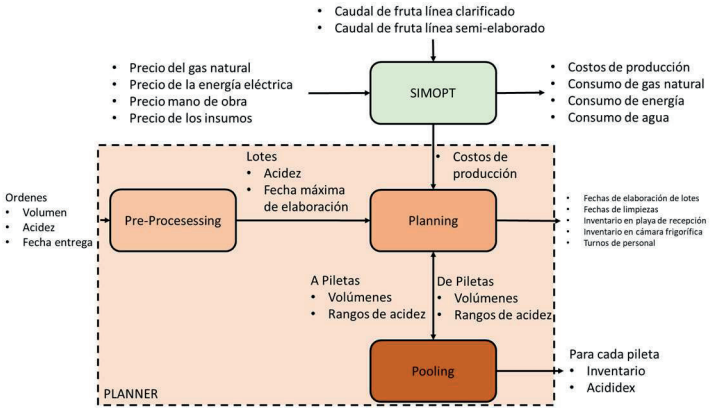

Fig. 3. Módulos basados en modelos y sus interacciones.

5.1 Módulo SIMOPT

El módulo SIMOPT consta de balances de masa y energía detallados en cada nodo del diagrama de flujo de la Fig. 2. Las corrientes del proceso se describen por tres componentes principales: sólidos solubles, sólidos insolubles y agua. La acidez no se controla en este módulo ya que es un parámetro ajustado en los procesos de mezcla que tienen lugar en la jerarquía de planeamiento de la producción. Dado un cierto flujo de fruta

que alimenta cada una de las líneas (clarificado y semielaborado), se resuelve un modelo orientado a optimizar el beneficio instantáneo del proceso, definido como el ingreso debido al jugo producido menos el costo total de la operación. Este último incluye el costo del uso de gas natural y electricidad y el costo por las operaciones de limpieza, envasado, transporte y almacenamiento. Como resultado, el caudal, la composición y la temperatura de cada corriente se reportan junto a los parámetros operativos más relevantes de cada equipo. Asimismo, se pueden elegir funciones objetivo adicionales, para realizar estudios específicos, como maximizar la producción, por ejemplo.

Dado que los balances de masa en los nodos de mezcla introducen bilinealidades y las ecuaciones de eficiencia de la mayoría de los equipos son regresiones no lineales de las variables de entrada, el modelo es no lineal. Además, también se incluyen varias variables binarias para modelar si un equipo en particular está funcionando o no. En particular, los turbos, *decanters*, plantas de ósmosis, evaporadores y calderas se encienden y apagan mediante el uso de variables binarias. Por lo tanto, el modelo es de programación no lineal mixto-entera (MINLP) y se resuelve con el *solver* DICOPT de la plataforma GAMS. Algunos datos básicos de los modelos se presentan en la Tabla 2. El panel de control SIMOPT se muestra en la Fig. 4.

Tabla 2. Estadísticas del Modelo.

	SIMOPT	**PLANNER**		
	Optimización	***Preprocessing***	***Planning***	***Pooling***
Tipo de Modelo	MINLP	MILP	MILP	MINLP
Ecuaciones	2 200	15 000	765 000	74 000
Variables Continuas	1 900	25 000	1 555 000	22 000
Variables Binarias	70	1 700	10 900	17 000
Tiempo de CPU (min)	0.2	7	7	0.3

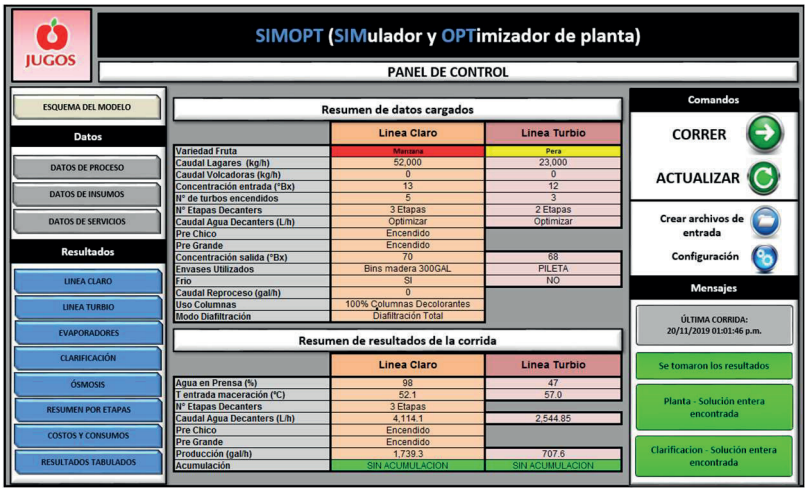

Fig. 4. Panel de control del módulo SIMOPT.

5.2 Módulo PLANNER

Para manejar de forma práctica la gran cantidad de decisiones involucradas, el planeamiento de la producción se organiza mediante una herramienta PLANNER, que coordina la interacción de tres submódulos (*Preprocessing*, *Planning*, y *Pooling*) que realizan actividades diferentes y complementarias. El panel de control correspondiente se muestra en la Fig. 5.

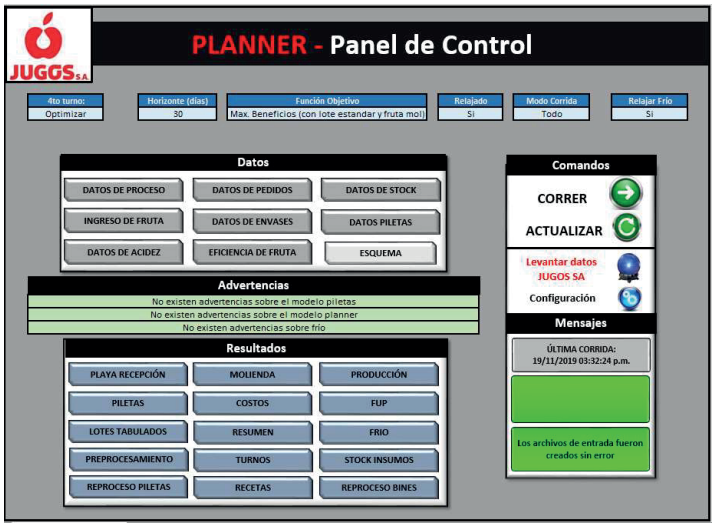

Fig. 5. Panel de control del módulo PLANNER.

El modelo de planeamiento propuesto adopta un enfoque multiperíodo que abarca tres meses con resolución diaria. Para un conjunto establecido de pedidos de jugo de diferentes tipos (manzana, pera, orgánicos, etc.) y rangos de acidez que se deben entregar a lo largo del horizonte de planeamiento y una dada estimación de la disponibilidad de fruta fresca en el futuro, el módulo calcula los días específicos en que deben fabricarse los lotes de cada tipo de jugo. El objetivo es optimizar el beneficio total del negocio, definido como el ingreso por el jugo producido menos todos los costos involucrados integrados a lo largo del horizonte de planeamiento.

Además de las decisiones de producir un lote de jugo en particular en un día específico, se deben tomar muchas otras decisiones binarias cada día del horizonte. Dichas decisiones involucran, por ejemplo, la manera en que se distribuye un determinado pedido de jugo en los lotes cuya producción se programará, el momento en que se apagan las diferentes líneas para su limpieza, la cantidad de jugo retirado de las cámaras de frío los días de envío, la cantidad de jugo semielaborado de cada tipo de fruta enviado y retirado de las piletas, etc. El número de variables binarias es, por lo tanto, enorme. Además, las piletas de jugo semielaborado introducen una complejidad considerable ya que la mezcla de jugos de diferente acidez tiene lugar en estas piletas, introduciendo no linealidades en el modelo. Por estas razones, un modelo único para el planeamiento completo de la producción es un problema MINLP enorme cuya resolución es

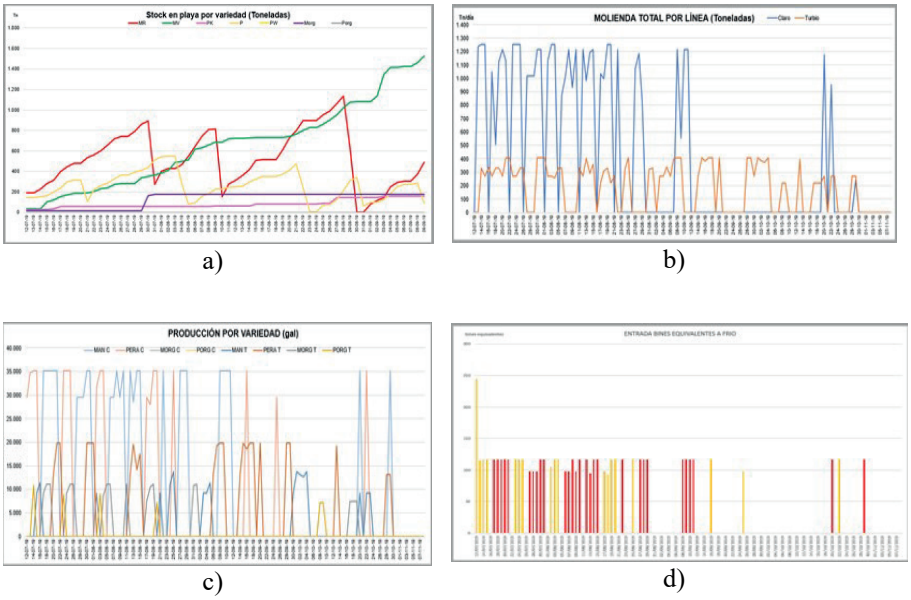
incompatible con la toma de decisiones diaria. Para desarrollar herramientas prácticas, el módulo de planeamiento se estructuró en tres submódulos interactivos, cada uno orientado a un conjunto específico de decisiones.

Preprocessing. Este submódulo recibe los pedidos de jugo realizados por los clientes. Estas órdenes definen un cierto volumen de jugo concentrado clarificado de un tipo particular (manzana, pera, orgánico, tradicional) dentro de un rango de acidez específico (ej. 1.0 - 1.4 g / L), en un empaque determinado (contenedores, tambores, etc.) que debe ser entregado en una fecha particular o distribuido a lo largo de ciertas fechas específicas. Cada día la planta puede producir un lote con un volumen específico (en galones) de jugo clarificado de cualquier tipo. Dado que algunos pedidos pueden ser más pequeños que un lote y otros requerir varios lotes para completarlos, surge un problema sobre cómo distribuir los pedidos en los lotes para que se elaboren a tiempo, verificando la acidez y los requerimientos de empaque de cada uno.

El submódulo de *Preprocessing* realiza esta tarea resolviendo un problema específico para cada tipo de jugo: (i) jugo de manzana convencional, (ii) jugo de pera convencional, (iii) jugo de manzana orgánico, (iv) jugo de pera orgánico. Para cada tipo de producto, se resuelve un modelo MILP que asigna las órdenes a los lotes a producir. De esta manera, un lote puede tener jugo que pertenece a más de un pedido que tienen el mismo rango de acidez y tipo de empaque. En todos los casos, el objetivo principal es minimizar el número de lotes para cumplir con todas las órdenes. La fecha de producción de cada lote tiene que verificar, por supuesto, la fecha de entrega de la orden asignada más cercana. El problema de asignar las órdenes a los lotes se resuelve con el *solver* CPLEX. El detalle de las órdenes se obtiene del sistema de la empresa y se alimenta automáticamente al submódulo *Preprocessing*. Los resultados de este módulo son los lotes que se deberán producir antes de ciertas fechas máximas, los que se cargan, de manera automática, al submódulo *Planning* donde se obtiene la programación final de los mismos.

Planning. El submódulo *Planning* es el componente principal de la herramienta de planeamiento de la producción (PLANNER). Recibe desde el submódulo *Preprocessing* el número de lotes para un determinado tipo de fruta y acidez que se deberán producirán en el futuro con las fechas máximas correspondientes. También tiene acceso a un pronóstico de ingreso para los distintos tipos de fruta. Desde el módulo SIMOPT, *Planning* recibe los valores actualizados de los costos de producción y almacenamiento. El resultado principal del submódulo es la programación de lotes a lo largo del horizonte de planeamiento. Algunos lotes corresponden a órdenes de compra específicas según lo requerido por el submódulo *Preprocessing*. No obstante, cuando la producción de jugo semielaborado no alcanza a evitar la acumulación excesiva de fruta en el área de recepción, *Planning* programa, automáticamente, la producción de lotes de jugo de calidad estándar para almacenar en frío.

El programa obtenido proporciona, además, las fechas en que las líneas deben apagarse para su limpieza antes de cambiar entre especies de frutas. Asimismo, considera las fechas específicas para la limpieza programada de las líneas de acuerdo con las normas correspondientes. Después de la temporada de cosecha, el modelo también



predice los períodos en los que la planta debe permanecer inactiva esperando que se acumule fruta en cantidades significativas para reiniciar la producción. Otros resultados incluyen inventarios del área de recepción y de la cámara de frío.

Otro conjunto de decisiones importantes se refiere a la cantidad de jugo semielaborado que se producirá cada día y será almacenado en piletas, así como la cantidad de jugo semielaborado que reingresa al proceso desde las piletas para elaborar los lotes. Estas decisiones demandan un número significativo de variables binarias para su modelado. Además, la mezcla de jugo en las piletas introduce bilinealidades dado que tanto los volúmenes como la acidez son variables de decisión. Por lo tanto, la operación de las piletas tiene asociado un subconjunto de ecuaciones no lineales mixto-enteras, lo que complica aún más el ya complejo modelo de programación de la producción. Para evitar la complejidad de este proceso, la acidez se manejó de manera simplificada a nivel *Planning* y los balances rigurosos de las piletas se asignaron en un submódulo complementario denominado *Pooling*.

Aunque el modelo sigue siendo lineal, la gran cantidad de variables binarias impide su resolución en tiempos de cálculo razonables para todo el horizonte de planeamiento adoptado de 90 días. Para generar un programa en tiempos razonables, digamos unos 30 min de CPU, se optó por resolver secuencialmente una serie de subproblemas relativamente pequeños y fáciles de 10 días de extensión en un esquema de horizonte móvil. Por lo tanto, se resuelven nueve subproblemas de diez días para cubrir el horizonte de planeamiento de 3 meses. La solución obtenida para cada modelo se fija antes de abordar la solución del siguiente problema. La función objetivo principal a optimizar es el beneficio general de la operación definida como el ingreso producido por la venta de los lotes menos los costos de ejecutar el proceso. Para estudios específicos se pueden elegir funciones objetivo adicionales, tales como maximizar la producción de jugo concentrado (clarificado, semielaborado o ambos). En la Tabla 2 se informa el tamaño del modelo de *Planning* para un período de diez días, que se resuelve con el *solver* CPLEX. En la Fig. 6, se presentan los perfiles de algunas variables características para ilustrar algunos de los resultados del submódulo *Planning*. La Fig. 6 a) muestra los perfiles típicos de los inventarios de las diferentes variedades de fruta en el área de recepción. La Fig. 6 b) muestra las cantidades de fruta procesadas por las líneas de jugo clarificado y semielaborado (azul y naranja, respectivamente). La capacidad de la línea de jugo clarificado es aproximadamente tres veces mayor que la de la línea de jugo semielaborado. La Fig. 6 c) presenta las cantidades de jugo de diferentes tipos producidas cada día. Finalmente, en la Fig. 6 d) se muestran, en formato de barras, los lotes de diferentes productos que ingresan a la cámara frigorífica.

Existen muchas fuentes de infactibilidad en el modelo de *Planning*. Por ejemplo, si no hay suficiente fruta en el sitio de recepción y jugo semielaborado en las piletas de almacenamiento, la producción de algunos lotes puede no ser factible en los próximos días. En estos casos, cuando se detecta la infactibilidad, se activan secuencialmente varias relajaciones que se manifiestan lo más lejos posible en el horizonte de planificación, de modo de generar un programa factible. Por ejemplo, si el nivel de acidez de algún lote no se puede lograr en el futuro, se relaja en cierta medida utilizando un valor menos restrictivo. De esta manera, generalmente se logra una solución factible y se muestra una señal de advertencia en la interfaz de resultados, para que pueda ser

analizada luego por los ingenieros de proceso. Las soluciones relajadas no tienen un impacto práctico en las decisiones que se tomarán en los días inmediatos y advierten, por lo general, sobre la escasez de ciertos tipos de fruta que puede ocurrir en el futuro.

a) b) c) d)

Fig. 6. Resultados del módulo *Planning*.

Pooling. Como se describió previamente, el manejo del jugo semielaborado se aborda de manera muy simple en la etapa de *Planning* para evitar no linealidades y variables binarias que complicarían excesivamente una solución práctica del modelo de planeamiento de la producción. Para seguir en detalle el tipo, nivel de inventario y acidez del jugo en cada pileta, se representó el funcionamiento del sistema de piletas de almacenamiento con otro modelo denominado *Pooling*. Para cada pileta, los balances de inventario (lineales) y los balances de acidez y °Brix (no lineales) se realizan cada día del horizonte de planeamiento. Además, se utilizan variables binarias para controlar el tipo de jugo que se almacena en cada pileta cada día.

Una vez que se resuelve el *Planning* para el período de 90 días, se establecen las cantidades de jugo semielaborado que se envían cada día a las piletas de almacenamiento, así como las cantidades de jugo semielaborado que se requieren de las piletas cada día para producir lotes específicos de jugo clarificado. Por lo tanto, *Pooling* recibe como parámetros las entradas específicas de jugo (cantidad y acidez) al sistema de piletas y también las salidas (cantidad y acidez) que se retirarán del sistema cada día del horizonte de planeamiento. En esta etapa, se resuelve un problema de optimización para distribuir el jugo entrante a la pileta de almacenamiento más apropiada y para satisfacer lo más ajustadamente posible, en cantidad y acidez, el jugo para reprocesamiento.

Para evitar infactibilidades en caso de que la cantidad exacta de jugo semielaborado con el nivel de acidez requerido no se puede entregar en algunos períodos futuros, la función objetivo del *Pooling* es minimizar las desviaciones con respecto a los valores requeridos. Si estas desviaciones son significativas, se generan advertencias en la interfaz de usuario. *Pooling* es un modelo MINLP de 90 días resuelto con el *solver* DICOPT. Para aumentar la robustez proporcionando un buen punto de partida para el sistema no lineal se resuelve, en primer lugar, un problema lineal aproximado utilizando valores de acidez promedio para todas las corrientes. La solución de este problema se utiliza como punto inicial del modelo no-lineal original de mezclado. Las estadísticas básicas de este modelo se presentan en la Tabla 2.

6 Conclusiones

El desarrollo de las herramientas descritas para asistir en el proceso de toma de decisiones de la compañía Jugos S.A. presentó varios desafíos para el equipo de desarrollo integrado por miembros de nuestro grupo de investigación e ingenieros de la compañía. El primero fue alcanzar un consenso en cuanto al número y tipo de modelos a desarrollar y al nivel de detalle a incluir en cada uno. Aunque prácticamente cada parte importante del proceso fue modelada y ajustada con datos de planta, en los módulos centrales descritos en este trabajo (SIMOPT y PLANNER), algunos de los subprocesos finalmente fueron representados por regresiones sencillas generadas con datos obtenidos de esos modelos más sofisticados. De esta forma se logró conciliar un nivel de detalle adecuado con tiempos de resolución prácticos.

Otro desafío al que se enfrentó nuestro equipo fue reunir la cantidad de información necesaria sobre las unidades, el proceso y el negocio. Cabe destacar que el negocio cambia año tras año debido al contexto e incertidumbre tanto local como internacional. Además, el proceso es flexible y se adapta a los nuevos requisitos de producción. Abordamos estos desafíos discutiendo cada tema específico en profundidad, proponiendo una determinada solución de modelado, probándola, comparando los resultados con las estimaciones esperadas e introduciendo mejoras hasta llegar a un acuerdo sobre la validez del enfoque adoptado. Por ejemplo, la definición de la función objetivo más conveniente para que cada módulo se asemeje a la práctica operativa real, fue una actividad laboriosa a lo largo de toda la duración del proyecto.

A nivel de desarrollo, los cuatro modelos descritos en este documento plantearon importantes desafíos de modelamiento. La estrategia de descomposición ideada para producir programas razonables en tiempos prácticos de ejecución es compatible con la gran incertidumbre que enfrenta el sistema en el horizonte de planeamiento adoptado.

Además de una herramienta para generar automáticamente programas detallados y permitir estudios de escenarios, el sistema también proporciona pautas para operar el proceso a largo plazo. La información reportada por los modelos constituye hoy en día una forma sistemática de visualizar todo el proceso/negocio entre el personal de diferentes departamentos y proporciona un marco común para la discusión del planeamiento estratégico dentro de la empresa. Esta experiencia ha sido reportada en [10].

Agradecimientos

Los autores desean agradecer al Ing. Carlos Aeberhard por inspirar e iniciar el proyecto y al Dr. Daniel Cecive por incluir sus objetivos dentro de la visión estratégica de la compañía. Se hace extensivo este agradecimiento a todo el personal de JUGOS S.A. por la predisposición a facilitar la información requerida y los invaluables aportes recibidos a lo largo de la fase de desarrollo.

Resumen. En las últimas décadas se han tomado medidas para dar solución a los diferentes problemas de salud pública causados por alimentos. Entre ellas, es de destacada importancia la trazabilidad, cuyo fin es, rastrear los productos de forma eficiente. El objetivo de este trabajo es minimizar la dispersión total de los lotes en la cadena de suministros de productos cárnicos para optimizar su trazabilidad. Para ello se desarrolla un modelo de programación mixta entera lineal (MILP), cuyas variables de decisión se emplean para determinar la existencia y el número de lotes en cada nivel, las cantidades involucradas y los actores que participan. Los resultados muestran que se puede generar una cantidad de lotes óptima y disminuir la dispersión de los mismos, minimizando así, los costos de retiro de los productos ante una crisis de seguridad alimentaria. Además, la formulación permite el rastreo de los lotes de producto en cada punto de la cadena de suministro identificando los lotes de animal y materias primas utilizados en su elaboración.

Palabras Claves: Cadena de Suministro de la Carne, Dispersión por Lotes, Trazabilidad, MILP, Optimización.

1 Introducción

Debido a los diferentes problemas de salud pública causados por los alimentos en las últimas décadas, los consumidores exigen cada vez más información sobre su calidad e inocuidad. Esta creciente preocupación por la seguridad alimentaria ha generado una mayor presión no sólo sobre los productores y distribuidores de alimentos sino también sobre las autoridades competentes para establecer sistemas y reglamentaciones que permitan identificar, controlar y rastrear un alimento desde su origen hasta el final de su comercialización [1]. Es en este contexto que los sistemas de trazabilidad han tomado notoriedad constituyendo una herramienta clave para gestionar el riesgo y calidad de los productos en diferentes Cadenas de Suministro (CS) agroalimentarias, en general, y en la CS de la Carne (CSC), en particular.

Aunque existen diversas acepciones de trazabilidad, según el *Codex Alimentarius* [2], se la define como “la capacidad para seguir el movimiento de un alimento a través de etapa(s) específica(s) de la producción, transformación y distribución”. Así,

establecer un sistema de trazabilidad es un método efectivo para garantizar la seguridad alimentaria acreditando que los alimentos son sanos y fiables y que, ante cualquier problema, se cuenta con la información para limitar su riesgo permitiendo, si es necesario, retirar partidas del mercado. Sin embargo, este sistema no disminuye la cantidad de productos retirados en aquellos casos en que la producción se realice por mezcla de lotes como sucede, por ejemplo, en la elaboración de productos cárnicos.

En la industria de los alimentos, lotes de materia prima provenientes de diversos proveedores, con diferentes calidades y precios, a menudo se mezclan para obtener lotes de productos terminados. Esto se conoce como el problema de dispersión por lotes, en el cual se tienen procesos de desensamblado/desarmado y ensamblado/armado durante la producción [3]. La mezcla de lotes de materias primas en distintos lotes de producto incrementa no sólo la complejidad en su trazabilidad hacia atrás o *tracing* sino también la probabilidad de contaminación del alimento que podría causar el retiro de productos.

A nivel planta, Dupuy y col. [4] es uno de los trabajos pioneros en abordar a el problema de dispersión por lotes desde un enfoque de modelado matemático. Estos autores desarrollaron un modelo de programación mixta entera lineal (MILP) para optimizar la trazabilidad minimizando la dispersión durante la elaboración de salchichas, controlando la mezcla de lotes de producción para limitar el tamaño y, en consecuencia, el costo y el impacto mediático del retiro de los lotes de producto en caso de problemas. Luego, Tamayo y col. [5] emplearon algoritmos genéticos para resolver el mismo problema propuesto en [4]. Hu y col. [6] propusieron un modelo matemático basado en programación dinámica para mejorar el sistema de trazabilidad en una fábrica China de dumplings al minimizar los lotes de producto retirados del mercado ante posibles crisis de seguridad alimentaria. Dabbene y col. [7] plantearon una nueva formulación MILP para optimizar la trazabilidad en el que se utiliza un grafo interconectado para representar al proceso de producción. Estos autores adoptan directamente el costo de retirada del mercado para el peor caso como criterio desempeño del modelo y para demostrar su efectividad lo aplican al mismo ejemplo presentado en [4].

Respecto a la trazabilidad en la CSC, Vélez Cervantes [8] desarrolló un modelo lineal (LP) para planificar la CS pesquera de Esmeraldas (Ecuador) donde implementa un "sistema de gestión de trazabilidad" considerando la calidad de los mariscos alrededor de cada nodo de la CS. Por otra parte, Mohammed y col. [9] desarrollaron un modelo MILP difuso multiobjetivo para el diseño y planificación de la distribución de productos en la CSC que incorpora la trazabilidad mediante el cálculo de los costos por el uso del sistema de identificación por radiofrecuencia (RFID).

De acuerdo a nuestro conocimiento, no se ha implementado aún la integración de la trazabilidad y la dispersión por lotes en las CSCs. Por ello, en este trabajo se presenta un modelo MILP para la optimización de la trazabilidad mediante la reducción de la dispersión de los lotes en toda la CSC. El problema permite además determinar los actores involucrados en la producción de los productos cárnicos y calcular el tamaño y número de lotes de materias primas y productos generados en las plantas y aquellos producidos en los frigoríficos, identificando los que serán utilizados en la elaboración de cada producto final logrando así su rastreo a lo largo de la cadena.

2 Definición del Problema

El problema bajo estudio se basa en optimizar el sistema de trazabilidad de la CSC compuesta por tres eslabones, como se muestra en la Fig. 1. Cada frigorífico $f \in \{1,\ldots, F\}$ faena una o más especies animales $a \in \{1,\ldots, A_f\}$, generándose los lotes $h \in \{1,\ldots, H_{af}\}$ para cada una de ellas. Los animales son vendidos en forma de media res a los establecimientos elaboradores $e \in \{1,\ldots, E\}$ donde se los desposta en $m \in \{1,\ldots, M_e\}$ materias primas, generándose $i \in \{1,\ldots, I_{me}\}$ lotes de las mismas. En una etapa posterior de la planta, la materia prima se corta para obtener los componentes $c \in \{1,\ldots, C_e\}$ que luego, de acuerdo a una receta conocida, se mezclan en las proporciones adecuadas para obtener los lotes $k \in \{1,\ldots, K_{pe}\}$ de cada producto $p \in \{1,\ldots, P_e\}$ elaborado por el establecimiento *e*. Finalmente, los productos *p* serán distribuidos a cada minorista $r \in \{1,\ldots, R\}$ de manera de satisfacer su demanda D_{pr} en un horizonte de tiempo *HT*.

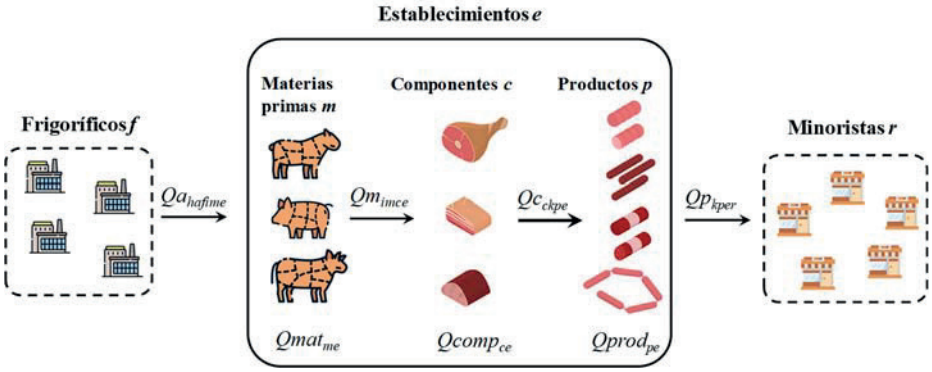

Fig. 1. Estructura de la CSC en estudio.

En este problema se tiene como datos en cada establecimiento *e*, la especificación de los diversos cortes *m* que se realizan a las medias reses de cada animal *a* procesado, la definición del trozado de la materia prima *m* para obtener los componentes *c* y las recetas de producción que detallan los componentes *c* utilizados en la elaboración de los productos finales *p*. Los siguientes parámetros representan esta información:

- Pa_{am}: es la proporción de materia prima *m* que se obtiene del animal *a*.
- Pm_{mc}: es la proporción de componente *c* que se obtiene de la materia prima *m*.
- Pc_{cp}: es la proporción de componente *c* que formará parte del producto *p*.

La cantidad de producto *p* demandada por cada minorista *r*, D_{pr}, es un parámetro del modelo y se conocen, además, los tamaños máximos y mínimos posibles para los lotes de animal *a* en cada frigorífico *f* ($bt_{af}^{\max}$, $bt_{af}^{\min}$) y, para cada lote de materia prima *m* ($b_{me}^{\max}$, $b_{me}^{\min}$) y producto *p* ($bs_{pe}^{\max}$, $bs_{pe}^{\min}$) dentro de los establecimientos *e*. Dichas cotas se basan en la capacidad máxima y mínima de procesamiento o almacenamiento del actor o etapa correspondiente. Es importante destacar que se propone el número máximo de lotes de animal, materia prima y producto (es decir, el número máximo de

elementos de los conjuntos H_{af}, I_{me} y K_{pe}), respectivamente. Este número se determina en función del mínimo tamaño posible del lote correspondiente y de la demanda.

La función objetivo del problema consiste en minimizar la dispersión de los lotes durante la elaboración de productos cárnicos, es decir, desde la compra del animal al frigorífico hasta obtener el producto, considerando cada paso del proceso de elaboración.

En resumen, el problema consiste en determinar simultáneamente lo siguiente:

a) el frigorífico proveedor, la cantidad de animal requerida y el tamaño de sus lotes, identificando el lote que se envía a cada establecimiento,
b) el tamaño y la cantidad de lotes de materia prima generados en cada establecimiento y cuál de ellos se usa en la elaboración de cada producto,
c) el tamaño y número de lotes de producto en cada establecimiento,
d) el establecimiento que abastece a cada minorista, identificando el producto y el lote que recibe cada uno.

Por lo tanto, este modelo permite identificar el lote de animal (de un dado frigorífico) que genera el lote de producto que recibe el minorista, representando así la trazabilidad del producto.

3 Formulación del Modelo

En esta sección se detalla la formulación del modelo MILP propuesto para minimizar la dispersión de los lotes en la CSC.

3.1 Restricciones de los frigoríficos

En primer lugar, para determinar los lotes generados en los frigoríficos se define la siguiente variable binaria:

$$x_{haf} = \begin{cases} 1 \text{ si el batch } h \text{ de animal } a \text{ se genera en el frigorífico } f \\ 0 \text{ en caso contrario} \end{cases}$$

$$BT_{haf} \leq bt_{af}^{\max} \cdot x_{haf} \qquad \forall h \in H_{af}, a \in A_f, f \tag{1}$$

$$BT_{haf} \geq bt_{af}^{\min} \cdot x_{haf} \qquad \forall h \in H_{af}, a \in A_f, f \tag{2}$$

Las Ecs. (1) y (2) establecen que el tamaño del lote h de animal a en el frigorífico f, BT_{haf}, se encuentre entre su cota superior e inferior ($bt_{af}^{\max}$, $bt_{af}^{\min}$), respectivamente. Además, estas restricciones aseguran que el tamaño del lote sea cero si el lote no se genera ($x_{haf} = 0$).

$$x_{h+1,af} \leq x_{haf} \qquad \forall\, 1 \leq h < H_{af}, a \in A_f, f \tag{3}$$

La Ec. (3) asegura que los lotes *h* en cada frigorífico *f* se generen en orden ascendente, es decir, el lote *h*+1 puede generarse sólo si el lote *h* ya fue generado.

$$Qan_{af} = \sum_{h \in H_{af}} BT_{haf} \qquad \forall a \in A_f, f \tag{4}$$

La Ec. (4) define la cantidad total de animal *a* procesada en el frigorífico *f*, Qan_{af}, como la suma de las bachadas *h* generadas en el mismo.

$$Pa_{am} \cdot BT_{haf} = \sum_{e} \sum_{i \in I_{me}} Qa_{hafime} \qquad \forall h \in H_{af}, a \in A_f, f, m \in MR_{ae} \tag{5}$$

La Ec. (5) expresa que cada lote *h* de medias reses del animal *a* que se envía a los establecimientos productores *e*, es despostado para obtener los cortes de materia prima *m*, respetando la proporción Pa_{am}. La variable continua Qa_{hafime} representa la cantidad de animal *a* en el lote *h* enviada desde el frigorífico *f* al establecimiento *e* contenida en el lote *i* de materia prima *m* y el subconjunto MR_{ae} contiene aquellas materias primas *m* que se obtienen del animal *a* en la planta *e*.

$$\sum_{e} \sum_{m \in MR_{ae}} \sum_{i \in I_{me}} Qa_{hafime} \leq Qa_{af}^{\max} \cdot x_{haf} \qquad \forall h \in H_{af}, a \in A_f, f \tag{6}$$

Si el batch *h* de animal *a* en el frigorífico *f* existe (es decir, $x_{haf} = 1$), la Ec. (6) asegura que la cantidad Qa_{hafime} sea menor que la cantidad máxima de animal que se puede procesar en el frigorífico *f*, $Qa_{af}^{\max}$.

$$BT_{h+1,af} \leq BT_{haf} \qquad \forall\, 1 \leq h < H_{af}, a \in A_f, f \tag{7}$$

Para evitar soluciones alternativas, la Ec. (7) asegura que los tamaños de bachada también sigan un orden creciente.

3.2 Restricciones de los establecimientos

Restricciones de las materias primas
Se define la variable binaria:

$$w_{ime} = \begin{cases} 1 \text{ si el batch } i \text{ de materia prima } m \text{ se genera en el establecimiento } e \\ 0 \text{ en caso contrario} \end{cases}$$

$$\sum_{e} \sum_{m \in MR_{ae}} w_{ime} \leq \sum_{f} \sum_{h \in H_{af}} x_{haf} \quad \forall a \in A_f, i \in I_{me} \tag{8}$$

La restricción (8) asegura que si no se generan bachadas *h* del animal *a* entonces no se podrán generar lotes *i* de las materias primas *m* que provienen de ese animal en ningún establecimiento *e*.

$$B_{ime} \le b_{me}^{\max} \cdot w_{ime} \qquad \forall i \in I_{me}, m \in M_e, e \tag{9}$$

$$B_{ime} \ge b_{me}^{\min} \cdot w_{ime} \qquad \forall i \in I_{me}, m \in M_e, e \tag{10}$$

En caso de que se genere el batch *i* de materia prima *m* en el establecimiento *e*, es decir w_{ime} = 1, su tamaño B_{ime} estará delimitado por sus cotas superior $b_{me}^{\max}$ e inferior $b_{me}^{\min}$ como establecen las Ecs. (9) y (10), respectivamente.

$$w_{i+1,me} \le w_{ime} \qquad \forall 1 \le i < I_{me}, m \in M_e, e \tag{11}$$

Mediante la Ec. (11) se garantiza que la generación de lotes *i* se realice en orden creciente.

$$B_{ime} = \sum_{f} \sum_{a \in A_f} \sum_{h \in H_{af}} Qa_{hafime} \qquad \forall i \in I_{me}, m \in M_e, e \tag{12}$$

Debido a que un lote *i* de materia prima *m* en cada establecimiento *e* se puede obtener a partir de diferentes lotes *h* del animal *a* recibidos de distintos frigoríficos *f*, la Ec. (12) establece que su tamaño, B_{ime}, es igual a la sumatoria de las cantidades que llegan desde todos ellos para formarlo.

$$\sum_{f} \sum_{a \in A_f} \sum_{h \in H_{af}} Qa_{hafime} \le Qa_{af}^{\max} \cdot w_{ime} \qquad \forall i \in I_{me}, m \in M_e, e \tag{13}$$

Si el batch *i* de materia prima *m* en el establecimiento *e* existe (w_{ime}=1), entonces, según lo establece la Ec. (13), la cantidad de animal *a* en el lote *h* enviada por el frigorífico *f* al establecimiento *e* contenida en el lote *i* de materia prima *m* Qa_{hafime}, no debe superar su cota superior, $Qa_{af}^{\max}$.

$$Qmat_{me} = \sum_{i \in I_{me}} B_{ime} \qquad \forall m \in M_e, e \tag{14}$$

La cantidad total de materia prima *m* disponible en cada establecimiento *e*, $Qmat_{me}$, queda definida por la suma de los lotes *i* generados para la misma (Ec. 14).

$$Pm_{mc} \cdot B_{ime} \ge Qm_{imce} \qquad \forall i \in I_{me}, m \in M_e, c \in CS_{me}, e \tag{15}$$

La Ec. (15) representa el desarmado de la materia prima *m* para obtener los componentes o trozos de carne *c*, respetando la proporción conocida Pm_{mc}. Aquí, la variable continua Qm_{imce} es la cantidad del componente *c* que proviene del batch *i* de la materia prima *m* y el subconjunto CS_{me} incluye a los componentes *c* que provienen de la materia prima *m* en el establecimiento *e*.

$$Qmat_{me} \geq \sum_{c \in CS_{me}} \sum_{i \in I_{me}} Qm_{imce} \qquad \forall m \in M_e, e \tag{16}$$

La Ec. (16) establece que la suma de las cantidades de todos los componentes *c* obtenidos a partir de los lotes *i* no podrá ser mayor que la cantidad total de materia prima *m* a partir de la cual se originan.

$$Qm_{imce} \leq Qm_{me}^{\max} \cdot w_{ime} \qquad \forall i \in I_{me}, m \in M_e, c \in CS_{me}, e \tag{17}$$

La Ec. (17) impide que la cantidad del componente *c* proveniente del batch *i* de la materia prima *m* en el establecimiento *e,* supere la cantidad máxima de materia prima que se puede procesar en el establecimiento, $Qm_{me}^{\max}$.

$$B_{i+1,me} \leq B_{ime} \qquad \forall 1 \leq i < I_{me}, m \in M_e, e \tag{18}$$

La Ec. (18) garantiza que el de tamaño de los lotes de materia prima se generen en orden ascendente evitando así soluciones alternativas.

Restricciones de los componentes

$$Qcomp_{ce} = \sum_{m \in MS_{ce}} \sum_{i \in I_{me}} Qm_{imce} \quad \forall c \in C_e, e \tag{19}$$

La Ec. (19) establece que la cantidad de componente *c* producida en el establecimiento *e*, $Qcomp_{ce}$, proviene exclusivamente de la suma de los lotes *i* de las materias primas *m* que se procesaron en la planta. El subconjunto MS_{ce} contiene a las materias primas que pueden generar el componente *c*.

$$Qcomp_{ce} = \sum_{p \in PS_{ce}} \sum_{k \in K_{pe}} Qc_{ckpe} \qquad \forall c \in C_e, e \tag{20}$$

A su vez, la Ec. (20) define que $Qcomp_{ce}$ sea igual a la suma de las cantidades de componente *c* utilizadas en la elaboración de todos los lotes *k* de los productos *p*, Qc_{cpke}. Aquí, el subconjunto PS_{ce} incluye a los productos que se pueden elaborar con el componente *c* en la planta *e*.

Restricciones de los productos
Se define la variable binaria:

$$z_{kpe} = \begin{cases} 1 \text{ si el batch } k \text{ de producto } p \text{ se genera en el establecimiento } e \\ 0 \text{ en caso contrario} \end{cases}$$

$$BS_{kpe} \leq bs_{pe}^{\max} \cdot z_{kpe} \qquad \forall k \in K_{pe}, p \in P_e, e \tag{21}$$

$$BS_{kpe} \geq bs_{pe}^{\min} \cdot z_{kpe} \qquad \forall k \in K_{pe}, p \in P_e, e \tag{22}$$

La variable z_{kpe} se activa mediante las Ecs. (21) y (22) donde el tamaño del lote k de producto p en el establecimiento e, BS_{kpe}, puede tomar un valor distinto de cero sólo si $z_{kpe} = 1$. Los parámetros $bs_{pe}^{\max}$ y $bs_{pe}^{\min}$ son las cotas máximas y mínimas, respectivamente.

$$z_{k+1,pe} \leq z_{kpe} \qquad \forall 1 \leq k < K_{pe}, p \in P_e, e \tag{23}$$

Al igual que en las secciones previas, la Ec. (23) se incorpora con la finalidad de reducir el espacio de búsqueda garantizando que las bachadas k del producto p en el establecimiento e se generen en orden ascendente.

$$Qprod_{pe} = \sum_{k \in K_{pe}} BS_{kpe} \qquad \forall p \in P_e, e \tag{24}$$

La cantidad total de producto p elaborado en el establecimiento e, $Qprod_{pe}$, se define en la Ec. (24) igual a la suma de todos los lotes k del producto p elaborados en el mismo.

$$Pc_{cp} \cdot BS_{kpe} = Qc_{ckpe} \qquad \forall c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{25}$$

La cantidad de componente c que formará parte del lote k de producto p en un dado establecimiento e, Qc_{ckpe} se calcula en la Ec. (25) donde cada batch k de producto p elaborado debe respetar la proporción Pc_{cp} dada en la receta de producción. El subconjunto CR_{pe} incluye los componentes que se utilizan para elaborar el producto p en el establecimiento e.

$$Qc_{ckpe} \leq Qc_{ce}^{\max} \cdot z_{kpe} \qquad \forall c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{26}$$

La Ec. (26) impide que la cantidad de componente c usada para elaborar el batch k de producto p en el establecimiento e supere la cantidad máxima de componente que se puede procesar, $Qc_{ce}^{\max}$. Esta cota solo se aplica si existe el lote k de producto p en el establecimiento e.

$$Qprod_{pe} = \sum_{c \in CR_{pe}} \sum_{k \in K_{pe}} Qc_{ckpe} \qquad \forall p \in P_e, e \tag{27}$$

El balance de masa de la Ec. (27) establece que la cantidad de producto p será igual a la suma de los componentes c que lo conforman.

$$BS_{k+1,pe} \leq BS_{kpe} \qquad \forall 1 \leq k < K_{pe}, p \in P_e, e \tag{28}$$

Para mejorar el proceso de resolución del problema la Ec. (28) elimina soluciones equivalentes al obligar que el tamaño de bachada de un número de lote menor, sea mayor o igual que el tamaño del número de lote siguiente.

3.3 **Restricciones de los minoristas**

$$D_{pr} = \sum_{e} \sum_{k \in K_{pe}} Qp_{kper} \qquad \forall p \in P_e, r \tag{29}$$

Sea Qp_{kper} una variable no negativa que representa la cantidad de producto p perteneciente al lote k que se elabora en la planta e y se distribuye al minorista r. La Ec. (29) asegura que la satisfacción de la demanda del producto p en los distintos minoristas r, la cual será cubierta utilizando tantos lotes k del producto p como sean necesarios que podrán provenir de uno o más establecimientos e.

$$\sum_{r} Qp_{kper} \leq BS_{kpe} \qquad \forall k \in K_{pe}, p \in P_e, e \tag{30}$$

La Ec. (30) establece que la cantidad de producto p perteneciente al batch k producido en un dado establecimiento e que se envía a todos los minoritas de la CS deberá ser menor o igual que el tamaño de lote, BS_{kpe}.

$$\sum_{k \in K_{pe}} \sum_{r} Qp_{kper} \leq Qprod_{pe} \qquad \forall p \in P_e, e \tag{31}$$

A su vez, la cantidad total de producto p que se puede enviar a los minoristas, no puede superar a la cantidad de producto p disponible en el establecimiento e, $Qprod_{ep}$, como se evidencia en la Ec. (31).

3.4 **Restricciones de utilización de bachadas**

Con el fin de relacionar los lotes en la CS, se introducen las variables binarias:

v_{hafime} = { 1 si el batch h de animal a es usado en el batch i de materia prima m en el establecimiento e
0 en caso contrario

y_{imckpe} = { 1 si el batch i de materia prima m genera el componente c y este es utilizado en el batch k de producto terminado p en el establecimiento
0 en caso contrario

$$v_{hafime} \leq x_{haf} \qquad \forall h \in H_{af}, a \in A_f, f, i \in I_{me}, m \in MR_{ae}, e \tag{32}$$

$$v_{hafime} \leq w_{ime} \qquad \forall h \in H_{af}, a \in A_f, f, i \in I_{me}, m \in MR_{ae}, e \tag{33}$$

Las Ecs. (32) y (33) implican la generación previa del lote *h* del animal *a* en el frigorífico *f* ($x_{haf} = 1$) y la generación del lote *i* de materia prima *m* en el establecimiento *e* ($w_{ime} = 1$), respectivamente, para que el lote *h* de animal pueda asignarse a algún lote *i* de materia prima en alguno de los establecimientos de la CS.

$$Qa_{hafime} \leq Qa_{af}^{\max} \cdot v_{hafime} \qquad \forall h \in H_{af}, a \in A_f, f, i \in I_{me}, m \in MR_{ae}, e \tag{34}$$

La Ec. (34) establece que la cantidad Qa_{hafime} está acotada por la cantidad máxima de animal que se puede procesar en el frigorífico.

$$y_{imckpe} \leq w_{ime} \qquad \forall i \in I_{me}, m \in MS_{ce}, c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{35}$$

$$y_{imckpe} \leq z_{kpe} \qquad \forall i \in I_{me}, m \in MS_{ce}, c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{36}$$

Si no se genera el batch *i* de materia prima *m* ($w_{ime} = 0$) o no se genera el batch *k* de producto *p* en el establecimiento *e* ($z_{kpe} = 0$), la variable binaria y_{imckpe} será nula, de acuerdo con las Ecs. (35) y (36), respectivamente.

$$Qmcp_{imckpe} \leq Qcomp_{ce}^{\max} \cdot y_{imckpe} \qquad \forall i \in I_{me}, m \in MS_{ce}, c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{37}$$

$$\sum_{p \in PS_{ce}} \sum_{k \in K_{pe}} Qmcp_{imckpe} = Qm_{imce} \qquad \forall i \in I_{me}, m \in MS_{ce}, c \in C_e, e \tag{38}$$

$$\sum_{m \in MS_{ce}} \sum_{i \in I_{me}} Qmcp_{imckpe} = Qc_{ckpe} \qquad \forall c \in CR_{pe}, k \in K_{pe}, p \in P_e, e \tag{39}$$

Las Ecs. (37) a (39) vinculan a la variable continua $Qmcp_{imckpe}$ definida para rastrear el lote *i* de materia prima *m* que forma parte del lote *k* de producto final *p* en el establecimiento *e* con la variable binaria y_{imckpe} y las cantidades tanto de materia prima *m* que se transforma en componente *c* como con la cantidad de componente *c* que se utiliza para elaborar el producto *p*.

3.5 Función Objetivo

$$FO = \sum_{e} \sum_{m \in MS_{ce}} \sum_{i \in I_{me}} \sum_{c \in CR_{pe}} \sum_{p \in P_e} \sum_{k \in K_{pe}} y_{imckpe} + \sum_{f} \sum_{a \in A_f} \sum_{h \in H_{af}} \sum_{e} \sum_{m \in MR_{ae}} \sum_{i \in I_{me}} v_{hafime} \tag{40}$$

La función objetivo del problema planteado consiste en minimizar la dispersión de los lotes en toda la CSC.

4 Caso de Estudio

El caso de estudio planteado para la aplicación del modelo propuesto considera una CSC formada por tres frigoríficos ($F = 3$), dos establecimientos productores ($E = 2$) y

tres minoristas (R =3). Además, se contempla la faena de 2 tipos de animales (A = 2) y la elaboración de 12 productos distintos (P = 12), a saber: chorizo puro cerdo (p1), salame (p2), chorizo de segunda calidad o mezcla (p3), mortadela (p4), salchicha de viena (p5), jamón cocido (p6), morcilla (p7), queso de cerdo (p8), longaniza (p9), bondiola (p10), lomito (p11) y panceta (p12). Para la elaboración de dichos productos se consideran siete materias primas (M =7) que representan los principales cortes de carne de los animales mencionados y trece componentes (C = 13) que corresponden a los subcortes de las materias primas.

En el frigorífico f1 se faenan cerdos (a1), en f2 vacas (a2) y en f3 las dos especies (a1 y a2). A su vez, para cada frigorífico se propone el número máximo de lotes a saber: H_{f1} = 5 para f1, H_{f2} = 3 para f2 y H_{f3} = 4 para f3. En cuanto a los establecimientos, e1 elabora los productos p1, p2, p3, p4, p7, p8 y p9 (P_{e1} = 7) mientras que e2 elabora p2, p3, p4, p5, p6, p10, p11 y p12 (P_{e2} = 8). El número máximo de lotes i de materia prima y k de producto terminado propuestos son, I = 5 y K = 4, respectivamente, en ambos establecimientos.

En la Tabla 1 se muestran los datos referidos a las proporciones tanto de materia prima proveniente de cada animal como de componente obtenido de cada materia prima. Las proporciones de componente usadas en la elaboración de cada producto y las demandas mensuales de los minoristas por cada uno se detallan en la Tabla 2.

Tabla 1. Datos de desarmado del animal y las materias primas.

El modelo MILP presentado fue implementado y resuelto en el software GAMS 31.1.1 en un procesador Intel(R) Core i7-10700, 2.9GHz empleando el código CPLEX 12.10. El problema involucra 6.527 ecuaciones con 3.924 variables continuas y 1.685 variables binarias. El tiempo de resolución es de 13,58 CPU s con una diferencia de integralidad de 3%. En la solución óptima, el valor de la función objetivo para la dispersión de los lotes es 100, lo que significa que los 10 lotes *h* de los 2 tipos de animal generados en los frigoríficos 1 y 3, se dispersan en 30 lotes *i* de materias primas los que, a su vez, forman parte de 19 lotes *k* de producto final en los 2 establecimientos.

En la Fig. 2 se ilustran los resultados obtenidos donde se pueden apreciar los lotes generados tanto para cada animal en los 2 frigoríficos utilizados como para las materias primas y productos de los 2 establecimientos productores, así como su dispersión a lo largo de toda la CSC. En la Tabla 3 se presenta un detalle de las cantidades de cada lote de animal enviado a cada establecimiento para formar los distintos lotes de materia prima mientras que en las Tablas 4 y 5 se reportan las cantidades de cada lote de producto enviadas a cada minorista por parte de los establecimientos 1 y 2 respectivamente.

Como se planteó anteriormente, el modelo desarrollado permite identificar el lote de animal con el que se elabora cada producto. Si se rastrea, por ejemplo, el chorizo de segunda calidad (p3) en la Fig. 2, se puede ver que la demanda total de los tres minoristas se cumple generando un único lote (k1) en el establecimiento 2 utilizando para su producción, 270 kg de c2 provenientes del batch i1 de m1, 150 kg de c3 aportados por el lote i1 de m2 y 180 kg de c4 generados a partir del batch i1 de m3. A su vez, en la Tabla 3, se puede observar que el lote i1 de m1 se genera a partir del lote h3 de cerdo (a1) proveniente de f1 y del lote h4 de f3, el lote i1 de m2 es generado por el lote h2 de f3 y el lote i1 de m3 proviene del lote h2 de vaca (a2) de f3. Si bien el lote i1 de m2 podría generarse utilizando lotes de un mismo frigorífico, con el fin de minimizar la dispersión y generar las cantidades exactas de componente, es que se produce esta situación. Cabe aclarar que, en este problema, no estamos considerando los costos, por lo cual, para el modelo es indistinto elegir entre lotes de un frigorífico u otro, pues lo que se busca es minimizar la dispersión.

5 Conclusiones

En este trabajo se ha propuesto un modelo MILP para resolver del problema de dispersión por lotes en la CSC con el fin de optimizar su trazabilidad a lo largo de la misma.

Se estudió una CSC compuesta por 3 niveles: frigoríficos que faenan varios animales, establecimientos que elaboran diferentes productos cárnicos y los minoristas que los demandan. La formulación desarrollada permitió determinar tipo y cantidad de animal que provee cada frigorífico, el número y tamaño de los lotes generados y la cantidad de los mismos que se envía a cada planta. A su vez, en estas últimas se decide qué materias primas y productos procesar, con qué número y tamaño de lote, respectivamente, y se establece la cantidad de componente intermedio producido y con qué lote/s de producto y cantidad del mismo se abastece la demanda de los minoristas. Asimismo, al minimizar la suma de las dispersiones de todos los lotes de animal, materias primas

y productos en la CSC el modelo propuesto minimiza, en caso de ocurrir algún problema con los lotes de algún producto, los costos de retirada del mercado de los mismos.

El caso de estudio presentado evidencia la capacidad del modelo de abordar la trazabilidad en la CSC mediante un enfoque integrado, al dimensionar los lotes para cada eslabón de la CS, al mismo tiempo que se resuelve el problema de la dispersión.

En trabajos futuros, se pretende desarrollar una formulación multiobjetivo en la que se incorpore el costo total de la CSC como criterio de desempeño adicional.

Resumen. Con el propósito de modelar detalladamente un proceso de producción de metanol modificado para aceptar gas natural con un alto contenido de CO_2 (50-60%) como alimentación, se estudió la reacción de hidrogenación de CO_2 sobre un catalizador comercial de Ni. Se comprobó la simultaneidad de la reacción de reformado seco (RS) con la hidrogenación de CO_2 (RWGS) a 600ºC y 1,62 bar, empleando una mezcla $H_2/CO_2/CH_4$. Se intentó utilizar la información experimental para realizar por vía computacional el ajuste de los parámetros cinéticos de ecuaciones tipo LH-HW para RWGS y ley de la potencia para RS. Con la primera surgieron problemas de sensibilidad e ineficiencia lo que llevo a adoptar modelos tipo ley de potencia para ambas reacciones. Se facilitó la estimación de los parámetros iniciales para RS en razón del limitado grado de avance de esta reacción De este modo, se obtuvieron resultados satisfactorios, particularmente para RS, pudiéndose detectar los valores atípicos previamente a reiterar la predicción de los parámetros. Será necesario realizar experimentación adicional para mejorar el modelado de la reacción RWGS, si se pretende la simulación rigurosa y control global del proceso de interés.

Palabras clave: Metano, CO_2, Cinética, RWGS

1 Introducción

El metanol es una importante materia prima primaria para la energía y las industrias químicas, debido a su amplia gama de aplicaciones. Puede ser utilizado como combustible o para producir formaldehído, olefinas, ácido acético, ésteres, biodiesel, etc. Para la producción de metanol, se requiere la generación de gas de síntesis (syngas), que es una mezcla que contiene esencialmente H_2, CO y CO_2, en proporciones adecuadas. La generación de syngas se logra mediante la aplicación del conocido proceso de steam reforming (SR) aplicado al gas natural. Este proceso opera a alta temperatura (850-900ºC) y dado el carácter endotérmico de la reacción tiene un alto consumo energético dando origen a significativas emisiones de CO_2. Como alternativa en la última década

se han intensificado los estudios de diferentes procesos que usan como materia prima CO_2 cuya hidrogenación (a ≈ 600ºC) da lugar al gas de síntesis. La implementación a escala industrial de estos procesos se encuentra limitada por el alto costo del H_2, si es producido mediante procesos electrolíticos para evitar la generación de CO_2.

En estudios previos [1,2] se ha demostrado que una opción válida, desde el punto de vista técnico y económico, es la utilización de gas natural con alto contenido de CO_2 como materia prima. Mediante el proceso de reformado combinado (RC), es decir haciendo uso simultáneo de las reacciones de SR y reformado seco (RS) se logra generar syngas a menor costo y consumo energético. En nuestro país existen numerosos yacimientos de gas natural con alto contenido de CO_2, justificando su eventual utilización para producir metanol. Sin embargo, cuando el contenido de CO_2 es superior al 30%, es necesario reducir la concentración de CO_2 para mantener las ventajas mencionadas. En Cañete et al. [3,4] se demostró que la disponibilidad de yacimientos de gas natural con alto contenido de CO_2 (50-60%) permiten la generación de gas de síntesis para la producción de metanol mediante la introducción de un reactor de hidrogenación de CO_2 (RWGS), antes del reformador.

En esos estudios la simulación de dicho reactor se efectuó utilizando un modelo cinético reportado por Joo [5] para un catalizador (Fe_2O_3/Cr_2O_3) del tipo empleado en la reacción de gas de agua (WGS). Este catalizador no es adecuado para la reacción RWGS a alta temperatura (>400ºC) con exceso de H_2. Con el objeto de diseñar y simular rigurosamente el proceso, y ante la ausencia de expresiones cinéticas para la reacción RWGS en presencia de CH_4, hemos efectuado el estudio cinético de un catalizador comercial de Ni. Se resume aquí el trabajo experimental y la metodología empleada para obtener los parámetros cinéticos correspondientes.

En la Sección 2 se plantean los modelos cinéticos y los balances de masa correspondientes al sistema de ecuaciones diferenciales a resolver para el ajuste de parámetros. Posteriormente, en la Sección 3 se describen los equipos y la técnica empleada para la recolección de datos experimentales. En dicha sección referida a la metodología, también se presenta el esquema de optimización utilizado para resolver el problema de estimación de parámetros. En la sección siguiente se detallan los resultados obtenidos y los métodos de inicialización empleados en la búsqueda de parámetros. Finalmente, la última sección está destinada a las conclusiones.

2 Modelamiento cinético

2.1 Antecedentes

En la década del 50, presumiblemente debido al advenimiento del cálculo computacional en el campo de la ingeniería química, el modelado de velocidades de reacción en catálisis heterogénea tuvo un gran impulso, habiéndose estudiado variadas técnicas de determinación y análisis de los parámetros. En Kittrell y Mezaki [6] se describen modelos cinéticos y métodos clásicos de construcción. Los autores advierten que, en muchos casos, las conclusiones deben extraerse de conjuntos pequeños de datos cinéticos poco claros y por ende enfatizan la importancia del adecuado diseño experimental para

evitar conclusiones ambiguas. Una eficiente estrategia experimental recomendada involucra realizar una iteración continua entre el modelado computacional y la experimentación dentro del laboratorio. Por su parte, Seinfeld [7] enfatiza el uso de estimaciones no lineales para encontrar parámetros cinéticos a partir de datos de reactores experimentales, discutiendo en forma teórica la exactitud de los estimados en ecuaciones diferenciales ordinarias (ODEs). Este autor afirma que es necesario computar el coeficiente de sensibilidad correspondiente.

Los estudios cinéticos hasta la fecha abarcan numerosas reacciones heterogéneas de interés industrial, entre las que se puede mencionar particularmente el reformado de CH_4 con vapor de H_2O sobre catalizadores de Ni. Al-Ubaid [8] caracterizó dichos catalizadores. Aunque hay estudios cinéticos anteriores, cabe citar el realizado en nuestro país por Agnelli et al. [9]. Los autores utilizando un catalizador comercial de Ni estudiaron la reacción a diferentes temperaturas hasta 750ºC. Demostraron claramente que a esa temperatura la reacción de reformado va acompañada de la reacción WGS, siendo esta última cercana al equilibrio. Esta situación complica la obtención de los parámetros cinéticos. Aunque plantearon diferentes modelos cinéticos, concluyeron que la reacción puede simplificarse asumiendo que es de primer orden respecto al CH_4. Xu y Froment [10] reportaron ecuaciones cinéticas útiles para el diseño, simulación y optimización de un reformador industrial que aún son utilizadas. Vista la simultaneidad de las reacciones de reformado y WGS, ya reportada por Agnelli et al. [9], como así también la de metanación, los autores estudiaron las reacciones por separado, en diferentes rangos de temperatura. A baja temperatura (300-400ºC) se determinaron los parámetros cinéticos de la reacción RWGS y de metanación y a mayor temperatura (400-575ºC), los de SR. Derivaron una gran cantidad de modelos cinéticos para estas reacciones, asumiendo diferentes etapas elementales, por el conocido método Langmuir- Hinshelwood- Hougen- Watson (LH-HW). El ajuste final de parámetros se realizó empleando los datos experimentales obtenidos a todas las temperaturas.

Posteriormente, Hou y Hughes [11] estudiaron la reacción SR sobre Ni/α-Al_2O separando también en diferentes intervalos de temperatura la reacción principal de RWGS. Los resultados experimentales de conversión de CH_4 y CO_2 en función de W/F se correlacionaron mediante polinomios, y se obtuvieron las correspondientes velocidades de reacción por derivación. Se plantearon seis modelos cinéticos, asumiendo diferentes etapas elementales con bastante similitud con el tratamiento de Xu y Froment [10]. Los parámetros cinéticos óptimos se obtuvieron aplicando el método de cuadrados mínimos a la diferencia entre las velocidades de reacción experimentales y las estimadas por el modelo. Los autores mencionan que las diferencias observadas con el modelado de Xu y Froment [10], se deben a características del catalizador. Recientemente, Meloni et al. [12] ofrecen un panorama general de los aspectos más relevantes del proceso de SR incluyendo detalles de diferentes catalizadores de Ni. y sus condiciones operativas.

Es sabido que el catalizador a base de Ni utilizado comúnmente para el reformado con vapor también cataliza la reacción inversa del gas de agua (RWGS) y no presenta desactivación a corto plazo cuando se alimenta CO_2 e H_2 a baja temperatura, como demostraron Xu y Froment [10] y Hou y Hughes [11]. Por tal motivo y debido a su bajo costo comparado con catalizadores basados en metales nobles, se ha seleccionado un

catalizador comercial de Ni para realizar las experiencias y a partir de ellas estimar los parámetros cinéticos.

La bibliografía específica sobre el modelado cinético de la reacción RWGS es escasa y relativamente reciente. Wolf et al. [13] afirmaron que el catalizador de Ni es capaz de catalizar la reacción RWGS en forma muy efectiva, trabajando a 900º C. A esta temperatura la presencia de CH_4, debido a la metanación del CO, es muy baja. Los autores desarrollaron un modelo cinético del tipo ley de la potencia, trabajando en primer lugar a baja conversión para determinar el orden de reacción del CO_2 y del H_2. Los resultados fueron 1 y 0,3 respectivamente. Dicha expresión fue complementada con un término de retroceso imponiendo la condición de reacción nula en el equilibrio. Para la reacción de WGS a baja temperatura, Maklavany et al. [14] estimaron los parámetros cinéticos de una expresión tipo ley de potencia. Aunque este trabajo no se refiere a RWGS y se utiliza un catalizador $CuO/ZnO/Al_2O_3$, es oportuno citarlo porque discute en mayor detalle el método computacional utilizado para la estimación de los parámetros y su validación. Más relevante para nuestros objetivos es el estudio de Vidal Vazquez et al. [15], quienes utilizaron los modelos cinéticos de Xu y Froment [10] y Hou y Hughes [11] como así también una expresión basada en la adsorción molecular de reactivos y productos, siendo la siguiente reacción en superficie la etapa controlante: $CO_2.S + H_2.S \leftrightarrow CO.S + H_2O .S$

De esta forma se obtiene una ecuación con un denominador cuadrático que involucra las constantes de adsorción de CO_2, H_2, H_2O y CO. La reacción de hidrogenación de CO_2 y la de metanación se estudiaron en el rango 550 -850ºC a presión atmosférica y 30 bar, empleando catalizadores de Ni y de Rh. Los autores demostraron que el modelo propuesto por Xu y Froment [10] es el mejor para representar el comportamiento de los catalizadores estudiados. La revisión bibliográfica resumida aquí demuestra que no existen estudios cinéticos previos sobre RWGS en presencia de CH_4.

2.2 Reacciones intervinientes

Al combinarse GN con alto contenido de CO_2 e H_2 se produce la reacción RWGS:

$$CO_2 + H_2 \leftrightarrow CO + H_2O$$

Además, la combinación de metano con CO_2 puede dar lugar a la reacción RS:

$$CH_4 + CO_2 \leftrightarrow 2CO + 2H_2$$

Asumimos que el reactor tubular de lecho fijo es isotérmico, opera en estado estacionario y corresponde al modelo homogéneo en una dimensión. En este caso, el balance de masa puede expresarse con la Ec. 1, donde F_i^0 es el caudal inicial de alimentación del *i*-ésimo componente, X_i es la conversión del componente *i*, W es la masa de catalizador expresada en gramos y r_i es la velocidad de reacción del *i*-ésimo componente.

$$F_i^0 \frac{dX_i}{dW} = r_i \quad (1)$$

Dado que se producen simultáneamente la reacción RWGS y de RS, la Ec. 1 se aplica al CO_2 y al CH_4. El sistema de ecuaciones que representa este proceso corresponde a

las Ecs. 2 y 3. En ambos casos se han asumido expresiones del tipo ley de la potencia. En dichas ecuaciones, p_i es la presión parcial del *i*-ésimo componente, k_{fRWGS} y k_{fRS} son las constantes cinéticas de la reacción de avance y K_{RWGS} es la constante de equilibrio termodinámico. Las presiones parciales se calculan como $p_i = P\,Y_i$, donde P es la presión total e Y_i es la fracción molar del *i*-ésimo reactivo.

$$F_{CO2}^{0}\frac{dX_{CO_2}}{d(\mathrm{W})} = k_{fRWGS}{p_{CO_2}}^{a}{p_{H_2}}^{b}{p_{CO}}^{c}{p_{H_2O}}^{d}\left(1-\frac{p_{CO}\,p_{H_2O}}{K_{RWGS}\,p_{CO_2}\,p_{H_2}}\right)+k_{fRS}\,p_{CH_4}^{e}\;p_{CO_2}^{f}{p_{CO}}^{g}{p_{H_2}}^{h} \quad (2)$$

$$F_{CH_4}^{0}\frac{dX_{CH_4}}{dW} = k_{fRS}{p_{CH_4}}^{e}{p_{CO_2}}^{f}{p_{CO}}^{g}{p_{H_2}}^{h} \quad (3)$$

En la Ec. 3 se ha eliminado el paréntesis que contiene la constante de equilibrio porque la conversión máxima de esta reacción es de 15% en nuestras condiciones operativas.

3 Metodología

En las Ecs. 2 y 3, se desea ajustar simultáneamente los siguientes diez parámetros cinéticos: todos los órdenes de reacción *a, b, c, d, e, f, g* y *h*, junto con ambas constantes cinéticas k_{fRWGS} y k_{fRS}. Cabe aclarar que la constante termodinámica K_{RWGS}, no es un parámetro de ajuste (no se hicieron mediciones en condición de equilibrio). Con los datos obtenidos experimentalmente para el catalizador de Ni, el ajuste de dichos parámetros se realizó resolviendo el sistema de ecuaciones mediante técnicas de optimización multivariable.

3.1 Sección Experimental

La obtención de datos experimentales fue llevada a cabo en un reactor conformado por un tubo de cuarzo de 1 metro de longitud y 4 mm de diámetro ubicado en el interior de un horno eléctrico Lindberg-Blue M, el cual posee 3 zonas de calentamiento independiente. El reactor se encuentra alimentado por tubos de gas de CH_4, H_2, CO_2 y Ar regulados por un controlador y sus respectivos caudalímetros másicos. La corriente de salida del horno es alimentada a una trampa de agua, que es un lecho fijo de sílica gel y tamiz molecular. Posteriormente, es analizada en un cromatógrafo gaseoso Perkin Elmer Autosystem que opera con un detector de conductividad térmica (TCD). La temperatura del lecho de catalizador (600º C) fue determinada con una termocupla tipo K colocada a la salida del lecho de catalizador y la presión con un manómetro de baja presión (1,6 bar). Un esquema del equipamiento empleado se muestra en la Figura 1. Previo a cada experiencia, el catalizador fresco es reducido con una corriente de hidrógeno durante media hora a una temperatura de 500°C. Posteriormente, luego del inicio de la reacción, el sistema es monitoreado durante 2 o 3 horas para asegurar que las mediciones de composición de los productos correspondan al estado estacionario.

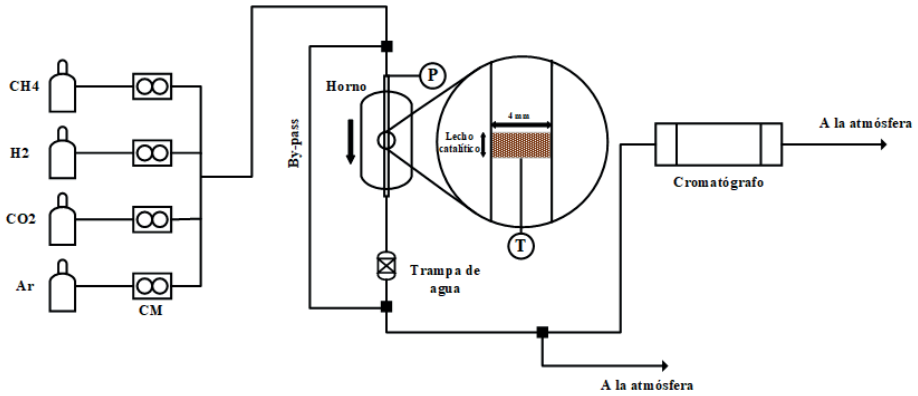

Fig. 1. Diagrama de flujo del equipo empleado.

Debido a su bajo costo y disponibilidad, se decidió utilizar un catalizador comercial de Ni del tipo empleado en el reformado de CH_4 con vapor de agua: Ni (9%)/Al_2O_3. Las pastillas de catalizador se molieron hasta alcanzar un diámetro promedio de 0,3 mm para minimizar efectos difusionales. La ausencia de resistencia a la transferencia de masa interna y a la transferencia de calor fue verificada empleando criterios conocidos [16]. Se utilizaron para el conjunto de experiencias, masas de catalizador en el rango 10-70 mg. Con estas cantidades de sólido la longitud de lecho osciló entre 0,2 y 1,4 cm. Se investigó el comportamiento de distintas mezclas en un rango de caudal de 135-144 cm^3/min. Las 6 composiciones de alimentación y las cargas de catalizador empleadas se muestran en la Fig. 2.

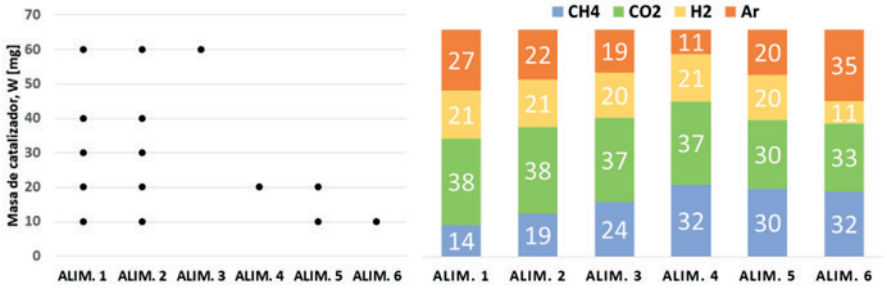

Fig. 2. Composición volumétrica de cada alimentación y cargas de catalizador empleadas en los ensayos experimentales.

Se realizaron 15 experiencias, las que permitieron obtener conversiones de CH_4 entre 3,5 y 16%, y conversiones de CO_2 en el rango 22-31%. Para las composiciones de alimentación seleccionadas, el análisis de equilibrio termodinámico predice conversiones de CH_4 de 69 a 75% y de CO_2 entre 38 y 52%. Por lo tanto, los valores experimentales indican que la reacción predominante es RWGS.

3.2 Estimación de parámetros cinéticos

Este caso se puede abordar como un problema de optimización multivariable no restringida. Vistos el modelo cinético propuesto y las composiciones de la alimentación, donde las derivadas son iguales a cero en el punto inicial, los métodos de optimización con gradientes diferenciales no se aconsejan. Por tal motivo, para la optimización se eligió un método libre de derivadas denominado Simplex Nelder Mead [17].

Los parámetros cinéticos conforman el siguiente vector de variables de optimización: $z^T = [k_{fRWGS}, k_{fRS}, a, b, c, d, e, f, g, h]$. Como se muestra en la Fig. 3, el optimizador se encuentra acoplado a un resolvedor de ecuaciones diferenciales ordinarias (ODEs) con un método explícito Runge-Kutta de segundo y tercer orden [18,19]. Este procedimiento se emplea para resolver el sistema de ecuaciones comprendido por las Ecs. 2 y 3.

Por su parte, el optimizador compara las conversiones predichas por dicho modelo con las experimentales. En el sentido de cuadrados mínimos, la función objetivo OF a minimizar se puede expresar (Ec. 4) como la sumatoria de las diferencias para cada punto obtenido entre las conversiones de CO_2 y CH_4 predichas X_i y experimentales $\hat{X}_i$.

$$OF = mín \sum \left(X_i - \hat{X}_i\right)^2 \tag{4}$$

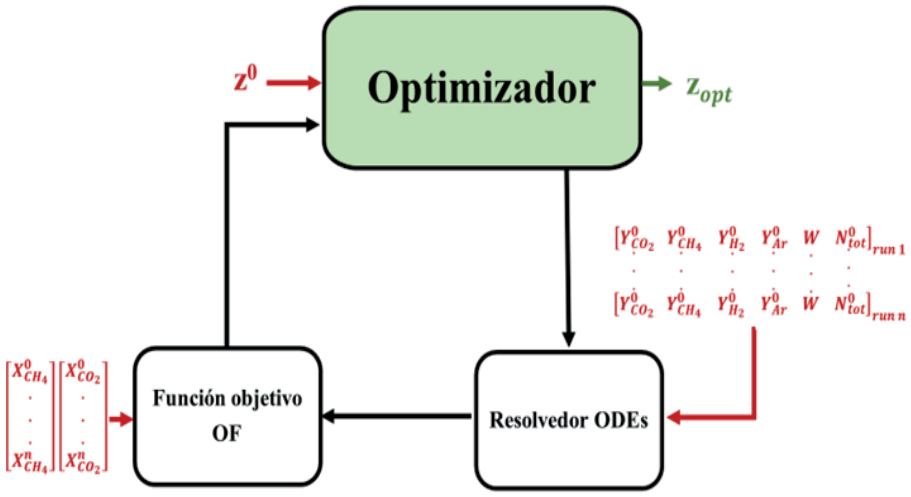

Fig. 3. Esquema del método de optimización de parámetros cinéticos

Para determinar las bondades del ajuste se calculó el error porcentual absoluto medio (MAPE) para ambos componentes (Ec. 5). En esta ecuación n es el número de experiencias realizadas.

$$MAPE_i = \frac{1}{n} \sum_1^n \left| \frac{(X_i - \hat{X}_i)}{X_i} \right| 100 \tag{5}$$

El método de Nelder-Mead empleado, cuyo algoritmo está explicado en detalle en [17], es un método de búsqueda directa que sirve para optimización multidimensional sin restricciones, sin emplear información sobre derivadas (ni explícitas ni implícitas). Mediante su aplicación, tuvimos éxito para resolver nuestro problema de interés, mientras que usando la bien conocida técnica de búsqueda Levenberg-Marquardt [20], la cual emplea Jacobianos en su algoritmo, no hemos logrado arribar a una solución completamente satisfactoria con su parámetro de ajuste fijado en $\mu_k = 10^{-2}$.

Dado que Nelder-Mead no usa derivadas, es menos probable que quede atrapado en un mínimo local, en comparación con Levenberg-Marquardt. Esta característica podría ser la razón del mejor desempeño observado del algoritmo Nelder Mead. Dicho método fue eficaz, pero demostró ser bastante lento y fuertemente dependiente del punto inicial. Por esta razón, sería interesante continuar explorando en detalle otras alternativas. Sabemos que Levenberg-Marquardt es una técnica standard especialmente robusta y ampliamente usada para la minimización de funciones del tipo cuadrados mínimos. Por lo tanto, para lograr mayor efectividad, se investigará una estrategia adecuada para elegir μ_k en el algoritmo clásico de Levenberg-Marquardt pues, en la práctica, este parámetro modifica el subproblema de cuadrados mínimos lineales a resolver.

Por otra parte, el estudio del comportamiento de las técnicas metaheurísticas ante estos problemas es un tema de investigación abierto. Dichas técnicas, por ejemplo Algoritmos Genéticos u Optimización con Enjambre de Partículas, exploran eficientemente grandes espacios de búsqueda y podrían constituir alternativas útiles. Se las suele utilizar cuando no existe un método exacto de resolución, cuando existe un método exacto que consume mucho tiempo para ofrecer la solución óptima, cuando existen limitaciones de tiempo o bien como paso intermedio para obtener una solución inicial para la aplicación de otra técnica. En tal sentido, como trabajo futuro, planificamos evaluar el comportamiento de una hiperheurística eficiente [21] ante este problema de ajuste de parámetros.

4 Resultados

En primera instancia, para la reacción de RWGS se evaluó la posibilidad de emplear una ecuación cinética del tipo LH-HW propuesta por Xu y Froment [10]. Para RS, por su menor grado de avance, se postuló la ley de potencia. Después de numerosos intentos no se lograron resultados satisfactorios ya que estos dependían fuertemente de los valores iniciales seleccionados.

Con el propósito de disminuir la complejidad numérica y evitar los problemas de sensibilidad inherentes al modelo LH-HW, se decidió adoptar expresiones cinéticas tipo ley de la potencia para ambas reacciones. (Ec. 2 y Ec. 3). Se aplicó el criterio de cuadrados mínimos utilizando diversos puntos iniciales, lo cual demandó excesivo tiempo de cómputo. Hemos observado que la fijación de cualquier conjunto de parámetros iniciales conduce a una convergencia extremadamente lenta. Este comportamiento indica la necesidad de adoptar algún método de selección de los valores iniciales estimados, o bien ciertos cambios en el diseño experimental [9, 22].

En nuestro caso, el contexto permite realizar ciertas suposiciones con el fin de obtener valores iniciales más cercanos. Así, teniendo en cuenta que el grado de avance de la reacción del RS es limitado, se puede asumir operación diferencial. Por lo tanto, la velocidad de reacción r_{RS} se calculó utilizando la Ec. 6, donde X_{CH_4} corresponde a la conversión experimental de CH_4, $F^0_{CH_4}$ el flujo molar inicial de CH_4 en mol/h y W es la masa de catalizador en gramos.

$$r_{RS} = \frac{X_{CH_4} F^0_{CH_4}}{W} \tag{6}$$

Además, se procedió a la linealización de la Ec. 3 mediante logaritmos obteniéndose la expresión de la Ec. 7.

$$\log r_{RS} = \log k_{RS} + e \log p_{CH_4} + f \log p_{CO_2} + g \log p_{CO} + h \log p_{H_2} \tag{7}$$

Las presiones parciales utilizadas en la Ec. 6 fueron calculadas como un promedio entre las presiones de entrada y las de salida. Así, utilizando los 15 datos experimentales disponibles, se realizó el ajuste de parámetros por cuadrados mínimos entre el $\log r_{RS}$ experimental y el predicho por el modelo.

Tabla 1. Valores iniciales obtenidos por reformulación de la Ec. 3

k_{RS}	e	f	g	h	MAPE [%]
0,290	0,574	1,574	-0,737	-0,820	4,92

En particular, los valores obtenidos en la Tabla 1 fueron utilizados como punto de inicialización para la optimización del problema completo. El optimizador convergió a los parámetros reportados en la primera fila de las Tablas 2 y 3.Los valores corresponden a las masas de catalizador expresadas en gramos, las presiones parciales, en bar y el caudal $F^0_{CO_2}$, en mol/h.

Tabla 2. Parámetros cinéticos estimados para RWGS.

¿Con Valores atípicos?	k_{fRWGS}	a	b	c	d
SI	0,14	1,43	1,07	-1,13	-1,16
NO	0,06	0,59	0,61	-0,65	-1,47

Tabla 3. Parámetros cinéticos estimados para RS

¿Con Valores atípicos?	k_{fRS}	e	f	g	h
SI	0,08	0,47	1,05	-0,48	-0,82
NO	0,043±0,006	0,386±0,003	0,731±0,055	-0,702±0,082	-0,685±0,031

Dada la limitada cantidad de datos experimentales, en nuestro caso ha sido imposible identificar a priori los valores experimentales atípicos (outliers), pues las técnicas existentes para su detección previa [23] son inherentemente estadísticas. Una vez realizado un primer ajuste de parámetros, dichos valores recién pudieron ser detectados comparando las conversiones experimentales de CO_2 y CH_4 versus las predichas por el modelo. En la Fig. 4 puede observarse la existencia de valores atípicos, indicados como los puntos A, B y C.

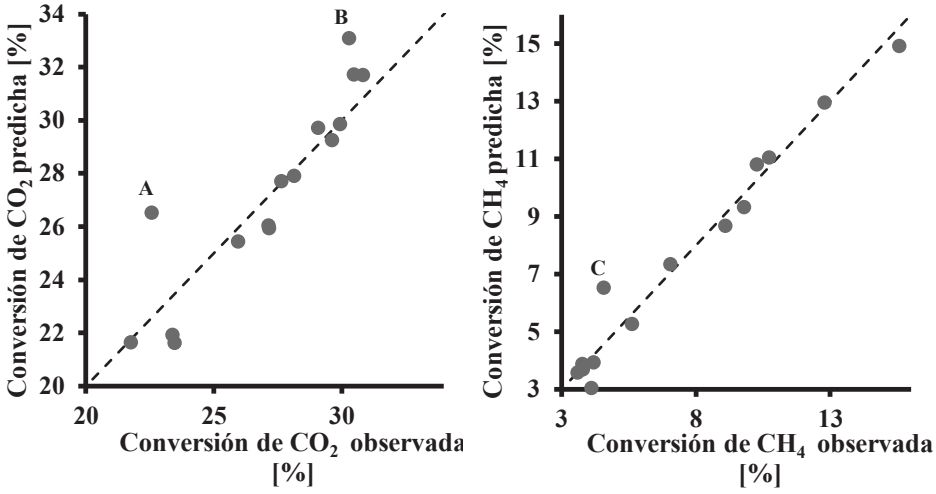

Fig. 4. - Gráficos de paridad.

Al eliminar los tres outliers y realizar nuevamente el ajuste de parámetros, se obtuvieron los resultados que se muestran en la última fila de las Tablas 2 y 3. Esta combinación de parámetros es la más confiable que hemos podido hallar hasta el presente, con un MAPE asociado menor al 7%.

A los efectos de acotar el valor de estos parámetros se procedió a la determinación de los intervalos de confianza. Para esto se utilizaron los resultados de 39 ajustes, realizados con diferentes valores iniciales, que permitieron el cálculo de la desviación standard. Para la reacción de RS se obtuvieron los valores máximos y mínimos que se muestran en la Tabla 3. Se puede apreciar que la menor diferencia se obtuvo en el orden de reacción para el CH_4 reactante cuya concentración fue modificada en un rango mas amplio (ver Figura 2). Cuando se realizó el mismo trabajo para RWGS el rango de variación de los parámetros fue excesivo (40-50%), y por esta razón no son informados. Este comportamiento se atribuye a condiciones del trabajo experimental. En primer término es evidente que el número de experiencias realizadas es reducido. Por otra parte, como se observa en la Figura 2, la concentración de CO_2 e H_2 se mantuvo prácticamente constante, por lo que es de esperar menor incidencia en la reacción RWGS. Además, la

conversión de CO_2 fue en la mayoría de las experiencias cercana al valor de equilibrio. Solo en 4 de las 15 corridas la diferencia entre la conversión de equilibrio y la experimental fue superior al 20%. Esta condición es el resultado de la velocidad espacial empleada. .Para obtener resultados más confiables será necesario: a) realizar un mayor número de experiencias explorando el efecto de los productos de reacción (CO y/o H_2O) en la alimentación, b) aumentar el caudal de alimentación para obtener conversiones de CO_2 más alejadas del valor de equilibrio y c) utilizar un mayor rango de concentraciones de H_2.

Utilizando los parámetros cinéticos obtenidos cabe estimar la velocidad de reacción de RWGS y RS a efectos comparativos. Para presiones parciales promedio entre los valores de entrada y salida, de una experiencia realizada con 30 mg de catalizador resulta: r_{RWGS} = 4,11 gmol CO_2 /gcat h; r_{RS} = 0,17 gmol CH_4/gcat h comprobándose que las ecuaciones cinéticas predicen la mayor actividad catalítica de la reacción de interés.

A 600ºC, Cui et al. [24] estudiaron la cinética de RS sobre un catalizador de Ni (8%)/α-Al_2O_3 utilizando una ecuación tipo ley de la potencia. Encontraron órdenes de reacción de 0,72 y 0,41 para el CH_4 y el CO_2, respectivamente. Para el H_2 el orden es prácticamente nulo y el de CO es -0,37. En nuestro caso, el orden de reacción del CH_4 es menor (0,39) y el de CO_2 es más elevado (0,73). Dado que el estudio fue realizado con presiones parciales muy bajas, la velocidad de reacción no es comparable. Como se ha mencionado anteriormente, no existen estudios de RWGS en presencia de CH_4 lo que impide un mejor análisis de nuestros resultados.

5 Conclusiones

Con el propósito de modelar detalladamente un proceso de producción de metanol modificado para aceptar gas natural con un alto contenido de CO_2 (50-60%) como alimentación, se estudió la reacción de hidrogenación de CO_2 sobre un catalizador comercial de reformado de Ni. En este manuscrito se analizan los datos recolectados experimentalmente, para luego realizar el ajuste de los parámetros cinéticos correspondientes. Se comprobó que se producen simultáneamente la reacción RWGS y la de reformado seco., siendo la primera la de mayor grado de avance.

Se investigó en primer lugar un modelo cinético propuesto en la literatura para la reacción de RWGS [10]. Mediante un análisis de sensibilidad, se detectaron las severas limitaciones del modelo referidas al efecto de las perturbaciones. Más aún, al efectuar el ajuste de datos, hemos observado que el problema de cómputo que surge de dicho modelo tiene problemas numéricos de estabilidad.

Dadas las dificultades numéricas inherentes al modelo L-H tradicional, se decidió recurrir a expresiones del tipo ley de la potencia para ambas reacciones. No se puede afirmar que existe una técnica general infalible para atacar el problema de estimación de parámetros mediante cuadrados mínimos no lineales. Hemos comprobado que la fijación de cualquier conjunto de parámetros iniciales es ineficiente pues la convergencia requiere un prohibitivo esfuerzo computacional. Para RS ha sido posible la linealización del modelo cinético para obtener valores iniciales aproximados. Esta técnica

condujo a un ajuste exitoso, solo para RS. En el caso de la reacción RWGS los parámetros obtenidos son solo aproximados, debido esencialmente a condiciones operativas de la experimentación que han sido identificadas y deberán ser modificadas. A continuación, se identificaron los valores atípicos que fueron removidos para lograr el ajuste final.

Dado que la metodología propuesta emplea la totalidad de la información experimental disponible con fines de ajuste, resulta necesaria una validación de los resultados con datos experimentales independientes. Por lo tanto, como trabajo futuro, se planifica efectuar algunos experimentos adicionales con el fin de validar los parámetros cinéticos hallados. A pesar de las dificultades encontradas, el ajuste con la ley de la potencia presentado aquí servirá para una primera estimación del tamaño y costo del reactor de hidrogenación si se optara por la utilización de un catalizador típico de reformado.

abandoni@plapiqui.edu.ar

Resumen. El trabajo presenta un modelo de tipo MILP que incluye alternativamente cuatro actividades típicas (perforación, terminación, fractura hidráulica y mantenimiento) en la industria del gas y petróleo. El mismo consiste en un núcleo común de ecuaciones que modelan el problema y una serie de restricciones específicas de las operaciones que se incluyen en el caso a resolver.

Palabras claves: Gas y Petróleo, Upstream, Planificación, Optimización.

1 Introducción

La administración óptima de las actividades en el sector upstream de la industria petrolera, es compleja y crítica para la rentabilidad del negocio. En yacimientos no convencionales (Vaca Muerta), se pueden realizar perforaciones de múltiples pozos con diferentes tipos de unidades de perforación. En equipos móviles, de tecnología más moderna, la limitante crítica es su disponibilidad (tipo y cantidad), mientras que, en equipos no móviles, que deben ser desmontados y vueltos a montar para su traslado, la restricción fuerte es el tiempo insumido en las operaciones.

Otra operación de relevancia es el mantenimiento de los pozos que están operativos (pulling). Esto se realiza con unidades móviles preparadas para izar las varillas del tubing de producción de cualquier tipo de pozo. Su uso más intensivo es en campos convencionales en recuperación primaria con problemas en la bomba de fondo, ya sean mecánicos o eléctricos. En grandes campos se puede tener simultáneamente del orden de cientos de pozos a reparar [1], por lo que planificar la actividad de pulling resulta muy complejo.

La Ingeniería de Sistemas de Procesos está teniendo un rol importante en estos temas. Varios trabajos abordan aspectos específicos de la planificación de decisiones en el upstream [2], [3], [4], etc., si bien las planillas de cálculo son aún muy utilizadas. A pesar de estos trabajos, la consideración integrada de los diferentes problemas de planeamiento de las múltiples actividades del upstream, aún no ha sido totalmente abordada en la literatura.

2 Modelo desarrollado

$$\text{Min } FO_1 \text{ o } FO_2 \text{ o } FO_3 \text{ o } FO_4$$
$$\text{Sujeto a:}$$
$$\{\text{Modelo núcleo de asignación y traslado de equipos}\}_{i,j,k,t} = 0$$
$$\{\text{Estimación de variables y función objetivo } (FO_{1,2,3,4})\}_{i,j,k,t} = 0$$
$$\{\text{Restricciones operativas y contractuales}\}^{OP}_{1,2,3,4} \leq 0$$

Sets (i: Equipos ; j:Pozos ; k: Secuencias ; t: Periodos.

El modelo considera la planificación, en un dado horizonte de tiempo, de decisiones económicas de las operaciones (monto de inversiones y plan de erogaciones, costos de infraestructura y operativos, ingresos por ventas de gas y petróleo, etc.), decisiones de diseño y uso de recursos (selección del tipo y cantidad de tecnologías de perforación y servicios, etc.) y operativas (orden y secuenciado de tareas, tiempos de ejecución, ruteo).

Se trata de un modelo de Programación Mixto Entera Lineal (MILP), que extiende trabajos previos de los autores [5]. Para su implementación y resolución se utiliza el programa de modelado y optimización GAMS (General Algebraic Modeling System) [6]. El modelo es de carácter general, adaptado para optimizar la planificación de cuatro operaciones en yacimientos convencionales o no convencionales. Estas son: (i) para el período de desarrollo del campo de pozos: perforación, terminación y fractura hidráulica, (ii) para el período de operación de los pozos: reparación y mantenimiento. El enfoque integral del modelo resulta ser particularmente adecuado en desarrollos donde una de las decisiones fundamentales a tomar es la selección óptima de equipos de perforación de torres móviles, como lo son los walking rigs y skidding rigs, entre otros. Se requiere información diferente para los cuatro escenarios de planificación de operaciones. Estos son: (i) OP1: perforación; (ii) OP2: fractura; (iii) OP3: perforación y fractura; (iv) OP4: Pulling y mantenimiento.

En OP1 (perforación), se utilizan datos de tiempo de ejecución, además de los costos fijos y variables que se solicitan en todos los casos. Sin embargo, no es relevante la distancia entre los pads, ni se considera producción luego de finalizada esa operación. En cambio, en OP4 (pulling + mantenimiento) si es relevante considerar la distancia entre pads y con ello se deben activar las restricciones de costo por distancia que penalizan la función objetivo. Esto se debe a los tipos de contrato que tienen las empresas con cada servicio y a las variables que impactan sobre los costos: la distancia entre operaciones, el tiempo de ejecución de cada secuencia, y la producción asociada a la ejecución. La producción a su vez, está asociada a parámetros de diseño del pozo tales como el número de etapas de fractura en pozos no convencionales, y el tipo de bomba y arreglo de fondo para los pozos convencionales. A su vez, el tiempo de ejecución, depende del largo del pozo y otras características de arquitectura que se pueden simplificar y calcular en el pre-procesamiento de los datos indicando únicamente el número de etapas productivas de cada pozo, junto con lo que produce cada etapa y lo que insume en tiempo de ejecución. Es decir, en la Operación 2 (fractura) se indica cuánto tiempo de operación se requiere para cada etapa de fractura que a su

vez corresponde a la longitud del tramo horizontal de la perforación y de esta manera se construye la estructura de costos y beneficios.

3 Caso de estudio (Operación 3: Perforación + fractura):

Se presenta un caso de estudio consistente en un proyecto de desarrollo y operación de pozos en un yacimiento no convencional, en el que se involucra el movimiento de diferentes tipos de equipos en una determinada área concesionada, para realizar actividades de perforación, tareas de terminación, y las operaciones de workover, involucradas en la fractura hidráulica de cada etapa del pozo, englobados en lo que llamamos OP3.

En el caso de estudio se opta entre 4 tecnologías de equipos de torre con métricas distintas, con el objetivo de perforar 8 pozos agrupados en 2 pads, cada uno de ellos con un diseño propio previamente definido en cuanto a número de etapas de fractura y largo del pozo. Los datos tales como costos, velocidades de operación, producción por pozo, etc., se obtuvieron de información típica de explotaciones en nuestro país en los últimos dos años, publicadas en portales oficiales de la Secretaria de Energía de La Nación. El horizonte de planeamiento considerado es de mediano plazo y con un tiempo discreto de 24 periodos o meses.

Como tecnologías de perforación se seleccionan y combinan varios tipos de los que se utilizan en nuestro país, cuyos parámetros DTM y ROP se muestran en la Tabla 1.

Tabla 1: Indicadores de performance (K.P.I.´s) de los equipos.

Tipo de Rig	Flex (i_1)	Walking (i_2)	Skidding (i_3)	Convencional (i_4)
DTM_1 (dentro del pad)*	2	1	1	15
DTM_2 (fuera del pad)*	7	15	15	15
ROP_1 (tramo vertical)*	156	140	120	120
ROP_2 (tramo horizontal)*	120	110	90	90

*DTM (Días de montaje y transporte); ROP (tasa de penetración del trepano, metros/día)

El modelo desarrollado y aplicado en este caso permite estudiar el diseño del conjunto de pozos prospectivos, la selección del proveedor de cada equipo y asignación de una serie de pozos a perforar por cada uno y sus rutas. Así mismo, se consideran diferentes funciones objetivo de tipo económico, de producción y de eficiencia operativa. Permite que el modelo minimice costos, minimice el makespan, o el tiempo total de actividades, y también permite maximizar ingresos, ganancias, valor presente o indicadores económicos más acordes al negocio como EBITDA o Breakeven-cost. Se considera la actividad de fractura hidráulica seguida inmediatamente a la perforación. Por simplicidad, se asume que todas las etapas de fractura se realizan con los mismos volúmenes de agua y arena y con el mismo tipo de terminación y con equipos idénticos lo que define costo y tiempo fijo para cada etapa junto con su producción por periodo esperada, para pozos de gas, en zonas altamente productivas. Los resultados de asignación y movimiento de los equipos del caso de estudio se muestran para cada

rig en la tabla 2 junto con las variables más relevantes para las 4 funciones objetivo propuestas.

Tabla 2. Resultados del caso de estudio. OP3: Perforación + Fractura

Corridas	FO_1 Max Ganancias	FO_2 Max Producción	FO_3 Min Costo	FO_4 Min Breakeven
Costo*	71.979	73.146	**67.344**	70.26

Rig_{i3}	j_3-j_5-j_8	j_3-j_5-j_7	j_3-j_5-j_6-j_7-j_8	j_3-j_5-j_8
Rig_{i4}	j_4-j_{11}-j_6	j_4-j_{11}	j_4-j_{10}-j_9-j_{12}-j_{11}	j_4-j_{12}-j_7-j_6

*Costo, ingreso y ganancias (10^6 U$S); Producción ($10^6 m^3_{gas}$); Breakeven (U$S/$10^3 m^3_{gas}$).

4 Conclusiones

Se presentó un modelo integral para gestión óptima de actividades típicas del sector upstream de la industria del gas y petróleo. La comparación de los resultados de las distintas FO demuestra la capacidad y flexibilidad del modelo para cubrir distintas estrategias de operación y objetivos del sector. La secuencia en que se intervienen los pozos cambia según la estrategia que se decida implementar por lo que se concluye que el modelo de asignación es de utilidad. Se alcanzan mejoras de 15% en la producción, 29% en las ganancias del proyecto y un corte de rentabilidad mínimo de 94.84 U$S por cada 1000 m^3 de gas en boca de pozo a un precio de 4.7 U$S / MM Btu.

Propuesta de una biorrefinería en una industria azucarera cubana aprovechando la biomasa

Ana Celia de Armas Martínez[1] [0000-0002-0147-0704], Yailet Albernas Carvajal[1] [0000-0003-4363-4401], Gabriela Corsano[2] [0000-0002-0235-4262] y Erenio González Suárez[1] [0000-0001-5741-8959]

Resumen. La industria azucarera cubana abre posibilidades para el desarrollo de una biorrefinería por las características de sus corrientes y sus facilidades para la obtención de diferentes productos, coproductos y energía. En el presente trabajo se propone el desarrollo de una biorrefinería considerando la obtención de azúcar, energía, etanol, xilosa, torula en crema y biogás como productos principales, empleando como biomasa la caña y el bagazo sobrante. En la obtención de etanol de segunda generación se utilizan como fuentes azucaradas el hidrolizado de bagazo, el jugo de los filtros extraído de la producción azucarera y la melaza, lo que permite disminuir en un 24% el consumo de esta última en la etapa fermentativa. La ganancia del esquema propuesto fue optimizada considerando 120 y 150 días de zafra, obteniéndose que la producción de alcohol extrafino pueda aumentar a 800 y 900 hL/d respectivamente, manteniendo constante la producción de alcohol etílico rectificado. Al analizar económicamente los procesos, solo se logra rentabilidad de forma independiente en la producción de etanol, aunque el esquema integrado sí resulta rentable para los dos períodos de zafra analizados.

Palabras clave: biorrefinería, caña de azúcar, integración, factibilidad económica.

1 Introducción

Una definición de biorrefinería es: "una instalación donde, mediante diversos procesos de transformación de la biomasa, se genera bioenergía (calor, electricidad, biocombustibles) y un amplio espectro de bioproductos (materiales, productos químicos, alimentos y piensos), requiriéndose para ello la integración de diferentes procesos y tecnologías en una misma instalación". Diversos autores han estudiado los posibles esquemas de biorrefinería que se pueden adaptar a una industria azucarera, entre ellos [1]. En ellas puede existir un grado de flexibilidad en las capacidades de procesado, permitiendo la creación de una base de producción y coproducción biológica, sostenible económicamente en el concepto de biorrefinería, siendo sus principales productos azúcar, etanol y energía [2]. Esto se puede manifestar como una solución sostenible para la reducción de la dependencia energética de las fuentes fósiles, además de contribuir a que la industria del azúcar y el alcohol sea menos vulnerable a las variaciones en el desempeño del mercado [1]. Fito y col. [3] plantean que la biorrefinería de la caña de azúcar obliga a la integración de la destilería con el proceso azucarero y la caña como materia prima principal, lo que posibilita no sólo el empleo de las mieles finales, sino también de los jugos y mieles intermedias. En el presente trabajo se proponen alternativas que tienen como objetivo lograr un

aprovechamiento integral de corrientes derivadas del proceso azucarero e integrarlas a una industria azucarera como una biorrefinería de primera y segunda generación.

2 Desarrollo

El proceso inicial es la obtención de azúcar crudo a partir de la caña de azúcar y del cual se derivan las demás producciones. Considerar un esquema de segunda generación implica utilizar en mejor medida la biomasa lignocelulósica, en este caso bagazo, siendo no solamente para producir energía, sino para aprovechar su contenido de glucosa y xilosa. Por ello se propone para la obtención de etanol no emplear agua en la etapa de fermentación y usar la mezcla de sustratos azucarados formada por hidrolizado de bagazo, jugo de los filtros y miel, así como separar la xilosa contenida en la fibra de bagazo.

La obtención de etanol a partir de miel, jugo de los filtros e hidrolizado de bagazo consta de tres etapas fundamentales: pretratamiento, fermentación y destilación. La materia prima empleada es el bagazo sobrante de la fábrica de azúcar, del cual una parte considerable se utiliza como combustible en la generación de vapor. La incorporación de la etapa de hidrólisis enzimática en un central azucarero, con una planta de etanol tradicional, permitirá una reducción del consumo de miel por concepto de compra en tiempo de no zafra, incrementando capacidades de producción no aprovechadas, así como la adaptación de la industria azucarera como una biorrefinería integrada.

En la primera etapa de pretratamiento, para la obtención del hidrolizado de bagazo, se obtiene un líquido que contiene mayormente xilosa, glucosa y arabinosa. El mismo puede ser sometido a diferentes etapas de tratamiento para obtener una corriente con mayor contenido de xilosa que pueda constituir materia prima para la producción de xilitol. Los balances de materiales, para la obtención de una corriente rica en xilosa, se realizan a partir de la cantidad de líquido separado en la primera etapa del pretratamiento del bagazo. Por otra parte, en la elaboración de concentrados proteicos se pueden utilizar diferentes fuentes de sustratos. Para esta alternativa se considera la producción de levadura torula en crema utilizando *Cándida utilis* y las vinazas provenientes de la destilería como materia prima, de forma tal que se aproveche su contenido de materia orgánica y que una vez finalizado este proceso la vinaza residual se pueda emplear en la producción de biogás [4]. Esta es una alternativa que permite aprovechar las vinazas como fuente de sustratos azucarados, siendo una materia prima más económica que la miel final. De esa forma se evita el empleo de miel en el proceso, destinándola para la producción de etanol, y se obtiene una crema proteica que pueda ser aprovechada como alimento animal. Este proceso, además, ofrece una remoción de la DQO de un 40% aproximadamente, al disminuirla a 30000 mg/L, según los resultados de [5]. Con estos valores de carga orgánica se puede realizar la producción de biogás, mediante digestión anaerobia, disminuyendo el tiempo de retención en el biodigestor. Esto permite reducir en un 75% la carga orgánica contaminante, obtener lodo fertilizante y aguas residuales para ser utilizadas en el fertirriego. Este biogás producido puede ser empleado para la generación de vapor en la destilería, lo que representa un ahorro de combustible a emplear en la misma. Un resumen de lo antes expresado se manifiesta en la Figura 1, mientras que los resultados de los balances de materiales correspondientes a los principales productos se exponen en la Figura 2.

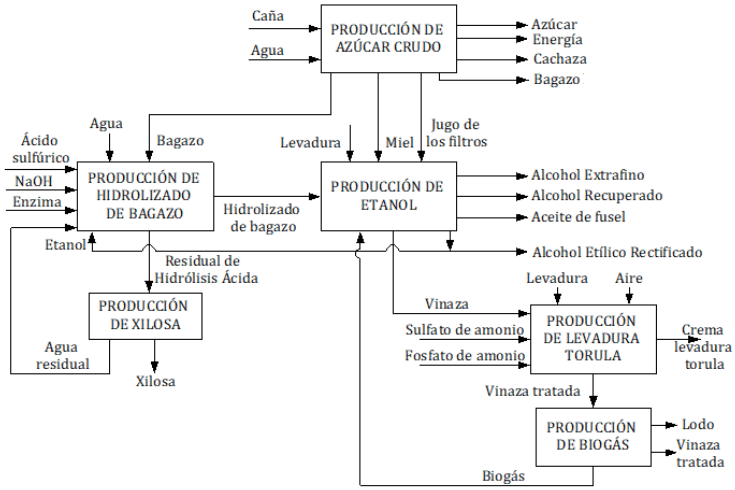

Figura 1. Esquema de biorrefinería propuesta.

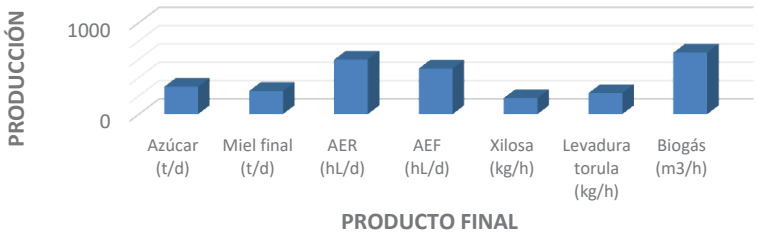

Figura 2. Principales resultados alcanzados a partir de los balances de masa.

El análisis económico se realiza aplicando la metodología planteada en [6], con el equipamiento necesario para cada proceso. Los costos totales de producción (CTP) se obtienen, entre otros aspectos, a partir de los consumos en materias primas, mano de obra y requerimientos. Mientras que, la ganancia se determinó en función del valor de la producción y del costo total de producción, para 300 días de operación al año (Figura 3). Con el objetivo de valorar la factibilidad de inversión del esquema de biorrefinería, se determinan los indicadores dinámicos de rentabilidad: VAN, TIR y PRD, tomando una tasa de interés del 15%. Inicialmente se realizan para cada proceso por separado. Los resultados se resumen en la Tabla 1. Como se puede observar, solo se logra rentabilidad en la producción de etanol como proceso independiente, sin embargo, cuando se analiza el complejo de forma integral como una biorrefinería, las ganancias que se alcanzan en la totalidad permiten la rentabilidad, con un período de recuperación de 5,5 años para 120 días de zafra. Con estos resultados se demuestra que la propuesta de esquema de biorrefinería es económicamente viable, considerando la producción azucarera establecida, realizándose extracción del jugo de los filtros y produciendo hidrolizado de bagazo con el bagazo sobrante.

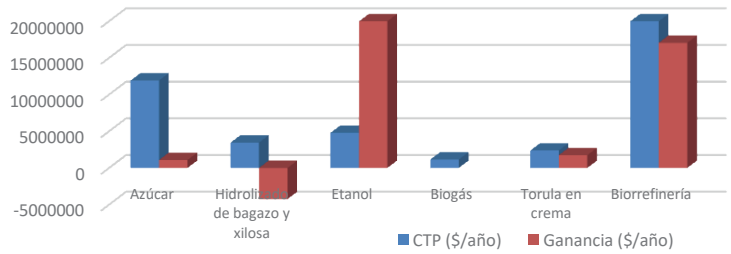

Figura 3. Costo total de producción y ganancia para cada tecnología analizada.

Tabla 1. Indicadores dinámicos de rentabilidad**.**

	Hidrolizado de Bagazo y xilosa	Etanol	Torula en crema	Biorrefinería
VAN ($)	-81 781 666	90 585 492	-14 297 833	48 389 965
TIR (%)	-	74	-	34,3

3 Conclusiones

La integración a una biorrefinería de segunda generación, que emplea el bagazo como materia prima lignocelulósica para obtener hidrolizado, unido al jugo de los filtros y la miel en la fermentación, reduce el consumo de esta última en un 24% y no necesita agua para realizar la dilución. Por otro lado, es posible obtener xilosa a partir del líquido residual del pretratamiento del bagazo por hidrólisis ácida, reduciendo el consumo de esta etapa en un 51 %.

La producción de levadura torula a partir de vinazas permite aumentar el valor agregado de este residual antes de ser usado en la producción de biogás. Desde el punto de vista económico, al analizar los procesos por separados, solo es factible la producción de etanol, pero el esquema general de biorrefinería resulta rentable para el período de zafra analizado.

Resumen. En este trabajo se describe el desarrollo de un modelo matemático como herramienta de ayuda para la toma de decisiones durante el proceso de elaboración de sidra en una escala piloto de producción. El objetivo principal del modelo es optimizar la molienda de fruta respecto de los tanques de fermentación disponibles considerando satisfacer el volumen mensual de cada emprendedor que requiere el servicio. Dicha herramienta computacional proporciona condiciones operativas óptimas para definir un programa de producción mensual, pero además suministra información para elaborar diferentes escenarios a mediano y largo plazo que faciliten la planificación estratégica en la Planta Piloto de Alimentos Sociales (PPAS).

Palabras Claves. Modelado matemático - Programación mixto-entero lineal - Sidra - Optimización de la producción

1 Introducción

El Alto Valle de Río Negro y Neuquén, en la Patagonia Norte, es la principal área de producción de frutas de pepitas de Argentina. Esta región concentra aproximadamente el 85% de la producción de manzanas y el 75% de la producción de pera [1]. La producción de manzanas y peras alcanzó en el año 2017 aproximadamente un millón de toneladas, con una distribución prácticamente en partes iguales [2]. El 60% de la producción de manzana se destina al consumo en fresco mientras que el 40% restante se industrializa. De este último porcentaje destinado a la industria, aproximadamente el 70% se emplea en la producción de jugos concentrados, mientras que el 30% restante se destina principalmente a la producción de caldos de sidra [3].

Los altos niveles de calidad exigidos por los mercados internacionales derivaron en un incremento progresivo de los niveles de descarte de pera y manzana que alcanzan el 30 y 40%, respectivamente [4]. Este descarte es el que se emplea en la elaboración de sidra. En los últimos años, la fruticultura ha sufrido una constante crisis económica, lo cual sumado a los bajos precios pagados por la industria de transformación, obliga al sector a repensar sus estrategias para mejorar su rentabilidad.

El consumo mundial de sidra se duplicó en los últimos 10 años fundamentado sobre todo en la innovación de nuevos tipos de productos, similar a lo que ocurre con otras bebidas fermentadas como la cerveza, donde se observa una fuerte tendencia al desarrollo de productos distintivos [5]. Aún con este contexto internacional favorable, en Argentina la situación es diferente. En nuestro país se consumen aproximadamente 900.000 hL/año de sidra [6]. Sin embargo, el consumo ha descendido aproximadamente 6% por año en promedio durante los últimos 5 años, lo cual representa una pérdida de aproximadamente 20 millones de litros [7]. Por lo tanto, revalorizar el consumo nacional de sidra es importante desde varios puntos de vista.

En primer lugar, existe estacionalidad en el consumo, limitándose a una época específica, entre octubre y diciembre, donde se concentra aproximadamente el 80% del consumo anual. En segundo lugar, si bien gran parte de la industria sidrera se asienta en el Alto Valle, en la región sólo se elaboran los caldos que luego son enviados a Buenos Aires donde se fracciona y embotella el producto [6]. Por último, muchas de las sidras elaboradas industrialmente no cumplen con las regulaciones del Código Alimentario Argentino (CAA), pudiéndose deber a que se emplea el descarte de fruta para su producción [8]. Por lo tanto, es un desafío lograr elaborar productos con características distintivas que sean consumidos en cualquier época del año.

En los últimos años, además, se evidencia una marcada industria artesanal de la sidra llevada adelante por emprendedores, vinculados algunos con iniciativas de turismo rural. Este impulso ha sido dado por los nuevos emprendedores del sector donde cada uno normalmente procesa alrededor 200 - 300 kg de fruta de buena calidad. Muchos de estos emprendedores se orientan a la obtención de la sidra espumosa mediante la aplicación del método Champenoise [5].

Por otra parte, recientes investigaciones resaltan el potencial de cepas de levaduras nativas de *Saccharomyces uvarum* y *Saccharomyces eubayanus* como *starters* en la fermentación de mostos de manzana para la elaboración de sidras con calidad distintiva regional [5] [7]. Estas cepas muestran características distintivas como el contenido de glicerol y la baja producción de etanol con respecto a las cepas tradicionalmente empleadas en la elaboración como *S. cerevisiae* [5][7].

Con respecto al modelado durante las etapas de fermentación, se han propuesto modelos cinéticos para predecir la utilización de azúcares que permite anticipar medidas correctivas durante la fermentación de jugo de uva [9]. Además, se ha estudiado el efecto del contenido inicial de nitrógeno y la temperatura inicial de fermentación de jugo de manzana aplicando modelos basados en la cinética de Monod [10].

Teniendo en cuenta el contexto anterior, estudiar de manera integral el proceso completo de elaboración de sidras desde el lavado de la fruta hasta la obtención del producto terminado resulta de gran interés. El análisis del proceso permitirá optimizar las diferentes etapas de elaboración alcanzando una mejor rentabilidad del sector.

La simulación presenta una multiplicidad de ventajas para analizar un proceso productivo. Por ejemplo, las etapas de elaboración pueden ser analizadas disminuyendo el riesgo de inversiones de alto costo de implementación de equipos y procesos, permitiendo a la vez, evaluar modificaciones en cada una de las etapas de elaboración [11]. En la industria vitivinícola se han desarrollado plataformas de asistencia en la

toma de decisiones [12], mientras que para la producción de cerveza se aplicó optimización dinámica para el proceso de malteado [13].

En este sentido, el modelado matemático de procesos industriales se presenta como una alternativa interesante para el análisis global de una planta de elaboración de bebidas fermentadas. El desarrollo de herramientas computacionales que faciliten la asistencia en la toma de decisiones basadas en modelos matemáticos, permitirá optimizar la producción por medio del control de cada una de las variables que intervienen en el proceso de elaboración de sidras a partir de la fermentación del jugo de manzana y pera generando productos de mayor calidad, optimizar la utilización de recursos humanos y minimizar los costos de elaboración siendo esto la llave para tener productos competitivos a nivel nacional e internacional. Se han desarrollado modelos de simulación y optimización en la industria de jugos concentrados de manzana y pera destinados a mejorar la toma de decisión al momento de la elaboración de los diferentes productos [14]. Sin embargo, hasta el momento no se han encontrado en la literatura estudios sobre modelados matemáticos que optimicen la elaboración del proceso global de producción de sidras involucrando todas las etapas.

A nivel local, la PPAS perteneciente a la Universidad Nacional de Río Negro que se encuentra ubicada en la ciudad de Villa Regina, presenta múltiples objetivos y desafíos en la producción de sidra. Por un lado, permite el análisis y desarrollo de nuevas bebidas fermentadas de carácter regional y la obtención de subproductos intermedios para el desarrollo de otros productos como pueden ser los jugos, vinagres y destilados, todos a partir de diversas variedades de fruta de pepita a las que se tiene fácil acceso y de abundante producción en la zona del Alto Valle de Río Negro. Por otro, se pretende dar valor agregado a la producción frutícola de la provincia mediante la diversificación más allá de la producción primaria tradicional, buscando aprovechar los subproductos generados durante este proceso productivo para la elaboración de alimentos como fuente de fibra y antioxidantes, entre otros. En este sentido, la prestación de servicios a emprendedores de la región y el país, que pretendan optimizar su producción como así también mejorar o desarrollar productos nuevos, resulta de muchísimo interés. Por lo que es fundamental, el análisis del proceso productivo de manera global e integral a fin de evaluar la potencialidad de la planta piloto con el objetivo de cumplir las metas establecidas, donde el desarrolla de herramientas computacionales de apoyo para la toma de decisiones basadas en modelos matemáticos resultan fundamentales como soporte en las decisiones tácticas y operativas.

El objetivo de este trabajo fue desarrollar un modelo matemático de optimización del proceso de elaboración de sidras desde la recepción de la fruta hasta el embotellado y la obtención del producto terminado. Este modelo de optimización involucra un escenario de servicios solicitados por cuatro emprendedores en simultáneo durante el mes en análisis, por lo que es importante considerar el estado actual de ocupación de tanques de la planta piloto para ir habilitando las moliendas de cada emprendedor. De esta manera, el modelo de optimización permite obtener la planificación de producción en el horizonte de tiempo de 35 días en función de la capacidad de planta piloto y disponibilidad del personal.

2 Proceso de la Planta Piloto de Sidra

La planta piloto de elaboración de sidra (Figura 1) presenta las capacidades de producción que se detallan en la Tabla 1. Por otro lado, en la Tabla 2 se detallan los volúmenes de los 15 tanques que se disponen para la elaboración de sidra con su respectiva etapa de producción antes de comenzar a resolver el problema de optimización.

Tabla 1. Datos de la planta piloto de elaboración de sidra.

Capacidad de molienda (kg fruta/h)	400
Capacidad operativa (L)	1.950
Capacidad de llenado de botellas (botella 750 cm^3/h)	150

Tabla 2. Capacidad de almacenamiento y estado de ocupación en el día 1 del horizonte de planeamiento de cada uno de los tanques de la planta piloto.

Tanque	Capacidad [L]	Disponibilidad	Etapa
1	200	No	Ninguna
2	200	No	Ninguna

La Figura 1A muestra el equipamiento utilizada en la etapa física de la planta piloto de producción de sidra, mientras que la Figura 1B muestra los tanques de fermentación donde ocurre la etapa microbiológica así como también el equipamiento necesarios para la gasificación y embotella del producto. El proceso de producción de sidra se observa en la Figura 2, donde se detallan todas las etapas de elaboración desde el lavado de la fruta hasta el envasado de la sidra producida. Además, el diagrama de flujo muestra las salidas de productos de interés en las diferentes etapas del proceso.

La fruta seleccionada para ser procesada es volcada en una cuba lavadora donde se realiza un riguroso lavado, asegurando la correcta higiene del fruto. La fruta ya limpia es captada por un elevador a paletas que ingresa a una cinta de inspección donde se realiza el descarte de la fruta en mal estado. La fruta que avanza es transportada por

otro elevador a paletas que eleva la misma hasta la boca de ingreso a un molino triturador tipo martillo para ser triturada y convertirse en una pulpa homogénea. En el siguiente paso del proceso la pulpa ingresa a una prensa de bandas donde se obtiene el jugo, que es colocado en los diferentes tanques para realizar la fermentación donde se obtendrá el caldo de sidra. Para cada una de las etapas es posible utilizar un tanque con bomba para realizar los trasvases y recirculaciones, así como también un sistema de filtrado móvil.

El equipamiento se complementa con una saturadora con sistema isobárico de llenado, una tapadora diafragmática con sistema de vacío y una bozoladora para obtener un producto terminado en botella de vidrio [15].

Fig. 1. Equipamiento de etapa física (a) y etapa microbiológica con sistema de gasificación (b) de la planta piloto de sidra.

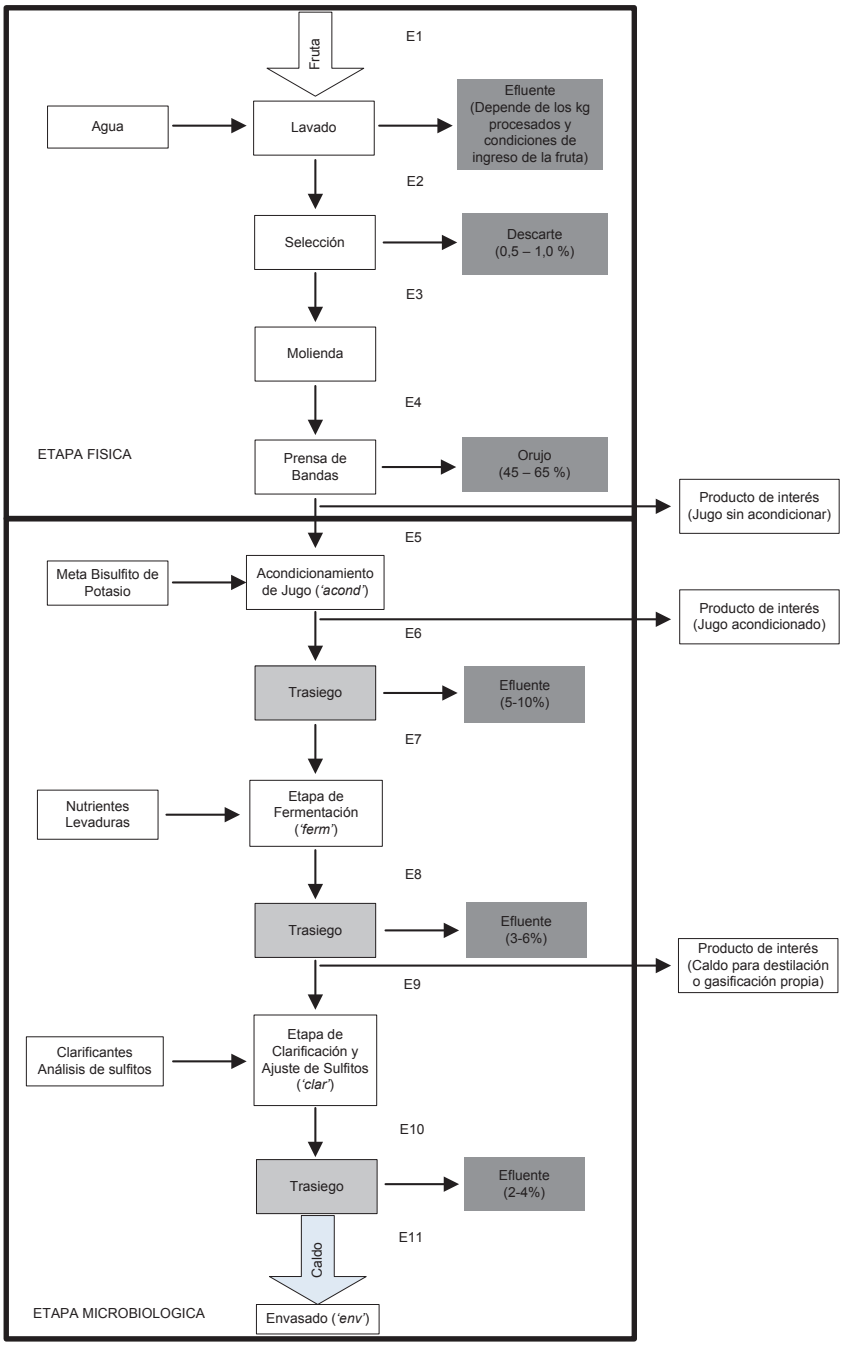

Fig. 2. Diagrama de flujo del proceso de producción de sidra y productos intermedios a escala piloto.

3 Modelo Matemático

En el modelo matemático desarrollado se presentan dos funciones objetivos que permiten abordar escenarios diferentes. La primera función objetivo (fobj=1), minimiza la cantidad de tanques utilizados durante el proceso de producción de sidra prefijando la cantidad de emprendedores y los litros de sidra que estén interesados en elaborar mensualmente. La segunda función objetivo (fobj=2), maximiza la productividad de la planta piloto de sidra en función de las restricciones operativas (tanto del equipamiento, cumplimiento del protocolo del COVID-19 y del personal disponible en la PPAS) que se detallarán más adelante.

Para el análisis, la elaboración de sidra se dividió en dos etapas: física y microbiológica. Cada etapa tiene un tiempo de duración mínimo y se incluye su correspondiente pérdida o descarte histórico de acuerdo con la Figura 2. Es importante destacar, que el modelo tiene la capacidad de considerar el estado actual de la planta al momento de la resolución del problema de optimización en ambas funciones objetivo. Es decir, se considera que tanques se encuentran ocupados, que volumen de jugo o caldo contienen, y por cuantos días en el horizonte de tiempo continuarán ocupadas según la etapa del proceso en la cual se encuentren.

Etapa Física: La etapa física involucra las etapas de lavado, selección de fruta y molienda. Se restringió la molienda a dos días a la semana, con el objetivo de representar una situación de trabajo real con el personal de planta disponible. Se consideró el ingreso de fruta a la etapa de lavado sólo los días, martes y jueves.
La molienda requerida por cada emprendedor debe realizarse una única vez en el horizonte, y se encuentra representada por la Ec. (1):

$$\sum_t y_emp_{t,emp} = 1 \tag{1}$$

Donde, *emp* es un set que indica los emprendedores e $y_emp_{t,emp}$ es una variable binaria que indica si el día *t* se está realizando la molienda del emprendedor *emp*. También se indica que sólo se puede procesar lo solicitado por un emprendedor cada día, a los fines de cumplir con los protocolos de COVID-19 establecidos en la PPAS como se muestra en la Ec. (2):

$$\sum_{emp} y_emp_{t,emp} \leq 1 \tag{2}$$

Para todas las demás subetapas de las fases física y microbiológica, la entrada está dada por el siguiente balance de masa que muestra la Ec. (3):

$$E_{j,t} = E_{j-1,t} * (1 - perdida_{j-1}) \tag{3}$$

Donde *j* representa lavado, selección, molino y prensa de bandas en la etapa física y los trasiegos de la etapa microbiológica como se muestran en la Figura 2. El parámetro *t* representa la etapa en la que se encuentre del proceso.

Etapa microbiológica: Abarca el acondicionamiento del jugo (*'acond'*), fermentación (*'ferm'*), clarificación y corrección de sulfitos (*'clar'*) y envasado ('*env'*) como se muestra en la Figura 2. El ingreso a esta etapa de elaboración comienza con el jugo obtenido en la etapa física el cual será distribuido en los tanques disponibles, y luego será acondicionado para dar inicio a la etapa de fermentación mediante la utilización de una levadura comercial *Saccharomyces cerevisiae*. Además del aporte de jugo que viene de la etapa de acondicionamiento, es posible que al inicio del horizonte, algún tanque tuviese jugo en la etapa de acondicionamiento y, por ende, debiera ingresar a la etapa de fermentación dentro del horizonte, sin estar relacionado a una molienda programada. Por lo tanto, se deben tener en cuenta los dos aportes para el ingreso de caldo a la etapa de fermentación como indica la Ec. (4):

$$E_{6,t} = \sum_{tq} ent_tq_{tq,t,'ferm'} + \left[\sum_{tq} cap_tq_{tq} * y_tq_0_{tq,'acond'} * (1 - perdida_{acond})\right]_{si\ t=ocupado_{tq}+1} \quad (4)$$

Donde $ent_tq_{tq,t,'ferm'}$ es una variable continua que representa el volumen que está ingresando al tanque *tq* el día *t* para la etapa de fermentación (*'ferm'*), cap_tq_{tq} es un parámetro que determina la capacidad del tanque *tq*, $y_tq_0_{tq,'acond'}$ es un parámetro que define si el tanque *tq* estaba ocupado originalmente para la etapa de acondicionamiento (*'acond'*) y $ocupado_{tq}$ es un parámetro que define la cantidad de días del horizonte que el tanque *tq* permanecerá ocupado. El +1 indica que al día siguiente se liberará y deberá ingresar a la etapa de fermentación. El mismo concepto se utilizó para modelar la etapa de clarificación (*'clar'*) y envasado/gasificación (*'env'*).

Una buena práctica de manufactura en el proceso de elaboración de sidra (y de bebidas fermentadas en general) es evitar que el tanque contenga demasiada cantidad de aire para que no repercuta negativamente en la etapa microbiológica. Por lo tanto, se debe asegurar que el contenido de líquido se mantenga por encima del 80% del volumen del tanque. A los fines de satisfacer este requerimiento operativo, se incluye la Ec. (5) como restricción:

$$ent_tq_{tq,t,e} \geq cap_tq_{tq} * 0.8 - 100 * cap_tq_{tq} * (1 - y_e_tq_{tq,t,e}) \quad (5)$$

Donde, $y_e_tq_{tq,t,e}$ es una variable binaria que indica si el día *t* ingresó jugo al tanque *tq* para la etapa *e*. En este problema e representa las diferentes etapas: [*'acond', 'ferm', 'clar', 'env'*]. La variable binaria $y_e_tq_{tq,t,e}$ sólo se debe activar si está ingresando jugo al tanque *tq*, el día *t* para la etapa *e*. Para esto se deberán cumplir las siguientes restricciones que se muestran en las Ec. (6) y (7):

$$ent_tq_{tq,t,e} \leq cap_tq_{tq} * y_e_tq_{tq,t,e} \quad (6)$$

$$ent_tq_{tq,t,e} \geq 10 * y_e_tq_{tq,t,e} \quad (7)$$

Para asegurar que un dado tanque asignado a una etapa del proceso de un dado emprendedor no pueda ser utilizado en simultáneo en otra operación, se incluyeron

restricciones como la que muestra a continuación para la etapa de fermentación ('*ferm*') Ec. (8):

$$y_e_tq_{tq,t,'ferm'} + \sum_{i=1}^{6} y_e_tq_{tq,t+i,e} \leq 1 \tag{8}$$

En cuanto a la función objetivo, la misma queda expresada como se muestra en la Ec. (9), donde si fobj=1 se minimiza la utilización de tanques de la planta y si fobj=2 se maximiza la producción siempre y cuando se maximice la variable OBJ:

$$OBJ = \begin{cases} -\sum_{t,tq,e} y_tq_{tq,t,e} & si\ fobj = 1 \\ \sum_{t} E_{1,t} & si\ fobj = 2 \end{cases} \tag{9}$$

El modelo fue desarrollado en la plataforma de alto nivel para optimización matemática General Algebraic Modeling System (GAMS) y está constituido por un sistema de 55.235 ecuaciones y 9.976 variables. Con respecto a las ecuaciones, 425 son restricciones de igualdad y el resto restricciones de desigualdad. Relacionado con las variables, 2.661 son continuas mientras que el resto son variables binarias. La primera función objetivo se resuelve en 1,3 segundos y la segunda función objetivo en 0,5 segundos, ambas con un gap (diferencia entre la mejor posible solución entera y la mejor solución entera encontrada) igual a cero.

4 Discusión y Resultados

La Figura 3 muestra la ocupación global de tanques en la línea de producción (fobj=1) en un período de 35 días para la elaboración de sidra de cuatro emprendedores que procesan en promedio 515 kg mensuales. La resolución de este problema nos permite detectar la capacidad disponible en la planta piloto permitiendo incluir nuevos emprendedores para la elaboración de sidra o considerar aquellos usuarios que utilizan una parte de la línea de producción porque elaboran otros tipos de productos. Este es el caso de emprendedores que obtienen el jugo de manzana y elaboran en otros establecimientos diferentes productos, como por ejemplo vinagre, que para evitar contaminaciones no pueden llevarse a cabo en la PPAS o el caso de los que utilizan el caldo sin clarificar para realizar destilaciones con el fin de obtener calvados. Para este último caso es fundamental que las condiciones iniciales de la fruta que se utiliza sean óptimas, ya que en la etapa de destilación es crucial tener una buena recuperación de aromas para los productos que diseñan.

Sin embargo, cuando se resuelve el problema de maximización de la producción (fobj=2), se observa un aumento considerable de la ocupación de tanques en la planta piloto. Esto se traduciría directamente en un aumento sustancial de la cantidad de fruta procesada (aproximadamente se duplicaría el promedio mensual), repercutiendo en una mayor cantidad de producto terminado en el mismo horizonte de tiempo.

De esta manera, esta herramienta computacional permite maximizar el factor de utilización de la planta reduciendo costos mediante un mayor procesamiento de cantidad de fruta. Los resultados de la optimización no solo permiten aumentar la produc-

ción de cada emprendedor, sino que también ponen en evidencia que se alcanza el máximo de la capacidad de producción de 1.950 L en los días 14 y 16 del horizonte de planeamiento.

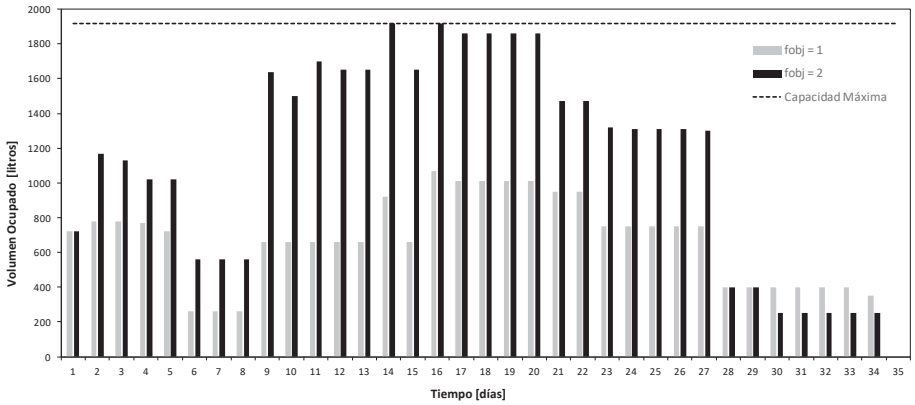

Fig. 3. Ocupación global de tanques en la línea de producción de sidra para las diferentes funciones objetivo (fobj=1 y fobj=2).

La Figura 4 muestra un diagrama de Gantt de los tiempos de elaboración de sidra para cuatro emprendedores que ingresan a elaborar sidra en ese período de tiempo a la planta, y donde se resuelve el problema utilizando la función objetivo que minimiza la utilización de tanques en la planta (fobj=1). La optimización del proceso permitiría disponer de un esquema de producción específico y diseñado para cada emprendedor evitando solapamiento de tanques durante el proceso de elaboración durante ese período de tiempo, donde además, esto queda sujeto a las restricciones operacionales y restricciones relacionadas con el cumplimiento de protocolo de COVID-19 detalladas en la sección anterior. Los resultados indican que se utilizarían solamente siete tanques de la planta piloto, donde se compartirían entre los emprendedores solamente los tanques 1 y 2 en la etapa física y los tanques 3, 4 y 5 en las etapas de fermentación y clarificación. Estos resultados tienen importantes implicancias prácticas, ya que este esquema le permitiría al emprendedor tener definido el tiempo a partir del cual tendría disponible el caldo para su posterior acondicionamiento y gasificación, permitiéndole establecer un esquema de compromisos de ventas de productos de manera precisa. Además, permitiría establecer una mejor coordinación con los nuevos lotes de producción evitando traer fruta a destiempo en la línea de elaboración lo que impacta negativamente en dos aspectos. Por un lado, se evitaría la sobremaduración de la fruta lo que puede significar una pérdida de la materia prima ocasionando además especificaciones que queden fuera de rango para obtener el producto deseado. Por otro lado, el aumento de costos por la utilización de las cámaras de frío para mantener la madurez de la fruta un tiempo determinado.

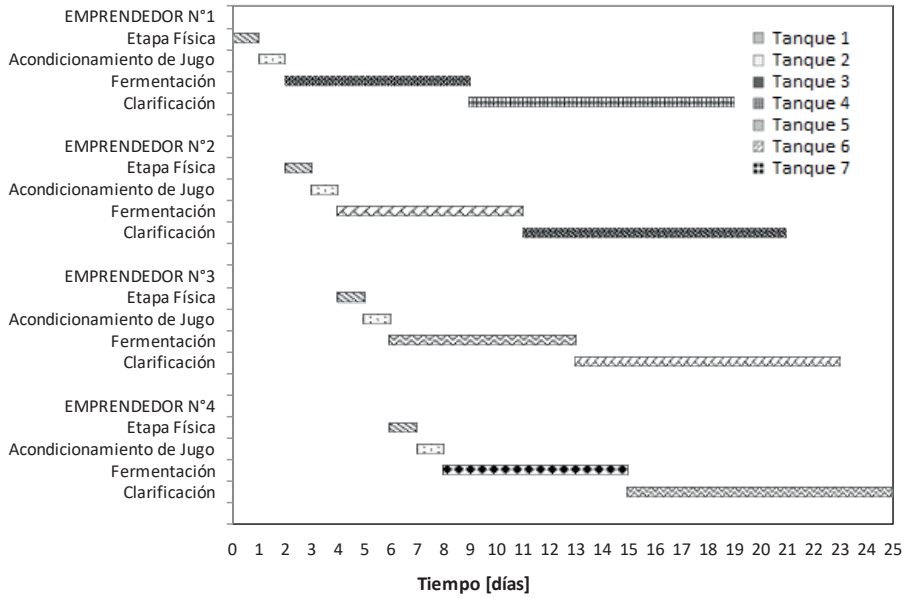

Fig. 4. Diagrama de Gantt para la producción de sidra para cuatro emprendedores.

5 Conclusiones

Las estrategias de simulación y optimización han sido habitualmente empleadas para investigar acerca de procesos y operaciones de muchos sectores de producción, tanto químicos como petroquímicos. Recientemente, la industria de alimentos comenzó a abrirse a este tipo de herramientas con el objetivo de optimizar sus procesos de producción. En este trabajo, se demuestra como la utilización de este tipo de herramientas computacionales brinda un soporte que permite sistematizar el proceso de toma de decisiones. Además, se desarrolló un modelo matemático de optimización de una planta piloto de elaboración de sidra. La herramienta desarrollada permitió organizar los esquemas de producción de la planta, disminuir o ajustar costos de producción, asegurándose de tener disponibilidad de equipos y personal para cumplir con los compromisos asumidos con los emprendedores que solicitan un servicio de elaboración de sidra.

A su vez, permitió visualizar el estado en el que se encuentra cada lote en cada día en el horizonte de planificación, permitiendo así, reducir las pérdidas de fruta en mal estado o sobremaduración durante la etapa de almacenamiento en la cámara de frío antes de ser procesada. Esto no es un aspecto menor, ya que los emprendedores destacan y diferencian sus productos con la adquisición de fruta de excelente calidad, pagando en muchos casos precios diferenciales con el objetivo de obtener las especificaciones que buscan para el desarrollo de sus productos.

El modo "maximizar producción" permitió encontrar un escenario donde se cumpla con todos los compromisos y a su vez permite aumentar la molienda para lograr una

mayor producción. Con esta función objetivo se puede calcular la producción máxima que se lograría en la planta con los equipos y personal disponible debido a las restricciones de personal que la pandemia del COVID-19 ha generado; así como también detectar cuellos de botellas en el proceso de elaboración.

Abstract. *Nannochloropsis oceanica* CCALA 978 is a promising native species for biodiesel and other value-added bioproducts. However, no models have been developed to predict lipid production in this microalga allowing production process improvement yet. A dynamic mathematical model was formulated for the optimization problem from different batch culture variables. Nitrogen and phosphorus limitation conditions of this strain were considered. The resulting optimization problem was formulated and based on orthogonal collocation methods as special class of implicit Runge-Kutta methods. The following nonlinear programming (NLP) problem was solved with an Interior Point method using AMPL (A Mathematical Programming Language) platform. Numerical results provide temporal profiles in good agreement with experimental data.

Keywords. Parameter Estimation – Simultaneous Dynamic Optimization – *Nannochloropsis oceanica* CCALA 978 – Biodiesel Production

1 Introduction

Microalgae have been widely proposed as a biomass resource for third and fourth generation of biofuels [1]. Oleaginous microalgae as some species of *Nannochloropsis* have been proposed as biodiesel source due to their robustness and growth capacity, high neutral lipid content (NL) and fatty acid quality [1]. Specifically, *Nannochloropsis oceanica* CCALA 978 is a native oleaginous strain which is characterized by accumulating neutral lipids up to 36% d.w [2], main raw material for biodiesel production. On the other hand, growth kinetic and physiological parameter modeling is an effective way to study the microalgal performance in terms of light distribution, nutrient uptake and temperature, among other variables [3]. Thus, mathematical modeling is presented as a powerful tool that allow analyzing the different

variables involved in microalgal culture for the optimization of biomass, lipids and other bioproducts production, and, at the same time, evaluating costs and profitability in obtaining biodiesel [3]. The main objective of this study was developing a dynamic model and fitting it using experimental data of biomass and chlorophyll *a*, phosphorus and nitrogen consumption and neutral lipid production in a batch culture of *N. oceanica* CCALA 978 under full nutrient conditions.

2 Experimental Data

Experimental data (data set) for parameter estimation problem and model developing were taken from Bongiovani [2]. For the parameter estimation problem, experimental data corresponding to first stage of cultivation batch (7 days of cultivation) under full conditions of nitrate (NO_3) and phosphate (PO_4) were used. Date set for the dynamic optimization problem were: biomass dry weight, dissolved nitrate, dissolved phosphate, neutral lipid accumulation and content of chlorophyll *a*.

3 Mathematical Model

The proposed model in the present work was based on the Packer [4] model for other microalgae species. Dynamic mass balances were formulated for main components of the system: biomass (equation 1), phosphate (equation 2), nitrate (equation 3), neutral lipids (equation 4), chlorophyll *a* (equation 5), growth rate (equation 6), temperature limitation (equation 7), photosynthesis maximum ratio (equation 8) and light collection (equation 9). The optimization problem for estimating parameters of the dynamic model is solved by minimizing the objective function (equation 10).

$$\frac{d[X]}{dt} = \mu * [X] - k_d * [X] \quad (1)$$

$$\frac{d[PO_4]}{dt} = -Y_{px} * \mu * [X] \quad (2)$$

$$\frac{d[NO_3]}{dt} = -Y_{nx} * \mu * [X] \quad (3)$$

$$\frac{d[L]}{dt} = p * [X] - CC * \mu * [X] \quad (4)$$

$$\frac{d[H]}{dt} = \frac{CC}{p} * \rho * \mu - \mu * [H] \quad (5)$$

$$\mu = \mu_{max} * fT \quad (6)$$

$$fT(Temp) = \left(\frac{Temp}{Topt}\right) * e^{[1-(Temp/Topt)]} \quad (7)$$

$$p = pm * [H] * \left(1 - e^{-I/Imax}\right) \quad (8)$$

$$I = I_0 * \left(1 - e^{-aa*[H]}\right) \quad (9)$$

$$\min \varphi = \sum_{i=1, j=Compound}^{N_D} \left(x_{estimated,j} - x_{experimental,j}\right)^2 \quad (10)$$

$$where\ j = [biomass, NO3, PO4, neutral\ lipids\ and\ chlorophyll\ a]$$

The objective function is subject to the differential-algebraic (DAE) systems described above and is minimized by manipulating the degrees of freedom presented in the Table 1.

Table 1: Estimated parameters results for the dynamic optimization problem.

Parameter	Meaning	Value	Unit
μ_{max}	*Maximum growth rate*	0.4987	[1/day]
k_d	*Mortality rate*	0.001	[1/day]
$Topt$	*Optimal temperature*	29	[°C]
Y_{px}	*Biomass phosphate yield*	3.604	[g PO_4/g Biomass]
Y_{nx}	*Biomass nitrogen yield*	0.149	[g NO_3/g Biomass]
CC	*Subsistence quota*	4.564	[g LN/g Biomass]
pm	*Maximum photosynthesis rate*	1.696	[m^3/(g chl . day)]
I_0	*Incident irradiance*	$1.051x10^5$	[mol photons/(m^2 . day)]
aa	*Optical cross section of chl factor * Light path factor*	0.0156	[m^3/g chl]

The NLP problem obtained from the orthogonal collocation over finite elements was addressed with AMPL [5] platform and coupled to the Interior Point method [6] which has been compiled with third parties dependencies under Windows operating systems. The correlation index (d) obtained, which is a standardized measure of the prediction error degree in the model, which it could be found between 0 and 1, was calculated [7].

4 Results and discussion

In Figure 1 (A-E), the kinetics of biomass, chlorophyll *a*, nitrate, phosphate and neutral lipids are presented. It is possible to note that profiles obtained were adequately fitted to experimental data values used in the parameter estimation problem.

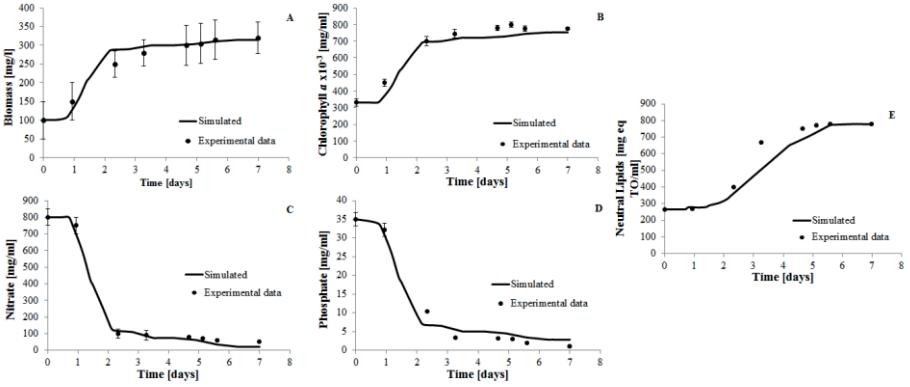

Figure 1: Experimental data and optimization results for biomass (A), chlorophyll *a* (B), dissolved nitrate (C), dissolved phosphate (D) and neutral lipids (E).

This was verified by statical index. This index demonstrated the good performance of model fitting with dimensionless values for correlation index (d) are closed to 1 (biomass: 0.9906; phosphate: 0.9874; nitrate: 0.9898; chlorophyll *a*: 0.9868; neutral lipids: 0.9751), indicating a good agreement between experimental data and obtained mathematical model profiles.

5 Conclusion

In this work, the mathematical model was a suitable tool for estimation of physiological parameters of *N. oceanica* CCALA 978.These results are promising for modeling a stage where functional inocula can be produced and then could be destined in a second induction phase for increasing neutral lipid concentrations under stress culture conditions. The mathematical model was calibrated with experimental data and it is a powerful tool to describe the physiological behavior in terms of biomass and neutral lipid production, nitrogen and phosphorus uptake in *Nannochloropsis oceanica* CCALA 978. This tool also allowing to obtain the behavior prediction and optimization of large-scale cultures for biodiesel production and other bioproducts with high added-value. Regarding computational cost, it was very small in time and iteration numbers for the IPOPT algorithm due to good initialization in primal and dual variables.

Resumen En este trabajo se presenta una metodología matemática-algorítmica para la programación de operaciones de instalaciones discontinuas multiproducto multietapa, desarrollada apuntando a resolver problemas de tamaño industrial. La propuesta se basa en la construcción iterativa de una solución mediante la resolución de una secuencia de subproblemas correspondientes a cada etapa, identificando y fijando las decisiones críticas en cada paso, y manteniendo información rigurosa de las cotas. La metodología se aplica a un caso de estudio real obteniendo soluciones de muy buena calidad en tiempos de cómputo competitivos.

Keywords: Plantas discontinuas multiproducto, Programación de operaciones, Optimización

1. Introducción

A pesar de innumerables esfuerzos en la formulación y solución de problemas de "scheduling" aún existe una importante brecha entre la teoría y la práctica, particularmente caracterizada por la dificultad intrínseca de resolver problemas de escala industrial. Harjunkoski y colab. [1] sostienen que las herramientas de optimización actuales pueden aplicarse satisfactoriamente para aumentar la eficiencia de la producción en piso de planta, aunque observan que existe mucho potencial de mejora. En este trabajo se presenta una metodología de programación de operaciones para plantas batch multiproducto multietapa considerando equipos en paralelo, almacenamiento ilimitado, y tiempos de transición dependientes de la secuencia, la cual es aplicada a un caso de estudio de escala industrial [2].

2. Metodología Matemática-Algorítmica Propuesta

La metodología propuesta consiste en un algoritmo iterativo que resuelve una secuencia de modelos matemáticos de tipo mixto entero lineal (MILP). Cada

uno de estos modelos corresponde a un subproblema del problema general, que considera una de las etapas y un subconjunto de las tareas previas y posteriores, requeridas en las etapas aguas arriba y aguas abajo del proceso. Para modelar los subproblemas se desarrolló una nueva versión del modelo de tiempo continuo basado en "ranuras" de tiempo de Pinto y Grossmann [3], en la cual es posible adicionar en un dado equipo una ranura o slot "comodín". Es decir, un slot multivaluado al cual puede asignarse un número arbitrario de lotes.

El algoritmo se estructura con una iteración principal y una iteración interna. La iteración principal, que considera todas las etapas del proceso, construye gradualmente una solución del problema completo fijando una a una las soluciones de cada etapa. En cada iteración principal, el conjunto de etapas pendientes (no fijadas) es analizado, resolviendo una secuencia de subproblemas (iteración interna) para cada etapa. Se busca así identificar la etapa crítica, es decir aquella que produce mayor deterioro al valor de la función objetivo (makespan). Una vez que esta etapa es identificada, las decisiones de asignación y secuenciación obtenidas en el subproblema correspondiente son fijadas, y el conjunto de etapas pendientes se reduce. La iteración principal finaliza cuando todas las etapas han sido fijadas y se obtiene una solución completa del problema (schedule).

La iteración interna, por su parte, se utiliza para resolver los subproblemas correspondientes a cada etapa. En esta iteración se resuelven, en forma alternada, un modelo aproximado y un modelo exacto. El subproblema aproximado se utiliza para obtener una configuración de ranuras candidata para la etapa, incorporando ranuras multivaluadas en todos los equipos. Posteriormente, el subproblema exacto fija la configuración de ranuras obtenida previamente para hallar una solución factible para la etapa. En base a la calidad de esta solución y los parámetros del algoritmo se decide terminar la iteración interna o repetir el proceso. En caso de continuar, la configuración de ranuras recientemente evaluada será descartada en los subproblemas aproximados siguientes mediante la incorporación de restricciones de tipo entero. La iteración interna retorna la mejor solución factible encontrada e informa en forma precisa las cotas (solución entera MIP y mejor solución posible) a la iteración principal.

Los parámetros considerados para la iteración interna en una etapa dada son los siguientes: (a) el número de ranuras R a considerar para los equipos de las etapas anteriores (aguas arriba) y posteriores (aguas abajo) del proceso, (b) un tiempo límite T para la resolución de cada subproblema, (c) un tiempo límite para la iteración interna, y (d) un número máximo de iteraciones admitidas. La terminación de la iteración interna ocurre luego de obtener una solución del subproblema exacto cuya mejor solución posible no puede mejorarse, o bien al excederse los límites fijados en (c) o (d).

3. Resultados y Discusión

El método propuesto fue aplicado a un caso de estudio real de la industria farmacéutica (ver [2]) que involucra una instalación "batch" multiproducto con 17 equipos operando en paralelo distribuidos en 6 etapas. Tomando como base el

problema de 30 baches, se evaluaron instancias incluyendo los primeros 10, 15, 20, 25 y 30 lotes. Se consideraron distintas alternativas para los parámetros (a) con valores R=2, R=3 y (b) con valores T=300, 600, 1200 s. Además, se fijó un tiempo máximo de 1 h y un límite de 10 repeticiones para la iteración interna.

La metodología fue implementada en GAMS, utilizándose el "solver" GUROBI 7.5 para la resolución de los subproblemas de la iteración interna. A fin de comparar el desempeño computacional y la calidad de la solución obtenida (valor de la función objetivo y cota de integralidad), se resolvieron además dos formulaciones completas del problema (es decir, considerando todas las etapas) fijando en este caso un tiempo límite de 5 h. Por un lado, se utilizó un modelo con un número de "slots" fijo equivalente a aquel de la mejor solución obtenida con la metodología propuesta (denominado FULL FIXED). Por otro lado, se resolvió un modelo que considera el número máximo de "slots" posible en cada equipo (FULL). Todas las evaluaciones computacionales se realizaron en un equipo PC genérico, con procesador Intel Core i7 3.2 GHz y 16 GB de RAM.

La Figura 1 muestra cómo al aumentar la cantidad de lotes la estrategia propuesta permitió obtener soluciones de mejor calidad y cotas inferiores similares a los problemas completos (FULL y FULL FIXED), a pesar de resolver únicamente subproblemas. Los tamaños de los modelos y tiempos de CPU para el problema de 30 lotes se comparan en la Tabla 1, donde se observa que la metodología propuesta considera problemas más pequeños, en particular con respecto al número de variables binarias. Finalmente, el diagrama de Gantt de la mejor solución obtenida para este problema se presenta en la Figura 2.

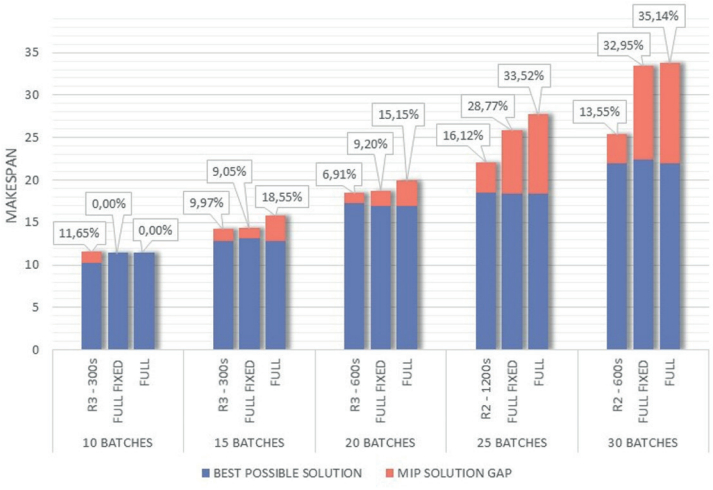

Figura 1: Comparación de las mejores soluciones obtenidas por la metodología propuesta con aquellas de modelos completos con número de ranuras fijo (FULL FIXED) o máximo (FULL).

Tabla 1: Comparación de tamaños de modelo y tiempos de CPU para 30 batches.

		Binary vars	Cont. Vars	Equations	Time (s)
R=2, T=600s	min	120	395	2935	5221
	max	1556	775	19583	
FULL FIXED		4090	775	19847	18000
FULL		10264	1384	50190	18000

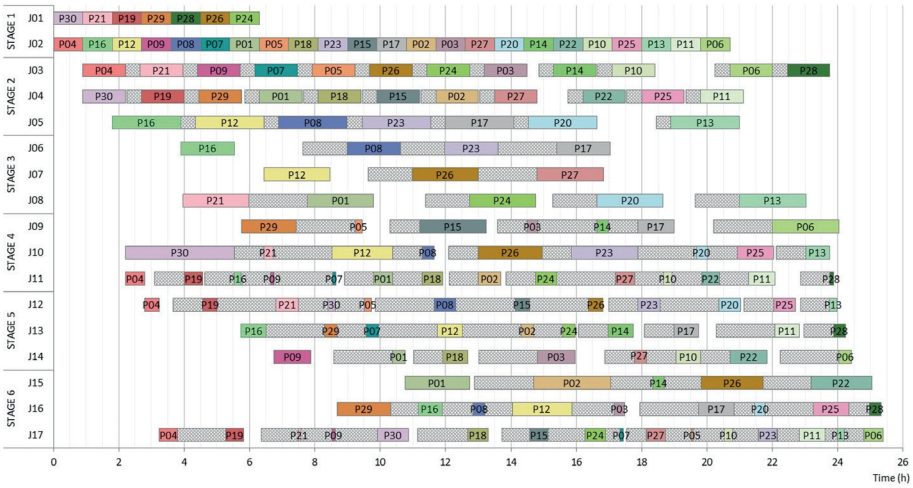

Figura 2: Diagrama de Gantt de la mejor solución obtenida (makespan: 25.38 h) para el problema de 30 lotes, con parámetros R=2 y T=600 s.

4. Conclusiones

Se presentó una metodología matemática-algorítmica basada en la resolución de una secuencia de subproblemas que permitió no sólo obtener soluciones de buena calidad en tiempos competitivos para problemas de escala industrial sino también proveer información rigurosa de las cotas de integralidad asociadas.

Análisis de Incertidumbre en Modelos de Celdas de Combustible de Hidrógeno de tipo PEM

Ignacio Pérez Correa, Pablo Giunta y Javier Francesconi

Instituto de Tecnologías del Hidrógeno y Energías Sostenibles (ITHES - UBA),
Intendente Güiraldes 2160, Ciudad Universitaria - 1428, CABA, Argentina.
igperez@fi.uba.ar

Abstract. Las celdas de hidrógeno de membrana de electrolito polimérico son una prometedora fuente de energía limpia que, combinada con H_2 de origen renovable, presenta numerosas ventajas frente a la actual generación fósil. Dichas celdas convierten parte de la energía química de los reactivos (H_2 y O_2) en energía eléctrica, mientras que la otra parte se intercambia como calor. Una herramienta conveniente para calcular o estimar cuánta de la energía química se transfiere en cada una de estas formas es mediante la curva de polarización. En este trabajo se analizó la dispersión existente entre diversos modelos macroscópicos hallados en bibliografía para predecir la curva de polarización de este tipo de celdas de combustible. El objeto de este análisis fueron los modelos denominados 0-D. De estos fueron hallados y comparados 25, clasificables en 9 combinaciones según como son considerados los aportes del potencial electroquímico. De los resultados puede apreciarse cierta variación entre los diferentes autores. Existen ciertos comportamientos extremos, pero con una serie de modelos que siguen una tendencia central bastante similar. En esta primera etapa la dispersión fue analizada en función de la densidad de corriente donde se observa una elevada dispersión a altos valores de corriente y mínimos de dispersión en valores cercanos a (0,2-0,6 A/cm^2) donde suele operar este tipo de celdas. De todas maneras, lo recomendable es ajustar el modelo elegido a la celda con la que se desee trabajar.

Keywords: PEMFC, Modelado matemático, Análisis de dispersión.

1 Introducción

Las necesidades energéticas de la sociedad se han incrementado significativamente en los últimos años y las estimaciones proyectan que la tendencia seguirá en aumento, esperándose que para 2040 la demanda aumente entre 20% y 40% [1]. Actualmente la principal fuente de energía a nivel global es de origen fósil, causante de numerosos problemas ambientales y calentamiento global, además de ser no renovable. En este contexto, las fuentes renovables emergen como una posible solución para la generación de energía limpia. Una de ellas, foco de nuestro estudio, es la obtenida mediante celdas de combustible alimentadas por hidrógeno ya que poseen una gran eficiencia, no producen emisiones nocivas al ambiente y en los recientes años han tenido avances

significativos que permitirían la implementación comercial de estos equipos [2]. La celda tiene el propósito de convertir la energía química de los gases hidrógeno y oxígeno en energía eléctrica a través de una reacción electroquímica, generando una cantidad similar de energía que debe ser removida en forma de calor. Adicionalmente, si el gas hidrógeno utilizado se produce a partir de una fuente renovable el proceso se vuelve sostenible.

Una de las posibles formas renovables de obtención de hidrógeno para alimentar las celdas es a través del reformado de biomasa y posterior purificación de la corriente para eliminar el CO generado, que resulta un veneno para el electrocatalizador del ánodo. Dado que el proceso de reformado consume mucha energía resulta una buena práctica llevar a cabo una integración energética, consumiendo la menor cantidad posible de energía y aumentando el rendimiento energético global del sistema.

Desde la óptica del diseño del proceso, la pila de combustible es un reactor de flujo que tiene entradas y salidas de materia y energía, pero los simuladores comerciales de procesos no tienen dispositivos electroquímicos como operaciones unitarias, y sólo son capaces de informar la entalpía específica de reacción (Δh_{RQ}) y, mediante el caudal reaccionante, la entalpía total de reacción (ΔH_{RQ}). Según el Primer Principio de la Termodinámica para sistemas abiertos, se puede escribir para la celda:

$$\Delta H_{RQ} = P_{el} + Q_{int} \tag{1}$$

Dónde P_{el} es la potencia eléctrica y Q_{int} el calor generado intercambiado que debe ser removido. La potencia eléctrica es en definitiva lo que nos interesa producir, mientras que el calor es lo que nos interesa integrar. Por lo tanto, es requerida una herramienta externa que nos permita determinar los valores de P_{el} y Q_{int}. Dicha herramienta es la curva de polarización, que es la "huella digital" de un dispositivo electroquímico. El presente estudio discute diferentes modelos presentados en literatura, en particular los llamados 0-D.

Si bien existen diversos tipos de celdas de combustible, este estudio se enfoca en las celdas de membrana de electrolito polimérico (PEMFC). El "combustible" de la celda (H_2) es introducido en el ánodo, donde ocurre la oxidación al estado H^+ catalizada mediante platino, liberando electrones en el proceso. En el cátodo, se inyecta el agente oxidante (O_2) que se reduce captando los electrones liberados por el H_2. La reacción global que ocurre en la celda es:

$$H_2(g) + \frac{1}{2} O_2\ (g)\ \rightarrow H_2O\ (l) \tag{2}$$

En donde se forma agua liberando calor al medio. Usualmente este tipo de celdas operan en temperaturas alrededor de 60 a 90 °C.

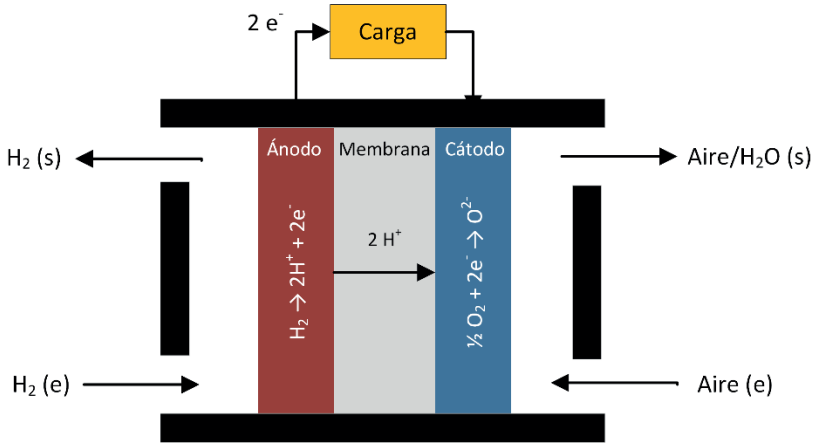

Fig. 1. Esquema de una celda de combustible de tipo PEM.

Es fundamental para el estudio de las celdas poseer un modelo que caracterice de la mejor manera posible el comportamiento de esta a través de su potencial electroquímico en función de la densidad de corriente circulante. Existe una gran cantidad de trabajos publicados [3-28] acerca de desarrollos de modelos para la curva de polarización.

El objetivo del presente trabajo es el de estudiar la dispersión existente entre los diversos modelos hallados en bibliografía con el fin de analizar el impacto de la selección del modelo (y de sus parámetros) en su capacidad para predecir la potencia, eficiencia y calor generado, variables fundamentales en la caracterización de una celda PEM.

2 Comparación de modelos de potencial de celda

El potencial de la celda (E_{tot}) puede modelizarse en función de 4 aportes distintivos:

$$E_{tot} = E_{nernst} - \eta_{act} - \eta_{ohm} - \eta_{conc} \tag{3}$$

Donde E_{nernst} es el potencial termodinámico (o de Nernst), y η_{act}, η_{ohm} y η_{conc} son, respectivamente, los sobrepotenciales de activación, óhmico y de concentración. A continuación, se describen estos aportes.

2.1 Contribuciones al potencial de la celda

Potencial de Nernst (E_{nernst}). Es el potencial reversible de la celda:

$$E_{nernst} = -\frac{\Delta g^{\theta}_{RQ}}{RT} + \frac{RT}{2F}\ln\left(p_{H_2}\, p_{O_2}^{1/2}\right) \tag{4}$$

Los modelos utilizan la expresión teórica arriba mencionada, cuya dependencia explícita con la temperatura absoluta (K) se muestra a continuación [3]:

$$E_{nernst} = 1{,}229 - 8{,}5.10^{-4}(T - 298{,}15) + 4{,}3085.10^{-5}\ \mathrm{T}\ \ln\left(p_{H2}.p_{O_2}^{1/2}\right) \quad (5)$$

Sobrepotencial de activación (η_{act}). Representa la energía que debe emplearse en la reacción electroquímica para apartarla del equilibrio de modo tal que pueda proceder y generar la circulación de electrones. Desde este punto de vista, la activación representa un gasto de energía que no podrá emplearse para realizar trabajo eléctrico sobre el medio. La descripción teórica de este fenómeno puede hacerse a partir de la ecuación de Tafel que permite estimar el sobrepotencial requerido en función de la densidad de corriente circulante (i):

$$\eta_{act} = a + b\log(i) \quad (6)$$

Los autores dan distintos ajustes numéricos para el cálculo de los valores de a y b en función de propiedades del sistema. Se muestran dos representaciones utilizadas:

Tabla 1. Modelos de potencial de activación.

Modelo	Ecuaciones	Fuente
Act 1(*)	$\xi_1 + T\left[\xi_2 + \xi_3 \ln\left(C_{O_2}\right) + \xi_4 \ln\left(i.A_{celda}\right)\right]$	[3]
Act 2(**)	$(\Delta V_0) + (\Delta V_a)\ .\ [1 - \exp\{-\chi_1\ i\}]$	[4]

(*) $\xi_2 = \xi_{2,0} + \xi_{2,1} \ln(A_{celda}) + \xi_{2,2} \ln\left(C_{H_2}\right)$

(**) $\Delta V_0 = \chi_{0,1} + \chi_{0,2}[\ln\left(p_{cat} - p_{sat,H_2O}\right) + \chi_{0,3}\ ]$; $\Delta V_a = \chi_{a,1}\left(\frac{p_{O_2,cat}}{0{,}1173} + p_{sat,H_2O}\right)^2 + \chi_{a,2}\left(\frac{p_{O_2,cat}}{0{,}1173} + p_{sat,H_2O}\right) + \chi_{a,3}$

Donde ξ y χ son parámetros ajustables del modelo. La relación entre la presión de los gases y las concentraciones en el líquido se realiza a través de la ecuación de Henry propuesta en [5]:

$$p_{O_2} = \left[5{,}08.10^6\ e^{-498/T}\right]C_{O_2} \quad (7)$$

$$p_{H_2} = \left[1{,}09.10^6\ e^{77/T}\right]C_{H_2} \quad (8)$$

Respecto de la presión de vapor del agua se utilizará el siguiente ajuste numérico [6]:

$$\log\left(p_{H_2O}\right) = -2{,}1794 + 0{,}02953\ T - 9{,}1837.10^{-5}T^2 + 1{,}4454.10^{-7}T^3 \quad (9)$$

Pérdida de potencial por resistencia óhmica (η_{ohm}). Se divide en dos aportes. Por un lado, la circulación de iones a través de la membrana (R_M) y, por el otro, la resistencia de contacto entre la membrana y los electrodos (R_C) que está relacionada con la circulación de electrones.

$$\eta_{ohm} = (R_C + R_M)\ i\ A_{celda} \quad (10)$$

La resistencia a la conducción de electrones se suele asumir independiente de los parámetros operativos de la celda [7], lo que varía entre los autores es la forma de estimar la resistencia a la conducción de protones. Esta se modela como un conductor:

$$R_M = r_M \frac{l_M}{A_{celda}} \tag{11}$$

La resistencia específica de la membrana r_M tiene un origen empírico y se muestran a continuación algunas expresiones halladas en bibliografía.

Tabla 2. Modelos de la resistividad de membrana (r_m).

Modelos	Ecuaciones	Fuente
Ohm 1	$\frac{181{,}6[1 + 0{,}03\, i + 0{,}062\, (T/303)^2\, i^{2{,}5}]}{[\lambda - 0{,}634 - 3\, i]\, \exp\{4{,}18(1 - 303/T)\}}$	[7]
Ohm 2	$[\alpha_1 T + \alpha_2\, i\, A_{celda}](l_M/A_{celda})$	[8]
Ohm 3	$\frac{1}{[\epsilon_1\, \lambda - \epsilon_2]\, \exp\{\epsilon_3(1/303 - 1/T)\}}$	[6]

Donde α y ε son parámetros ajustables del modelo. Adicionalmente el espesor de la membrana (l_M) y el contenido de agua de la membrana (λ) se toman como constantes en el modelado de la membrana.

Pérdida de potencial por concentración (η_{conc}). Su importancia se incrementa cuando la velocidad de consumo de los reactivos es elevada (altas densidades de corriente) lo que lleva a establecer perfiles de concentración más pronunciados en la celda. Existe una densidad de corriente máxima (i_{max}) en donde la velocidad de consumo de reactivo por la celda está dada por la máxima capacidad de difusión en la fase gaseosa.

Tabla 3. Modelos de potencial de concentración.

Modelos	Ecuaciones	Fuente
Con 1	$-b \ln (i/i_{max})$	[9]
Con 2	$a \exp\{b\, i\}$	[10]
Con 3	$\zeta_1 (i/i_{max})^{\zeta_2}$	[4]

Siendo a, b y ζ parámetros del modelo. En la tabla 4 se muestran 9 clases de modelos en base a como los diversos autores combinan las tres caídas de potencial que experimenta la celda.

3 Análisis de incertidumbre

Los diversos modelos de celda hallados en bibliografía fueron estudiados para analizar la dispersión existente en su capacidad de predecir el comportamiento de la celda frente a las variables operativas con el fin de proveer herramientas útiles en la selección de un modelo que permita caracterizar las celdas de hidrógeno. Los parámetros

sobre los que se practicará este análisis son la eficiencia de la celda (ε_{celda}), la potencia eléctrica generada (P_{gen}), cuyas expresiones son:

$$\varepsilon_{celda} = E_{tot}/\left(\Delta h_{RQ}/2F\right) \tag{12}$$

$$P_{gen} = E_{tot}\ (i\ A_{celda}) \tag{13}$$

Tabla 4. Combinaciones de modelos de celda electrolítica de tipo PEM.

Modelo	Activación	Ohm	Concentración	Fuentes
1	Act 1	Ohm 1	-	[5], [7], [11], [12]
2	Act 1	Ohm 2	-	[3], [8], [13]
3	Act 1	Ohm 3	-	[14]
4	Act 1	Ohm 1	Con 1	[9], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24]
5	Act 1	Ohm 1	Con 3	[25]
6	Act 2	Ohm 2	Con 2	[10], [26]
7	Act 1	Ohm 2	Con 1	[27]
8	Act 1	Ohm 3	Con 1	[28]
9	Act 2	Ohm 3	Con 1	[4]

También serán tenidos en cuenta el calor intercambiado (ecuación (1)) y el potencial electroquímico de la celda (ecuación (3)). Para realizar este estudio se mantuvieron constantes los diversos parámetros físicos y operativos de la celda (A_{celda}, T_{celda}, p_{H2}, p_{O2}, λ y l_M) cuyos valores son informados en la Tabla 5. A continuación, se muestran los gráficos de las variables de estudio:

Tabla 5. Parámetros de celda utilizados en el análisis de dispersión.

Parámetro	Valor
Área (A_{celda})	50 cm^2
Temperatura (T_{celda})	85 °C
Presión H_2 en ánodo (p_{H2})	3 atm
Presión O_2 en cátodo (p_{O2})	2 atm
Contenido de agua en membrana (λ)	23
Espesor de membrana (l_M)	178 µm

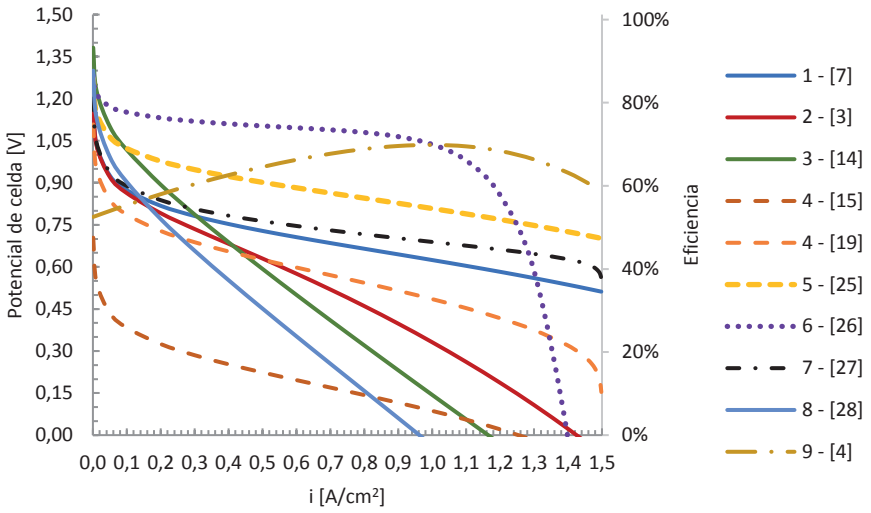

Fig. 2. Comparación de la predicción de la eficiencia y potencial de la celda PEM en función de la densidad de corriente para distintos tipos de modelo.

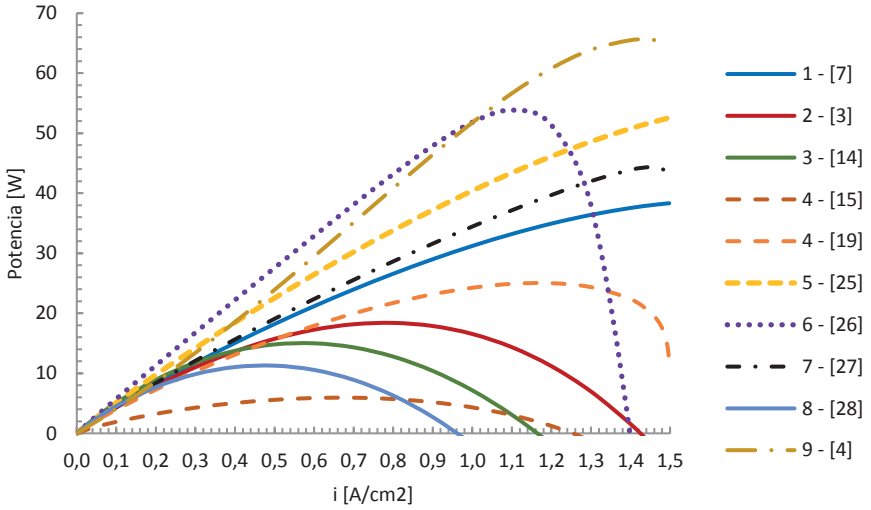

Fig. 3. Comparación de la predicción de la potencia generada por la celda PEM en función de la densidad de corriente para distintos tipos de modelo.

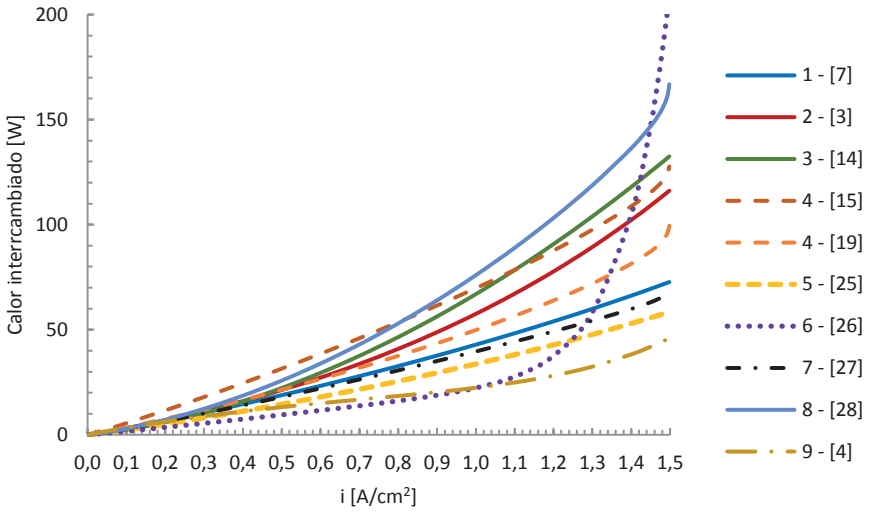

Fig. 4. Comparación de la predicción del calor generado en la celda PEM en función de la densidad de corriente para distintos tipos de modelo.

Los datos se muestran agrupados por combinación de modelo y luego por autor. Considerando que la eficiencia y el potencial de la celda tienen la misma forma ya que están relacionados por la constante ($\Delta h_{RQ}/2F$), se decidió mostrar ambas variables en el mismo gráfico. También cabe destacar que se muestran solo algunos de los modelos analizados, representativos de todas las combinaciones, quedando los restantes comprendidos entre el 4-[19] y el 5-[25] en las tres figuras. Como puede apreciarse, existe cierta similitud para la potencia y eficiencia a pequeños valores de densidad de corriente y, luego, existe una mayor dispersión a altos valores. Dado que a altas densidades de corriente el paso limitante es el de transferencia de materia, es de esperar que los parámetros de transporte (i.e. los coeficientes de difusión) sean posibles fuentes de dispersión entre modelos. A su vez, la resistencia específica r_M depende también de los parámetros de transporte, con lo cual su efecto se propaga también aquí y hace que la dispersión se manifieste antes de alcanzarse la zona de control por transporte de masa, a altas densidades de corriente. Respecto del calor generado hay una mayor concordancia para todas las densidades de corriente.

De todas maneras, con el fin de estudiar con mayor profundidad las diferencias existentes entre los modelos, se optó por graficar el coeficiente de variación (o dispersión relativa) (CV) que es representado como el desvío estándar (σ) sobre el valor medio (μ):

$$CV = \sigma/\mu \tag{14}$$

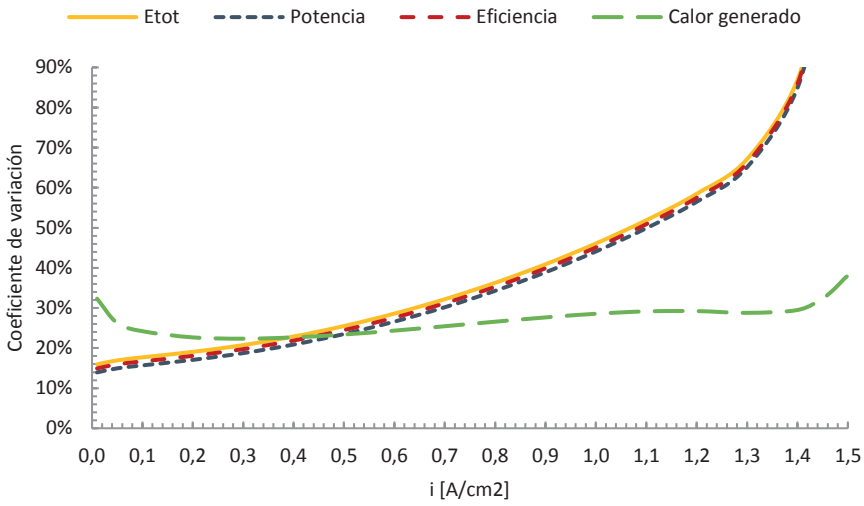

Fig. 5. Dispersión relativa de los modelos en la predicción del potencial electroquímico, potencia, eficiencia y calor generado de la celda PEM.

A bajas densidades de corriente se aprecia una pequeña dispersión relativa para las cuatro variables. Cabe destacar que el potencial total, potencia y eficiencia poseen la misma dispersión relativa ya que los tres se encuentran relacionados por constantes a una dada densidad de corriente (ecuaciones (12) y (13)):

$$E_{tot} = \left(\frac{1}{i\ A_{celda}}\right) P_{el} = \left(\frac{\Delta h_{RQ}}{2F}\right) \varepsilon_{celda} \tag{15}$$

A medida que aumenta la densidad de corriente la dispersión se hace mayor, aunque de manera menos significativa para el calor generado que para los otros tres parámetros.

4 Conclusiones

En este trabajo fueron testeados 25 modelos de celdas de hidrógeno de tipo PEM con el objetivo de analizar la dispersión existente entre ellos y entender el impacto que tendría la selección de cada uno en las distintas variables de la celda como la potencia generada, la eficiencia y el calor liberado.

En base a los tres términos que se deben representar del potencial de la celda (activación, ohm y concentración) estos 25 modelos pueden ser clasificados en 9 combinaciones distintas.

Del análisis realizado se puede observar que la dispersión relativa entre los modelos es pequeña para bajas densidades de corriente y luego aumenta con la densidad de corriente, aunque en el caso del calor generado esta variación es pequeña debido a una suerte de compensación que existe entre el incremento de la potencia y, a su vez, el

consumo de hidrógeno en la celda. De esto se podría suponer que la fuente de dispersión está en los parámetros de transporte ya que las mayores diferencias ocurren en la zona dominada por este fenómeno.

Por tanto, se concluye que la dispersión entre los modelos no es tal como para afectar significativamente los cálculos en una simulación en el rango en el que suelen operar las celdas de combustible tipo PEM (0,2-0,6 A/cm^2), aunque fuera de este rango se vuelven importantes las desviaciones halladas. Siempre será lo ideal ajustar datos empíricos de una celda en particular que sea la de interés en la aplicación ingenieril con el objetivo de minimizar el error de los parámetros operativos de la celda.

Abstract. Different researchers have proposed the treatment of uncertainties in measurements because they interfere in the process state estimation. Data reconciliation procedure improves the information supplied by measurements, minimizing the discrepancy existent between measurements and accurate process model. This problem allows obtaining unbiased estimation when measurements follow exactly a normal distribution. Nevertheless, the presence of outliers do not allow the use of the former procedure, therefore Robust Data Reconciliation is developed. This latter provides accurate solutions when measurements follow approximately the normal distribution. Although many advances have been developed to treat measurement uncertainties in Data Reconciliation framework, there are not research works that consider model and measurement uncertainties simultaneously in presence of outliers. In this work, a Simple robust Method, which takes advantage of temporal redundancy, is applied to benchmarks that contain uncertain parameters. Performances measures are tested for different magnitudes of simulated outliers and compared with the ones provided by a classic Data Reconciliation procedure. Results show that the Robust Data Reconciliation procedure can yield unbiased estimations of measurements and parameters when outliers and parametric uncertainties are present.

Keywords: Robust Data Reconciliation, Model uncertainty, Measurement uncertainty, Parameter estimation, Outliers.

1 Introduction

Uncertainties in measurements are given by random events which always are present and produce fluctuations in the observation provided by instruments. These errors can be dealt with procedures as Data Reconciliation (DR). It's well known that DR gives accurate estimations when the assumptions of normality and model accuracy are true. Nevertheless, the presence of systematic errors in measurements or uncertainty in models is a common scenario in an industrial process. Therefore, both should be taken into account for the study of process state.

Systematic errors, as outliers, deteriorate the assumed distribution. Thus, different tests or techniques to detect and eliminate outliers before executing a DR procedure have been proposed [1]. Using Robust Data Reconciliation (RDR) stands out from the

former methodologies since it is able to mitigate the effect of outliers without using auxiliary methodologies [2, 3].

Researchers have proved RDR effectiveness in different operational conditions [2, 3]. This procedure uses M-estimators as objective function instead of the Least Square (LS) function. M-estimators are a generalization of the Maximum Likelihood function and can be classified as monotone or redescending according to their first derivative, which is called Influence Function (IF) [4].

In real-time operation, multiple sources of uncertainties deteriorate the model. This consideration allows avoiding the use of inappropriate models which leads to incorrect state estimation [5]. Some examples are ignored changes of physical flows state, chemical reactions conditions which change kinetics parameters; inaccuracies in model parameters related to energy balances and changes in the process state.

There are few proposals to deal with parametric uncertainty in models using DR. In this sense, [6] and [7] treated linear model which contain error measurements that follow the normal distribution ($\mathcal{N}$). The former research was a semi-empirical technique which used an iterative procedure to weight each constraint regarding to its uncertainties, while the latter research presented two modified DR procedures. Both DR problems provided identical estimations of parameter uncertainties, however the second highlighted because this allowed computing the variables estimation that satisfies the updated model. Furthermore, the latter authors discussed the concepts of redundancy and observability and showed that both diminish when the model contains uncertain parameters. Vasebi et al. [8] demonstrated the importance of selecting uncertainty covariance matrices to treat bilinear system. The three aforementioned research works did not take into account outliers. Recently, the presence of outliers was addressed at the development of a decision support tool when stochastic uncertainty in the demand exists [9]. Although the uncertainty studied was not parametric, this work remarks the importance of obtaining accurate estimation as a first step in the chain of an economic optimization problem.

The papers reviewed show the usefulness of RDR for a posterior step of optimization. This allows proposing the following hypothesis: RDR can treat model with uncertainty when outliers are present. To verify the hypothesis, this research work uses two linear benchmarks which contain parameter uncertainties. A RDR procedure is devised which uses a Simple Method (SiM) developed by [2] to get unbiased estimations of measurements and parameters for two models of error propagation. First, three case studies are presented which compare the results of SiM with the ones obtained by a classic DR problem using a model extracted from [7]. Different magnitudes of outliers are simulated and results of Performance Measure (PM) are presented in performance curves. Finally, a second model is treated with two methodologies which take advantage of temporal redundancy.

This research work is organized as follows. Section two briefly describes the RDR strategy executed for the estimation of measurements and uncertain parameters. Section 3 presents the measurement models considered and Performance Measures (PM) selected to inform the improvement attained. The results in terms of PM for two linear benchmarks are presented in Section 4. Finally, section 5 presents the conclusions achieved.

2 Methodology

Data reconciliation is an optimization problem which uses as objective function the LS. This procedure takes advantage of the spatial redundancy provided by the model equation to minimize the discrepancy between measurements and restrictions. [10]

In general, the solution of DR is a vector of estimated measured, $\hat{\mathbf{x}}^{LS}$, and unmeasured variables, $\hat{\mathbf{u}}^{LS}$, that strictly satisfy the model.

$$
\begin{aligned}
[\hat{\mathbf{x}}^{LS}, \hat{\mathbf{u}}^{LS}] = \underset{\mathbf{x},\mathbf{u}}{Min} & \left(\mathbf{y}-\mathbf{x}\right)^T \boldsymbol{\Sigma}^{-1} \left(\mathbf{y}-\mathbf{x}\right) \\
st. \quad & \\
& \mathbf{f}(\mathbf{x},\mathbf{u})=\mathbf{0} \\
& \mathbf{h}(\mathbf{x},\mathbf{u}) \le \mathbf{0} \\
& \mathbf{x}^{\mathrm{L}} \le \mathbf{x} \le \mathbf{x}^{\mathrm{U}} \\
& \mathbf{u}^{\mathrm{L}} \le \mathbf{u} \le \mathbf{u}^{\mathrm{U}}
\end{aligned}
\qquad (1)
$$

where $\boldsymbol{\Sigma}$ represents the covariance matrix, while $\mathbf{y}$ stands for the vector of random measurements. Furthermore, $\mathbf{f}$ and $\mathbf{h}$ stand for equality and inequality constraints, respectively. The upper and lower bounds of the optimization variables are represented with the suffix U and L respectively.

Narasimhan et al. (2012) treated parameter uncertainties solving the problem 2:

$$
\begin{aligned}
[\hat{\mathbf{x}}^{LS}, \hat{\boldsymbol{\theta}}] = \underset{\mathbf{x},\boldsymbol{\theta}}{Min} & \left(\mathbf{y}-\mathbf{x}\right)^T \boldsymbol{\Sigma}^{-1} \left(\mathbf{y}-\mathbf{x}\right) + \sum_p \left(\frac{\theta_p - \hat{\theta}_p}{\sigma_{\theta,p}} \right) \\
st. \quad & \\
& \mathbf{A}_\theta \mathbf{x}=\mathbf{0}
\end{aligned}
\qquad (2)
$$

where $\hat{\mathbf{x}}^{LS}$ and $\hat{\boldsymbol{\theta}}$ represent the state and parameter reconciled vectors and $\mathbf{A}_\theta$ the model with uncertain parameters [7]. This formulation considers that all the variables are measured. However, if there are unmeasured variables, procedures as QR factorization can provide a reduced problem which includes measured variables [10].

Problem (2) allows address model with uncertainty but does not consider that outliers may exist. Such errors invalidate the assumption of normality, thus the use of classic DR is not suitable. Conversely, Robust Data Reconciliation (RDR) yield unbiased estimation not only when measurements follow exactly the $\mathcal{N}$, but also when they do approximately [4]. Regards uncertain parameters, the presence of outliers can corrupt their estimation, therefore a RDR seems to be a promising strategy to get unbiased estimations of measurements and parameters.

2.1 M-estimators

M-estimator of location, $\hat{x}$, of the *i*-th variable is the solution provided by the following minimization problem:

$$\sum_{i=1}^{n} \rho\left(y_i - \hat{x}\right) = Min! \tag{3}$$

where ρ symbolizes the robust estimator. Based on this function the mathematical expressions of the IF (ψ) and Weight functions (W) are developed.

$$\sum_{i=1}^{n} \psi\left(y_i - \hat{x}\right) = 0 \tag{4}$$

$$\sum_{i=1}^{n} W_i \left(y_i - \hat{x}\right)\left(y_i - \hat{x}\right) = 0 \tag{5}$$

where $\psi = d\rho(x)/dx$ and W is defined in terms of ψ [4].

According to their IF, M-estimators are classified as monotone or redescending. The former are convex functions, therefore they always converge to the optimal solution. The latter W tend or are equal to zero, because of that redescending estimators are more efficient for heavy-tailed data. However, they require a good starting point to ensure attaining the global solution. Examples of monotone functions are the Huber (HU) and Fair functions, while classical redescendig estimators are the Biweight (BW) and Hampel functions [11]. Taking into account the former analysis, researchers proposed a Simple Method (SiM) which takes advantage of the M-estimators characteristics. [2]

2.2 Simple Method

Different strategies have been developed to solve the RDR problem, a comparison among their performances established that SiM can be applied for the measurement treatment in real-time optimization loops because it provides a good balance between the estimation accuracy and the computational load. The SiM comprises two sequential steps, which are the following:

Step 1: A robust median $\tilde{y}_i$ of the i-th variable, (i= 1: I), is calculated using a moving window of measurements, which length is N, and the BW function.

$$\tilde{y}_i = Min \sum_{p=j-N+1}^{j} \rho_{BW}\left(\frac{y_{ip} - \tilde{y}_i}{\sigma_i}\right) \tag{6}$$

where σ_i stands for the measurement standard deviation and j represents the actual time.

Equation (6) takes advantage of the temporal redundancy supplied by a window of observations and eliminates the outlier effect because BW is a redescending function. This problem is initialized with the solution of the j-1 time for j>1 or the mean of a data moving window if j=1.

The BW function is defined as follows:

$$\rho_{BW} = \begin{cases} 1-\left[1-(a/c_{BW})^2\right]^3 & if \quad |a| \le c_{BW} \\ 1 & if \quad |a| > c_{BW} \end{cases} \qquad (7)$$

$$a = \left(\frac{y_{ip} - \tilde{y}_i}{\sigma_i} \right)$$

where c_{BW} stands for the tuning constant calculated to fix the asymptotic efficiency of the BW estimator.

Step 2: The state of the system at the time interval j, $\hat{\mathbf{x}}_j^R$, is obtained by solving the following optimization problem

$$[\hat{\mathbf{x}}_j^R] = \underset{\mathbf{x_j},\mathbf{u_j}}{Min} \quad \sum_{i=1}^{I} \rho_{HU}\left(\frac{\tilde{y}_i - x_i}{\sigma_i} \right) \qquad (8)$$

$$st.$$

$$\mathbf{Ax=0}$$

where ρ_{HU} and a corresponds to:

$$\rho_{HU} = \begin{cases} a^2 & if \quad |a| \le c_{HU} \\ 2c_{HU}|a| - {c_{HU}}^2 & if \quad |a| > c_{HU} \end{cases} \qquad (9$$

$$a = \left(\frac{\tilde{y}_i - x_i}{\sigma_i} \right)$$

where c_{HU} is the tuning parameter of the HU function and a stands for the standardized measurement error. The solution achieved is optimal, because this step applies a monotone estimator. The computation time of the RDR is reduced initializing the problem with a good starting point that is the robust median obtained in Step 1.

2.3 RDR with uncertainty parameters

Fluctuations around a state or variations of operative conditions generate uncertain models since they affect the model equations. In this first approach, the parametric uncertainty is tackled.

The following development is based on a maximum likelihood procedure which assumes independence between measurements and model with uncertain parameters, which are distributed following $\mathcal{N}(0,\ \sigma^2_{\theta,p})$ [6].

A RDR problem is formulated which allows obtaining the measurement and parameter estimations for process operating in steady-state. Equation (10) presents the RDR problem formulated at the j-th time:

$$\left[\hat{\boldsymbol{x}}_j^{\,R}, \hat{\boldsymbol{\theta}}_j\right] = \underset{\mathbf{x_j}, \boldsymbol{\theta}_\mathbf{j}}{Min} \quad \sum_{i=1}^{I} \rho_{Hu}\left(\frac{\tilde{y}_i^R - x_i}{\sigma_i}\right) + \sum_{p=1}^{P}\left(\frac{\theta_p - \hat{\theta}_p}{\sigma_{\theta,p}}\right)^2$$

$$s.t. \qquad \mathbf{g}(\mathbf{x}, \boldsymbol{\theta}) = 0 \tag{10}$$

where $\hat{\boldsymbol{x}}_j^R$ and $\hat{\boldsymbol{\theta}}_j$ stand for the reconciled measurements and parameter vectors, respectively, $\mathbf{g}(\mathbf{x}, \boldsymbol{\theta})$ represents the model with p, p=1:P, uncertain parameters.

The problem (10) uses as initial point the robust median presented in Eq.6. The major differences between the problem devised in this work and [6] are the use of a robust estimator to mitigate the presence of outliers and the temporal redundancy that is taken into account at the robust median computation. It is expected that this formulation allows achieving accurate estimations independently of the lack of redundancy of some variables.[12]

3 Implementation

The RDR problem of (Eq. 10) is implemented for two measurement models which include measurements that follow the $\mathcal{N}$ and measurements which contain outliers.

3.1 Measurements Models

Random errors. They are caused by unknown and unpredictable fluctuations which may occur in the measuring instruments or in the operational conditions. These errors generate inconsistencies between the measurements and the process model.
The measurement model at the *j*-th time of the *i*-th variable, y_{ij}, is the following:

$$y_{ij} = x_i + e_{ij} \tag{11}$$

where x_i stands for the true value of the variable and e_{ij} represents the random error.
Outliers. These are extreme values deviated from the bulk of observation. A low probability (p_G) of outliers occurrence is defined since they are presented with a lower frequency than random errors. The outlier model equation is:

$$y_{ij} = x_i + e_{ij} + K\sigma_i \tag{12}$$

where *K* stands for the magnitude of the outlier.

3.2 Performance Measures

Mean Square Error (MSE) and Root (RMSE). These PMs are related to the variance and bias achieved with the estimated values. Such parameters can be computed globally and individually for each variable as follows:

$$MSE = \frac{1}{I\ J}\sum_{j=1}^{J}\sum_{i=1}^{I}\left(\frac{\hat{x}_{ij}-x_i}{\sigma_i}\right)^2 \tag{13}$$

$$RMSE_{\rho,i} = \sqrt{\frac{1}{J}\sum_{j=1}^{J}\left(\frac{\hat{x}_{ij}-x_i}{\sigma_i}\right)^2} \qquad \rho = LS, RDR \tag{14}$$

where $\hat{x}$ stands for the estimated value and J stands for the number of trials simulation.
Ratios. Different ratios are evaluated and compared to analyze the improvement or deterioration achieved with the DR procedure. The root mean square error ($RMSE_y$) of measurements is calculated as follows:

$$RMSE_{y,i} = \frac{1}{J}\sum_{j=1}^{J}\left(\frac{y_{ij}-x_i}{\sigma_i}\right)^2 \tag{15}$$

Ratios are calculated as follows:

$$R_{\rho,i} = \frac{RMSE_{\rho,i}}{RMSE_{y,i}} \tag{16}$$

Spatial Redundancy (SR). This PM is computed following the procedure presented by Maronna and Arcas (2010).

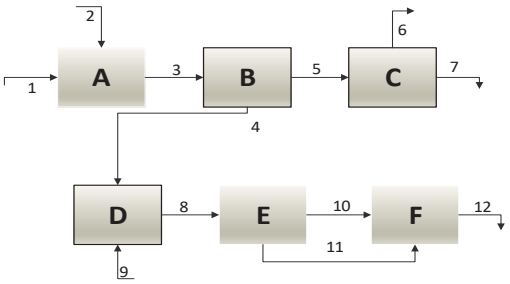
$$SR_i = 1 - h_i \tag{17}$$

where h_i is the i-th diagonal element of the hat matrix **H**. This matrix allows calculating the reconciled variable values as a linear transformation of the measurements. It is defined in terms of the matrix that represents the process model and the measurement covariance matrix [13].
Parameter mean ($\tilde{\theta}_p$) and standard deviation (std ($\hat{\theta}_p$)). Both are calculated for each parameter using the estimations of J trials.

$$\tilde{\theta}_p = \frac{\sum_{j=1}^{J}(\hat{\theta}_{p,j})}{J} \qquad p = 1:P \tag{18}$$

$$std(\hat{\theta}_p) = \sum_{j=1}^{J} \left(\frac{\hat{\theta}_{pj} - \tilde{\theta}_p}{J} \right) \qquad p = 1:P \tag{19}$$

3.3 Useful consideration for the RDR implementation



- A matrix of measurements of size [I x J] is generated to treat the same set of data for all the simulations of a benchmark.
- The global probability of outliers is fixed on p_G=0.1
- Outliers magnitudes are simulated on the range [0:10]
- Linear models are transformed into nonlinear because of uncertainty
- Equation (16) is used for computing the *SR* of variables of nonlinear models. Such models have been previously linearized

4 Results

Two linear benchmarks are treated with the proposed technique. The first one is extracted from [7]. Its PMs obtained with SiM and the procedure used in [7] are compared at different scenarios. The second model compares the DR solution when temporal redundancy is considered.

4.1 Model 1

This linear model comprises 12 measured variables, which are interconnected by six balance equations. Three balances include uncertain parameters, these are highlighted in Figure 1. The values of variables and parameters considered in [7] are reported in Tables 1 and 2.

$$F_1 + F_2 - F_3 = 0;$$
$$F_3 - F_4 - p_1 F_5 = 0;$$
$$F_5 - F_6 - p_2 F_7 = 0;$$
$$F_4 - p_3 F_8 + p_4 F_9 = 0;$$
$$F_8 - F_{10} - F_{11} = 0;$$
$$F_{10} + F_{11} - F_{12} = 0;$$

Fig. 1. Model 1 with 4 uncertain parameters

Table 1. Flows true values

I	1	2	3	4	5	6	7	8	9	10	11	12
F	70	30	100	60	40	20	20	91	31	44	47	91
σ_i	3.5	1.5	4.9	3.0	0.4	0.15	0.1	1.7	1.5	1.05	0.5	1.65

Three cases of study are proposed. Case 1 tests an accurate model. Case 2 estimates the uncertain parameters using as initial point the values informed by [7]. Finally, Case 3 formulates a model that fixes the uncertainty in the values reported at [7]. This case is analyzed to show the deterioration estimation when uncertainties exist but are not considered. Results of PMs are reported in Tables 3, 4, 5 and Figures 2, 3 and 4.

Table 3 present the SR and Ratios (R) for all the variables of the first model. The comparison of SR between Cases 1 and 2 shows that the lowest values of SR are obtained for Case 2, thus estimations accuracy diminishes. This fact represents an increment of RMSE for the model with uncertainty.

Table 2. Parameters and standard deviation values

θ_p	p_1	p_2	p_3	p_4
Value	1.8651	2.3325	0.7493	1.4603

Ratios are computed as the division between $RMSE_{LS}$ or $RMSE_{SiM}$ in relation to $RMSE_y$. Ratios below 1 mean that the estimation procedure achieves more accurate results than measurements. Let analyze the PMs of variable F_4 at Case 2. Its redundancy is $SR_{4,2}=0$, while its ratios are $R_{LS,2}=1$ and $R_{SiM,2}=0.33$, $R_{SiM,2}<R_{LS,2}$. These results show that LS is not able to enhance estimation, however SiM allows correcting the measurements. This is due to the fact that SIM uses temporal redundancy. A general ratios comparison shows:

- LS: the R of Cases 1, 2 and 3 confirm that uncertainty deteriorates the accuracy of the estimation procedure. Estimation of Case 2 provides better results than

raw measurements, but non-redundant variables (*SR*=0) are not corrected. This is in concordance with theory. Case 3 presents the worst results, therefore not treating the uncertainty is not a smart decision.

- SiM: this procedure shows similar tendency than the obtained for LS. However, for Cases 1 and 2, the most accurate results are attained with SiM. The use of *SR* and temporal redundancy allows achieving more accurate results for redundant and non-redundant variables.

In Case 3 there is not a clear tendency between the ratios of SiM and LS, however this is a limit case since both estimation procedures present high deterioration.

The *MSE* of the measurements (*y*) and the three cases studied are reported in Table 4. A rough comparison lets arrive at similar conclusions than the ones obtained with R of Table 3. However, Case 3 shows that the highest deviation is reached with SiM.

The ability to mitigate the presence of outliers and get accurate parameter estimations are analyzed for Case 2. Results are presented in Table 5, and Figures 2, 3 and 4. The *MSE* results demonstrate that the most accurate results are attained with SiM for all the *K* considered. Least Square estimations are deteriorated whit the increment of *K*, while the robust procedure does not present significant changes.

Table 4. MSE of cases studied for random measurements

	Case 1		Case2		Case 3	
y	LS	SiM	LS	SiM	LS	SiM
0.9913	0.4955	0.0508	0.7463	0.0785	271.6773	405.7392

Table 5. MSE for different outlier magnitudes

K	0	2	4	6	8	10
y	0.9913	2.4091	5.0099	9.6123	16.9779	27.9915
SiM	0.0785	0.1058	0.1192	0.0909	0.0885	0.0912
LS	0.7463	1.0628	1.9339	3.4379	5.5103	8.2281

The selection of four variables with different let analyze this PM influence, these are F_2, F_5, F_8 and F_{10}. Their RMSE curves are presented in Fig. 2. Figures 2.a and 2.b stand for variables non-redundant (F_5) and with low redundancy (F_2), while Fig. 2.c and 2.d represent variables with *SR* equal to 0.40 (F10) and 0.76 (F_8). As it was expected, it is observed that LS achieves better results when *SR* increase, however this estimator is not able to enhance the estimation of non-redundant variables. On the other hand, SiM results show that all the variables can give accurate results independently of their *SR*.

Figures 3 and 4 present the means and standard deviations (stds) estimated with the LS and SiM for different outlier magnitudes.

- LS: The first parameter (p_1) presents the highest deviation, while the lowest is obtained for p_4. The stds of the first parameter p1 takes values between [0.1073-0.3415] and p_4:[0.0166-0.0545]

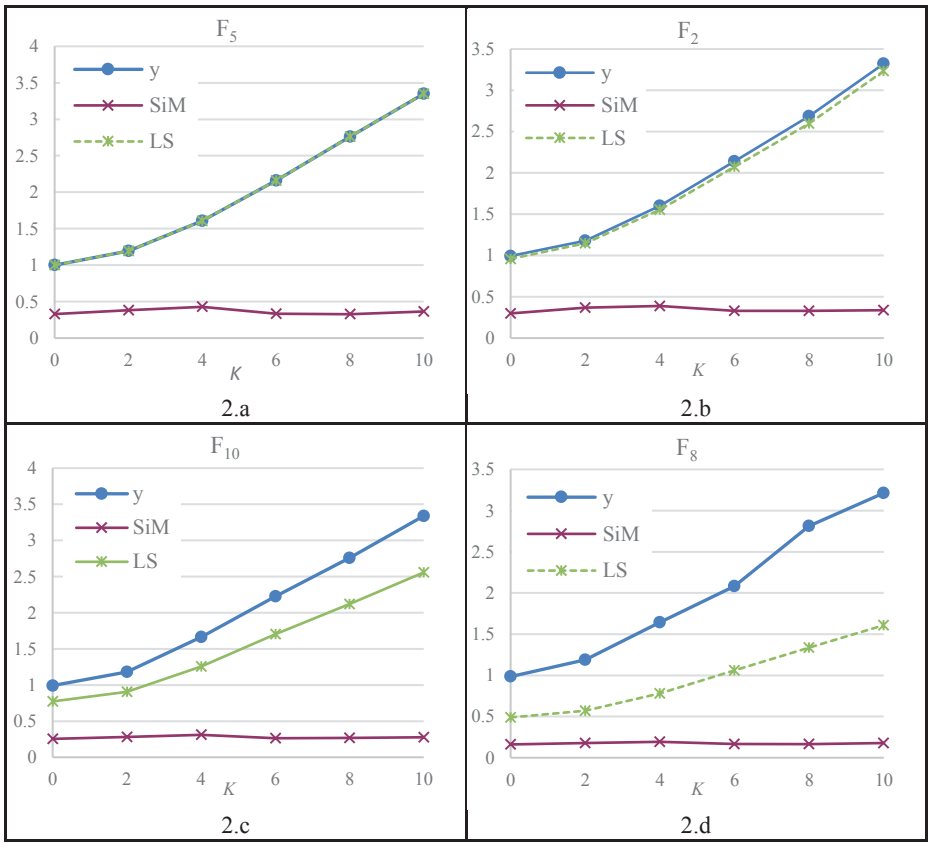

Fig. 2. Curves of RMSE for variables with different *SR*.

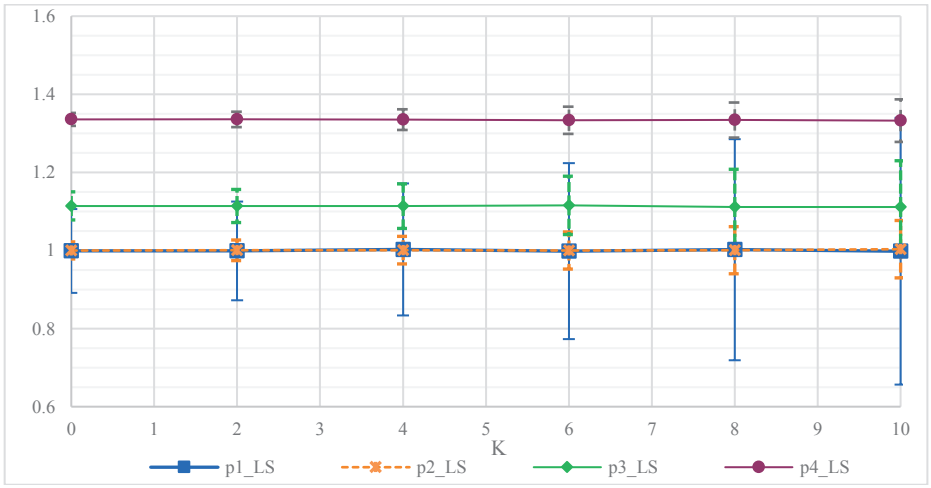

Fig. 3. Parameters' mean and standard deviation estimated using LS

- SiM: Similar to LS, the std of p_1 and p_4 present the highest and lowest std($\tilde{\theta}_p$). However, these parameters take values between [0.0351-0.0431] and [0.0054-0.0065] respectively.

A comparison of both methods shows that the means calculated for SiM and LS are similar, nevertheless the stds computed with LS are bigger than the ones corresponding to SiM. This tendency is observed for all the *K* tested.

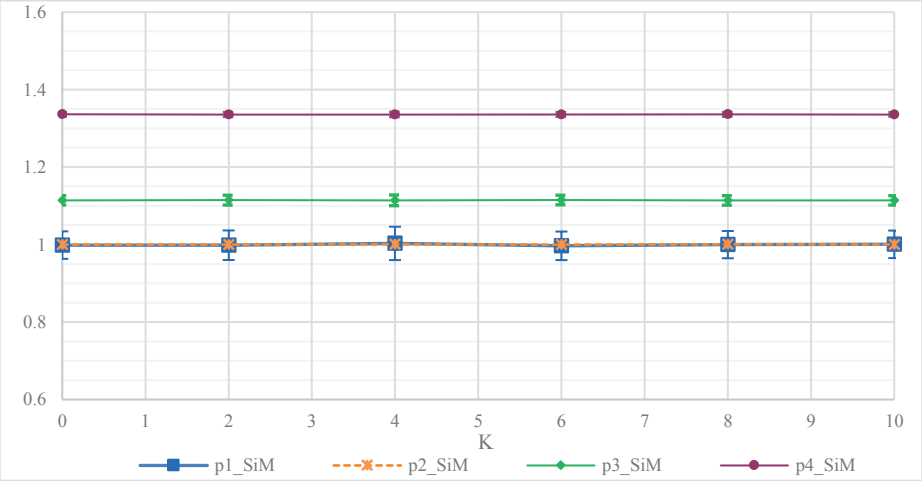

Fig. 4. Parameters' mean and standard deviation estimated using SiM

4.2 Model 2

This case of study allows compares the behavior of M-estimators and LS function when temporal redundancy is taken into account. The classic DR problem is initialized with the mean of a measurement data window that is called LSw.

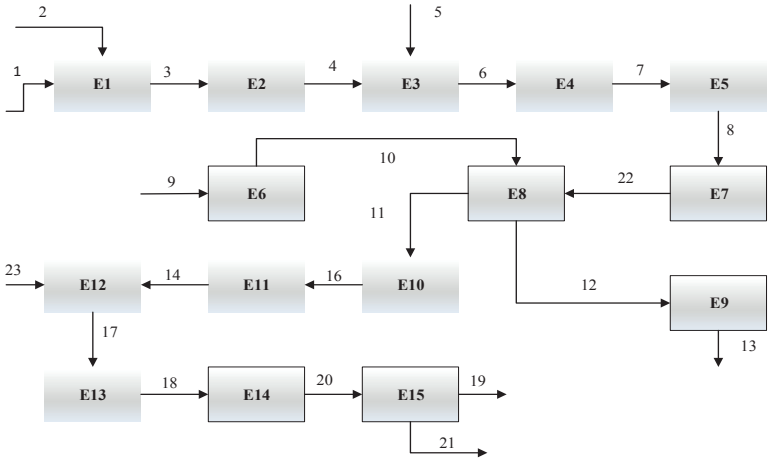

Fig. 5. Model 2 with uncertainty

Model 2 is a linear model composed of 23 flows related by 15 process units. The 6 units highlighted in Fig. 5 are the ones which have uncertain parameters, their initial values are presented in Table 6. Differently to Model 1, Table 7 presents the suggested values for parameters and standard deviation. These are improved by solving the DR or RDR problem for K=0. Then, the upgraded parameters are fixed as initial values for the following simulations. Results are displayed in Table 8, Figures 5 and 6.

Table 6. Balances Equation with uncertainty

$F_9 p_1 - F_{10} p_2 = 0;$	$F_{12} p_3 - F_{13} p_4 = 0$
$F_8 - p_6 F_{22} = 0;$	$F_{18} - F_{20} p_5 = 0;$
$F_{10} p_2 + F_{22} p_6 - F_{12} p_3 - F_{11} = 0;$	$F_{20} p_5 - F_{19} - F_{21} = 0;$

Table 7. Initial values of parameters and std

$\hat{\theta}_p$	p1	p2	p3	p4	p5	p6
Value	1,8	1,5	2	1,8	1,5	1,2
$\sigma_{\theta,p}$	2	0,8	2	1,6	2	0,8

Table 8. MSE for different K

K	0	2	4	6	8	10
y	0.9991	2.3946	4.9611	9.5848	16.9928	27.8381
SiM	0.0639	0.0865	0.0932	0.0738	0.0716	0.0711
LSw	0.0620	0.0865	0.1505	0.2720	0.4342	0.6162

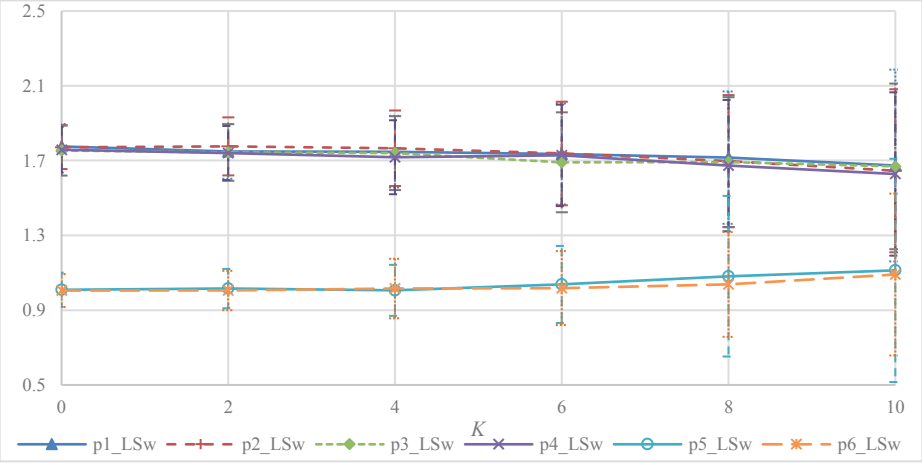

Fig. 5. Water Network parameter means and std of LSw

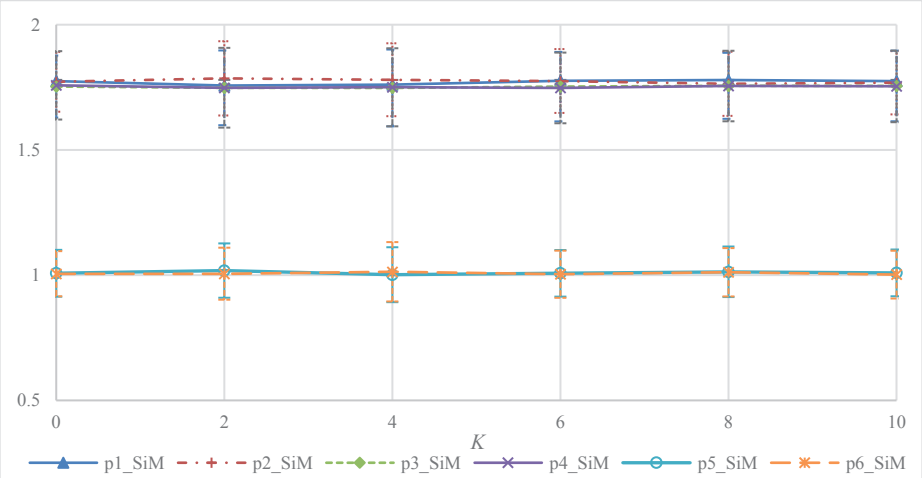

Fig. 6. Water Network parameter means and std of SiM

Table 8 shows that both procedures achieve more accurate results than the ones provided by the measurements. The LSw presents the most accurate estimation for $K \leq 2$ for $K>2$ the MSE increases until reaching the maximum value for $K=10$. The deterioration is smaller than the observed in the first example, this is as a result of the use of temporal redundancy. The SiM gets similar MSE for all the range of K analyzed.

Figures 5 and 6 display the means and stds of uncertain parameters. The lowest stds are achieved by LSw when measurements follow the $\mathcal{N}(K=0)$. However, this PM deteriorates with the increment of K, achieving stds that are 3 or 6 times bigger than the ones corresponding to SiM for $K=10$.

In conclusion, Figure 5 shows that the stds of all the parameters get worse with the increment of K, therefore the means of the parameters also deteriorate. Opposite, Figure 6 shows that uncertain parameters do not present changes with the increment of K. This is because of the use of a robust estimator in the DR procedure.

5 Conclusion

In this first approach, two linear models with uncertainty were treated with RDR and a classic DR formulation, the analysis of results allows to conclude that:

Robust data reconciliation can treat models with uncertainty when outliers are present. In this sense, the Simple Method (SiM) can achieve accurate estimations of parameters and variables when measurements follow exactly or approximately the $\mathcal{N}$.

Uncertainty diminishes the SR. The analysis of RMSE curves for variables with different redundancy degree showed that SiM provided accurate estimation for all the types of variables. Because SiM takes advantage of temporal redundancy.

It is demonstrated that outliers deteriorate the estimations of measurements and uncertain parameters when classic DR is used. Conversely, the use of SiM allows obtaining good results for parameters and variables estimations independently of the presence and magnitude of outliers.

Model 2 shows that the use of temporal redundancy in the LS problem allows achieving the most accurate results for measurement that follows the $\mathcal{N}$. However, the presence of outliers deteriorates the estimations accuracy of measured variables and uncertain parameters.

Regards the robust procedure, SiM gives unbiased estimations for all the variables and parameters for the outlier magnitudes analyzed. Therefore, implementing RDR procedures is a suitable alternative to treat models with uncertainty. Future research will address nonlinear models and explore uncertainty caused by dynamics and uncertain parameters when measurements follow approximately the $\mathcal{N}$.

Resumen. La cantidad de residuos aumenta con la población y es un problema creciente en nuestra sociedad. La posibilidad de producir biometano es una alternativa amigable con el medio ambiente. En Neuquén la fracción orgánica de los residuos FORSU alcanza el 44 % y es una potencial fuente de energía de biogas.

La cantidad de éste, se puede medir empleando el método de la jeringa y tiene la ventaja de ser un procedimiento experimental de bajo costo. El presente trabajo consistió en comparar la cantidad de gas generado en función de la concentración de sólidos totales. Su potencial es el volumen de biogas producido por la cantidad de materia prima expresada como sólidos volátiles. En este ensayo se usó la fracción orgánica de los residuos como sustrato (FORSU) y el agua residual de laguna anaerobia (AR LA) como inóculo, empleando jeringas de 60 ml a 35 °C con concentraciones de sustrato 5, 10, 15, 20 y 40 % de ST (sólidos totales) de FORSU y 10 ml de inóculo de agua residual de laguna anaerobia (AR LA).

Además, para la concentración de 5% y 20% se determinó un mayor potencial de biogás.

Palabras clave: Residuos, Fracción orgánica de los residuos FORSU, potencial de biogas, método de jeringa.

1 Introducción

El problema de la basura es un tema de interés mundial que está asociado a las actividades humanas [20]. Asimismo, el incremento de la población genera un aumento de la producción de los residuos y, por lo tanto, se deben enfrentar serias dificultades debido a estos [26]. Por ejemplo, los desechos generan organismos patógenos, vectores, enfermedades y contaminación ambiental [2]. En particular, cuando se arrojan los desechos de comida directamente al vertido, estos producen afectaciones negativas en el medio ambiente [24].

Una alternativa a este problema es el uso de la digestión anaerobia (DA) para transformar la fracción orgánica de los residuos en recursos, es decir, en metano y compost. La DA ocurre en forma natural, es una de los tecnologías más antiguas y común para producir energía a partir de biomasa [10]. La misma consiste en la descomposición de la materia orgánica en ausencia de oxígeno molecular. Es un proceso biológico de complejas reacciones bioquímicas asociadas a la actividad bacteriana de determinadas especies, por ende, tiene una fuerte dependencia de la composición del sustrato [3].

La información de la composición de los residuos es fundamental para la gestión y tratamiento de los mismos [25]. Estos datos se recopilan aplicando una metodología estandarizada para la caracterización de desechos domiciliarios [1].

En Argentina, en el año 2015, para una población 44.226.652 de personas se generaron 44.623 tn/d de residuos sólidos urbanos (RSU), mientras que en la Provincia del Neuquén con 550.344 habitantes se produjeron un total 455 tn/d [6]. A su vez, particularmente en la ciudad que lleva el mismo nombre, en ese año habían 245.419 personas [15] y la producción de RSU era de 209 tn/d. Cabe destacar, que en la ciudad de Neuquén el 44 % corresponde a la fracción orgánica de los residuos (FORSU) que es la constituida principalmente por restos de comida y cocina, cuyas características son heterogéneas.

Esta cantidad de residuos al ser transformado puede contribuir a una economía circular, es decir, "reducir, reutilizar y reciclar" [12]; lo que ayuda a disminuir el impacto negativo asociado a las actividades humanas.

El presente estudio tiene por objetivo determinar la cantidad de biogás a partir de FORSU de la ciudad de Neuquén usando como inóculo una agua residual de laguna anaerobia ARLA y un método experimental denominado test de Hohemheim HBT; si tenemos en cuenta que el potencial de biogas consiste en determinar el biogas generado para el inoculo seleccionado [11] se puede hallar la concentración optima de sólidos la mayor producción.

2 Materiales y métodos

2.1 Toma de muestra y composición de residuos

En Argentina la norma de referencia para la clasificación de residuos domésticos es ASTM D5231, dado a que es la fuente de datos disponibles [25]; la misma describe un método de cómo medir la composición de los residuos sólidos urbanos sin procesar, usando clasificación manual. Además, establece el proceso de recolección de una muestra de RSU representativa, así como, la reducción de datos y el.reporte de resultados.

Luego de la aplicación de la norma estandarizada, se tomó una muestra compuesta de la FORSU.,La cual fue transportada desde el centro de transferencia del Neuquén al laboratorio de Bioprocesos de la Universidad Tecnológica Nacional Facultad Regional Neuquén.para su conservación. Inmediatamentese redujo el tamaño cortando en trozos de 2 cm y se secó a 60°C hasta peso constante. Según lo que menciona Carneiro [5] esta instancia de secado es una etapa previa para poder triturar y homogeneizar los residuos, porque permite mantener sus propiedades. Luego de enfriar la muestra se

guarda en la heladera a 4 °C. Al momento del ensayo la muestra de FORSU se prepara con agua destilada y se tritura con miniprimer, de manera que quede homogénea.

Y en el caso de la muestra de agua residual de laguna anaerobia (ARLA), empleada como inóculo, se recolectó de la planta de tratamiento de efluente de la localidad de Plaza Huincul EPAS.

2.2 Caracterización de residuos

Se determinó en las muestras bajo normas estandarizadas: sólidos totales, sólidos volátiles, pH, conductividad y demanda química de oxígeno DQO; los métodos usados se resumen en la Tabla 1.

Los sólidos totales (ST) son los residuos de material que quedan en un recipiente después de la evaporación de agua en estufa a 103-105 ºC y los Sólidos fijos o cenizas corresponden a los residuos sólidos remanentes del calentamiento a 550 ºC. Mientras, los sólidos volátiles corresponden a los compuestos perdidos o volatilizados durante la calcinación a 550 ºC.

El pH es la medida de concentración de protones. En los residuos urbanos, es un parámetro que está asociado al origen y el estado de descomposición de la fracción orgánica. Por su naturaleza, presenta un pH ácido [19] En este estudio el pH se determinó con un pHmetro Hanna HI8424 previamente calibrado con soluciones amortiguadoras de pH=4,00 pH: 7.01 y pH=10 [8].

La conductividad es una expresión numérica de la capacidad de una solución para transportar una corriente eléctrica. Por lo tanto, es un valor que depende del total de iones que existe en la solución. En este estudio la conductividad se midió usando un conductímetro portátil Aquacombo.

La demanda química de oxígeno DQO es la cantidad de materia orgánica susceptible a ser oxidada por medio químico. Se utilizaron medir la DQO, los siguientes elementos: tubos de digestión HACH comerciales de 16 x 100 mm cuya capacidad es de 10 ml , un termoreactor Velp Eco8 para 150 + 2 º C y un espectrofotómetro Metash UV-Visible para leer a 600 o 420 nm.

Tabla 1. Resumen de técnicas usadas para análisis de FORSU y ARLA.

Parámetro	Unidad	Norma
Sólidos totales	%	Standard Method 2540B 17th Ed (APHA 1989)
Solidos volátiles	%	Standard Method 2540B 17th Ed (APHA 1989)
DQO	mg/l O_2	Standard Method 17th Ed (APHA 1989).
pH		Norma Boliviana de Residuos Sólidos 747.
Conductividad	mS/cm	Standard Method 2510B 17th Ed (APHA 1989)

2.3 Adaptación del inóculo

La muestra de ARLA luego de recolectarla se guardó por 1 semana en la cámara termostática a 35°C, para adaptarla a la temperatura del ensayo [14]. Se verifica la actividad del inoculo diariamente mediante su desgasificación. De esta manera se asegura que el inóculo este activo en condiciones operacionales definidas.

2.4 Ensayo de potencial de biogás por el método de jeringa

El método empleado para la determinación del biogás es el de Hohenheim denominado HBT [7], el cual consiste en utilizar jeringas como biodigestores a las cuales se les agrega el sustrato y el inóculo. Luego, se ajusta el émbolo sin que quede aire y se sella para evitar pérdidas.
Para mantener la temperatura constante se construyó una cámara térmica en el laboratorio de Bioprocesos de la Universidad Tecnológica Nacional Facultad Regional Neuquén, que utiliza un sistema de control Arduino y un caloventor 2000 watt, El ensayo se mantiene a 35°C y se registra el volumen generado de biogás en tiempo determinado,

Para la caracterización se emplean 3 réplicas con la misma concentración de residuos. Se usaron jeringas plásticas de 60 ml descartables. Las concentraciones ensayadas fueron: 5%, 10%, 15%, 20% ,40% ST de FORSU y una grupo, usando inóculo solo. La producción del biogás se comprueba mediante llama.

3 Resultados y discusiones

Los valores de la composición de residuos varían según la población, sus costumbres y poder adquisitivo. La fracción orgánica es el porcentaje más elevado de 44.2 % como se observa en la Tabla 2. En general se aprecian valores altos de FORSU en países subdesarrollados.

Tabla 2. Caracterización de residuos ciudad Neuquén ASTM D5231-92 (2016)

N=60	RSU-NQN
Papel	5.2
Carton	6.0
Plástico	10.9
FORSU	44.2
Ferrosos	0.5
Aluminio	0.6
Vidrio	4.6

En Latinoamérica según Sáez (2014) “el porcentaje de material putrescible es elevado”, y según los datos publicados en este artículo la fracción orgánica de los residuos oscila entre un 44% y 75%. Tomando datos de ciudades de Argentina con una población

entre 200 y 500 mil habitantes, como se muestra en la Tabla 3; se observan variaciones entre 17,22% y 45,61% de FORSU. El promedio de las mismas es 34.91 % [9] lo que evidencia que la cantidad de FORSU en Neuquén es un 5% más alta que el promedio.

Table 3. Cantidad de FORSU generado en Argentina por ciudad (2015). Elaborado a partir (Deluca y Giorgi, 2015).

CIUDAD	POBLACIÓN hab.	FORSU %
Avellaneda	342.677	45,61
Esteban Echeverria	300.959	31,85

DQO mg/l O_2	13017±152	6839+-213
Acidez	783±29 mg/l $CaCO_3$	93±29 mg/l

En la Tabla 4 se muestran los resultados obtenidos para la FORSU de la ciudad de Neuquén, como así también, para agua residual de laguna anaerobia AR LA. En el caso del pH tienen un valor de 5,16 indicando un carácter ácido. Los sólidos totales de la FORSU-NQN tienen un valor de 67,12% ST y son mayores que los expuesto en la Tabla 5, por ejemplo, el valor más alto es el de 38,8% ST [16], en el caso de los sólidos volátiles el porcentaje en este estudio es menor que en los presentados en la Tabla 5.

La variación en la composición de los desechos cambia con los hábitos y costumbres de cada población, y esto, se evidencia en los distintos estudios. Por lo cual, la elevada variabilidad hace necesaria la caracterización de las materias primas [20].

En la Tabla 5 se muestra que a mayor temperatura mayor producción de biogas; sin embargo, para este ensayo se elogió una temperatura de 35°C porque permite un proceso más estable en la producción de biogas.

Tabla 5. Caracterización de residuos y aguas residuales.

SUSTRATO	INÓCULO	T	SV	ST	BIOGÁS	Referencia
		°C	gr/kg	gr/Kg	ml CH4/ gr SV	
FORSU	LA	35	326.2	388.3	221	[16]
RCC	LA	55	234,24	244	441	[18]
RFV	LA	37	48,97	59	459	
FORSU	LA	37	322,14*	354	430	
RAS	LA	55	8	10,32	678	[13]
FORSU	LA PTAR	30	93016.67*	113036.7*	179,19	[19]
FORSU	LA PTAR	35	34,6	35,83	127,8	[22]
RPC	LA RAFA	37	253	290	600	[23]

FORSU: fracción orgánica de los residuos; RCC: residuos cocidos de cocina; RAS: residuos de alimento de supermercado; RPC: residuos de poda y comida; LA: lodo anaerobio; PPTAR: planta de tratamiento de agua residual y RAFA: reactor anaerobio de flujo ascendente. Léase*mg/l

Los resultados del potencial de biogas se representan en la Figura se observa que hay mayor acumulación de biogas para las concentraciones de 5% y 20% de FORSU con inóculo ARLA. De acuerdo Yi et al. (2014) [27] “a medida que aumentan los sólidos totales aumenta la cantidad de biogas acumulada”, esta condición se evidencia para las concentraciones de 10%, 15% y 20%

Sin embargo, de acuerdo a este ensayo, el biogas acumulado es similar para un 5% y 20 % de ST FORSU. Esto se explica para concentraciones de sustrato e inoculo menores a 1[4], como sucede del 5% FORSU, en el cual se favorece la producción e biogas [4].

En el caso del 40% de FORSU no se produjo biogas, y se infiere que se debe a alguna sustancia inhibidora. Dado que cuando se aumenta la carga orgánica se presentan efectos que evitan la generación de metano [17]

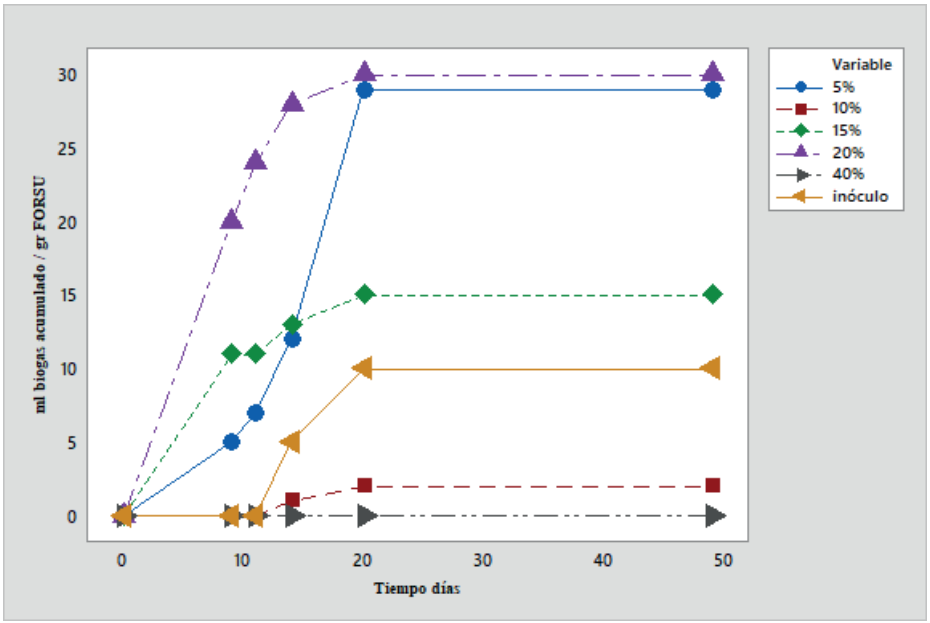

Fig. 1. Cantidad de biogás ml por día.

4 Conclusión

La fracción orgánica de los residuos del Neuquén es la fracción más significante de los residuos municipales y conforma un 44 % del total de los residuos. Según la caracterización, la muestra FORSU n=3; pH 5,18±0, Conductividad: 2ms/cm2, ST 67.12 %, SV: 17.37 %, DQO: 13017 ± 152mgO/l, Acidez total: 783± 29 mg/l CaCO3, NTK 11%. El inóculo empleado n=3 ARLA pH 6±0, Conductividad: 1002 ms/cm2, ST 0.687mg/l, SV: 0.171 mg/l, Acidez total 93± 29 mg/ l CaCO3.

La cantidad de biogas acumulada es similar para concentraciones de 5 y 20 % ST FORSU.

La cantidad de biogas acumulada para 10, 15 y 20 % ST FORSU aumenta con el aumento de los sólidos totales.

No se evidenció producción de biogas en el ensayo con 40% de sólidos.

Resumen. La Región Pampeana es una de las áreas más productivas de la Argentina y por ello muy dependiente de las condiciones climáticas. El conocimiento de su variabilidad climática es esencial para orientar políticas destinadas a mejorar la calidad de vida de la población y el ambiente. El objetivo de este estudio fue analizar las tendencias de la precipitación y la temperatura durante las últimas seis décadas. Se utilizaron series de datos diarios de 50 estaciones meteorológicas durante el período 1960-2019. Luego, se analizó la tendencia termo-pluviométrica a escala local y regional, aplicando el test de Mann Kendall. La Región Pampeana presentó un aumento de las precipitaciones de 116 mm en los últimos 60 años, mientras que la temperatura mostró tendencias positivas y significativas en la mayor parte del área de estudio. Se identificó un aumento térmico regional superior a 1 ºC. La información generada en esta investigación es esencial para que los actores locales y tomadores de decisiones diseñen planes de adaptación a las condiciones a las que está expuesta el área de estudio.

Palabras clave: test de Mann Kendall, precipitación, temperatura.

1 Introducción

En la actualidad, el cambio climático y el calentamiento global son los fenómenos que mayores impactos ambientales generan a escala global (Wang et al., 2015). Particularmente, la variabilidad climática tiene efectos negativos sobre la calidad de vida de la población y el desarrollo de sus actividades económicas, principalmente las agropecuarias (Sun et al., 2016). En este contexto, la Región Pampeana (Argentina) adquiere gran relevancia dado que es una de las regiones productivas más importantes del país. Está localizada en el centro-este de Argentina y tiene una extensión de 613.532 km^2 (Fig. 1). Por ello, el objetivo de este estudio fue analizar las tendencias de la precipitación y la temperatura durante los últimos 60 años. La finalidad de este

trabajo es la de proporcionar información destinada a generar políticas públicas orientadas al manejo de los recursos naturales y a garantizar la sustentabilidad de las actividades agropecuarias.

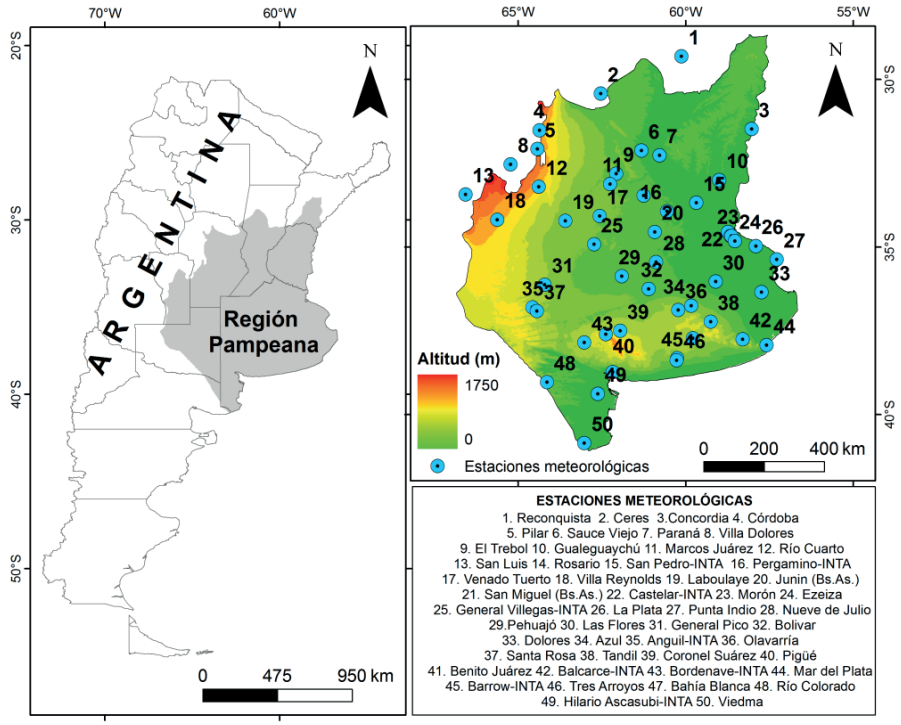

Fig. 1. Localización del área de estudio y de las estaciones meteorológicas utilizadas.

2 Metodología

Se recolectaron datos diarios de temperatura media, máxima y mínima y precipitación de 50 estaciones meteorológicas pertenecientes al Servicio Meteorológico Nacional (SMN) y al Instituto Nacional de Tecnología Agropecuaria (INTA) (Fig. 1). En una primera instancia, se evaluó la homogeneidad y la calidad de la información para completar las series de tiempo del período 1960-2019, aplicando un Análisis de Componentes Principales. Para ello, se consideraron las estaciones con datos faltantes y/o registros atípicos superiores al 5 % con sus vecinos más próximos. Como resultado, se obtuvo una matriz de confusión necesaria para crear las componentes principales. Se utilizó la matriz de Spearman para analizar la información y detectar la correlación entre ellas.

Como resultado, se obtuvo un nuevo set de variables resultante de la combinación lineal de las variables originales, capturando la mayor parte de la varianza original observada en los datos medidos *in situ*. Con esta información se completaron las se-

ries originales. Posteriormente, se estudiaron las tendencias con el test de Mann-Kendall (Mann, 1945; Kendall, 1975), a través de utilización del paquete Trend en el software R Studio. La tendencia se analizó a escala local y regional y la variación espacio-temporal fue graficada en un Sistema de Información Geográfica (ArcGIS 10.5).

3 Resultados

A escala local, la temperatura máxima se incrementó en todas las estaciones meteorológicas, con tendencias mayormente significativas. La temperatura mínima registró una tendencia hacia el calentamiento, aunque en el 36 % del área las tendencias fueron negativas. Estas zonas se corresponden con las áreas de mayor altura. La temperatura media presentó una tendencia al incremento, exceptuando la región sudeste (Fig. 2) del área de estudio. La temperatura máxima presentó el mayor incremento regional que fue estadísticamente significativo (+1,8 ºC en los últimos 60 años, $p < 0,01$). La temperatura mínima aumnetó en menor medida, pero también mostró evidencia estadística (+1,1 ºC en el período 1960-2019, $p < 0,01$). Por último, la temperatura media regional aumentó 1,2 ºC en el período 1960-2019 con significancia estadística

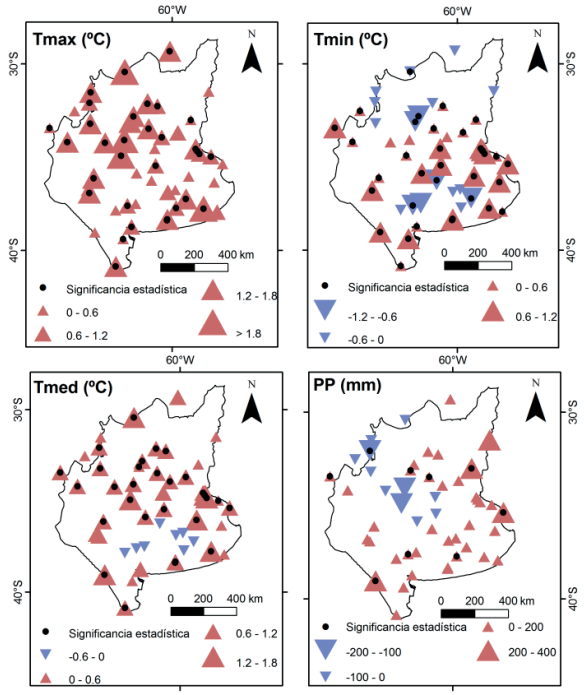

Fig. 2. Tendencia de la temperatura máxima, mínima, media y la precipitación en la Región Pampeana (Argentina) durante el período 1960-2019. Tmax. Temperatura máxima; Tmin. Temperatura mínima; Tmed. Temperatura media; PP. Precpitación.

La precipitación presentó una tendencia positiva en el 78 % de la Región Pampeana. El área localizada en el centro y noroeste mostró una tendencia negativa, registrando una disminución de 67 mm en las últimas seis décadas. Los mayores incrementos se identificaron en el noreste, en donde aumentó 398 mm/período. A pesar de ello, los cambios fueron estadísticamente significativos sólo en el 18 % de la región (vea Fig. 2). A escala regional, se identificó una tendencia positiva que no fue estadísticamente significativa ($p > 0,05$), marcando un incremento de 116 mm en los últimos 60 años.

4 Conclusión

Se analizó el comportamiento local y regional de la temperatura y la precipitación en la Región Pampeana durante 60 años. Las tendencias regionales de la temperatura identificaron que la región está expuesta a los efectos del calentamiento global. Tanto las temperaturas máximas y mínimas registraron un incremento superior a 1 ºC. Por otro lado, la precipitación mostró un patrón espacial heterogéneo, con menor significancia estadística. Sin embargo, se observó en el análisis regional que presentó una tendencia positiva. Los resultados obtenidos sirven de base para el orientar las propuestas de manejo del territorio destinadas a reducir y mitigar los efectos negativos que la variabilidad climática tiene sobre los ecosistemas y sobre la salud de la población y sus actividades económicas.

Agradecimientos

Se agradece a la Universidad Nacional del Sur (UNS) y al Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) por el financiamiento de la presente investigación. Además, se destaca al Servicio Meteorológico Nacional (SMN) y al Instituto Nacional de Tecnología Agropecuaria (INTA) por brindar la información climática analizada en este estudio.

Resumen. El objetivo de este estudio fue analizar la tendencia de la temperatura y la precipitación actual y futura de la Región Pampeana (Argentina). Se utilizó información de precipitación y temperatura máxima y mínima *in situ* y datos futuros provistos por el modelo CCSM4. Se definieron cinco períodos de estudio: presente (2000-2019), futuro cercano RCP 4.5 y RCP 8.5 (2020-2039) y futuro lejano RCP 4.5 y RCP 8.5 (2080-2099). En cada uno de ellos, se calculó la tendencia termo-pluviométrica con el test de Mann Kendall. El área de estudio mostró señales de calentamiento atmosférico con significancia estadística en el presente y el futuro cercano y lejano bajo el escenario RCP 8.5. La precipitación tuvo tendencia negativa en el presente y se incrementó hacia el futuro. La variabilidad termo-pluviométrica impacta negativamente sobre la producción agropecuaria. Por lo tanto, estos resultados son esenciales para los tomadores de decisiones y los productores agropecuarios, dado que sirven de base para el diseño de medidas de mitigación orientadas a reducir los impactos de la variabilidad climática sobre las economías regionales.

Palabras clave: precipitación y temperatura actual y futura, datos *in situ* y modelados, producción agropecuaria.

1 Introducción

El calentamiento global, principal causa del cambio climático, ha ocasionado el incremento de la temperatura atmosférica impulsada por la emisión de gases de efecto invernadero (Padhiary et al., 2018). Como consecuencia, se han registrado cambios en el régimen y la intensidad de las precipitaciones producto de una mayor concentración del vapor de agua en la atmósfera (Muthuwatta et al., 2018). La Región Pampeana (613 mil km^2, Argentina) (Fig. 1) es el área productiva más importante del país y además es altamente vulnerable a las variaciones climáticas. Por ello, el objetivo de este estudio fue analizar la tendencia de la temperatura y la precipitación actual y futura de la Región Pampeana. Los resultados de esta investigación servirán de base para el diseño de medidas de mitigación orientadas a reducir los impactos de la variabilidad termo-pluviométrica sobre las economías regionales.

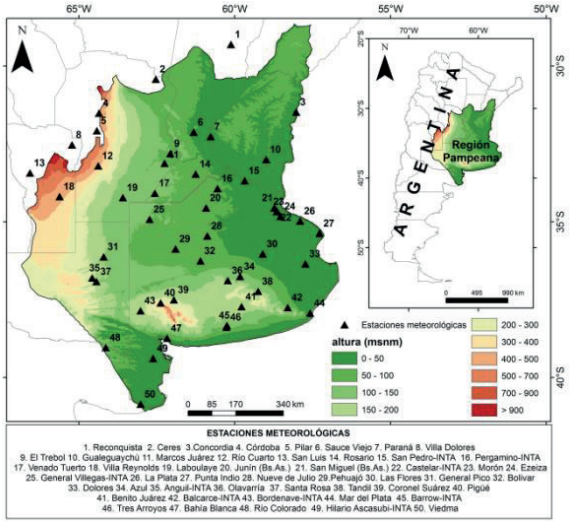

Fig. 1. Topografía y localización a de la Región Pampeana (Argentina) y de las estaciones meteorológicas utilizadas.

2 Método de trabajo

Se utilizaron datos mensuales de precipitación, temperatura máxima y mínima de 50 estaciones meteorológicas localizadas en la Región Pampeana durante el período 2000-2019, denominado período presente (Fig. 1). Estos fueron cedidos por el Servicio Meteorológico Nacional y el Instituto Nacional de Tecnología Agropecuaria. Por otro lado, se utilizaron datos provistos por el modelo global CCSM4 (Community Climate System Model 4) perteneciente al Centro Nacional de Estudios de la Atmósfera (NCAR, Estados Unidos). Estos datos fueron obtenidos de la página del Centro de Investigaciones del Mar y la Atmósfera de Argentina (CIMA - http://3cn.cima.fcen.uba.ar). La selección de este modelo se basó considerando los resultados de la validación de 24 modelos realizado por el CIMA, quienes indicaron que este modelo es el más preciso para representar las condiciones hídricas y térmicas futuras de la Región Pampeana. La información fue analizada en dos períodos de tiempo. Uno se denominó futuro cercano (2020-2039) y el otro futuro lejano (2080-2099). Ambos fueron considerados en dos escenarios de concentración de gases de efecto invernadero en la atmósfera (RCP – Representative Concentration Pathways, por sus siglas en inglés). Finalmente, se analizó la tendencia de los tres índices en los cinco períodos de estudio. Para ello, se aplicó la prueba no paramétrica de Mann-Kendall (Mann, 1945; Kendall, 1975), mediante la utilización del paquete Trend en el software R Studio.

4 Resultados

La tendencia y la significancia estadística regional de la temperatura máxima, mínima y la precipitación durante los cinco períodos analizados se muestra en la Tabla 1, mientras que la variación espacial se presenta en la Figura 2. La temperatura máxima

mostró, durante el presente, tendencia positiva en el 98 % del área de estudio (Tabla 1). El incremento regional fue 1.1 °C y la significancia estadística fue observada en el 82 % de la región (Tabla 1). El centro de la región fue el que presentó los mayores incrementos, que fueron de hasta 2.1 °C durante los 22 años analizados (Fig. 2). Hacia el futuro, los cambios con evidencia estadística más importantes de este índice, se registraron bajo el escenario RCP 8.5 en ambos períodos. El aumento promedio fue 0.6 °C (Tabla 1). En el futuro lejano, el incremento regional fue mayor que en el futuro cercano y el presente (1.4 °C) y la tendencia fue positiva y estadísticamente significativa en la totalidad del área de estudio (Tabla 1). Estos cambios térmicos fueron más importantes en el N y W (Fig. 2).

La temperatura mínima presentó tendencia positiva en todos los períodos analizados. Sin embargo, fue significativa en el presente y el futuro lejano y cercano bajo el escenario RCP 8.5 (Tabla 1). El presente mostró tendencia positiva en el 68 % del área de estudio, siendo estadísticamente significativo en el 76 %. El aumento regional fue 0.5 °C (Tabla 1). Durante el futuro lejano y cercano RCP 8.5, se registró un 98 y 100 % de tendencia positiva, respectivamente. La región tuvo un aumento de la temperatura mínima de 0.6 °C en el futuro cercano y 0.9 °C en el futuro lejano (Tabla 1). Estos incrementos no presentaron una preferencia espacial en la zona de estudio (Fig. 2).

Tabla 1. Número de estaciones meteorológicas de la Región Pampeana que presentaron disminución (D) o incremento (I) de la temperatura máxima, mínima y precipitación durante los cinco períodos analizados. N°: número de estaciones meteorológicas; S: significancia estadística. P. Reg.: promedio regional.

La precipitación evidenció tendencia negativa sólo en el presente (Tabla 1). Esta situación se encontró en el 62 % del área de estudio (31/50), siendo estadísticamente significativa en el 74 %. En promedio, disminuyó 120 mm durante los 22 años analizados (Tabla 1). Durante el futuro cercano, el 62 % de las estaciones mostraron tendencia positiva y la significancia fue encontrada en el 68 %, mientras que en el futuro lejano la tendencia positiva se registró en un mayor número de estaciones meteorológicas (66 %). Finalmente, es importante destacar que en ambos futuros RCP 8.5, la precipitación presentó modificaciones espaciales importantes con respecto al presente (Fig. 2).

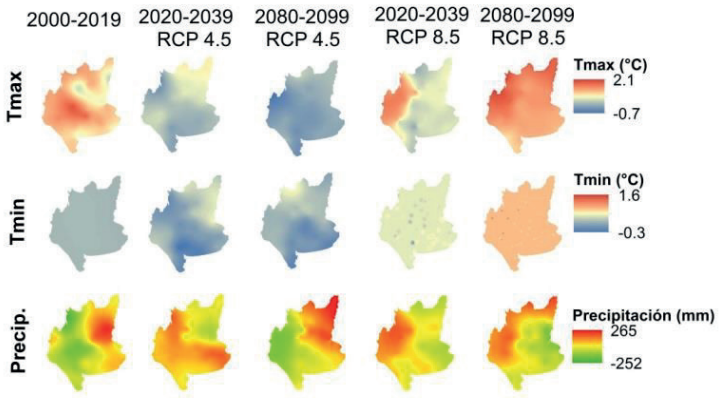

Fig. 2. Variación espacial de la temperatura máxima, mínima y la precipitación de la Región Pampeana durante los cinco períodos analizados.

5 Conclusión

Se analizó la tendencia de la temperatura máxima, mínima y la precipitación durante presente y el futuro en la Región Pampeana (Argentina) y se determinó las condiciones a las que el área de estudio estará expuesta en el futuro. La tendencia de los tres índices fue estadísticamente significativa en el presente y el futuro cercano y lejano bajo el escenario de mayor concentración de gases de efecto invernado (RCP 8.5). En estos tres períodos, se detectaron señales de calentamiento atmosférico que fueron de mayor magnitud en el futuro lejano bajo el RCP 8.5. La precipitación fue negativa en el presente y aumentó hacia el futuro. Por lo tanto, este trabajo presenta información esencial para los tomadores de decisiones y los productores agropecuarios que sirve de base para el diseño de medidas de mitigación orientadas a reducir los impactos de la variabilidad climática sobre las economías regionales.

Agradecimientos

Al Consejo Nacional de Investigaciones Científicas y Técnicas y a la Universidad Nacional del Sur por el financiamiento de este estudio. Además, al Servicio Meteorológico Nacional, al Instituto Nacional del Tecnología Agropecuaria y al Centro de Investigaciones del Mar y la Atmósfera de Argentina por el suministro de datos utilizados en esta investigación.

Resumen. El agua es un recurso natural indispensable para la actividad humana. En acuíferos costeros de espesor y extensión limitados, las variaciones en el uso del suelo pueden condicionar la calidad y cantidad de agua disponible para la explotación, ya sea para uso industrial o para abastecimiento de la población. El objetivo de este trabajo es cuantificar la expansión de las áreas forestadas y el efecto de esta expansión sobre la disponibilidad de agua subterránea, en la localidad de Mar de las Pampas, Partido de Villa Gesell, Provincia de Buenos Aires. A partir de imágenes satelitales y fotografías aéreas, mediante el mapeo manual detallado de los tipos de cobertura en la zona de estudio, se realizó un análisis del uso del suelo para los años 1975 y 2014. Se calcularon balances hídricos a partir de datos de precipitación, teniendo en cuenta las propiedades hidrológicas características del terreno, para asignar un valor de recarga a cada tipo de cobertura. Los resultados indican una reducción de la recarga de un 26% durante el período 1975-2014, lo cual deberá tenerse en cuenta para la planificación del uso sustentable del recurso hídrico subterráneo, en una localidad actualmente en crecimiento.

Palabras Clave: Agua Subterránea; Calidad Ambiental; Manejo de Recursos Hídricos.

1 Introducción

Las zonas costeras revisten gran importancia desde un punto de vista económico y ambiental, debido a que las poblaciones humanas suelen ubicarse cerca o dentro del ambiente costero. Las poblaciones costeras ejercen modificaciones sobre las condiciones naturales del ambiente, lo cual tiene un gran impacto en el equilibrio costero [1]. Uno

de los recursos más afectados por estas modificaciones es el agua subterránea, especialmente cuando se trata de ambientes de dunas costeras que albergan lentes de agua dulce [2].

La evolución a través del tiempo del uso del suelo en una zona determinada, tiene un gran impacto en varios aspectos aplicados y en las actividades humanas que se desarrollen en dicha zona. Las imágenes satelitales han sido aplicadas con éxito al estudio espacial de distintos tipos de áreas, incluyendo zonas costeras, urbanas, forestadas y agrícolas. Entre otros, fueron llevados a cabo estudios de uso del suelo y cambios en el paisaje [3, 4]. Es frecuente el uso de Sistemas de Información Geográfica (SIG) en forma conjunta con las técnicas de sensores remotos, para cuantificar la variación temporal uso del suelo [5, 6].

Existen numerosas aplicaciones de los sensores remotos a los estudios hidrológicos e hidrogeológicos; entre ellas, se cuentan el análisis de la variación areal en el tiempo de cuerpos de agua superficiales [7, 8], la identificación de áreas de recarga y descarga naturales [9, 10] y de áreas adecuadas para la recarga artificial en regiones áridas [11].

Las características del suelo afectan directamente al ciclo hidrológico de una zona, dado que la cobertura del suelo controla los procesos de evapotranspiración, infiltración y escurrimiento superficial que atraviesa el agua proveniente de las precipitaciones. Debido a esto, algunos trabajos se centran en la cuantificación de variaciones temporales en la cobertura impermeable, producto de la urbanización [12, 13]. Otros trabajos se centran en las modificaciones en la cobertura forestal de una zona y su impacto hidrológico. La forestación es una actividad antrópica frecuente en ambientes de dunas costeras debido a que la implantación de bosques provee protección contra la erosión y facilita la fijación de las dunas [14]. Sin embargo, se reconocen efectos adversos de la forestación sobre el ciclo hidrológico, específicamente sobre los balances hídricos. La implantación de bosques aumenta la evapotranspiración y disminuye los excesos de agua, por lo cual se ve disminuida la recarga al sistema subterráneo [15-17].

Existen antecedentes de este tipo de estudios en la costa de la Provincia de Buenos Aires. Carretero y Kruse [18] realizaron un análisis de detalle del uso del suelo en San Clemente, entre los años 1958 y 2005. Se estimó una disminución en la recarga de 47% en la zona urbanizada. El mismo análisis fue llevado a cabo en Las Toninas y Santa Teresita entre 1987 y 2012; los resultados mostraron un 30% de reducción en la recarga [19]. Posteriormente, Carretero et al. [20] analizaron la variación en la recarga debida al cambio en el uso del suelo en el Partido de La Costa (que incluye a las localidades mencionadas anteriormente) para el período 1973-2010. En este caso, los resultados indicaron un 10% de reducción en la recarga para la totalidad del área estudiada, aunque la reducción es de un 18 y 30% cuando se focaliza en los centros urbanos. Más recientemente, Rodrigues Capitulo et al. [21] aplicaron una clasificación supervisada a imágenes satelitales Landsat 7 TM del año 2015, para identificar superficies forestadas y suelo desnudo en el Partido de Pinamar. Según los resultados, la recarga sería un 33% menor en las áreas forestadas, respecto de las no forestadas.

En el presente trabajo se analiza la evolución del uso del suelo en un sector de la costa bonaerense (Argentina), vinculando los aspectos geomorfológicos y forestales, como base para la estimación de las modificaciones en la recarga del agua subterránea. A pesar de la importancia del recurso hídrico en la planificación y gestión urbana, aún

no hay estudios de este tipo sobre la zona, de forma que este trabajo resulta de utilidad para iniciar la tarea de cuantificar las reservas de agua dulce en el acuífero freático.

1.1 Área de Estudio

La localidad de Mar de las Pampas se encuentra emplazada en la región geomorfológica conocida como Cordón Costero, en la costa atlántica de la Provincia de Buenos Aires, Argentina (Fig. 1). Se centra en los 37°19′26″ de latitud sur y 57°01′30″ de longitud oeste. Forma parte de Partido de Villa Gesell y limita al noreste con la localidad homónima. Hacia el sur, limita con la localidad de Mar Azul; hacia el noroeste, fuera de los límites del cordón costero, dentro de la llanura continental, se encuentra el partido de General Madariaga.

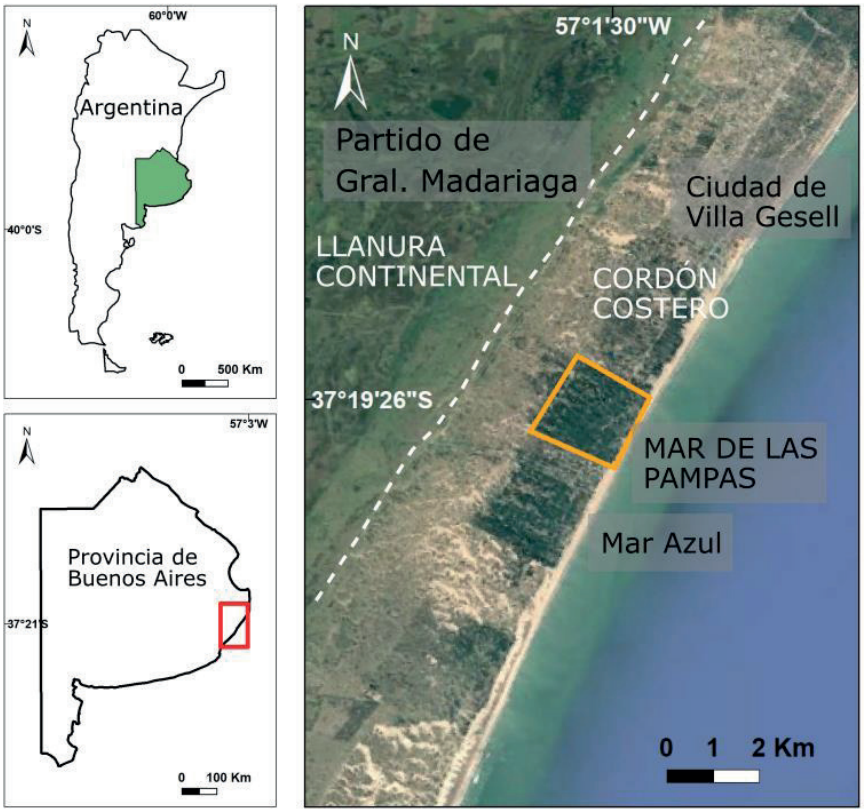

Fig. 1. ubicación del área de estudio.

Los trabajos de fijación de dunas en Mar de las Pampas comenzaron en 1957, pero recién en 1971 se aprobó el plan definitivo de forestación y trazado urbano, en el cual las calles y manzanas debían adecuarse a la morfología medanosa natural. En el año 2010, la población estable era de 1.797 habitantes [22]. Sin embargo, al tratarse de una

localidad balnearia, debe tenerse en cuenta el aumento estacional de la población debido a la avenida turística en la época estival.

El acuífero freático se aloja en el cordón arenoso, que fue construido durante el Holoceno como resultado de la acción conjunta de procesos costeros y procesos eólicos vinculados a la generación y migración de dunas costeras [23, 24]. El cordón costero presenta en esta región poco más de 3 km de ancho; y en el sector central las dunas se elevan hasta aproximadamente 20 msnm [25, 26]. El área de estudio se encuentra dentro de la Región II definida por el Consejo Federal de Inversiones [27]. Esta región presenta características geomorfológicas particulares, que tienen un fuerte impacto en su comportamiento geohidrológico. Rodrigues Capitulo [28] definió un modelo hidrodinámico para la localidad de Pinamar, que forma parte de la Región II y se ubica a pocos kilómetros de Mar de las Pampas. Según este modelo, la recarga de agua subterránea es de índole local y directa a partir de las precipitaciones. Dada la alta permeabilidad del sustrato arenoso, se considera nulo el escurrimiento superficial, de forma tal que los excesos de agua contribuyen en su totalidad a la infiltración. Una vez alcanzada la zona saturada, el agua se mueve desde la zona central del cordón hacia ambos bordes del mismo. Del lado oeste, una zona de interface separa el agua dulce del cordón costero del agua salobre contenida en los sedimentos de la llanura continental. Del lado este, se registra una interface entre el agua dulce y el agua salada del mar. Esta última fue identificada en el Partido de Villa Gesell por Hurtado et al. [29], mediante la realización de estudios geoeléctricos.

El acuífero costero constituye la única fuente de agua potable para la población. El aumento de la población estable y, especialmente, el desarrollo turístico de la zona, resultan en una creciente presión de explotación sobre el recurso hídrico. A su vez, debe tenerse en cuenta que el sistema costero presenta particularidades que lo hacen especialmente vulnerable respecto de los problemas con el agua, como son la posibilidad de intrusión salina y la sensibilidad a la contaminación por sobrebombeo.

2 Materiales y Métodos

La metodología de trabajo comprendió tareas de mapeo y manejo de datos en SIG (i.e., identificación de distintas unidades de mapeo, digitalización manual de las mismas, análisis multitemporal de su evolución para el período 1975-2014), así como otras propias de los estudios hidrológicos (realización de balances hídricos, asignación de un valor de recarga a los distintos tipos de cobertura del suelo en base a criterios hidrológicos, estimación de la recarga total en la zona de estudio para los diferentes escenarios analizados).

La base para el mapeo del uso del suelo fueron imágenes aéreas y satelitales. Se contó con fotos aéreas del año 1975 facilitadas por el Instituto Geográfico Nacional (IGN). Las imágenes satelitales del año 2014 fueron obtenidas de Google Earth. Se generaron mosaicos con los conjuntos de imágenes correspondientes a cada año, para poder visualizar en su totalidad el área de interés. Las imágenes así compuestas fueron introducidas en un SIG, donde se realizó su georreferenciación según el sistema de coordenadas POSGAR 2007 Transverse Mercator, Datum POSGAR 2007, Faja 6. El

área de mapeo coincide con los límites políticos de la localidad de Mar de las Pampas (Fig. 1). Hacia el sudoeste, noreste y noroeste, se tomaron como límite de mapeo las calles principales que actualmente bordean la localidad. En dirección sudeste, hacia al mar, el mapeo se realizó hasta el comienzo de la zona de playa.

2.1 Geomorfología

Las unidades geomorfológicas fueron definidas en la imagen del año 1975, sobre la base de la textura y tono (en escala de grises) observados en la imagen. Se identificaron dos unidades: (1) dunas costeras, caracterizadas por un tono claro correspondiente a la alta reflectancia de la arena seca, y (2) interdunas, caracterizadas por un tono más oscuro vinculado a la presencia de humedad superficial, y por una textura granular debida a la vegetación herbácea natural que se desarrolla en esas condiciones. Si bien las copas de los árboles pueden impedir puntualmente la observación directa de la superficie, entre las mismas puede identificarse una cobertura correspondiente a la clase (1) descripta, por lo que las áreas cubiertas por árboles fueron asignadas a la categoría de dunas costeras. La Fig. 2 muestra un ejemplo de las superficies de dunas costeras e interdunas.

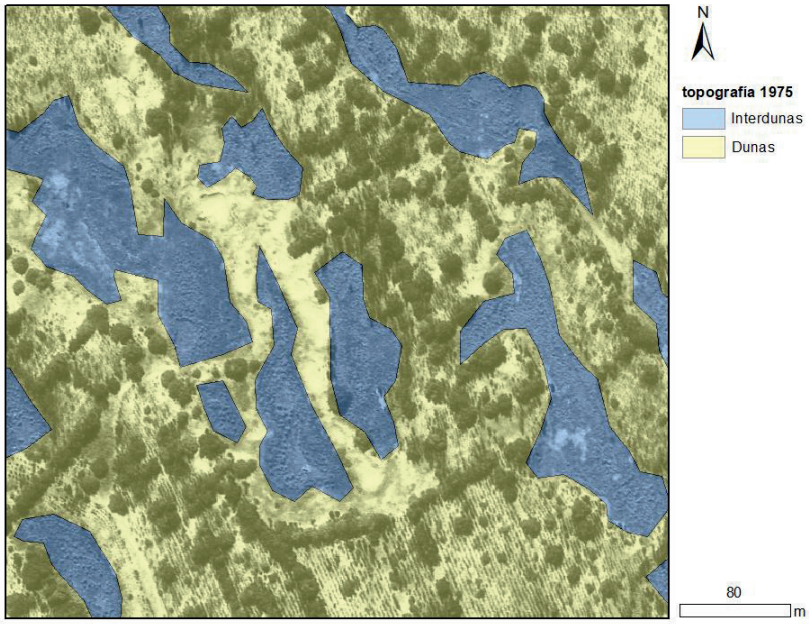

Fig. 2. dunas costeras e interdunas en el área de estudio.

2.2 Uso del Suelo

Se realizó la digitalización manual de las zonas de uso del suelo en los diferentes años a una escala de 1:2.000. El resultado fue la generación de archivos de tipo vectorial con polígonos que representan las diferentes zonas mapeadas. Los usos del suelo fueron definidos sobre la imagen de 1975, para luego extrapolar el criterio de mapeo a la imagen moderna. Dicho criterio consistió en la identificación visual de propiedades que permitieran asignar a la superficie una de las cinco categorías de uso del suelo consideradas, a saber: (1) nulo: no se observa acción antrópica. Incluye zonas de interdunas con tono oscuro por la presencia de arena húmeda y/o vegetación herbácea, así como zonas de alto albedo correspondientes al suelo arenoso desnudo, sin vegetación natural o artificial. (2) plantación inicial: zonas de dunas donde se observa la grilla de plantación de árboles, pero éstos aún no se han desarrollado. (3) ralo forestal: coexisten árboles de escaso desarrollo, apenas visibles en la fotografía aérea, con algunos árboles de mayor tamaño cuyas copas no se tocan entre sí. El suelo arenoso es visible en forma prácticamente continua. (4) medio forestal: similar a ralo forestal, pero con una mayor cobertura por parte de los árboles. Las copas frecuentemente se tocan entre sí, conformando líneas de forestación entrecruzadas; sin embargo, el suelo arenoso es aún visible. (5) denso forestal: las copas forman una cubierta coalescente prácticamente continua, con frecuentes pero pequeños espacios de raleo o cambios en la textura que indican diferentes etapas de desarrollo de los árboles y/o distintas especies.

El área total ocupada por cada categoría en los sucesivos años se obtuvo mediante la función Calculate Geometry presente en el SIG, que proporciona la extensión superficial de los elementos poligonales de formato vectorial incluidos en una capa.

2.3 Comparación Entre Desarrollo Forestal y Relieve

Resulta de interés conocer la evolución en la relación que guardan las variables relieve y uso del suelo a lo largo de la serie analizada. Originalmente, la forestación fue planificada en base a la geomorfología de la zona, con la intención de forestar únicamente las zonas altas (dunas costeras) y ubicar las calles y caminos en las zonas bajas (interdunas). Para determinar la distribución de clases de uso del suelo en las interdunas, así como en las dunas costeras, se realizó una intersección de las capas de uso del suelo y relieve, para cada año analizado.

2.4 Realización de Balances Hídricos

La importancia de cuantificar los excesos en el balance hídrico radica en que la totalidad de dichos excesos constituye la única recarga del acuífero freático, dado que, en el cordón medanoso, el escurrimiento superficial tiende a cero [21].

Para determinar los excesos de agua se realizaron balances hídricos según Thornthwaite y Mather [30], a partir de datos diarios de precipitación del Servicio Meteorológico Nacional en Villa Gesell. La serie de datos corresponde al período 1997-2016; dado que las precipitaciones no han cambiado significativamente en este período, estos

datos se consideran representativos de la lluvia en la región [21]. Se asumió que la intercepción contribuye en un 100% a la evapotranspiración (ET).

Se usaron valores medios diarios de evapotranspiración de referencia (ETo), estimados con la ecuación FAO Penman–Monteith [31]. La evapotranspiración potencial (ETc) puede calcularse mediante la ecuación (1):

$$ETc = ETo \times Kc \qquad (1)$$

donde ETc es la máxima evapotranspiración de la cobertura; ETo es la evapotranspiración de referencia y Kc es el coeficiente de cultivo o de cobertura.

La capacidad de campo (CC) media para este suelo dominado por arena fue de 160 mm/m, siguiendo a Falasca y Forte Lay [32], que definen un valor de 140 y 180 mm hasta una profundidad de 1 m a lo largo de la costa arenosa bonaerense. Se consideraron dos casos: suelo desnudo (suelo arenoso con escasa vegetación o sin ella) y forestal (suelo cubierto por un bosque de coníferas). En el primer caso, la profundidad efectiva asignada para el balance fue de 0,25 m y por lo tanto quedó definida una CC de 40 mm, dado que el efecto de la evapotranspiración no puede penetrar más profundo. En el segundo caso debió tenerse en cuenta una exploración de raíces de más de 1 m, ya que se trata de un bosque bien establecido. Por ello, se asignó una profundidad de 1,25 m, que derivó en una CC de 200 mm en el balance.

Se determinaron valores de Kc de acuerdo a FAO [31]. Para la zona de suelo desnudo el valor fue variable a lo largo del año; mientras que para la zona forestal se tomó Kc=1 constante todo el año.

Los valores de ETo y Kc adoptados fueron procesados con el software AGROAGUA v.5.0 [33]. Esta aplicación permite obtener balances hídricos mensuales a partir de variables como la capacidad de campo, evapotranspiración potencial diaria y precipitaciones diarias. Los balances mensuales así obtenidos fueron agrupados en valores anuales, para luego calcular un valor anual promedio de precipitación y de excesos para las categorías de recarga consideradas.

2.5 Agrupación de Usos del Suelo Según Criterio Hidrológico y Obtención de Valores de Recarga

Las características superficiales del terreno condicionan las posibilidades de infiltración del agua aportada por las precipitaciones. Es posible obtener un valor de recarga total para la zona de estudio, aplicando los balances hídricos explicados previamente a las clases de desarrollo forestal identificadas en el mapeo, y conociendo la distribución espacial de éstas.

Para esto, se agruparon las categorías de uso del suelo según un criterio hidrológico, de forma tal que las categorías nulo, plantación inicial y ralo forestal corresponden a la categoría de recarga de suelo desnudo, mientras que medio forestal y denso forestal se agrupan bajo la categoría hidrológica forestal. La Fig. 3 muestra la correspondencia entre las zonas de uso del suelo y las superficies de recarga para el año 1975.

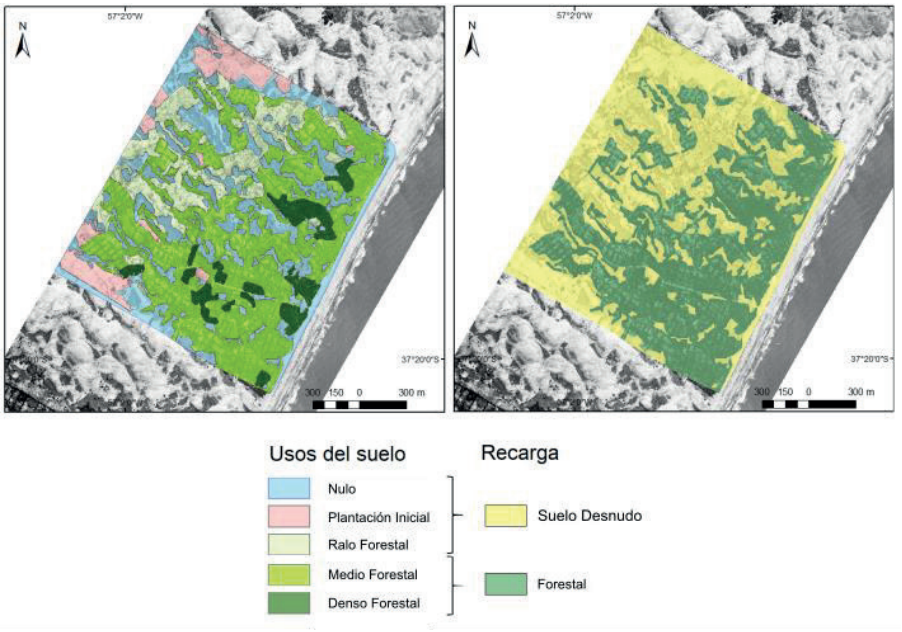

Fig. 3. Categorías de uso del suelo, y sus equivalentes según un criterio de recarga.

Finalmente, se calculó el volumen de agua que habría ingresado como recarga al sistema en las zonas de suelo desnudo y forestal, mediante la multiplicación de su extensión superficial en cada año por el promedio anual de excesos definido para cada zona. El valor total de recarga para cada año surge de la suma de los volúmenes de recarga correspondientes a cada zona. Esto permitió evaluar la variación en la recarga para el período considerado.

3 Resultados

3.1 Evolución del Uso del Suelo

La distribución de zonas de relieve definida en la fotografía de 1975 muestra que, de los 2,77 km^2 comprendidos en el área de mapeo, 81,7% corresponde a dunas costeras, y 18,3% a interdunas.

Se observan diferencias en la superficie ocupada por cada clase de uso del suelo en los dos momentos considerados (Fig. 4 y Fig. 5a). La Tabla 1 expresa dichas superficies en metros cuadrados.

El año 1975 representa una etapa inicial del proceso de forestación y amanzanamiento. Es por ello que una parte importante de la superficie corresponde al uso nulo (23,6%) y se observa la presencia de la categoría plantación inicial, con un 7,4% del total de la superficie mapeada. La categoría mejor representada es medio forestal, con un 45,8%, mientras que denso forestal se ubica en último lugar con un 6,8%.

En el año 2014 la superficie mapeada se encuentra ampliamente dominada por la categoría denso forestal (con un 83,0% de cobertura), mientras que medio y ralo forestal ocupan un lugar accesorio en la distribución territorial. Las zonas de uso nulo y plantación inicial han desaparecido por completo.

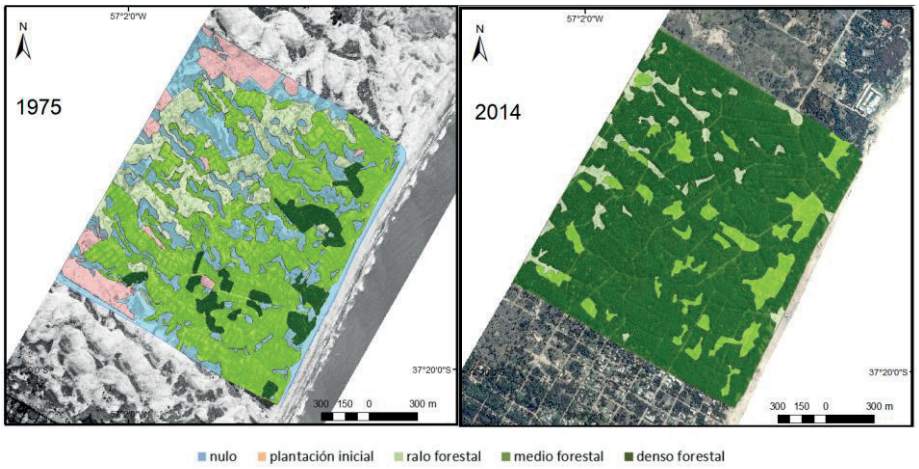

Fig. 4. Uso del suelo para 1975 y 2014.

Tabla 1. Usos del suelo en los años 1975 y 2014

	Área (%)	
Categoría	**1975**	**2014**
nulo	25,8	0,0
plantación inicial	7,5	0,0
ralo forestal	14,2	5,7
medio forestal	45,6	11,3
denso forestal	6,9	83,0
total	100	100

Las imágenes analizadas muestran el desarrollo de la forestación a lo largo de 39 años. Los cambios en la representación de las distintas categorías de uso del suelo indican un efectivo proceso de forestación, dado que, hacia el final del período, gran parte de la localidad se encuentra cubierta por un bosque bien desarrollado. Esto implica cambios en la disposición original de las superficies forestales, que debían ubicarse en las dunas costeras, no en las zonas de interduna. En 1975, el 96,0% de las áreas de interduna presentan un uso nulo, sin embargo, en 2014 la forestación ha ocupado por completo las zonas de interduna, con un predominio de la clase denso forestal (62,9%) (Fig. 5b). Las áreas de dunas costeras se encuentran ya forestadas en 1975, con un 56,5% de su superficie cubierta por el uso medio forestal, y las otras cuatro clases de

uso ocupando el 43,5% restante. En 2014, el 87,4% de la superficie de dunas costeras se halla cubierta por el uso denso forestal (Fig. 5c).

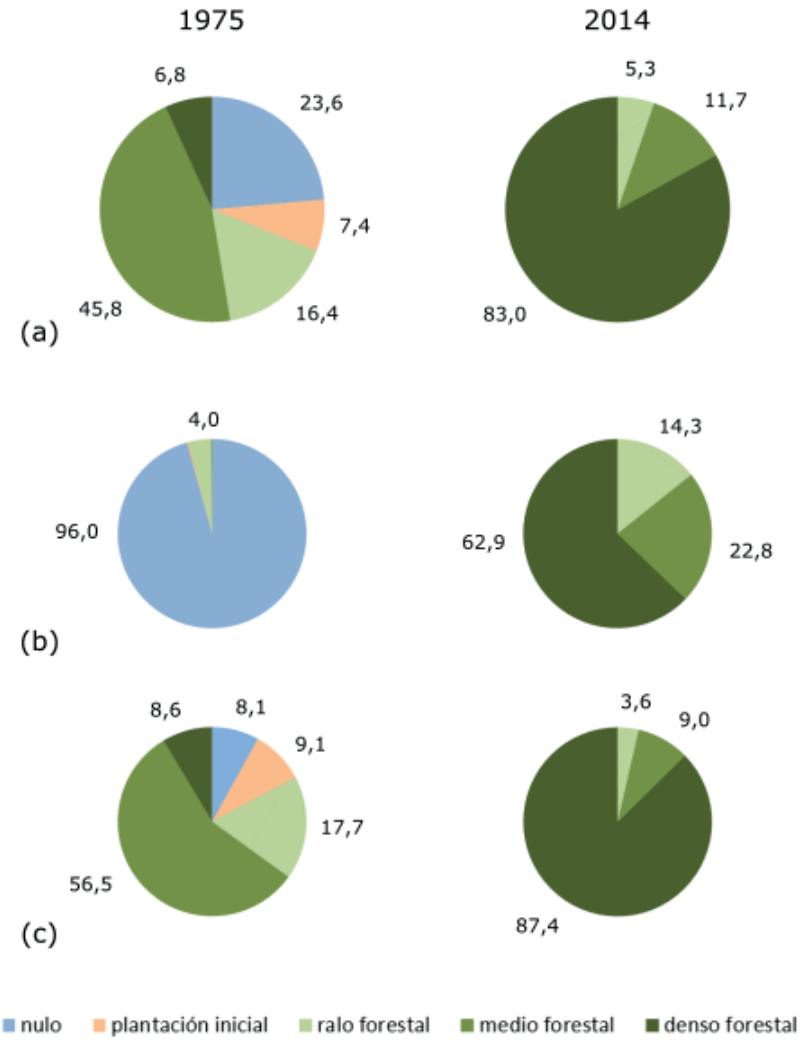

Fig. 5. Usos del suelo en 1975 y 2014, (a) en el área total de mapeo, (b) en las interdunas y (c) en las dunas costeras.

3.2 Evolución de las Superficies de Recarga

De acuerdo al criterio adoptado y la relación existente entre las clases de uso del suelo y las clases asignadas a la recarga, la Fig. 6 muestra la distribución de las superficies de recarga en 1975 y 2014.

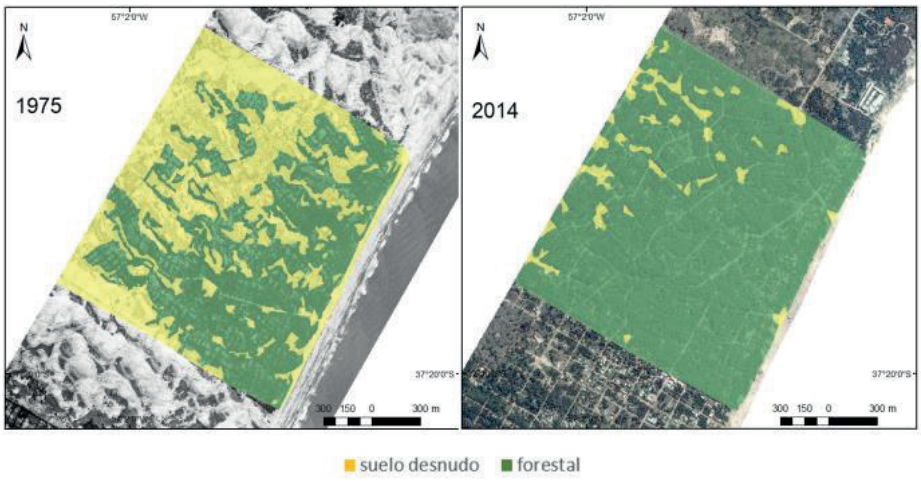

Fig. 6. Distribución de las superficies de recarga en 1975 y 2014.

En el año 1975, las clases suelo desnudo y forestal se encuentran casi igualmente representadas, con un 48 y un 52% de la superficie mapeada, respectivamente. En el año 2014, la clase forestal predomina ampliamente con un 94% de la superficie, mientras que la zona de suelo desnudo representa el 6% restante (Fig. 7).

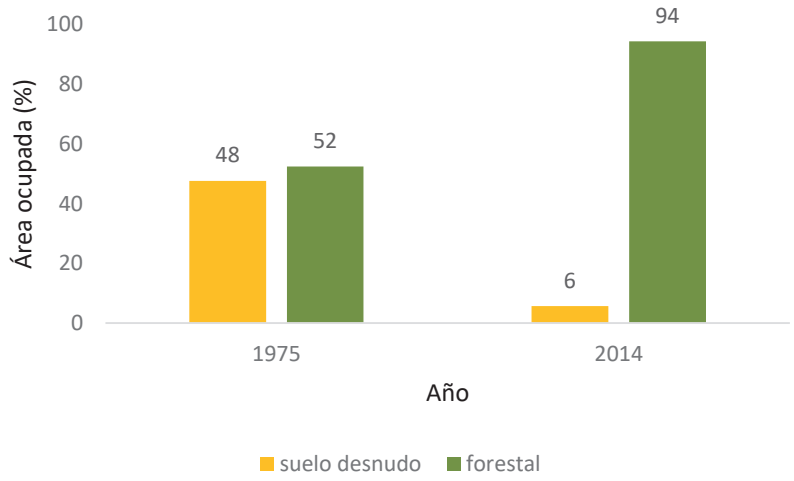

Fig. 7. Distribución porcentual de las clases de uso de suelo relacionadas a la recarga

Lo expuesto evidencia una clara tendencia a la expansión de la zona forestal, a expensas de la zona de suelo desnudo. Esto trae consecuencias sobre el ciclo hidrológico, dado que la capacidad de recarga asociada a la cobertura forestal es menor que la del suelo desnudo (Tabla 2).

Tabla 2. Datos promedio del balance hídrico para el periodo 1997-2016

		suelo desnudo			forestal		
Período	P[1] (mm)	ETP[2] (mm)	ETR[3] (mm)	Excesos (mm)	ETP (mm)	ETR (mm)	Excesos (mm)
1997-2016	930	669	506	422	912	711	223

[1]Precipitación, [2]Evapotranspiración Potencial,[3]Evapotranspiración Real

El promedio de precipitación anual es de 930 mm. Se aprecia casi el doble de excesos en la cobertura de suelo desnudo respecto de la forestal, con 422 mm y 223 mm anuales, respectivamente.

El volumen de agua que habría ingresado al sistema en el año 1975 es de 5,58 hm^3 en la zona de suelo desnudo y de 3,25 hm^3 en la zona forestal, lo cual suma una recarga total de 8,83 hm^3. Para el año 2014 la zona de suelo desnudo se encuentra drásticamente disminuida, y sólo aporta un volumen de 0,67 hm^3 a la recarga total, mientras que la zona forestal, ampliamente representada, presenta un volumen de recarga de 5,84 hm^3. La recarga total es de 6,51 hm^3, lo cual constituye una disminución del 26% respecto al valor de recarga de 1975 (Fig. 8).

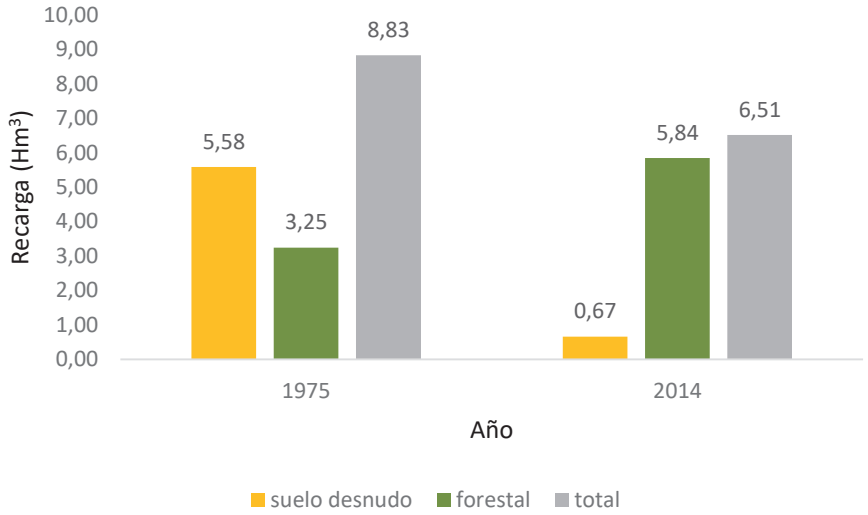

Fig. 8. Volumen de recarga para cada uso de suelo en los años estudiados

4 Conclusiones

Se realizó un análisis de la evolución de la cobertura del suelo en la localidad de Mar de las Pampas, Provincia de Buenos Aires, Argentina, entre los años 1975 y 2014.

Los resultados indican que las zonas forestales, inicialmente distribuidas en las dunas costeras, pasaron a ocupar las interdunas con el avance del tiempo. En 1975, casi la totalidad de las áreas de interduna correspondían a la clase de uso del suelo nulo, mientras que, en 2014, se encuentran enteramente cubiertas por forestación.

Considerando la superficie total de mapeo, la forestación muestra un claro aumento en su densidad a lo largo de la serie analizada. Entre los años 1975 y 2014, las clases de uso del suelo nulo y plantación inicial desaparecen, las clases ralo y medio forestal disminuyen su representación, y la clase denso forestal aumenta drásticamente, pasando de ocupar un 6,9% del área de mapeo en 1975, a un 83% de la misma en 2014.

En el año 1975, la forestación se hallaba en una etapa inicial y la superficie de recarga de suelo desnudo (compuesta por los usos nulo, plantación inicial y ralo forestal) ocupaba un 48% de la superficie. Sin embargo, la expansión del área forestada y el desarrollo de los árboles promovió la ocupación casi total de la zona por parte de la superficie de recarga forestal (categorías denso y medio forestal) para el año 2014. La disminución progresiva del área de suelo desnudo, que presenta un valor promedio de excesos de 422 mm, y el consecuente aumento del área forestal, con un promedio de excesos de 223 mm, modificó las condiciones hidrológicas superficiales de Mar de las Pampas. Se estimó que la recarga total en toda la superficie de la localidad varió de 8,83 hm^3 en 1975 a 6,51 hm^3 en 2014, lo cual representa una disminución del 26%.

Las diferencias en excesos de agua a causa de la forestación modifican significativamente la recarga en la localidad costera de Pinamar [21], que se ubica a pocos kilómetros y comparte características geomorfológicas y geohidrológicas con la zona de estudio. El presente estudio permite comprobar que la forestación también afecta la dinámica del agua subterránea en Mar de las Pampas, y produce una disminución de las reservas de agua dulce respecto de las condiciones originales del sistema. Mar de las Pampas aún no cuenta con cloacas, lo que puede ocasionar problemas de contaminación del acuífero por filtración de agua desde los pozos ciegos particulares. La combinación de este aspecto con las disminuciones en la recarga por causa de la expansión de la forestación, debe ser tenida en cuenta para lograr una planificación sustentable del recurso hídrico en la localidad.

La zona de estudio presenta un bosque de especies forestales exóticas (coníferas), originalmente instaurado con la finalidad de fijar las dunas para la construcción. Este bosque tiene, a su vez un valor paisajístico que actualmente es explotado, debido a la naturaleza turística de la localidad. Por otro lado, el presente trabajo demuestra el impacto negativo de la implantación de este bosque sobre la recarga del acuífero costero, en una zona donde el recurso hídrico subterráneo es limitado. Si bien se reconoce la importancia que actualmente reviste el bosque de coníferas para usos recreativos, el cuidado del agua subterránea debe ser incluido como prioridad a la hora de considerar la calidad ambiental de la zona. Se recomienda evitar la expansión de las coníferas en zonas donde aún no predominen, y en el caso de futuras expansiones de la zona forestada, recurrir a especies autóctonas para la fijación de dunas.

Abstract. The wood drying is an important stage in the production process of a sawmill since it is where lumber acquires the level of humidity required by the market. Generally, it is a batch process that is carried out in dryers that operate in parallel out of phase. To cover the energy needs of the process, boilers fed with the by-products generated in the productive stages of the sawmill are used. To operate efficiently, the filling and scheduling of the dryers and the boiler feed and operation must be planned simultaneously. In this paper, these decisions are addressed through a mixed integer linear programming model (MILP) using state-task network concepts based on a discrete time formulation. Different work criteria related to sawmill operation are analysed, achieving very significant results for the performance of this industry.

Keywords: Drying Kilns, Sawmills, State-Task Network, Planning, Scheduling, MILP Model.

1 Introduction

The forest industry plays an important economic, environmental and social role in the development of the northeast region of Argentina. In this region there are more than 85% of the forest plantations for industrial purposes in the country and it is made up of more than 1,000 factories, of which sawmills represent 95% and, therefore, lumber production becomes a fundamental pillar of this industry.

The process in the sawmills consists of several production stages, where one of the most important is the drying. In this stage, the boards acquire the characteristics required by the market, increasing the value and quality of the wood. Usually, this stage is a batch process that is carried out in dryers or drying kilns, which may have different characteristics. To heat these furnaces, boilers are employed that mainly use the by-products generated in the activities of the sawmill as fuel (bark, sawdust, wood shavings and chip). With the steam generated, the air is heated by means of a heat exchanger and is forced to circulate through the dryers.

To carry out the planning of this stage, the filling and scheduling of the dryers must be simultaneously considered with the feeding and operation of the boilers. To achieve

even drying of the products in each drying cycle, each kiln must be filled with boards of the same thickness. The duration of each cycle depends on the thickness of the boards and the dimension of the kiln. Likewise, for each board thickness there is a set of drying programs that vary the cycle time and, consequently, the energy demand.

With the rise of the plants generating electricity from forest biomass, the by-products of the sawmills have increased in value, ceasing to be just a residue of the production that was used to feed the boilers. Therefore, the use of sawmill by-products must be appropriately planned in order to cover the energy needs and increase the processes profitability, avoiding the tradeoffs between both productions: lumber and electric power.

In the literature, few papers study the drying operation and most focus on improving the energy efficiency of the process or addressing the implementation of new technological alternatives such as solar dryers [1, 2]. To the best of our knowledge, only the work of Gaudreault et al. [3] approaches the planning of this operation through the development of two models: a mixed integer linear programming (MILP) and a constrained programming. Both approaches minimize the delay of product delivery, determining the batch allocation to each kiln and the operating times, but they do not take into account energy requirements for drying.

The planning of the drying stage can be classified as a programming problem of non-identical parallel units, and has been the subject of several studies [4, 5]. For the approach presented in this work, a State-Task Network (STN) formulation based on discrete times was chosen, since it allows a better control of the resources involved in the process [6, 7]. STN formulation was introduced by Kondili et al. [8], and in Castro et al. [9] a description of its application in different scheduling problems is presented. This approach has proven to be very effective in tackling this problem because it has allowed a very complex problem to be represented in a simple way.

In this work a MILP model is presented for the optimal planning of the drying stage in a sawmill for a given time horizon, where all involved decisions are made simultaneously. In this way, an adequate drying plan is obtained according to the availability of boards to be dried, by-products to cover the energy demand and the production policies of the firm, assessing all the involved trade-offs.

2 Problem Description

The drying of the wood is an intermediate stage in the production process of the sawmills. Its correct planning avoids the accumulation of wet boards generated in the previous stage and delivers boards with the required humidity levels to the next stage. (Fig. 1).

Boards enter this stage with the objective of reducing their humidity level to comply with market requirements. These boards are grouped according to their thickness and put together with the inventory of non-dry boards, which are waiting to be dried. The frequency in which the boards arrive at this stage depends on the production in the previous stage of sawing.

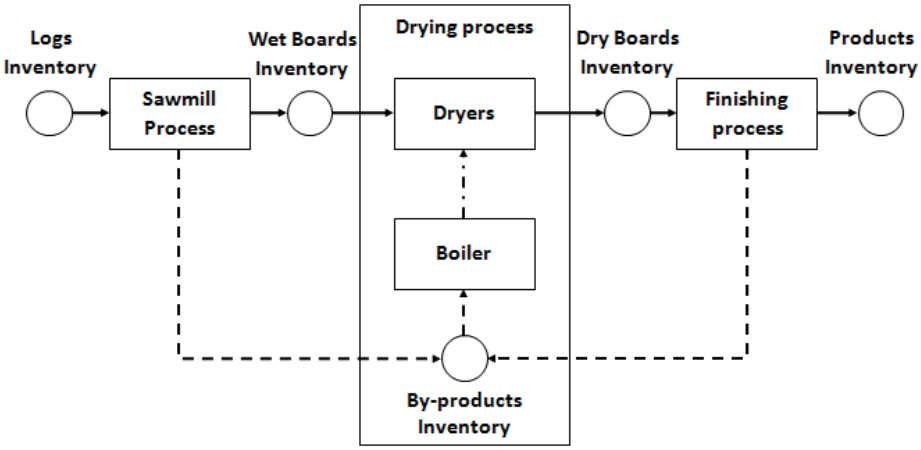

Fig. 1. Stages of a drying program

The sawmill has a set of drying kilns that do not necessarily have the same dimensions. When the dryer is loaded, it begins a drying cycle. To ensure even drying, each drying cycle must contain boards of a single thickness. On the other hand, to guarantee the efficient use of the dryers, a minimum load is established for each kiln. The duration of each cycle varies according to the size of the kiln and the thickness of the boards to be dried. At the same time, for each board thickness there is a set of drying programs with a different duration of the drying cycle and, consequently, a different energy demand. Each drying program considers three stages: kiln heating, drying, and cooling (Fig. 2). In addition, there is a setup time between each drying cycle, which depends on each dryer and corresponds to its filling.

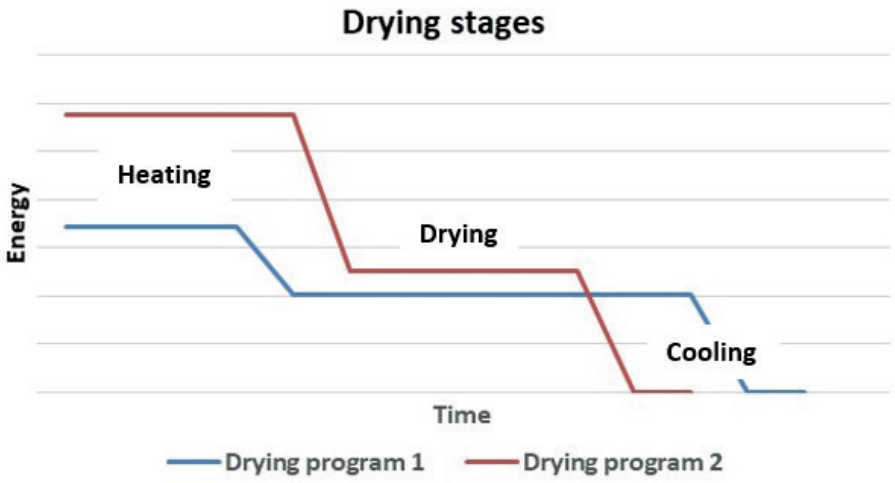

Fig. 2. Stages of a drying program

In order to cover energy requirements, a solid fuel boiler fed with by-products generated in the activities of the factory is used. For a correct operation of the boiler, the supply must fulfil certain proportion requirements between the various by-products to ensure humidity levels, volatility and ash generation in combustion. Just like boards, according to the sawing stage, by-products are available in the inventory for being used as fuel.

The objective of the presented approach is to plan the drying operation during a time horizon, considering different planning criteria. Explicitly, the thickness of boards to be dried in each drying kiln, the programs to be selected, and the operating times for the different kilns are simultaneously determined through a MILP model according to diverse objective functions for the planning. In addition, the resources used to satisfy the energy requirement are selected.

3 Model formulation

The proposed formulation is based on an STN model that uses a discrete time grid. The time horizon is divided into discrete times t of equal duration, which are determined according to the drying operation times and the regularity in the delivery of boards. In the STN, states are represented through index e and represent the thickness of the boards to be dried. The drying task is implemented according to program p in dryer d. As resources for the drying of boards, the by-products generated in the productive stages of the sawmill are considered as types of fuel b, and are used to cover the energy requirements of the drying (Fig. 1).

Let x_{dtep} be the binary variable that determines the beginning of a drying cycle in dryer d in time t using program p for boards of thickness e. Each drying program p is characterized by its duration (Tp_{dep}) and its energy requirement, taking into account kiln d being used and board thickness e. Also, energy consumption is determined according to the different phases explained in Fig. 1. It is estimated through parameter $ES_{dt'ep}$ that indicates the energy required in the period between times t' and t'+1, again taking into account the selected program p, board thickness e and dryer d being used when the drying cycle has started at time t, i.e. x_{dtep} equal 1.

Eq.(1) states that at most one single drying program p can be started in dryer d at each time t. This expression takes into account the duration of drying program p for boards of thickness e in dryer d (Tp_{dep}) and the setup time of the kiln (Ts_d).

$$\sum_{t'}^{t=t+Tp_{dep}+Ts_d-1} \sum_e \sum_p x_{dt'ep} \leq 1 \qquad \forall\, d, t \tag{1}$$

Let NE_{te} be the quantity of boards of thickness e that enter the drying stage in time t. These boards are added to the inventory of non-dried boards with the same thickness from the previous time ($I_{t-1,e}$). Eq.(2) states the material balance at time t, which establishes that the boards in stock at time t-1 plus the ones that enter at time t must be equal to the boards to be dried plus the remaining ones kept in inventory. Qp_{dte} represents the quantity of boards of thickness e that enter dryer d at time t.

$$I_{t-1,e} + NE_{te} = I_{te} + \sum_d Qp_{dte} \qquad \forall t > 1, e \tag{2}$$

For a correct operation, the load of the dryers is between minimum and maximum values ($CMin_d$ and $CMax_d$, respectively) established by the company while taking into account the capacity and technology of dryers (Eq.(3)).

$$CMin_d \sum_p x_{dtep} \leq Qp_{dte} \leq CMax_d \sum_p x_{dtep} \qquad \forall\, d, t, e \tag{3}$$

Eq.(4) determines the energy required by each dryer at time t (ER_{dt}). This expression considers the different stages if a drying cycle has started and takes into account consumption between times t and t+1.

$$ER_{dt} = \sum_e \sum_p \sum_{t'=0}^{Tp_{dep}-1} ES_{d(t')ep}\ x_{d(t-t')ep} \qquad \forall\, d, t < t' \tag{4}$$

The total energy required by dryers at time t cannot exceed the maximum energy that can be provided by the boiler ($EMax$) and must exceed a minimum value ($EMin$) for its proper operation (Eq.(5)).

$$EMin \leq \sum_d ER_{dt} \leq EMax \qquad \forall\, t \tag{5}$$

Eq.(6) determines the types of fuel b used by the boiler to cover the required energy.

$$\sum_d ER_{dt} = f \sum_b Qb_{tb} cp_b \qquad \forall\, t \tag{6}$$

where Qb_{tb} is the amount of fuel b consumed by the boiler in time t, cp_b is the calorific value of fuel b, and f is a factor of boiler efficiency.

Eq. 7 determines the total amount of fuel (Tb_t) used at each time t.

$$Tb_t = \sum_b Qb_{tb} \qquad \forall\, t \tag{7}$$

Fuel b being used at time t must not exceed a percentage (fb_b) of the total amount (Tb_t) being used in order to assure the proper functioning of the boiler (Eq.(8)).

$$Qb_{tb} \leq fb_b\, Tb_t \qquad \forall\, t, b \tag{8}$$

The availability of fuel b is determined according to Eq.(9), where IB_{tb} represents the inventory of fuel b at time t and NB_{tb} is the amount of fuel b that arrives at time t from sawmill activities for the boiler.

$$IB_{t-1,b} + NB_{tb} = IB_{tb} + Qb_{tb} \qquad \forall t, b \tag{9}$$

The operating criteria in the drying stage can vary according to both the level of production of sawmills and the policy adopted by the firm. These criteria can be contrasted among them, and this analysis is really interesting. Next, different objectives are posed.

3.1 Objective function 1 (FO 1): Maximization of the quantity of dried boards

This criterion tries to dry as many boards as possible over the time horizon. It is a widely used measure, but it loses sight of the costs generated in the process.

$$max\ FO\ 1 = \sum_d \sum_t \sum_e Qp_{dte} \tag{10}$$

3.2 Objective function 2 (FO 2): Costs minimization

The second criterion (Eq.(11)) minimizes costs due to the use of the drying kilns (*Cd*) and the cost of fuel consumption (*Cf*).

$$min\ \ FO\ 2 = Cd + Cf \tag{11}$$

Cd cost represents a fixed cost for each performed drying cycle, which depends on the dryer being used, the thickness of the boards to be dried, and the selected drying program ($Cdry_{dep}$). It is calculated as follows:

$$Cd = \sum_d \sum_t \sum_e \sum_p Cdry_{dep} x_{dtep} \tag{12}$$

Cf cost is obtained from the Eq.(13), where Cb_b is the unit cost of fuel *b*.

$$Cf = \sum_t \sum_b Cb_b Qb_{tb} \tag{13}$$

Furthermore, in order to assure a minimum quantity of dried boards, the inventory of boards by the end of the planning horizon must not exceed a certain percentage *fp* of the total available boards through the planning horizon (*Te*) (Eq.(14)). *Te* is defined as the sum of the tables that were in inventory at the beginning of the horizon and those that enter the drying stage (Eq.(15)). Another different and admissible approach is to set conditions for each board thickness instead of using a global condition. The following expression is used in this work:

$$I_{t=|T|,e} \leq fp\ Te \tag{14}$$

$$Te = fp\ \sum_e \left(I_{t=0,e} + \sum_t NE_{te}\right) \tag{15}$$

3.3 Objective function 3 (FO 3): Makespan minimization

The aim of this objective function is to dry the highest number of boards as soon as possible.

$$min\ FO\ 3 = MK \tag{16}$$

where *MK* corresponds to the end time of the last planned drying cycle in the time horizon, which is calculated in Eq.(17).

$$MK \geq\ ord(t) x_{dtep} + \left(Tp_{dep}\ + Ts_d\right) x_{dtep} \tag{17}$$

where ord(*t*) corresponds to the position in which time *t* is in the set. In this case, a requirement is added on the minimum of boards to be dried such as Eq.(14-15).

4 Examples

In order to evaluate the performance of the proposed model, an example corresponding to a sawmill with 4 dryers is presented and two cases with different availability of fuel will be analysed. In Case I, there is limited availability, while in Case II, availability is enough to meet any required demand. Table 1 shows the capacity of each dryer.

Table 1. Dryer capacity [*tn*]

Dryer	*CMin*	*CMax*
d_1-d_2	45	60
d_3-d_4	75	100

Note: tn, tons

At the beginning of the planning, two kilns are busy with drying cycles from the previous planning. The drying cycles of this plan must begin before time $t = 60$. At the beginning of the planning horizon, the inventory of tables and fuel is null ($I_{t=0,e}$=0 and $IB_{t=0,b}$ =0, respectively) and the boards are classified in 3 thicknesses which each one has 3 drying programs. Table 2 displays the duration of each drying cycle according to the dryer, thickness of boards and drying program, and the kilns setup time required for each dryer. Table 3 shows the fixed cost for each drying program, while Table 4 presents the costs for fuels and their calorific value.

Table 2. Processing times

Dryer	Board thickness	Drying program			Setup time
		p_1	p_2	p_3	
d_1-d_2	e_1	13	10	8	1
	e_2	18	14	11	
	e_3	23	21	17	
d_3-d_4	e_1	22	18	14	2
	e_2	30	23	19	
	e_3	39	30	24	

Table 3. Drying program cost [*$*]

Bark	2.39	5998.22	15
Chip	5.33	7117.39	100
Wood shavings	4.02	16486.45	20
Sawdust	3.39	6363.77	15

Note: tn, tons; MJ, mega joules

Table 5 and 6 indicate the quantity of boards and fuel that enter the drying stage throughout the studied horizon, respectively.

Table 5. Quantity of boards that enters drying stage in each time [*tn*]

Board thickness	Time				
	t_0	t_{12}	t_{24}	t_{36}	t_{48}
e_1	30	130	190	60	10
e_2	170	170	170	80	50
e_3	150	50	160	0	20

Note: tn, tons

Table 6. Fuel entering each time in Case I [*tn*]

Fuel	Time				
	t_0	t_{12}	t_{24}	t_{36}	t_{48}
Bark	15	9	8	11	12
Chip	169	107	91	127	140
Sawdust	84	53	45	63	70
Wood shavings	25	16	13	19	21

Note: tn, tons

In this example, the boiler can deliver up to 150000 MJ/h, but, at the beginning of the time horizon, a fraction of this power is reserved to cover the energy required by the previous drying plan. The example is implemented and solved in GAMS using CPLEX solver in an Intel(R) Core(TM) i7-3770, 3.40 GHz. The computational time limit is fixed to 3600 CPU sec. The model consists of 10834 equations, 8061 continuous and 2043 binary variables.

The global results are shown in Table 7. The value obtained for each objective function is highlighted in each column. For FO 2, the maximum allowed level for boards inventory at the end of the planning horizon (*fp*) varies from 25% to 5% of the available boards for drying. This is done in order to analyse different planning scenarios and the impact of the final inventory level when cost is minimized. Also, in order to carry out

appropriate comparisons, it is required for FO 3 to keep the same stock as the solution obtained with FO 1. The last 3 columns of the table correspond to Case II. For this case, only *fp* = 25% is analysed for FO 2. As it can be seen, optimal solutions are obtained with reasonable computing times in almost all cases, except when *fp* = 15%, which results in an optimality gap equal to 0.7.

Analysing FO 1 in Case I, 1,380 tons of boards are dried in 19 drying cycles, which end at time t = 100, leaving 4.2% of the total boards without drying in inventory. By not considering the costs within the objective function, the shortest programs are selected, with a higher consumption of fuel, which allow drying a greater number of boards.

With FO 2, as *fp* decreases, and with this the need to dry more boards at the same time, the number of drying cycles increases and simultaneously the use of the short drying program p3 tends to increase, generating higher fuel costs. Using FO 3, it is possible to dry the same as FO 1 but with lower cost and faster.

In Case II, the greater availability of fuel allows to improve the results of all objective functions. Using FO 1, the number of dried boards increases, but fails to dry the total, leaving 30 tons in inventory for the next planning. With FO 2 for *fp* = 25% the cost is decreased by 1.1%, and FO 3 shows a reduction of 17 units of time in manufacturing, but with a 40.7% increase in costs, with respect to the same objective function of Case I.

Fig. 3 shows the Gantt charts, depicting in red the drying cycles performed for boards of thickness e_1, in green those of thickness e_2 and in blue the corresponding to thickness e_3. The blocks with squares correspond to drying programs p_1; those with oblique lines are cycles with drying program p_2; and those in solid colour correspond to drying program p_3. The drying cycles from a previous drying plan are displayed in grey. For FO 2, only the planning for the case considering fp = 25% is shown.

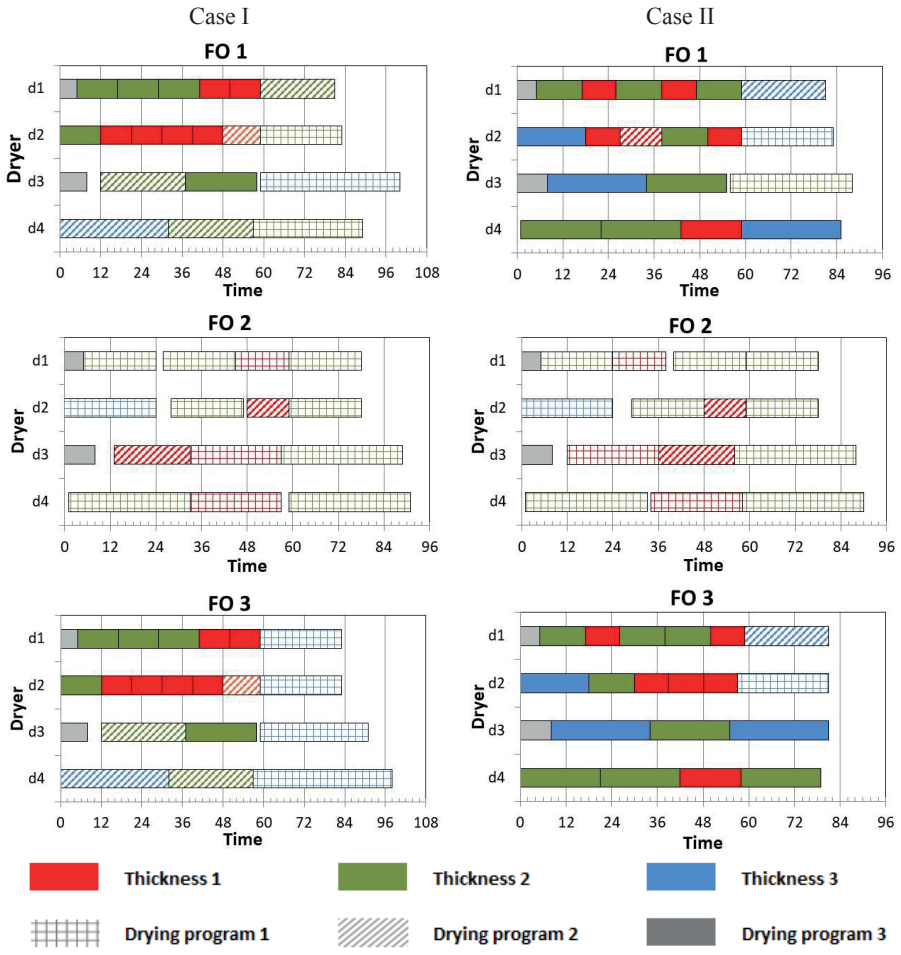

Fig. 3. Gantt chart of the drying plan

It can be seen in Fig. 3 that in FO 2, the dryers have the amount of chip a greater number of idle times, due to the low number of drying cycles. In FO 3 of Case I, the lack of fuel forces to select slower drying programs, preventing a significant reduction in the time of completion of the drying plan if compared to FO 1. This can be better understood by looking at Fig. 4a, which represents the consumption and inventory of each fuel over the horizon. Although at the end of the horizon even sawdust is available

(the only one in stock), it is not allowed to feed the boiler only with this fuel since the boiler does not work correctly (Eq. (7)).

Fig. 4b depicts the percentage of the type of fuel used to feed the boiler. Depending to the limit value of each fuel (fb_b), the amount of chips used at any given time is greater than 50% and, in some cases, corresponds to 100% of the boiler supply. Fig. 5 shows the energy generated by the boiler to cover the energy demand during the time horizon and the maximum limit it can generate. As it can be seen, at the beginning, the maximum limit of the boiler is reduced because the difference is reserved for the energy requirement of the previous drying plan.

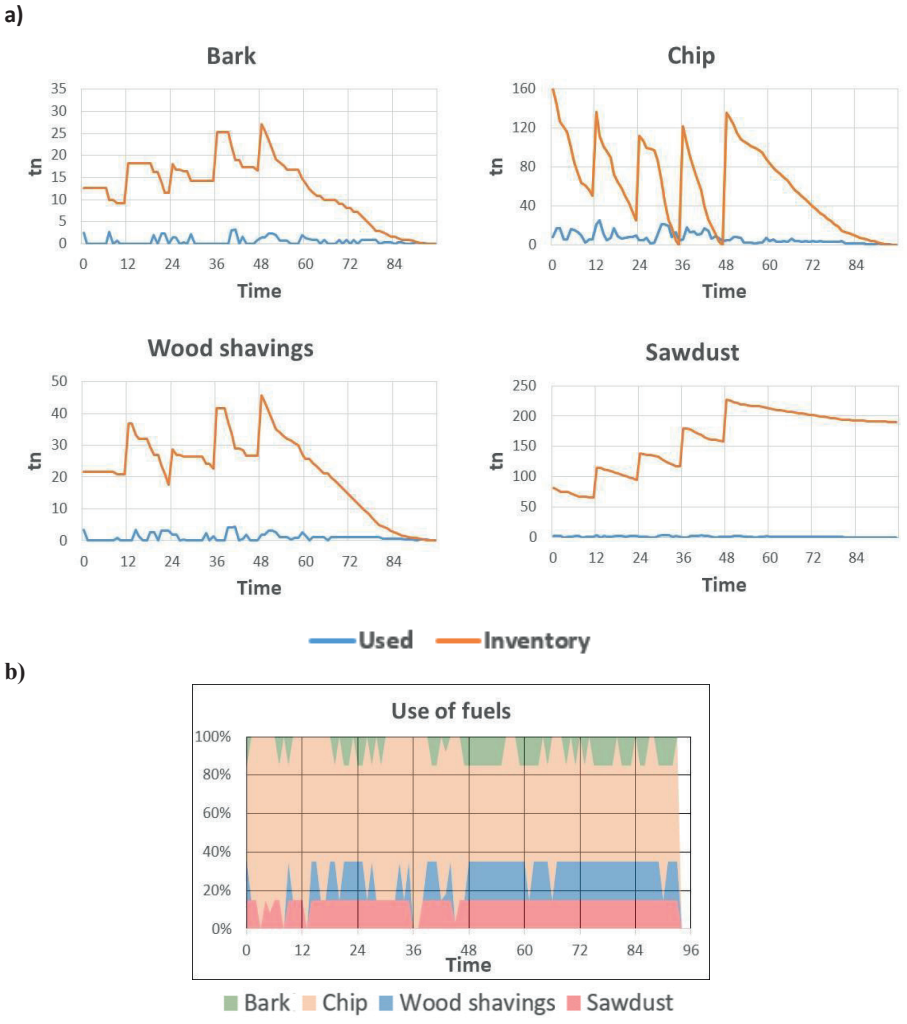

Fig. 4. Use of fuel for FO 3 of Case I

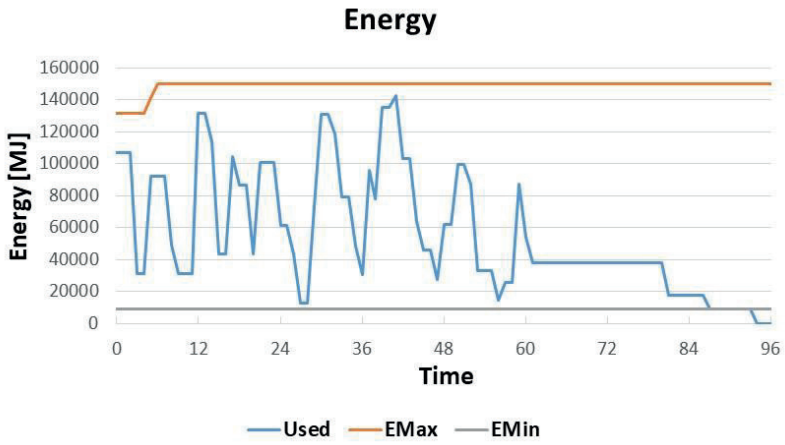

Fig. 5. Energy provided by the boiler for FO 3 of Case I

4.1 Comparative analysis and discussion of results

By comparing the obtained results, different drying plans are reached according to the considered objective function. Although FO 1 is usually more common in the forest industry when planning is addressed, many times with more heuristic tools or approaches, the presented approach allows evaluating different drying process scenarios. In this way, new perspectives are opened for companies in the sector in relation to the optimal management of the drying operation. This is reinforced if new options for the use of by-products, based on the use of biomass, are considered in the analysis. In this section, a discussion of the different criteria considered and the trade-offs between them is presented.

For FO 1, a greater number of boards are dried using a greater number of drying cycles. By not considering costs in this objective function, shorter drying programs are used, with higher energy consumption, generating the highest total costs. With FO 2, it is observed that the number of dry boards and drying cycles increases as *fp* decreases, using longer drying programs with less energy and fuel consumption, and consequently lower cost. As expected, when considering FO 3, the drying plan is carried out in less time, using a number of cycles similar to that of FO 1 but the downtimes between cycles decrease. By-product availability is an important factor in the planning, as can be glimpsed in Case I. All the objectives functions are improved when greater amount of fuel is available. However, the new possibilities to take advantage of these resources generate scenarios that this formulation can help to analyse.

Finally, the trade-offs between the different criteria considered are analysed. Obviously, generating an objective function that incorporates these 3 criteria would allow an adequate evaluation to be carried out. However, this is not possible as these criteria are expressed in different units (product, money and time). In the case of FO 1, the

value contributed in the drying operation could be weighed when the wet boards are transformed into dry boards, but as in reality the wet boards lack commercial value, it is an abstraction that is very difficult to be specified. Therefore, a more appropriate strategy to plan the operation is to incorporate restrictions that involve the criteria considered. In the previous example, this strategy has been implemented establishing conditions on the production level through restrictions on the final inventory of undried boards.

In the case of FO 2, which minimizes costs, the drying plan has been analysed by varying the final inventory of undried boards. The conditions on the time horizon could have been added using Eq. 17 and incorporating a limit for makespan. Similarly, in FO 3, MK is minimized and production limitations were considered. Here you could add restrictions to limit the cost of operation. In short, the formulation admits the combination of the different criteria, which enhances its capacity for analysis and evaluation. Given the difficulty of including the criteria in a single expression as an objective function, the best alternative is to incorporate them through restrictions in the formulation.

Therefore, evaluating and adjusting these criteria can guide planners to make a good decision to analyze the wood drying process.

5 Conclusions

A MILP model with a State-Task Network formulation based on discrete times was presented for optimal planning of the drying stage of a sawmill over a time horizon. This allows to simultaneously determine the type and quantity of boards to dry, the selected drying program and the start time, together with the energy required and how this requirement is covered with the use of fuels. Three objective functions were presented. Although FO 1 is generally more common in the forestry industry, the presented approach allows evaluating different drying process scenarios. Comparing the results obtained, different drying plans are reached according to the objective function considered, in reasonable CPU times.

Finally, the proposed approach is a useful tool for planning the drying stage of sawmills, allowing efficient use of available resources.

Abstract. In this work, a solution approach based on column generation for the log transportation problem in the Argentine forest industry is presented. This problem involves making decisions that covers aspects related to the size of the truck fleet, different types of delivered raw materials, different regional bases where trucks begin and end the routes, legal and contractual restrictions, among others, generating a problem very difficult to solve. This work is focused on the determination of the routes to be performed by the truck fleet to supply the plants with the available raw materials in the forest sites, at minimum cost. A representative case study of the Argentine forestry sector is presented and the corresponding results are detailed. The proposed approach allows solving problems with more than 500 full truck loads to transport per day (approximately 13,500 tons of raw materials) in less than 15 minutes of execution and with a negligible optimality gap.

Keywords: Transportation Planning, Forest Industry, Column Generation.

1 Introduction

According to the Ministry of Agroindustry [1], the industrial forest region of northeast Argentina (involving the provinces of Entre Ríos, Corrientes and Misiones) encompasses 766 production plants, which represents 37% of the country's forestry companies. Of this total, 42% corresponds to micro-companies (annual production level less than 940 m^3), 39% corresponds to small companies (between 940 and 4,720 m^3), 17% corresponds to medium companies (between 4,720 and 23,585 m^3), and the remaining 2% corresponds to large companies (annual production level greater than 23,585 m^3). Regarding the level of employment, this region generates direct employment for 12,332 people, 50% of whom are in the province of Misiones. The province of Misiones is the main consumer and producer of logs: 61% of the raw material (logs) was obtained in this province (more than 2 million tons per year) in the last census year [2]. The log extraction level in Misiones was 5,914,877 m^3 (4,731,902 tons) during the last census year, which is equivalent to 172,069 full truckloads to transport per year (550 full truckloads per day, approximately). Since log transportation is a very expensive activity, significant savings can be obtained through efficient transportation planning.

In this work, the distribution of logs from the harvest areas to the plants is addressed. This problem involves complex decisions, where the truck fleet size and the raw materials supply are the typical ones. There are several aspects to be considered, such as legal and contractual restrictions (time spent on the road, number of allowed daily trips, among others), that make the problem complex and difficult to be solved. The log transportation problem tackled in this work involves decisions related to: supply allocation (assignment of raw material from harvest areas to plants), truck routing (assignment of trips to trucks and the order in which they are made), and the size of the truck fleet (the number of trucks that are used to satisfy plants requirements). Many times scheduling decisions (determination of specific times for each truck activity) are also considered, but this is beyond the scope of this work. Taking into account the involved decisions, integrated formulations are required, which enlarges the model size and hinder the resolution. In this way, developing a tool capable of solving the problem efficiently and in a reasonable computing time is relevant for this industry.

However, there are few works presented in the literature that jointly address the allocation and routing problems. In fact, regardless of the methodology adopted, they resort to decomposition approaches in order to simplify problem resolution. Trips are assumed to be known in advance or are generated prior to the trucks routes determination; that is, first, the supply of each harvest area to each plant is determined (allocation problem) and, subsequently, the routes of each vehicle are generated (routing problem) and scheduled (scheduling problem) taking into account the previously selected flows. Many times, allocation problem is solved from a tactical perspective, assuming that the solution will be effectively implemented through appropriate routing and scheduling formulations ([3], [4], [5]). However, from a strictly mathematical point of view, this decomposition approach does not guarantee to reach the optimal solution of the problem, although, from a productive perspective it allows to achieve appropriate solutions. In this sense, metaheuristics approaches have been also used to address some of the aforementioned problems ([6], [7]).

In a previous work, Bordón et al. [8] propose a mixed integer linear programming (MILP) model to solve a simplified version of the aforesaid problem, assuming that each plant demands a single type of raw material. This assumption is a strong simplification that significantly limits the application of the proposed approach, taking into account that different raw materials are employed and transported in this industry. Unlike such work, in this paper is assumed that different raw materials are required by each plant taking into account that diverse specific production requirements must be daily met. In this way, the supply of specific raw materials is another decision variable to be considered. These assumptions significantly increase the model complexity and the number of model variables.

In addition, for real-practice problems of this industry, the model size is large, with numerous trips and involved vehicles, and, then, computational performance worsens. Therefore, an adequate solution approach must be developed in order to achieve reasonable performance for the real problems of this industry. So, a Column Generation (CG) based approach is proposed in order to obtain an integer feasible (near optimal) solution in a short computing time. The works of Palmgrem et al. [9]

and Rix et al. [10] are outstanding antecedents in the use of this methodology to solve transportation problems in the forest industry, although they solve different problems to the one posed in this article (i.e., allocation is not taken into account but scheduling is considered).

Summarizing, the focus of this article is on the operational planning, specifically, on the simultaneous optimization of allocation and routing problems in order to deliver logs and forest raw materials from harvest areas to production plants, at minimum cost. The capabilities of the proposed methodologies are shown through an example from the Argentine forest industry.

In the following section, the addressed problem is stated. In sections 3 and 4 the proposed mathematical model and the CG-based approach are presented, respectively. In section 5 a case study is analyzed and, finally, in the last section, conclusions are exposed.

2 Problem statement

The problem addressed in this work considers a set F of harvest areas. At each harvest area f, there is available a number of full-truckloads of raw material m, $supply_{f,m}$, $m \in M$, used to supply a set of plants I, which demand a certain number of full-truckloads, $demand_{i,m}$, of raw material m.

To transport the raw materials (logs) from harvest areas to plants, a set of trucks C is available. Each truck c, $c \in C$, begins and finishes its route in a regional base p, $p \in P$. In addition, each truck c can perform a limited number of trips, and transport only one type of raw material m at a time. Also, each truck c has a maximum number of working hours, $maxt$.

The route representation proposed by Bordón et al. [8] is used in this work. Accordingly, each route is composed of a series of trips v, $v \in V$, where a trip v is a sequence of different movements. As can be seen in Fig. 1, the first two types of trips are made up by three movements, two unloaded (dashed lines) and another loaded (solid lines), meanwhile the two remaining are conformed by two movements, one unloaded and another loaded. Therefore, according to the above trip definition, the proposed approach assembles the routes through trips composition which are simultaneously assigned to the truck in the overall model, using binary variables, one for each type of movement.

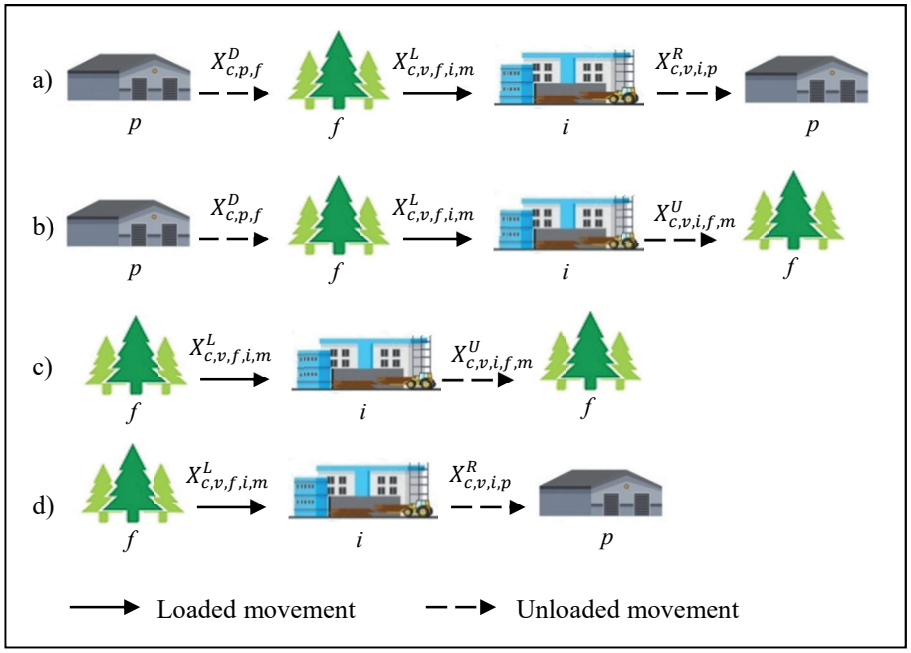

Fig. 1. Trips composition

Thus, the objective of the present work is the minimization of the total transportation costs, subject to demand fulfillment and legal and contractual restrictions.

3 Mathematical model

In this section the proposed mathematical model (P1) is presented. Note that the parameters are written in lower case, while the variables are written in upper case.

$$\min Z = \sum_{p\in P}\sum_{c\in C_p}\sum_{f\in F} cd_{p,f}\, dpf_{p,f}\, X^D_{c,p,f} +$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} cl_{f,i}\, dfi_{f,i}\, X^L_{c,v,f,i,m} +$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} cu_{i,f}\, dif_{i,f}\, X^U_{c,v,i,f,m} +$$

$$\sum_{p\in P}\sum_{c\in C_p}\sum_{v\in V}\sum_{i\in I} cr_{i,p}\, dip_{i,p}\, X^R_{c,v,i,p} + \sum_{p\in P}\sum_{c\in C_p}\sum_{f\in F} cfix\, X^D_{c,p,f} \quad (1)$$

Subject to:

$$\sum_{c\in C}\sum_{v\in V}\sum_{i\in I} X^L_{c,v,f,i,m} \le supply_{f,m} \quad f \in F,\ m \in M_i \quad (2)$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{f\in F} X^L_{c,v,f,i,m} \ge demand_{i,m} \quad i \in I,\ m \in M_i \quad (3)$$

$$\sum_{c}\sum_{v}\sum_{i}\sum_{m\in M_i} X^L_{c,v,f,i,m} = \sum_{c\in C}\sum_{p\in C_p} X^D_{c,p,f} +$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{i\in I}\sum_{m\in M_i} X^U_{c,v,i,f,m} \quad f \in F \tag{4}$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{f\in F}\sum_{m\in M_i} X^L_{c,v,f,i,m} = \sum_{p\in P}\sum_{c\in C_p}\sum_{v\in V} X^R_{c,v,i,p} +$$

$$\sum_{c\in C}\sum_{v\in V}\sum_{f\in F}\sum_{m\in M_i} X^U_{c,v,i,f,m} \quad i \in I \tag{5}$$

$$\sum_{f\in F} X^D_{c,p,f} \le 1 \quad p \in P,\ c \in C_p \tag{6}$$

$$X^D_{c,p,f} = \sum_{i\in I}\sum_{m\in M_i} X^L_{c,v,f,i,m} \quad p \in P,\ c \in C_p,\ f \in F,\ v = 1 \tag{7}$$

$$\sum_{f\in F} X^D_{c,p,f} \le \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X^L_{c,v,f,i,m} \quad p \in P,\ c \in C_p \tag{8}$$

$$\sum_{f\in F} X^D_{c,p,f} = \sum_{v\in V}\sum_{i\in I} X^R_{c,v,i,p} \quad p \in P,\ c \in C_p \tag{9}$$

$$\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X^L_{c,v,f,i,m} \le \sum_{f\in F} X^D_{c,p,f} \quad p \in P,\ c \in C_p,\ v \in V \tag{10}$$

$$\sum_{i\in I}\sum_{f\in F}\sum_{m\in M_i} X^U_{c,v,i,f,m} \le \sum_{f\in F} X^D_{c,p,f} \quad p \in P,\ c \in C_p,\ v \in V \tag{11}$$

$$\sum_{f\in F}\sum_{m\in M_i} X^L_{c,v,f,i,m} = X^R_{c,v,i,p} +$$

$$\sum_{f\in F}\sum_{m\in M_i} X^U_{c,v,i,f,m} \quad p \in P,\ c \in C_p,\ v \in V,\ i \in I \tag{12}$$

$$\sum_{i\in I}\sum_{f\in F}\sum_{i'=i}\sum_{f'\in F}\left(X^L_{c,v,f,i,m} - X^U_{c,v,i',f',m}\right) \ge 0 \quad c \in C,\ v \in V,\ m \in M_i \tag{13}$$

$$\sum_{i\in I}\sum_{m\in M_i} X^U_{c,v-1,i,f,m} \le \sum_{i\in I}\sum_{m\in M_i} X^L_{c,v,f,i,m} \quad c \in C,\ f \in F,\ v > 1 \tag{14}$$

$$X^L_{c,v+1,f,i,m} \le \sum_{f'\in F}\sum_{i'\in I}\sum_{m'\in M_i} X^L_{c,v,f',i',m'} \quad c \in C, f \in F, i \in I, m \in M_i, v < |V| \tag{15}$$

$$\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X^L_{c,v+1,f,i,m} \le \sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X^L_{c,v,f,i,m} \quad c \in C,\ v < |V| \tag{16}$$

$$maxt\ \sum_{f\in F} X^D_{c,p,f} \ge \sum_{f\in F}\left(\frac{dpf_{p,f}}{vd_{p,f}}\right) X^D_{c,p,f} +$$

$$\sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i}\left(\frac{dfi_{f,i}}{vl_{f,i}} + tload_f + tunload_i\right) X^L_{c,v,f,i,m} +$$

$$\sum_{v\in V}\sum_{i\in I}\sum_{f\in F}\sum_{m\in M_i}\left(\frac{dif_{i,f}}{vu_{i,f}}\right) X^U_{c,v,i,f,m} +$$

$$\sum_{v\in V}\sum_{i\in I}\left(\frac{dip_{i,p}}{vr_{i,p}}\right) X^R_{c,v,i,p} \quad p \in P,\ c \in C_p \tag{17}$$

$$X^L_{c,v,f,i,m}, X^U_{c,v,i,f,m}, X^R_{c,v,i,p}, X^D_{c,p,f} \in \{0,1\} \tag{18}$$

The aim of the proposed model is to minimize total transportation costs (Z), including costs per traveled kilometers (with and without load) and fixed costs per used trucks. Eq. (1) defines this objective function. The first four terms correspond to the costs for the different movements that constitute a trip while the last one represents the fixed costs per use of trucks. Parameters $cd_{p,f}$, $cl_{f,i}$, $cu_{i,f}$ and $cr_{i,p}$ represent the costs per

kilometer traveled (in $/km) between the corresponding nodes, *cfix* is the fixed cost per use of truck (in $) and the parameters $dpf_{p,f}$, $dfi_{f,i}$, $dif_{i,f}$ and $dip_{i,p}$ define the distances (in km) between the corresponding nodes.

Constraints (2) and (3) establish the maximum supply for each harvest area and the demand to be satisfied for each plant, respectively. Constraints (4) and (5) establish the node balances, that is, the number of trips that arrive at each harvest area / plant must coincide with the number of trips that departs from those nodes.

Restrictions (6) state that a truck can arrive at most once to a harvest area coming from its regional base, while restrictions (7) state that if a truck departs from the regional base, it must perform a loaded movement to any plant in its first trip.

Restrictions (8) state that if a truck is used, then it must perform at least one loaded movement. Constraints (9) force each truck to return to the regional base from which it started its route, while restrictions (10) and (11) establish that if a truck is not used then it must not have any loaded movement assigned.

In constraints (12) it is established that, after completing a loaded movement, the truck can either return to the regional base to finish the route or go to a harvest area to perform a new loaded movement.

Restrictions (13) guarantee that if a loaded movement is not performed, the associated unloaded movement must not be performed either. In addition, when a route is made up of more than one trip, before making an unloaded movement to return to the regional base (on the last trip) the corresponding loaded movement must be completed (equations (14)).

To avoid alternative solutions, the trips are created in ascending order, that is, if the trip v is not performed, neither does the trip $v + 1$ (constraints (15) and (16)).

Finally, in restrictions (17) the maximum time of use of a truck is defined (the working day is limited by *maxt* hours). Parameters $vd_{p,f}$, $vl_{f,i}$, $vu_{i,f}$ and $vr_{i,p}$ represent the average speed between the nodes (in km/h) while $tload_f$ and $tunload_i$ define the average loading (in harvest area) and unloading (in plant) times (in h), respective. Constraints (18) establish the nature of the involved variables.

4 Solution approach

Due to combinatorial nature of this type of formulation, the (P1) model for large-size problems cannot be optimally solved in a reasonable computing time. Therefore, in this section a solution approach is proposed in order to reduce the solution times. A closer look on the structure of the problem presented in the previous section shows that constraints (2) to (5) are coupling the trucks, while the remaining restrictions are dealing with each truck separately. This structure strongly suggests that the problem could be decomposed into a Master Problem (MP) with the linking constraints and a Sub-Problem (SP) per truck. A CG based approach appears to be an appropriate method to tackle the problem.

The idea behind CG is that many linear programs are too large to consider explicitly all the variables. Since most of the variables are non-basic and take value zero in the optimal solution, only a subset of variables needs to be considered when

solving the problem. CG takes advantage of this idea to generate only variables which have the potential to improve the objective function, that is, to find variables with negative reduced costs (for a minimization problem). In other words, in this methodology the original problem is decomposed into a MP and a SP: the first decides which variable (or column) is used while the second generates such variables (or columns). There is an extensive literature about CG; for further details, the reader is recommended the works by Desaulniers et al. [11] and Lübbecke and Desrosiers [12].

Thus, the original formulation (P1) is decomposed into a MP, in which only the constraints that links the trucks are considered (constraints (2) to (5)), and a SP per truck, including the rest of the restrictions (constraints (6) to (17)). The decision variables in the MP are related to used route (that is, which column is selected, Y_r), while in the SP the variables are related to the conformation of the routes (that is, which column is generated). According to the formulation proposed in this work, each generated column contains the information about the trips involved in the route (combination of movements from regional base to harvest area, between harvest area and plants, and from plants to regional base). The solution approach used in this work is presented in Fig. 2.

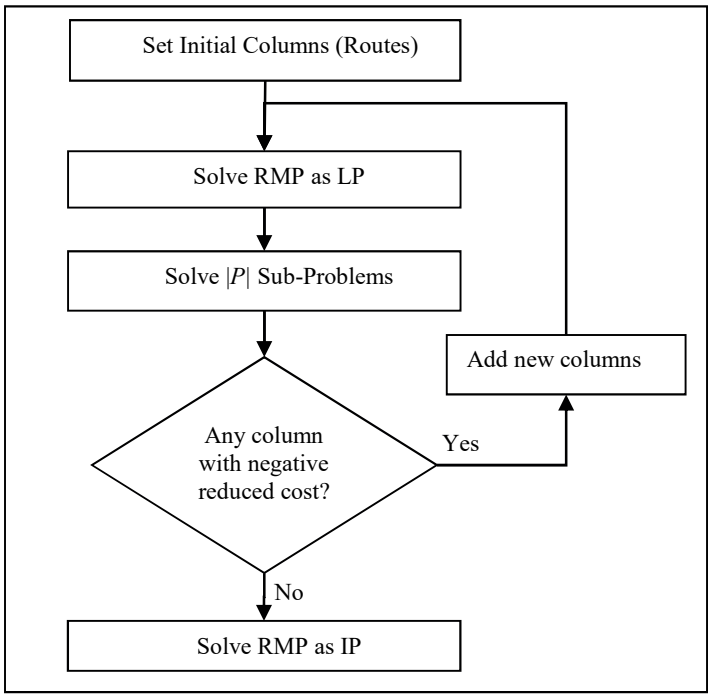

Fig. 2. Column generation-based approach

The algorithm presented in Fig. 2 performs the following: first, the initial columns (initial routes) are generated. After that, the relaxation of the Restricted Master

Problem (RMP), i.e., the MP with a limited number of columns or variables is solved to determine which columns (routes) are used and the corresponding dual information is obtained. With that information (the values of the dual variables are fixed as parameters), the SP is solved for each regional base p to obtain new columns. If one or more columns with negative reduced costs are obtained, they are added to the RMP and the process is repeated. Otherwise, the RMP is solved as IP (with the already generated columns) to obtain a feasible integer solution to the problem.

The MP model is the following:

$$\min Z_{MP} = \sum_{r \in R^+} croute_r \, Y_r \tag{19}$$

Subject to:

$$\sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} \sum_{i \in I} A^{XL}_{p,v,f,i,m,r} \, Y_r \leq supply_{f,m} \quad f \in F, \;\; m \in M_i \tag{20}$$

$$\sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} \sum_{f \in F} A^{XL}_{p,v,f,i,m,r} \, Y_r \geq demand_{i,m} \quad i \in I, \;\; m \in M_i \tag{21}$$

$$\sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} \sum_{i \in I} A^{XL}_{p,v,f,i,m,r} \, Y_r = \sum_{r \in R^+} \sum_{p \in P} A^{XD}_{p,f,r} \, Y_r + \sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} \sum_{i \in I} \sum_{m \in M_i} A^{XU}_{p,v,i,f,m,r} \, Y_r \quad f \in F \tag{22}$$

$$\sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} \sum_{f \in F} \sum_{m \in M_i} A^{XL}_{p,v,f,i,m,r} \, Y_r = \sum_{r \in R^+} \sum_{p \in P} \sum_{v \in V} A^{XR}_{p,v,i,r} \, Y_r + \sum_{r \in R^+} \sum_{p \in P} \sum_{f \in F} \sum_{m \in M_i} \sum_{v \in V} A^{XU}_{p,v,i,f,m,r} \, Y_r \quad i \in I \tag{23}$$

$$\sum_{r \in R^+} \sum_{f \in F} A^{XD}_{p,f,r} \, Y_r \leq ntrucks_p \quad p \in P \tag{24}$$

$$Y_r \in \{0, 1\} \tag{25}$$

Regarding the objective function, it consists of the minimization of the routing cost Z_{MP} (Eq. (19)), where $croute_r$ represents the cost of the feasible route r. Constraints (20) to (23) correspond to equations (2) to (5) of the original formulation, respectively. Restriction (24) must be incorporated into the MP model to consider the size of the truck fleet belonging to the regional base p, that is, the number of routes beginning at regional base p must be less or equal than the number of available trucks in that regional base ($ntrucks_p$). R^+ is the set of all feasible routes and the parameters $A^{XD}_{p,f,r}$, $A^{XL}_{p,v,f,i,m,r}$, $A^{XU}_{p,v,i,f,m,r}$ and $A^{XR}_{p,v,i,r}$ contain the information about the composition of each route r.

As was previously mentioned, since it is not practical to consider all feasible routes, the CG procedure works with a subset of them ($R^- \subseteq R^+$), where R^- is the set of the already generated routes. Thus, the RMP model is given by constraints (19) to (24), relaxing the binary condition of Y_r.

Since the truck fleet is homogeneous, it is not necessary to solve $|C|$ sub-problems (that is, a sub-problem per vehicle). It suffices to solve one SP per regional base considered, i.e. $|P|$ sub-problems, because the possible routes to be performed by each truck belonging to the regional base p are the same. Thus, the SP model is the following:

$$\min Z_{SP}^{p} = \sum_{f\in F} cd_{p,f}\ dpf_{p,f}\ X_f^{DSP} + \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} cl_{f,i}\ dfi_{f,i}\ X_{v,f,i,m}^{LSP}$$
$$+ \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} cu_{i,f}\ dif_{i,f}\ X_{v,i,f,m}^{USP} + \sum_{v\in V}\sum_{i\in I} cr_{i,p}\ dip_{i,p}\ X_{v,i}^{RSP}$$
$$+ \sum_{f\in F} cfix\ X_f^{DSP} - \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} \pi_{f,m}^{1}\ X_{v,f,i,m}^{LSP}$$
$$- \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} \pi_{i,m}^{2}\ X_{v,f,i,m}^{LSP}$$
$$- \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} \pi_{f}^{3}\left(X_f^{DSP} + X_{v,i,f,m}^{USP} - X_{v,f,i,m}^{LSP}\right)$$
$$- \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} \pi_{i}^{4}\left(X_{v,f,i,m}^{LSP} - X_{v,i,f,m}^{USP} - X_{v,i}^{RSP}\right) - \pi^{0} \quad (26)$$

Subject to:

$$\sum_{f\in F} X_f^{DSP} \le 1 \quad (27)$$

$$X_f^{DSP} = \sum_{i\in I}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} \quad f\in F,\ v=1 \quad (28)$$

$$\sum_{f\in F} X_f^{DSP} \le \sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} \quad (29)$$

$$\sum_{f\in F} X_f^{DSP} = \sum_{v\in V}\sum_{i\in I} X_{v,i}^{RSP} \quad (30)$$

$$\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} \le \sum_{f\in F} X_f^{DSP} \quad v\in V \quad (31)$$

$$\sum_{i\in I}\sum_{f\in F}\sum_{m\in M_i} X_{v,i,f,m}^{USP} \le \sum_{f\in F} X_f^{DSP} \quad v\in V \quad (32)$$

$$\sum_{f\in F}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} = X_{v,i}^{RSP} + \sum_{f\in F}\sum_{m\in M_i} X_{v,i,f,m}^{USP} \quad v\in V,\ i\in I \quad (33)$$

$$\sum_{i\in I}\sum_{f\in F}\sum_{i'=i}\sum_{f'\in F}\left(X_{v,f,i,m}^{LSP} - X_{v,i',f',m}^{USP}\right) \ge 0 \quad v\in V,\ m\in M_i \quad (34)$$

$$\sum_{i\in I}\sum_{m\in M_i} X_{v-1,i,f,m}^{USP} \le \sum_{i\in I}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} \quad f\in F,\ v>1 \quad (35)$$

$$X_{v+1,f,i,m}^{LSP} \le \sum_{f'\in F}\sum_{i'\in I}\sum_{m'\in M_i} X_{v,f',i',m'}^{LSP} \quad f\in F, i\in I, m\in M_i, v<|V| \quad (36)$$

$$\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X_{v+1,f,i,m}^{LSP} \le \sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i} X_{v,f,i,m}^{LSP} \quad v<|V| \quad (37)$$

$$maxt\ \sum_{f\in F} X_f^{DSP} \ge \sum_{f\in F}\left(\frac{dpf_{p,f}}{vd_{p,f}}\right) X_f^{DSP} +$$
$$\sum_{v\in V}\sum_{f\in F}\sum_{i\in I}\sum_{m\in M_i}\left(\frac{dfi_{f,i}}{vl_{f,i}} + tload_f + tunload_i\right) X_{v,f,i,m}^{LSP} +$$
$$\sum_{v\in V}\sum_{i\in I}\sum_{f\in F}\sum_{m\in M_i}\left(\frac{dif_{i,f}}{vu_{i,f}}\right) X_{v,i,f,m}^{USP} + \sum_{v\in V}\sum_{i\in I}\left(\frac{dip_{i,p}}{vr_{i,p}}\right) X_{v,i}^{R} \quad (38)$$

$$X_{v,f,i,m}^{LSP}, X_{v,i,f,m}^{USP}, X_{v,i}^{RSP}, X_f^{DSP} \in \{0,1\} \quad (39)$$

Constraint (26) performs the pricing (it determines the reduced costs), i.e., this objective function evaluates if the generated route could potentially improve the

objective function of the RMP model by incorporating it into the R^- set. The dual variables correspond to Eqs. (20) to (24) and are given by $\pi^1_{f,m}$, $\pi^2_{i,m}$, π^3_f, π^4_i and π^0, respectively. The aim of the $|P|$ sub-problems is to determine the route with the most negative reduce cost. Constraints (27) to (38) are related to restrictions (6) to (17) of the (P1) model; in turn, since the SP model is solve by regional base p (regardless of the truck c for which the route is created) the variables $X^D_{c,p,f}$, $X^L_{c,v,f,i,m}$, $X^U_{c,v,i,f,m}$ and $X^R_{c,v,i,p}$ must be rewritten as follows:

$$X^{DSP}_f = \sum_{r\in R^+}\sum_{p\in P} A^{XD}_{p,f,r}\, Y_r \quad f \in F \tag{40}$$

$$X^{LSP}_{v,f,i,m} = \sum_{r\in R^+}\sum_{p\in P} A^{XL}_{p,v,f,i,m,r}\, Y_r \quad f \in F, v \in V, i \in I, m \in M_i \tag{41}$$

$$X^{USP}_{v,i,f,m} = \sum_{r\in R^+}\sum_{p\in P} A^{XU}_{p,v,i,f,m,r}\, Y_r \quad f \in F, v \in V, i \in I, m \in M_i \tag{42}$$

$$X^{RSP}_{v,i} = \sum_{r\in R^+}\sum_{p\in P} A^{XR}_{p,v,i,r}\, Y_r \quad v \in V, i \in I \tag{43}$$

A set of initial routes is required to proceed with the column generation algorithm. All unitary length routes that can be made (regardless of the actual number of available trucks) are generated so as to achieve the first dual solution and thus initialize the CG algorithm. There are several heuristic techniques for route generation. In this work, a linear programming model (a classical transportation problem) is used to obtain the minimum supply distances traveled with load. Subsequently, this solution is converted into routes of unitary length (that is, routes with a single trip).

5 Illustrative example

To test both the mathematical programing model (P1) and the CG based algorithm, an example is developed. The considered supply chain involves 5 plants that demand 5 types of raw materials, which can be obtained from 15 harvest areas. There are 750 available trucks (spread across 12 regional bases) for hauling a total of 750 full-truckloads demanded by the plants. In Table 1 the used parameters are presented. In addition each truck can make at most 3 loaded trips beyond considering its maximum available working time (*maxt*). In

Table **2** supply and demand of raw materials are detailed. The distances between the nodes are presented in Table 3.

Table 1. Model parameters.

Parameter	Value	Parameter	Value	Parameter	Value
$cd_{p,f}$	0.8 $/km	$vd_{p,f}$	65 km/hr	$tload_f$	0.5 hr
$cl_{f,i}$	1.2 $/km	$vl_{f,i}$	55 km/hr	$tunload_i$	0.5 hr
$cu_{i,f}$	0.8 $/km	$vu_{i,f}$	65 km/hr	*cfix*	30 $
$cr_{i,p}$	0.8 $/km	$vr_{i,p}$	65 km/hr	*maxt*	10 hr

All the models are implemented and solved in GAMS [13] 24.7.3 version, using CPLEX 12.6.3 solver in an Intel(R) Core(TM) i7-4790, 3.60 GHz.

The (P1) model involves 978,750 binary variables and 448,601 equations. This formulation cannot be solved in one hour of execution using the selected solver. However, if the resolution time limit in (P1) is removed, the optimal solution (0% optimality gap) is found in 70,285 s (near 20 hours). The optimal solution has an objective value equal to $60,940 and 250 trucks are used to satisfy the demand. Each truck completes 3 loaded movements in their respective route.

By applying the CG based approach, the solution is reached in 122.95 s (resolution time of the column generation phase: 121.42 s; resolution time of the final RMP: 1.53 s). The final RMP involves 9,820 binary variables (columns) and the objective function is equal to $60,964, while 250 trucks are used (also making 3 trips each). As it can be noted, the proposed solution approach reaches a solution with a difference of 0.039% in the objective function given by the (P1) model, but in a considerable shorter resolution time.

It is interesting to note that the solution obtained from the last solved RMP can be used as initial starting point to solve the original formulation (P1) to global optimality. According to this, using a time limit of 15 minutes, then the objective function obtained is equal to $60,948 (0.009% optimality gap). While, if the time limit is omitted, the global optimal solution starting at the RMP solution is reached in 17,234 s, which represents a reduction of 75% with respect to the resolution of the (P1) model without starting point.

Table 4 shows the resolution times for five instances (the case study presented here correspond to the scenario 5). The characteristics of scenarios 1 to 4 are as follows:

- regional bases: 12, 8, 5 and 12, respectively
- plants: 5, 4, 4 and 5, respectively
- types of raw materials: 2, 4, 8 and 8, respectively
- harvest areas: 15, 10, 10 and 15, respectively
- total demand: 150, 250, 150 and 500, respectively.

In this table, “Gen.Time (s)” corresponds to the time needed to generate all the columns (feasible routes); “F.RMP (s)” is the resolution time of the final RMP; “F.RMP gap (%)”, “P1+IP (s)” and “P1+IP gap (%)” represent the optimality gap of the CG-based approach, the (P1) model with initial point and the (P1) model without

initial point, respectively; "Trucks CG", "Trucks P1[a]" and "Trucks P1[b]" represents the number of used trucks in the CG-based approach, in the (P1) model with initial point and in the (P1) model without initial point, respectively; and finally, "P1+IP (s)" and "P1-IP (s)" contain the time needed to solve the (P1) with and without initial point, respectively. It is worth mentioning that the time required to generate the starting point is not included in "P1+IP (s)". From the showed results, it can be derived that both formulations (the (P1) model and the CG-based approach) are effective to solve small/medium-size problems. Clearly, for large size problems, the CG-based approach is an efficient methodology to take into account.

Table 4. Resolution times for all the scenarios.

Scenario	Gen.Time (s)	F.RMP (s)	F.RMP gap(%)	Trucks CG	P1+IP (s)	P1+IP gap(%)	Trucks P1[a]	P1-IP (s)	P1-IP gap(%)	Trucks P1[b]
1	26.16	0.43	0	50	17.24	0	50	18.01	0	50
2	39.29	900	0.032	84	900	0.099	84	900	0.1	84
3	30.98	1.47	0	52	16.91	0	50	21.17	0	50
4	126.81	900	0.046	168	900	0.147	168	-	-	-
5	121.42	1.53	0	250	900	0.009	250	-	-	-

In Table 5 the objective functions of both CG-based approach and (P1) model with the initial point given by CG are compared to the LP relaxation of (P1) for the five scenarios. There is no time limit in the resolution of the LP relaxation of (P1). A time limit of 15 minutes is used in the final RMP and the same time is set for the (P1) model with the starting point defined by the CG-based approach. It is well known that the objective function of LP relaxation represents a lower bound for the objective function of the (P1) model, and therefore the quality of the solution can be assessed.

Table 5. Comparison between the objectives functions.

Scenario	LP Relaxation of P1 ($)	CG-Based Approach ($)	Optimality gap (%)	P1 with Initial Point ($)	Optimality gap (%)
1	10,501.73	10,542.8	0.39	10,517.2	0.147
2	24,362	24,394	0.131	24,384.4	0.092
3	12,733.73	12,912.8	1.387	12,734.8	0.008
4	39,813.33	39,895.2	0.205	39,872	0.147
5	60,935.46	60,964	0.047	60,942	0.011

The obtained results are closer to the LP relaxation of (P1), as can be seen in Table 5, which implies that the proposed approach can be applied in real size problems and guarantee a very good solution in less than 15 minutes of computing time.

6 Final remarks

Transportation planning in forest industry is a critical issue taking into account the high incidence of transportation costs in the profitability of the firms, given the large transported volumes and traveled distances. In the Argentine context, firms generally make decisions regarding the distribution of logs based on their experience. Therefore, the use of a planning tool to make these decisions could lead to significant improvements in the obtained results and the performance of the truck fleet.

In this work, a mathematical programming model is presented. Unlike the previous published works in the literature, the (P1) model simultaneously address product allocation and routing decisions, taking into account different raw materials and several depots or regional bases. In addition, the (P1) model allows determining the size of the truck fleet in such a way to guarantee the supply at minimum cost. The (P1) model is a generalization of the model developed in [8], in which the plants demand a single type of raw material. This generalization allows a better representation of the real problem. The developed mathematical model is robust enough and allows solving problems adjusted to the reality of the Argentine forest industry. In any case, beyond the analyzed example and the obtained results, the formulation could be improved to achieve a more detailed problem description, such as different types of trucks.

From the computational performance point of view, the (P1) model represents a highly combinatorial problem. Therefore, resorting to a CG based approach to solve the model in a reasonable computing time is a crucial aspect, especially if it is intended to have a planning tool that supports logistic planners on a day-to-day basis. An example was analyzed and solved with both solution methods. The CG based approach is able to find a good solution in a short computing time. Since the solution times of the CG based approach depends on the time taken by the column generation phase (the solution times of the sub-problems), it could be improved taking into account acceleration techniques in that phase to achieved a reduction in the total computing time; but this problem is out of the scope of this work and it will be considered in future works.

Finally, it should be noted that, although the CG based approach is not exact (reaching the optimal solution is not guaranteed), it allows obtaining solutions with negligible optimality gap, i.e., solutions very close to the optimal one. This tradeoff between solution quality and solution times makes this approach a viable option for its implementation in a real environment.

Resumen. En el presente trabajo se proponen distintos modelos de Programación Lineal Entera (PLE) que resuelven de forma exacta el problema de ruteo diario de camiones en la industria forestal. El objetivo en todos los casos es generar las rutas de los camiones involucrados a un costo mínimo, mientras se garantiza el suministro de materia prima a las plantas implicadas.
Los modelos que se encuentran habitualmente en la literatura asumen que los viajes que se deben realizar se conocen de antemano o se generan en una etapa previa. A diferencia de esos enfoques, en este trabajo se genera la configuración de cada viaje junto con las decisiones de asignación de materia prima y ruteo.
El modelo propuesto se evalúa en varios escenarios, demostrando en todos ellos que el enfoque propuesto resuelve eficientemente el problema abordado y mejora la performance respecto a los modelos ya existentes en la literatura.

Palabras claves: Ruteo · Industria forestal · Programación matemática · Optimización combinatoria

1. Introducción

En la industria forestal, el transporte de troncos (materia prima) para su distribución desde los puntos de suministro (frentes de cosecha) a las diferentes industrias que los requieren (plantas), representa uno de los factores de mayor impacto en los costos generales. Por lo tanto, hacer más eficientes las operaciones de transporte mediante una planificación adecuada, constituye un ahorro considerable para las empresas del sector, significando una tarea de gran interés.

En este trabajo se aborda un problema de ruteo que corresponde a una variación del Problema de Recogida y Entrega (PRE): el PRE en el transporte de troncos. El mismo fue definido por Borges y col. en [1] como un conjunto de rutas de vehículos que deben generarse para satisfacer un conjunto de puntos de demanda de acuerdo con un objetivo dado y sujeto a un conjunto de restricciones. Una ruta generalmente comienza y termina en la base de operaciones del vehículo y debe satisfacer diferentes limitaciones de tiempo, como la disponibilidad de horas de trabajo del vehículo (por ejemplo, no permitir trabajar de noche), la duración del turno de trabajo del conductor, las ventanas de tiempo en los puntos de oferta / demanda, etc. Además, los sitios de oferta y demanda se pueden visitar más de una vez (la disponibilidad de materia prima en los puntos de suministro generalmente supera el espacio de carga en los vehículos, así como las demandas de las industrias). Para llevar a cabo el transporte, hay disponible una flota de camiones, que puede consistir en el mismo tipo de camión o en diferentes camiones, cada uno con un conjunto único de características relevantes para el transporte (por ejemplo, capacidad, tipos de materia prima que se permite transportar, consumo de combustible, conjunto de sitios no permitidos o imposibles de visitar, etc.). Los camiones se distribuyen en un conjunto de sitios o se ubican en una sola base. Por lo tanto, el problema del transporte de troncos involucra muchas decisiones complejas, que incluyen una gran cantidad de camiones, nodos de oferta y demanda, diferentes tipos de materia prima, varios puntos de partida y aspectos legales y políticos, entre otros, lo que hace que el proceso de resolución sea muy complejo. Así, el desarrollo de una herramienta capaz de representar y resolver este problema de manera eficiente y en un corto tiempo de cómputo, supone un desafío relevante para la industria forestal.

Debido a la complejidad de este tipo de problemas y la dificultad para obtener una solución óptima en un tiempo de cómputo razonable, en la literatura se propusieron muchos enfoques basados en heurísticas (algunos de ellos pueden encontrarse en [2–4], entre otros). Son menos los enfoques exactos publicados, recientemente, Bordón y col. [5], presentaron una formulación exacta a través de un modelo de Programación Mixta Entera Lineal que simultáneamente genera rutas ordenando secuencias de viajes y asigna camiones a las rutas.

En el presente trabajo se proponen distintos modelos de Programación Lineal Entera (PLE) para la resolución de PRE en el transporte de troncos en forma exacta. Estos modelos mejoran la performance respecto a los existentes.

En la siguiente sección, se describe el problema a modelar. En la Sección 3 se presentan la función objetivo y las restricciones involucradas en los modelos matemáticos propuestos. En la sección 4 se trabaja en la evaluación de la performance de los mismos a través de la consideración de diferentes instancias. Finalmente, en la última sección, se exponen las conclusiones.

2. Descripción del problema

La Cadena de Suministro (CS) considerada cuenta con un conjunto M de materias primas, distribuidas en un conjunto de frentes de cosecha $F = \cup_{m \in M} F_m$,

donde F_m denota el conjunto de los frentes de cosecha que ofrecen la materia prima m. Cada frente $f \in F_m$ posee una cantidad disponible $Oferta_{f,m}$ de materia prima m (expresada en número de cargas completas de camiones). Estos abastecen a un conjunto de plantas $P = \cup_{m \in M} P_m$, donde P_m denota el conjunto de plantas que demandan la materia prima m. Cada planta $p \in P_m$ exige cierta cantidad de materia prima $Demanda_{p,m}$ (también expresadas en cargas completas de camiones).

Se dispone de una flota de camiones homogénea $c \in C$ distribuidos en un conjunto de bases regionales B. Se denota con C_b el conjunto de camiones en la base $b \in B$. Así, $C = \cup_{b \in B} C_b$. Cada camión $c \in C_b$ para $b \in B$, comienza y termina su ruta en la base regional b.

Por cuestiones gremiales, el tiempo destinado a cada ruta no podrá superar un determinado tiempo máximo $Max\,T$. Cada ruta es una sucesión de viajes. Consideraremos 4 tipos de viajes.

I) El primer viaje (descargado) de cada camión c que se realiza desde la base regional de c hacia un frente de cosecha.
II) Los viajes (cargados) desde frentes de consecha donde cada camión recoge materia prima y se dirige hacia una planta que la demande.
III) Los viajes (descargados) en los que, desde una planta el camión se dirige a un frente de cosecha.
IV) El último viaje (descargado) de cada camión en el cual este regresa a su base regional desde una planta.

Ciertas regulaciones imponen un número máximo lim de viajes que componen una ruta, sin importar si el camión tiene tiempo para realizar más viajes sin superar el tiempo $Max\,T$. Por lo tanto, cada ruta es una sucesión de viajes v, $v \in V = \{v_i : 1 \leq i \leq lim\}$. Cada camión transporta a lo sumo un tipo de materia prima $m \in M$ en cada viaje y, si va cargado, lo hace con la carga completa.

El costo total de transporte $TCOST$ que se busca minimizar es la suma de los costos de las rutas que realizan los camiones. Estos constan de dos partes: un costo fijo por camión utilizado y un costo variable que depende de los kilómetros recorridos por cada camión, si el camión se encuentra descargado o no, y las características de la carretera (tipo de pavimento, geografía, etc.). Así, para cada $b \in B$ y $f \in F$, $WUa_{b,f}$ denota el costo de realizar el viaje (descargado) desde la base regional b hasta el frente de cosecha f. Este costo está compuesto por la suma del costo fijo (en \$) de utilizar un camión de la base b más el costo de recorrer la distancia entre la base y el frente, proporcional a la distancia entre ellos. Adicionalmente, para cada $c \in C$, $f \in F$ y $p \in P$, $WL_{f,p}$, $WUb_{p,f}$ y $WUc_{p,b}$ son, repectivamente, el costo de realizar el viaje desde el frente de cosecha f hasta la planta p (cargado), desde la planta p hasta el frente de cosecha f (descargado) y desde la planta p hasta la base regional b (descargado). Estos costos son porporcionales a la distancia entre cada par de sitios.

También, para cada $b \in B$, $f \in F$ y $p \in P$, $TUa_{b,f}$, $TL_{f,p}$, $TUb_{p,f}$ y $TUc_{p,b}$ denotan, repectivamente, la duración (en horas) del viaje desde la base b al frente de cosecha f, desde el frente de cosecha f hasta la planta p (cargado), desde la

planta p hasta el frente de cosecha f (descargado) y desde la planta p hasta la base regional b (descargado).

3. Modelo de PLE

En esta sección se describe la función objetivo y se presentan las restricciones a considerar, las cuales se clasifican en las restricciones necesarias para la conformación de las rutas posibles, las restricciones que evitan soluciones alternativas y desigualdades adicionales válidas. Las primeras restricciones resuelven en el problema de ruteo de troncos, mientras que las dos últimas se consideran para evaluar si su inclusión en modelo mejora la performance del solver.

Las rutas de los camiones se describen como una sucesión de viajes que realizan. Así, para cada camión c, tenemos una variable binaria que determina cuál es el i-ésimo viaje $v_i \in V$ que realiza c. Formalmente, para cada $c \in C$, $f \in F$, $p \in P$, $m \in M$ y $v \in V$ tenemos las siguientes variables:

- $x^{v_1}_{c,f,m}$: toma el valor 1 si el camión c comienza su ruta y se dirige al frente f para cargar materia prima m.
- $x^{v_i}_{c,f,p}$, con i par : toma el valor 1 si el camión c en su i-ésimo viaje se dirige desde el frente f a la planta p.
- $x^{v_i}_{c,p,f,m}$, con $3 \leq i \leq lim - 2, i$ impar : toma el valor 1 si el camión c en su i-ésimo viaje se dirige desde la planta p al frente f para cargar materia prima m.
- $x^{v_i}_{p,c}$, con $i \geq 3, i$ impar : toma el valor 1 si el camión c en su i-ésimo viaje regresa a su base desde la planta p.

3.1. Función objetivo

El costo total de transporte TCOST que se busca minimizar, se modela como sigue:

$$\begin{aligned}\text{TCOST} = &\sum_{b\in B}\sum_{c\in b}\sum_{m\in M}\sum_{f\in F_m} WUa_{b,f}\, x^{v_1}_{c,f,m} + \\ &\sum_{c\in C}\sum_{v\in V_{par}}\sum_{m\in M}\sum_{f\in F_m}\sum_{p\in P_m} WL_{f,p}\, x^{v}_{c,f,p} + \\ &\sum_{c\in C}\sum_{v\in V_{impar}}\sum_{p\in P}\sum_{m\in M}\sum_{f\in F_m} WUb_{p,f}\, x^{v}_{c,p,f,m} + \\ &\sum_{b\in B}\sum_{c\in b}\sum_{v\in V_{impar}}\sum_{p\in P} WUc_{p,b}\, x^{v}_{p,c}, \end{aligned} \tag{1}$$

donde V_{impar} y V_{par} denotan los subconjuntos de V dados por

$$V_{impar} = \{v_i \in V : i \text{ es impar }, i \geq 3\} \quad \text{y} \quad V_{par} = \{v_i \in V : i \text{ es par }\}.$$

3.2. Restricciones que modelan las rutas posibles

- *A lo sumo una ruta por camión*
  Cada camión puede salir a lo sumo una vez desde su base regional y, en caso de hacerlo, debe dirigirse hacia un frente de cosecha:

$$\sum_{m \in M} \sum_{f \in F_m} x^{v_1}_{c,f,m} \leq 1, \ \ \forall c \in C. \tag{2}$$

- *Restricciones de conservación de flujo*
  Si un camión se utiliza, debe regresar a su base regional (y sólo puede hacerlo desde una planta):

$$\sum_{m \in M} \sum_{f \in F_m} x^{v_1}_{c,f,m} = \sum_{v \in V_{impar}} \sum_{p \in P} x^{v}_{p,c}, \ \ \forall c \in C. \tag{3}$$

  Si un camión desde su base regional se dirige a un frente de cosecha a recoger una determinada materia prima, en su segundo viaje debe dirigirse hacia una planta que requiera esta materia prima:

$$\sum_{p \in P_m} x^{v_2}_{c,f,p} = x^{v_1}_{c,f,m}, \, \forall c \in C, \, \forall m \in M, \, \forall f \in F_m. \tag{4}$$

  Del mismo modo, en los viajes subsecuentes desde un frente de cosecha que ofrece la materia prima m, el camión debe dirigirse hacia una planta que demande la materia prima m:

$$\sum_{p \in P} x^{v}_{c,p,f,m} = \sum_{p \in P_m} x^{v+1}_{c,f,p}, \ \ \forall c \in C, \ \ \forall v \in V_{impar}, \, \forall m \in M, \, \forall f \in F_m, \tag{5}$$

  (notar que, por definición, si $v \in V_{impar}$, entonces $v \geq 3$).
  Por otro lado, cada camión desde una planta puede regresar a su base regional o dirigirse hacia un frente de cosecha:

$$\sum_{f \in F} x^{v}_{c,f,p} = \left[x^{v+1}_{p,c} + \sum_{m \in M} \sum_{f \in F_m} x^{v+1}_{c,p,f,m} \right], \ \ \forall c \in C, \, \forall v \in V_{par}, \, \forall p \in P. \tag{6}$$

- *Tiempo máximo de duración de una ruta*
  La siguiente ecuación calcula el tiempo total en la carretera $TIME_c$ de cada camión $c \in C$. El mismo se obtiene sumando los tiempos utilizados en cada viaje.

$$\begin{aligned} TIME_c = & \sum_{m \in M} \sum_{f \in F_m} TUa_{b,f} \ x^{v_1}_{c,f,m} + \\ & \sum_{v \in V_{par}} \sum_{f \in F} \sum_{p \in P} TL_{f,p} \ x^{v}_{c,f,p} + \\ & \sum_{v \in V_{impar}} \sum_{f \in F} \sum_{p \in P} TUb_{p,f} \ x^{v}_{c,p,f} + \\ & \sum_{v \in V_{impar}} \sum_{p \in P} TUc_{p,b} \ x^{v}_{p,c}. \end{aligned} \tag{7}$$

La restricción (18) establece que cada camión no puede permanecer en la carretera más tiempo que $MaxT$:

$$TIME_c \leq MaxT, \quad \forall c \in C. \tag{8}$$

- *Límite de oferta y satisfacción de la demanda*
  La cantidad de materia prima disponible en cada frente de cosecha y la cantidad demandada de la misma por cada planta se expresan en términos del número de cargas completas de camiones. Por lo tanto, la cantidad total de viajes cargados con cada tipo de materia prima m que se realizan desde el frente de cosecha f a cualquier planta no pueden exceder la disponibilidad de ese tipo de materia prima en ese frente, denotada por $Oferta_{f,m}$:

$$\sum_{c \in C}(x^{v_1}_{c,f,m} + \sum_{p \in P} \sum_{v \in V_{impar}} x^{v}_{c,p,f,m}) \leq Oferta_{f,m}, \ \ \forall m \in M, \forall f \in F_m, \tag{9}$$

  Por otro lado, la cantidad total de viajes cargados de cierto tipo de materia prima m que llegan a la planta p deben cumplir con la demanda de esta planta $Demanda_{p,m}$:

$$\sum_{c \in C} \sum_{f \in F_m} \sum_{v \in V_{par}} x^{v}_{c,f,p} = Demanda_{p,m}, \ \ \forall m \in M, \forall p \in P_m. \tag{10}$$

Hasta aquí, si un camión c tiene asignada una ruta (la restricción (2) se satisface por igualdad para c), las restricciones de conservación de flujo ((3), (4), (5) y (6)) aseguran que esa ruta corresponda a un circuito que se inicia y termina en la base asociada al camión y, los viajes entre frentes de cosecha y plantas, se efectúan consecutivamente en forma correcta. Además las restricciones (8) aseguran que dicho tour no supere el tiempo máximo permitido para el camión en la carrretera. Las restricciones (9) y (10) imponen las condiciones de oferta y de demanda.

Llamaremos *Modelo A* al modelo que cuya función objetivo minimiza la expresión $TCOST$ (ecuación (1)), sujeto a las restricciones de esta sección: (2), (3), (4), (5), (6), (8), (9) y (10).

3.3. Restricciones que evitan soluciones alternativas

Si en cada base regional la flota de camiones es homegénea, dada una solución factible del *Modelo A*, intercambiando los valores de las variables asignados a dos camiones de una misma base obtenemos una solución factible alternativa, esto es, con mismo costo.

Si suponemos que los camiones en las bases, los frentes de cosecha y las distintas plantas están enumerados, es posible incorporar restricciones que evitan soluciones de este tipo y pueden mejorar la performance computacional del proceso de resolución del modelo. Una primera estrategia es la de ordenar los camiones de una misma base en forma decreciente en función de la duración de sus viajes. Esto es,

$$TIME_c \geq TIME_{c+1}, \quad \forall b \in B, \forall c \in C_b. \tag{11}$$

Estas restricciones también establecen que los camiones de una base salen en orden creciente ya que, si el camión c no viaja ($TIME_c = 0$), entonces tampoco viaja el camión $c+1$ ($TIME_{c+1} = 0$). Esta última condición puede ser modelada como

$$\sum_{m\in M}\sum_{f\in F_m} x^{v_1}_{c+1,f,m} \leq \sum_{m\in M}\sum_{f\in F_m} x^{v_1}_{c,f,m}, \quad \forall b \in B,\, \forall c, (c+1) \in C_b. \tag{12}$$

Otra forma de evitar soluciones alternativas entre camiones de una misma base es eligir las soluciones *monótonas en función de los índices de los camiones, los frentes y las plantas.* A continuación se describen distintas restricciones que cumplen esta tarea.

- "Monotonía camión-frente": las siguientes restricciones imponen que si dos camiones de una misma base se dirigen a dos frentes distintos (a buscar la misma materia prima), entonces el camión de índice menor debe ir al frente de índice menor.

$$x^{v_1}_{c_i,f_r,m} + x^{v_1}_{c_j,f_q,m} \leq 1, \forall b \in B,\, \forall c_i, c_j \in C_b,\, i < j,$$
$$\forall m \in M,\, \forall f_q, f_r \in F_m,\, q < r. \tag{13}$$

  En la Figura 1 se representa el tipo de recorrido que se está evitando. Es fácil ver que dada una solución representada por x que viole la desigualdad (13), o sea, tal que $x^{v_1}_{c_i,f_r,m} = x^{v_1}_{c_j,f_q,m} = 1$ para ciertos $c_i, c_j \in C_b$ con $i < j$ y $f_q, f_r \in F_m$ con $q < r$, podemos encontrar una solución z con el mismo costo que x que satisfaga la desigualdad (13). En efecto, si $x^{v_1}_{c_i,f_r,m} = x^{v_1}_{c_j,f_q,m} = 1$, entonces $x^{v_1}_{c_i,f_q,m} = x^{v_1}_{c_j,f_r,m} = 0$. Definimos z tal que $z^{v_1}_{c_i,f_r,m} = z^{v_1}_{c_j,f_q,m} = 0$, $z^{v_1}_{c_i,f_q,m} = z^{v_1}_{c_j,f_r,m} = 1$ y el resto de los viajes de z que coincidan con los de x. Claramente z verifica las restricciones de (2) a (10). Además, z satisface (13) y tiene el mismo costo que x.

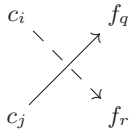

Figura 1. Viajes que evita la restricción (13) donde $c_i, c_j \in C_b$ para cierta base regional b, $i < j$, $f_q, f_r \in F_m$ para cierta materia prima m y $q < r$.

- "Monotonía frente-planta": las siguientes restricciones imponen que si dos camiones de una misma base, desde un mismo frente de cosecha se dirigen a dos plantas distintas (a llevar la misma materia prima), entonces el camión de índice menor debe ir a la planta de índice menor.

$$x^{v}_{c_i,f,p_r} + x^{v'}_{c_j,f,p_q} \leq 1, \forall v, v' \in V_{par},\, \forall b \in B,\, \forall c_i, c_j \in C_b,\, i < j,$$
$$\forall m \in M,\, \forall f \in F_m,\, \forall p_q, p_r \in P_m,\, q < r. \tag{14}$$

En la Figura 2 se representa el tipo de recorrido que se está evitando. Con un razonamiento análogo al anterior, es fácil ver que dada una solución x que viole la desigualdad (14), podemos encontrar una ruta z con el mismo costo que x que satisfaga la desigualdad (14).

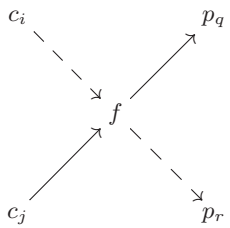

Figura 2. Viajes que evita la restricción (14) donde $c_i, c_j \in C_b$ para cierta base regional b, $i < j$, $p_q, p_r \in P_m$ para cierta materia prima m que ofrece el frente f y $q < r$.

- "Monotonía planta-frente": las siguientes restricciones imponen que si dos camiones de una misma base desde una misma planta se dirigen a dos frentes de cosecha distintos, entonces el camión de índice menor debe ir al frente de índice menor.

$$x^{v}_{c_i,p,f_r,m} + x^{v'}_{c_j,p,f_q,m} \leq 1, \forall v, v' \in V_{impar}, \forall b \in B, \forall c_i, c_j \in C_b, i < j \\ \forall p \in P, \forall m \in M, \forall f_q, f_r \in F_m, q < r. \quad (15)$$

En la Figura 3 se representa el tipo de recorrido que se está evitando. Como antes, se puede probar que dada una solución x que viole la desigualdad (15), podemos encontrar una solución z con el mismo costo que x que satisfaga la desigualdad (15).

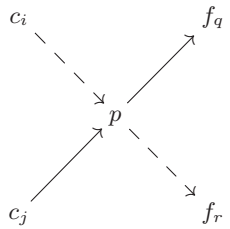

Figura 3. Viajes que evita la restricción (15) donde $c_i, c_j \in C_b$ para cierta base regional b, $i < j$, $p \in P$, $f_q, f_r \in F_m$ para cierta materia prima m y $q < r$.

- "Monotonía planta-base": las siguientes restricciones imponen que si dos camiones de una misma base llegan a una misma planta y uno se dirige a un

frente de cosecha mientras el otro regresa a su base, entonces el camión de menor índice sea el que retorna a su base.

$$x^v_{c_i,p,f,m} + x^v_{p,c_j} \leq 1, \forall v \in V_{impar}, \forall b \in B, \forall c_i, c_j \in C_b, i < j \\ \forall m \in M, \forall f \in F_m, \forall p \in P. \quad (16)$$

En la Figura 4 se representa el tipo de recorrido que se está evitando. Notar que, dada una solución x que viole la desigualdad (16), siguiendo la demostración realizada en el caso de la restricción (13) con menores cambios, podemos encontrar una solución z con el mismo costo que x que satisfaga la desigualdad (16).

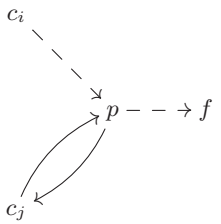

Figura 4. Viajes que evita la restricción (16) donde $c_i, c_j \in C_b$ para cierta base regional b, $i < j$, $p \in P$ y $f \in F$.

Con estas restricciones pueden aún sobrevivir soluciones simétricas correspondientes a dos camiones de una misma base cuyas rutas demoran el mismo tiempo pero sólo si esas rutas están compuestas por los mismos viajes y en el mismo orden.

3.4. Desigualdades válidas adicionales

A continuación se presentan desigualdades válidas que, aunque no ajustan la región factible de la relajación lineal del *Modelo A*, en experiencias computacionales sobre distintos escenarios se observa que alteran la performance del solver.

- Si el camión c no se utiliza entonces, no realiza viajes entre frentes y plantas.

$$\sum_{p \in P} \sum_{m \in M} \sum_{f \in F_m} x^v_{c,p,f,m} \leq \sum_{m \in M} \sum_{f \in F_m} x^{v_1}_{c,f,m}, \quad \forall c \in C, \forall v \in V_{impar}. \quad (17)$$

- Un camión que regresa a su base no realiza ningún otro viaje posteriormente. Esta condición se representa con las restricciones (18) y (19):

$$\sum_{f \in F} \sum_{p \in P} x^t_{c,f,p} \leq 1 - x^v_{p',c}, \quad \forall c \in C, \forall p' \in P, \forall v \in V_{impar}, \forall t \in V^{[v+1]}_{par}, \quad (18)$$

$$\sum_{p\in P}\sum_{m\in M}\sum_{f\in F_m} x^t_{c,p,f,m} \leq 1 - x^v_{p',c}, \quad \forall c \in C,\ \forall p' \in P,$$
$$\forall v \in V_{impar},\ \forall t \in V^{[v+2]}_{impar}, \qquad (19)$$

donde $V^{[v+1]}_{par}$ y $V^{[v+2]}_{impar}$ denotan, respectivamente, los conjuntos

$$\{t \in V_{par} : t \geq v+1\} \quad \text{y} \quad \{t \in V_{impar} : t \geq v+2\}.$$

Las restricciones (18) y (19) pueden combinarse de la siguiente manera:

$$\sum_{t\in V^{[v+1]}_{par}} \left[\sum_{f\in F}\sum_{p\in P} x^t_{c,f,p} + \sum_{p\in P}\sum_{m\in M}\sum_{f\in F_m} x^{t+1}_{c,p,f,m}\right] \leq (lim-3)(1 - x^v_{p',c}),$$
$$\forall c \in C,\ \forall p' \in P,\ \forall v \in V_{impar}, \quad (20)$$

o como sigue

$$\sum_{f\in F}\sum_{p\in P} x^t_{c,f,p} + \sum_{p\in P}\sum_{m\in M}\sum_{f\in F_m} x^{t+1}_{c,p,f,m} \leq \frac{lim-3}{2}(1 - x^v_{p',c}),$$
$$\forall c \in C;\ \forall p' \in P,\ \forall v \in V_{impar},\ \forall t \in V^{[v+1]}_{par}. \quad (21)$$

4. Análisis de la performance del enfoque

En esta sección, se evalúan las capacidades y el rendimiento de distintos modelos que se intengran por las restricciones presentadas en la sección anterior. Se presentan diversos escenarios basados en el contexto argentino, extraídos del trabajo de Bordón y col. [5]. En la Tabla 1 se establece la cantidad de camiones disponibles, bases regionales, frentes de cosecha, tipos de materia prima, plantas y demandas para cada instancia.

En todos los casos, se consideran los siguientes parámetros: el costo de utilización por camión es de $30, cada camión puede hacer un máximo de 7 viajes y cada ruta no puede exceder las 10 horas, la velocidad promedio del camión con y sin carga es igual a 55 y 65 km/h, respectivamente para todas las carreteras, los costos por kilómetro recorrido con y sin carga equivalen a 1.2 y 0.8 $/km, respectivamente, para todas las carreteras. Así las constantes $WUa_{b,f}$, $WL_{f,p}$, $WUb_{p,f}$ y $WUc_{p,b}$ se calculan como el producto de la distancia por el costo correspondiente por kilómetro recorrido con o sin carga, respectivamente; y las constantes $TUa_{b,f}$, $TL_{f,p}$, $TUb_{p,f}$ y $TUc_{p,b}$ como el cociente entre la distancia entre los lugares que intervienen y la velocidad promedio del camión con o sin carga, respectivamente.

Para la evalución de la performance todos los modelos se implementan y resuelven en la versión 24.7.3 de GAMS (ver [6]), utilizando el solver CPLEX 12.6.3 en un Intel(R) Core(TM) i5-2500k, 3.30 GHz.

Tabla 1. Características de cada escenario estudiado.

Escenario	Camiones diponibles	Bases regionales	Plantas	Tipos de materia prima	Frentes de cosecha	Demanda
1	50	1	1	1	5	100
2	120	1	1	1	5	300
3	400	1	1	1	5	1000
4	50	1	3	1	5	100
5	120	1	3	1	5	300
6	120	1	5	1	5	300
7	300	1	5	1	5	750
8	70	5	1	1	10	150

18	100	12	5	5	15	200
19	400	12	5	5	15	750
20	400	12	6	3	15	750

4.1. Modelo A

En primera instancia se analiza el *Modelo A* que, como ya se dijo, considera las restricciones que definen las rutas posibles: restricciones de la (2) a la (10) (ver subsección 3.2). En la Tabla 2 se muestran los resultados obtenidos. El límite de tiempo fijado para la resolución es de 300 segundos de CPU. Solo dos escenarios (3 y 16) no llegan a la solución óptima antes del límite de tiempo. Estos casos involucran el mayor número de camiones disponibles (400 y 500) y demandas requeridas (1000 cargas de camiones completas). Aunque el óptimo global en estos ejemplos no se alcanza en el tiempo límite fijado, el modelo encuentra una solución con un gap de optimalidad razonable (menos del 1 %).

A continuación se describe la solución completa de uno de los escenarios considerados con el fin de mostrar las potencialidades de esta formulación como una herramienta práctica para la industria.

Considerar la CS del caso 5, compuesta por 3 aserraderos, 5 frentes de cosecha y 1 base regional. Se dispone de 120 camiones para transportar 300 cargas completas de camiones de una materia prima única. Las distancias entre los frentes de cosecha y las plantas, entre la base regional y las plantas, entre la base regional y las áreas de cosecha, la disponibilidad de materia prima y las demandas de las plantas se muestran en la Tabla 3.

El modelo comprende 1248 variables binarias y 3849 ecuaciones. Se resuelve en 2.36 seg. con 0 % de gap de optimalidad y el valor de la función objetivo

Tabla 2. Estadísticas del *Modelo A* para cada escenario.

Escenario	Variables discretas	Ecuaciones	Tiempo CPU (seg.)	GAP	Costo total	Camiones utilizados
1	1900	1307	3.23	0.00 %	18484.0	34
2	4561	3127	6.59	0.00 %	61712.0	110
3	15201	10407	300.00	0.49 %	202486.0	337

Tabla 3. Distancias (en km) entre los nodos involucrados en el escenario 5 y cantidad de materia prima disponible y demandada (en cargas de camiones completos).

	p_1	p_2	p_3	b_1	Materia prima disponible (en cargas de camiones completos)
f_1	50	41	72	72	83
f_2	50	100	58	32	42
f_3	45	40	22	30	65
f_4	28	72	81	67	70
f_5	86	114	61	50	51
b_1	41	70	28		
Demanda (en cargas completas de camiones)	150	70	80		

es igual a $29165.2. En este caso se utilizan 100 camiones que realizan rutas compuestas por 7 viajes, es decir, el mayor número de viajes permitidos para cada camión. En la Tabla 4, por razones de espacio, solo se presentan algunas rutas de camiones para que se puedan apreciar las características de la solución. A partir de esta se puede detallar la sucesión de viajes que realiza cada camión y el tiempo total requerido para cada una de estas, las cargas que se usaron de cada frente de cosecha y las que quedaron luego de satisfacer todas las demandas (ver Tabla 5). Por ejemplo, el camión c_2 abastece en todos sus viajes a la planta p_1, la primera carga proviene del frente de cosecha f_2 mientras que las dos restantes desde f_4. En total requiere de 3.91 horas para esta tarea desde que sale hasta que regresa a la base regional. Como se puede ver en la Tabla 4, la duración de las rutas de los camiones es relativamente corta y todas se componen de 7 viajes, que es el límite fijo. La duración media de las rutas es de 4,43 horas. Por lo tanto, si se permiten más viajes por camión, se pueden utilizar una menor cantidad de camiones.

Tabla 4. Descripción de las rutas de los camiones de la solución óptima para el escenario 5.

Camión	Viaje 1	Viaje 2	Viaje 3	Viaje 4	Viaje 5	Viaje 6	Viaje 7	Duración de la ruta (h)
c_2	$b_1 - f_2$	$f_2 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - b_1$	3,91
c_3	$b_1 - f_1$	$f_1 - p_2$	$p_2 - f_1$	$f_1 - p_2$	$p_2 - f_1$	$f_1 - p_1$	$p_1 - b_1$	5,40
...	...	...	...	...	...	...	...	...
c_{50}	$b_1 - f_3$	$f_3 - p_2$	$p_2 - f_1$	$f_1 - p_2$	$p_2 - f_1$	$f_1 - p_1$	$p_1 - b_1$	4,74
c_{51}	$b_1 - f_5$	$f_5 - p_3$	$p_3 - f_3$	$f_3 - p_3$	$p_3 - f_3$	$f_3 - p_3$	$p_3 - b_1$	3,79
...	...	...	...	...	...	...	...	...
c_{119}	$b_1 - f_2$	$f_2 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - b_1$	3,91
c_{120}	$b_1 - f_2$	$f_2 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - f_4$	$f_4 - p_1$	$p_1 - b_1$	3,91

En la Tabla 5 se puede observar que las plantas, en el óptimo, son abastecidas por un subconjunto de frentes de cosecha, y en casos como p_1 y f_4, se advierte que hay frentes de cosecha dedicados exclusivamente al suministro de una sola planta. Además, en los casos de f_1, f_2, f_3 y f_4, se distribuye la cantidad total de cargas completas de camiones disponibles y, por lo tanto, sería beneficioso extender la cantidad de materia prima disponible allí.

4.2. Modelos alternativos

Buscando mejorar la performance del *Modelo A*, sobretodo en los escenarios donde no se alcanza la solución óptima, se realizaron experiencias computacionales con 27 modelos distintos de PLE obtenidos agregando las restricciones descriptas en las secciones 3.3 y 3.4 en diversas combinaciones. En la mayoría de los casos no se dieron cambios notables en los tiempos de resolución.

El modelo a destacar es el que llamaremos *Modelo B* compuesto por las restricciones del *Modelo A* más las desigualdades válidas (18) y (19). Los resultados

Tabla 5. Cantidad de viajes cargados generados entre frentes de cosecha y plantas en el escenario 5 y cantidad de materia prima sobrante.

	p_1	p_2	p_3	Materia prima sobrante (en cargas completas de camiones)
f_1	38	45		
f_2	42			
f_3		25	40	
f_4	70			
f_5			40	11

obtenidos para este modelo se detallan en la Tabla 6. Notar que, a diferencia del *Modelo A*, en este caso se alcanza la solución óptima para el escenario 16.

Cabe mencionar que en estos problemas en donde existen soluciones alternativas, no solo influye el tamaño del problema en la eficiencia computacional, sino también los valores de los parámetros y los tradeoffs entre ellos. Por tal motivo, en casos como el escenario 3, en donde el número de variables discretas es menor que en otros escenarios, el modelo no llega al óptimo global en el tiempo de cómputo límite.

Tabla 6. Estadísticas del *Modelo B* para cada escenario.

5. Conclusiones

La planificación del transporte en la industria forestal es un problema crítico teniendo en cuenta la alta incidencia de los costos de transporte en la rentabilidad de las empresas, dados los grandes volúmenes de materia prima que se deben transportar y las distancias que se deben recorrer. Esta industria presenta características específicas que generan muchas rutas alternativas. Esto genera un problema altamente combinatorio. Un suministro confiable de troncos que permita la disponibilidad de la madera adecuada en el momento apropiado, en el lugar indicado, es una ventaja competitiva.

En el contexto argentino, las empresas generalmente toman decisiones sobre la distribución de troncos en base a su experiencia, es decir, soluciones heurísticas. Por tanto, el uso de una herramienta de planificación para tomar estas decisiones mejora sustancialmente los resultados obtenidos.

Teniendo en cuenta este contexto, en este trabajo se presentaron modelos de PLE para el ruteo de vehículos en la industria forestal. Las formulaciones propuestas permiten generar simultáneamente todas las rutas posibles, evitando la necesidad de proporcionarlas de antemano mediante un largo procesamiento y recurriendo a grandes ordenamientos de datos. Los modelos presentados resuelven la formulación general en un tiempo de cálculo razonable para diversos escenarios de dimensiones reales. Las soluciones obtenidas muestran que los modelos de PLE abordan de manera eficiente y efectiva los objetivos de distribución de troncos, con un alto impacto en la rentabilidad de la industria forestal.

DESARROLLO DE UN SISTEMA DE PROGRAMACION DE ORDENES DE TRABAJO CON RESTRICCIONES DE SINCRONIZACION PARA UNA EMPRESA DE LA AGROINDUSTRIA DE FLORES

Freddy López, Alfonso Sarmiento, William Guerrero

Universidad de La Sabana, Facultad de Ingeniería. Campus del Puente del Común
Km. 7 Autopista Norte. Chía, 140013, Colombia
freddylogu@unisabana.edu.co

Resumen. Este trabajo estudia las decisiones logísticas asociadas a la asignación de un conjunto de pedidos de flores a un conjunto de plantas de producción con criterios de eficiencia y equidad. Adicionalmente se consideran restricciones de sincronización para la asignación de los productos con destino a los Estados Unidos. Se implementó un algoritmo de tipo heurístico para optimizar el balance entre oferta y demanda que evalúa tres reglas de ordenamiento de los subpedidos en conjunto con posibles días de desfase. La herramienta permitió resolver instancias con alrededor de 13000 subpedidos. El modelo se válida en un caso real de manufactura del sector agroindustrial de las flores. Los resultados de los experimentos logran demostrar la capacidad del algoritmo para la asignación y sincronización de los subpedidos. Utilizando días de desfase se alcanzaron porcentajes de asignación del 100% de los subpedidos con la regla de ordenamiento aleatoria y minimizando la cantidad de residuo.

Palabras clave: Agroindustria. Cadena de suministro. Problema de asignación. Heurística.

1 Introducción

Desde hace más de 40 años Colombia empezó a posicionarse en el mercado mundial de las flores[1]. El país se convirtió en el segundo exportador de flores de corte en el mundo sólo detrás de Holanda, con una participación del 13,25% de los flujos totales de estos productos[2]. Los Estados Unidos constituyen el principal destino de las exportaciones totales, con una participación del 79,96%, seguido por la Federación Rusa (4%), el Reino Unido (3,66%), Japón (2,73%) y España (2,16%) y para el 2002 dos de cada tres flores que se venden en los Estados Unidos provienen de Colombia.

El problema para trabajar en este proyecto trata de la sincronización en la entrega de producto final en agroindustrias de flores[3] y como se realiza la asignación de órdenes de producción(pedidos)[4] a las diferentes plantas de producción (proveedores), este ejercicio debe ser resultado de una integración de balances de producto, color, variedad, calidad, cantidad, longitud, la relevancia de fechas de despacho entre otros atributos[5]

del producto además de materiales e insumos para ejecutar la orden y la capacidad de proceso que tiene cada una de los proveedores que se encuentra asociados a la unidad logística[6].

El alcance de este documento será la implementación del algoritmo heurístico diseñado en un grupo de empresas exportadoras de flores, a través de una mejora en el aplicativo web con el cual se realizan las labores actualmente[7]. El aplicativo es implementado por la empresa de intermediación logística la cual distribuye los pedidos a sus empresas asociadas. El cambiar la forma en que se asignan los pedidos[8], permite profundizar en la metodología y determinar como la oferta se ajusta mejor a la demanda. Este ejercicio responde a la necesidad de realizar entregas a tiempo y ajustar dentro del proceso logístico las posibles desviaciones de entrega de los subpedidos que componen un pedido entre los proveedores[9] en busca de generar como una agremiación de productores de flores la atención en masa de diferentes clientes[10].

2 Metodología

Para esta investigación se propone un algoritmo heurístico de asignación de pedidos a plantas de producción, que desarrolla los siguientes pasos:

2.1 **Determinar días de desfase:** los días de desfase en el aplicativo que permiten definir una ventana móvil de entrega de los pedidos formada por el límite inferior (fecha de envío – días de desfase) y superior (fecha de envío + días de desfase) que tienen cada uno para ser despachados hacia el cliente final.

2.2 **Ordenar proveedores:** los proveedores son ordenados de forma descendente de acuerdo con su volumen total de tallos y el porcentaje de asignación que tienen cada uno de ellos.

2.3 **Ordenar pedidos:** Los pedidos siempre se ordenan de la fecha de envío más reciente a la fecha de envío más lejana. Luego de este ordenamiento inicial los pedidos se vuelven a ordenar dentro de cada fecha de acuerdo con tres posibles reglas: i) en forma aleatoria (RALE) ii) en forma ascendente (RME, de menor a mayor número total de tallos del pedido), iii) en forma descendente (RMA, de mayor a menor número total de tallos del pedido).

2.4 **Asignar pedidos a proveedores:** La asignación de subpedidos se realiza comparando cada uno de los atributos de la demanda con cada uno de los atributos de la oferta. Para que el pedido sea asignado se debe satisfacer que el proveedor cumpla con la disponibilidad de todos los atributos de la demanda.

2.5 **Estadísticas de asignación:** Después de realizado el proceso de asignación se generan unas medidas de desempeño i) los pedidos asignados, ii) los pedidos no asignados y iii) el porcentaje de asignación.

3 Resultados

El caso de estudio se basa en una oferta de 20.921.788 tallos de flores y una demanda total de 25.058.299 tallos de flores para todas las reglas. Automatizar la opción de "días de desfase" permite generar escenarios de planeación en tiempos muy cortos. Por ejemplo, se asignaron 13 mil subpedidos en un tiempo de 60 segundos. Se evaluaron escenarios de cero, uno y cinco días de desfase en las tres reglas de ordenamiento de pedidos (RMA, RALE, RME). Los resultados de los distintos escenarios se muestran en la Tabla1. Se aprecia que la regla RMA tiene la menor cantidad de residuo (tallos no asignados, disponibles para completar un subpedido), seguida por la regla RALE y con el mayor número de residuo quedaría la regla RME. Esto se debe a que la regla RMA les da prioridad a los pedidos más grandes (mayor número de tallos) mientras que la regla RME deja estos pedidos grandes al final con el resultado de un número mayor de tallos no asignados y a la vez un alto nivel de residuos (tallos de la oferta que no fueron asignados).

Este mismo patrón se cumple con las asignaciones con 5 días de desfase. Es decir, la regla RME tiene la mayor asignación de subpedidos y la regla RMA tiene la mayor asignación de tallos. Mientras que la regla RALE queda en segundo lugar, siempre bastante cercana a la regla ganadora. Es decir, en cantidad de subpedidos no asignados queda cerca a la regla RME y en cantidad de tallos asignados queda cerca a la regla RMA.

De acuerdo con los resultados presentados en los párrafos anteriores, la regla que logra un balance entre la satisfacción del cliente y la utilización de la capacidad de los proveedores es la regla RALE. Debido que a la hora de seleccionar los pedidos no tiene preferencia por los pedidos grandes o pequeños, los cuales tienen la misma probabilidad de ser elegidos. En la Tabla 1. Se muestran los subpedidos no asignados con un día de desfase, se cumple que la regla con el mayor número de subpedidos no asignados es RMA y la regla con el menor número de pedidos no asignados es RME. Sin embargo, es la regla RALE la que combina una menor cantidad de pedidos no asignados y un residuo mínimo. Condición deseada en el desarrollo del algoritmo.

Tabla 1. Numero de subpedidos no asignados y residuo en tallos para cada regla en 3 días de desfase diferentes.

DIAS DE DESFASE	REGLA	SUBPEDIDOS NO ASIGNADOS (Número)	RESIDUO (Tallos)
0	RMA	2.325	7.387.632
	RALE	2.325	7.387.632
	RME	2.325	7.387.632
1	RMA	5.566	53
	RALE	728	245
	RME	339	378.600
5	RMA	10.100	50
	RALE	1.979	185
	RME	136	209.172

4 Conclusiones

El método de asignación usado actualmente genera un 16% de productos disponibles no aprovechados para el cumplimiento de subpedidos. Situación poco favorable para los proveedores quienes buscan el mayor uso de sus productos y que estos retornen en ingresos monetarios para sus compañías. Se propone cambiar el método actual de asignación por un método propuesto que involucra una programación, un algoritmo y la capacidad de realizar centenares de cálculos en unos pocos minutos. El método propuesto permite que las medidas de desempeño puedan pronosticarse y ser definidas con antelación, buscando siempre el desempeño más adecuado en función de la relación recurso, proveedor, cliente. El método propuesto se automatizó en una herramienta que permite plantear escenarios que miden el impacto de la asignación (% de asignacion) y determina con anterioridad la cantidad de pedidos que se pueden cumplir (Pedidos asignados) y cuales no se logran cumplir (pedidos no asignados). Este punto a favor le da una capacidad de reacción al planeador en el proceso de decisión.

Resumen Con el objetivo de incrementar rendimientos metanogénicos en procesos de co-digestión anaerobia, se comparó el Potencial Bioquímico de Metano (PBM) de purín de cerdo y tres co-sustratos: macroalgas, plantas acuáticas, y restos de podas. Adicionalmente, para estimar parámetros cinéticos del bioproceso se implementó el Modelo de Remoción Biológica de Nutrientes N°2 (BNRM2). Los resultados de PBM indican que la macroalga *Spirogyra sp.* posee el mayor potencial para la generación de metano, produciendo 157,2 ± 66,1 $mlCH_4/gSV$, alrededor de tres veces más respecto a los otros co-sustratos. BNRM2 logró ajustar satisfactoriamente el comportamiento observado en las curvas de PBM, permitiendo identificar los parámetros más sensibles. Se concluye que la incorporación de macroalgas en bioprocesos de co-digestión anaerobia contribuye a potenciar la producción de metano. El empleo de BNRM2 en dichos bioprocesos puede servir tanto para estimar parámetros de difícil acceso empírico, como para predecir resultados empleando diversos co-sustratos.

Keywords: Sustentabilidad, Metano, Co-digestión anaerobia, Macroalgas, Modelado, BNRM2.

1. Introducción

En la última década, el crecimiento poblacional de la zona del Alto Valle de Río Negro y Neuquén ha ido acompañado de la intensificación de la producción ganadera, modificando el paisaje y la dinámica del entorno periurbano. La cercanía de los recintos productivos a los aglomerados urbanos exige a los productores la gestión de los residuos que la propia actividad genera, acorde a lo que establece la legislación argentina [15]. Un estudio reciente realizado en el corredor Plottier-Senillosa en la provincia de Neuquén, muestra que solo un 54 % de los productores realizan algún tipo de tratamiento con los residuos de sus animales, entre los que predomina el compostaje (58 %), amontona, junta o estaciona (26 %), solo esparce (11 %), quema (11 %) y amontona y riega (5 %). Entre los encuestados, un 36 % mostró interés por la producción de biogás [5].

Si bien la mayoría de los productores cría dos o más especies de animales, en este estudio nos centramos en dar una solución a la gestión y aprovechamiento de residuos porcinos, tal como el purín de cerdo.

La actividad porcina se relaciona estrechamente con la generación de gases de efecto invernadero. Los niveles de producción de dióxido de carbono (CO_2), metano (CH_4) y óxido nitroso (N_2O) dependen principalmente de las condiciones de cría, de la dieta y del tratamiento y gestión de las excretas. Las emisiones de CO_2 provienen de la exhalación de los cerdos y de la liberación de excretas, el CH_4 se genera en la degradación anaeróbica de la materia orgánica en el tracto digestivo y en las excretas, y el N_20 se genera solo a partir de las excretas, por un proceso incompleto de nitrificación/desnitrificación en la transformación de NH_3 a N_2 [12].Es decir, que un correcto tratamiento a las excretas podría reducir las emisiones de los tres gases de efecto invernadero mencionados. En tal sentido, el tratamiento vía Digestión Anaeróbica (DA) del purín de cerdo presenta importantes ventajas medioambientales, tales como la mitigación de emisiones de CH_4, mediante su acumulación y aprovechamiento energético, reducción de olores, y el aprovechamiento del N a través del uso del digerido como fertilizante orgánico [11]. Dado el moderado potencial metanogénico del purín, la incorporación de sustratos en co-digestión representa una alternativa viable si se desea hacer aprovechamiento energético a la vez que se tratan las excretas. Dada la presencia natural de macroalgas en el Río Limay (Neuquén) y sus alrededores, se consideró el empleo de las mismas como co-sustratos para procesos de DA de purines de cerdo. Diversos estudios han puesto en evidencia el incremento de la producción de metano al utilizar algas como co-sustratos. Por ejemplo, se evaluó una mezcla de algas azules (*Microcystis, Cyclotella, Cryptomonas y Scenedesmus*) como co-sustratos, obteniendo un rendimiento máximo de producción de metano equivalente a 212,7mL/gSV a 35°C [10]. También se llevó a cabo un estudio en donde se utilizó una muestra de *Scenedesmus sp.* como co-sustrato en la co-digestión anaerobia con purín de cerdo, registrando un valor máximo de metano producido de 245mL/gSV a 37°C [2].

Entre los estudios que involucran digestión anaeróbica, es ampliamente utilizado el Modelo de Digestión Anaerobia Nº 1 (ADM1) para representar la dinámica de los procesos que se corresponden con las etapas de degradación de la materia orgánica: hidrólisis, acidogénesis, acetogénesis y metanogénesis. Sin embargo, existen otros modelos, como el Modelo de Remoción Biológica de Nutrientes Nº 2 (BNRM2) [3] que, si bien ha sido mas bien utilizado para representar procesos de depuración de aguas residuales [14, 13] y poco explorado en el modelado de procesos de digestión anaeróbica, presenta algunas ventajas comparativas que resultan atractivas de explorar: considera la acidez en términos de pH, e incluye la actividad de bacterias sulfatorreductoras, lo cuál permite realizar un mejor ajuste en la estimación del rendimiento global de metano.

Los objetivos del presente trabajo incluyen mejorar el rendimiento de la producción de metano en procesos de DA de purines de cerdo, y conocer sus parámetros cinéticos para luego poder aplicarlos en una simulación que estime rendimientos metanogénicos y dinámicas de degradación de los componentes orgáni-

cos. Para ello se hará una comparación del Potencial Bioquímico de Metano (PBM) de tres co-sustratos en la DA de purines de cerdo: macroalgas, plantas acuaticas y restos de poda. Posteriormente se empleará el modelo BNRM2 sobre los resultados obtenidos de PBM, optimizando el ajuste entre resultados experimentales y teóricos, y tratando de identificar aquellos parámetros que tienen mayor influencia en la producción metanogénica.

2. Materiales y Métodos

2.1. Co-digestión anaeróbica de purines

Inóculo El inóculo se generó con el digerido de ensayos de digestión anaerobia llevados a cabo en biodigestores de escala de laboratorio. Se prepararon 4 litros de inóculo en un biorreactor de 6 litros de capacidad, a una temperatura de 35°C dentro de una cámara de cultivo. La alimentación consistió en el reemplazo de 400 ml de purín de cerdo (pH = [7.00-8.20]; Sólidos Totales (ST) = 10.5 % p/p; Sólidos Volátiles (SV) = 2.4 % p/p) cada una semana, o cuando la cantidad de biogás generada por el inóculo disminuyera por debajo de los 50 ml/día. Antes de utilizar el inóculo se lo caracterizó parcialmente según [1], llevando a cabo las siguientes determinaciones: pH = 7.13; conductividad (Λ) = 22.0 mS; Alcalinidad Total (AT) = 2607.1 ± 113 mgCaCO3 (n=2); Alcalinidad Parcial (AP) = 1850 ± 213 mg CaCO3 (n=2); ST = 10.2 ± 0.3 % p/p (n=3); SV = 2.0 ± 0.4 % p/p (n=3).

Sustrato y co-sustratos El sustrato empleado correspondió a purín de cerdo proveniente de un criadero de cerdo de pequeña escala, ubicado en la zona de chacras de la ciudad de Plaza Huincul, Neuquén. Se lo caracterizó mediante las siguientes determinaciones [1]: pH = 7.34; AT = 3005.0 ± 94 mgCaCO3 (n=2); AP = 2034.4 ± 56 mgCaCO3 (n=2); ST = 10.5 ± 0.2 %p/p (n=3); SV = 2.1 ± 0.3 %p/p (n=3). Se utilizaron los siguientes co-sustratos: *Spirogyra sp.* (macroalga verde filamentosa); una mezcla de *Azolla sp.* y *Salvinia sp.* (plantas acuáticas); y restos de poda de *Prunus armeniaca* (planta de damasco). Tanto la macroalga como las plantas acuáticas fueron recolectadas de las orillas del río Limay, a la altura de la ciudad de Neuquén, mientras que los restos de poda de la planta de damasco se recolectaron en una chacra de la ciudad de Plaza Huincul. Todos ellos fueron reducidos a trozos homogéneos mediante el empleo de un cutter. Al igual que ocurrió con el sustrato, a los co-sustratos se les determinó la cantidad de ST y SV; de esta manera se pudo conocer la cantidad inicial de SV en la mezcla de reacción, exhibida en Tabla 1. Los resultados de la determinación de ST fueron: macroalgas = 27.6 ± 0.4 %p/p (n=3); plantas acuáticas = 8.4 ± 1.2 %p/p (n=3); planta de damasco = 80.7 ± 7.3 %p/p (n=3).

Potencial Bioquímico de Metano (PBM) La determinación del PBM de las diferentes mezclas se llevó a cabo según los lineamientos de [7]. El dispositivo empleado como biorreactor fue un frasco de vidrio color caramelo de 150

ml de capacidad total, utilizando un volumen líquido final de 100 ml y un espacio de cabeza de 30 %. La tapa se adaptó para colocar una válvula de paso que se conectó a un sistema de recolección de biogás mediante una manguera de silicona. Dicho sistema consistió en un vaso de acrílico transparente graduado de 100 ml de capacidad, invertido en un recipiente con agua. La determinación de biogás se llevó a cabo por lectura directa del mismo. Para determinar el contenido de metano, el biogás fue extraído con una jeringa y se burbujeó en una solución de NaOH 1N. Luego de agitar durante 5 minutos, para favorecer la disolución del dióxido de carbono en dicha solución, se extrajo nuevamente con la jeringa y se registró el volumen. Posteriormente se llevó a cabo una confirmación cualitativa de la presencia de metano, iniciando una combustión controlada del metano registrado. El ensayo se llevó a cabo por triplicado, tanto para las mezclas sustrato/co-sustrato como para los blancos, respetando una relación inóculo/sustrato de 0.08 ± 0.01 (n=9) y un tiempo de incubación de 25 días. A cada biorreactor se le agregaron 90.0 ml de sustrato (purín), 9.0 ml de inóculo, 0.1 ml de solución de micro y macronutrientes [7], y los siguientes valores de cada co-sustrato según el caso de estudio: 5.5105 ± 0.049g de *Spirogyra sp.*; 2.0209 ± 0.0211g de *Pronus armeniaca*; 6.4710 ± 0.0578g *Salvinia sp.* y *Azolla sp.* Se registraron los valores iniciales en la mezcla de reacción, compuesta por inóculo, sustrato y co-sustrato (Tabla 1). El blanco consistió la misma mezcla de reacción, sin co-sustrato, donde la totalidad de los SV fueron aportados por el purín.

Tabla 1. Características fisicoquímicas de las mezclas de reacción y blanco

Cosustrato	pH	Λ (mS)	SV iniciales (%p/p)
Macroalgas	7.84 ± 0.02 (n=3)	11.20 ± 0.04 (n=3)	1.95 ± 0.00 (n=3)
Planta de damasco	7.46 ± 0.04 (n=3)	8.78 ± 0.37 (n=3)	3.05 ± 0.01 (n=3)
Plantas acuáticas	7.62 ± 0.12 (n=3)	9.68 ± 1.46 (n=3)	2.18 ± 0.00 (n=3)
Blanco	7.67 ± 0.04 (n=2)	8.93 ± 0.37 (n=2)	1.84 ± 0.01 (n=2)

2.2. Modelado Mediante BNRM2

El modelo BNRM2 considera los principales procesos físicos, químicos y biológicos que pueden desarrollarse en una planta de tratamiento. En relación a los procesos anaeróbicos, este modelo describe la evolución de i) bacterias acidogénicas (X_{ACID}) responsables de fermentar la materia rápidamente biodegradable, ii) bacterias acetogénicas (X_{ACET}) las cuales transforman los ácidos grasos volátiles como propiónico en acético e hidrógeno, iii) arqueas metanogénicas acetotróficas (X_{MAC}) responsables de transformar el ácido acético en metano, iv) arqueas metanogénicas hidrogenotróficas (X_{H2}) responsables de transformar el hidrógeno en metano y v) sulfato reductoras (X_{SBR}) las cuales consumen ácidos grasos volátiles e hidrógeno empleando como aceptor final de electrones el ión sulfato. Este ión se encuentra naturalmente en las aguas, y puede alcanzar

concentraciones significativas en el digestor dado que el purín de cerdo se diluye con agua en el procedimiento de limpieza de las camas de los criaderos. Si el agua utilizada proviene de las napas subterráneas, los niveles de ión sulfato pueden ser significativos. La presencia de bacterias sulfato reductoras puede explicar la disminución del metano producido respecto al teórico (290 ml CH_4 /gr SV), por esta razón es importante tenerlas en cuenta. El proceso anaeróbico considerado por el modelo BNRM2, el cual se implementó en Scilab, consta de 12 ecuaciones diferenciales con 32 parámetros. Se consideró que los parámetros más sensibles (aquellos cuya modificación producen una gran variación en la respuesta del modelo) están asociados a las velocidades de crecimiento específicas y las velocidades de lisis de las bacterias y arqueas (μ y b, respectivamente), la constante de hidrólisis de la materia lentamente biodegradable (K_H) y la constante de afinidad a la materia orgánica en el proceso de hidrólisis (K_X). Los valores de los parámetros más sensibles se identificaron por minimización de la suma del cuadrado del error entre los datos experimentales y los estimados por el modelo del volumen de metano acumulado por gramo de sólido volátil obtenido a partir de las experiencias de PBM. Los valores de los restantes parámetros se tomaron de bibliografía [3, 9, 4]. Se consideró que el contenido de sólidos volátiles representa la materia orgánica lentamente biodegradable y que la concentración inicial de sulfato es 50 g S-SO_4/m^3.

3. Resultados y Discusión

3.1. Co-digestión anaeróbica de purines

El PBM para *Spirogyra sp.* en la co-digestión anaeróbica con purines de cerdo mostró 157.2 $\pm$ 66.1 ml CH_4/g SV, triplicando la producción respecto a la digestión de purines con *Prounus armeniaca* (46.1 CH_4/g) y duplicandolá respecto a *Salvinia y Azolla* (70.7 CH_4/g SV). Cabe mencionar que la producción de metano del purín como monosustrato (blanco) fue de 33 ml CH_4/g SV, corroborando que el agregado de co-sustrato mejora el PBM en todos los casos. Los resultados obtenidos sugieren que independientemente del contenido de SV, la matriz interna del co-sustrato condiciona el acceso del consorcio microbiano para su reconversión energética en metano (Fig. 1). Las características bioquímicas de la macroalga, especialmente el contenido de hidratos de carbono, la convierten en un sustrato apropiado para su conversión a biogás [7].

3.2. Implementación del modelo BNRM2

En la Figura 1 se aprecia que el modelo permite ajustar en forma adecuada los datos experimentales de PBM obtenidos tanto para el blanco como para las experiencias de co-digestión.

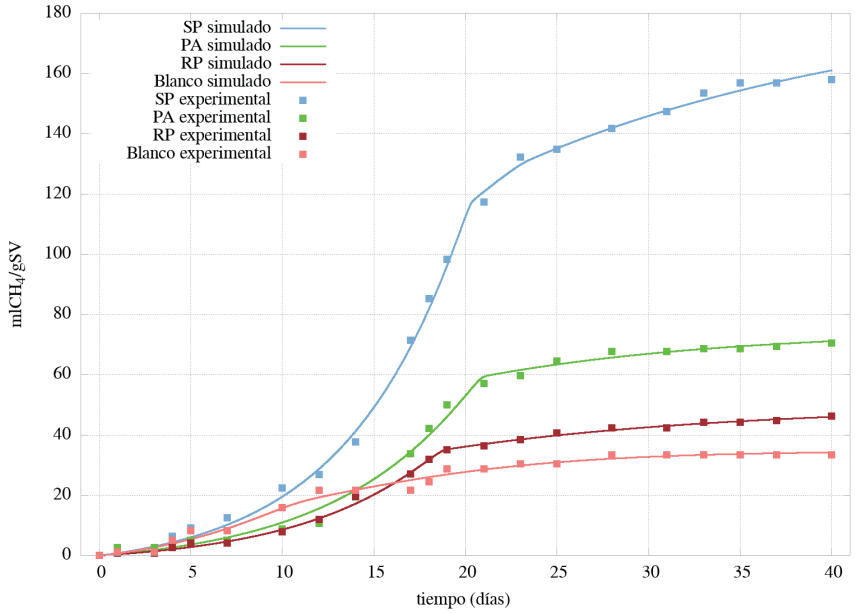

Fig. 1. Datos de PBM experimentales (■) y estimados con el modelo BNRM2 (-) para *Spirogyra sp.* (SP), Plantas Acuáticas (PA), Restos de Poda (RP) y Blanco

Por otro lado, en la Tabla 2 se puede observar que al incorporar un co-sustrato se produce un aumento significativo de la velocidad de hidrólisis de la materia orgánica lentamente biodegradable, lo cual se traduce en un aumento de K_H. Además, se aprecia un aumento en la K_X, o constante de afinidad, indicando que las bacterias acidogénicas son más eficientes para hidrolizar materia orgánica cuando la relación X_S/X_{ACID}, es superior, siendo X_S la materia orgánica lentamente biodegradable. Esto indica una mejora en la eficiencia de hidrólisis a mayores concentraciones de materia orgánica. La velocidad de crecimiento específica de las bacterias acidogénicas disminuye ligeramente en presencia de un co-sustrato, sin embargo, si el co-sustrato es la macroalga *Spirogyra sp.*, aumenta significativamente la velocidad de crecimiento de las acetogénicas. No se observa una variación significativa en los parámetros obtenidos para las arqueas metanogénicas. La materia lentamente biodegradable, puede clasificarse en rápida o lentamente hidrolizable [8, 6]. En base a los resultados obtenidos, el co-sustrato añadido presenta diferentes características de hidrólisis, siendo la macroalga la más fácilmente hidrolizable, de acuerdo a los valores obtenidos de K_H. El ajuste de los valores de los parámetros se llevó a cabo en base a minimizar la suma del cuadrado del error entre los datos experimentales de metano acumulado y los estimados por el modelo. Una mejora sustancial a la optimización se podría

lograr incluyendo en la función de costo los datos de pH, la concentración de ácidos grasos volátiles y de sulfuro de hidrógeno.

Tabla 2. Valores identificados de los parámetros del modelo BNRM2

	Unidad	Blanco	Restos de poda	Plantas Acuáticas	*Spirogyra sp.*
K_h	1/d	4.16	12.92	18.50	21.11
K_x	gDQO/gDQO	149.93	197.67	211.10	268.71
μ_{ACID}	1/d	7.56	2.56	3.53	4.28
b_{ACID}	1/d	0.65	0.14	0.17	0.07
μ_{ACE}	1/d	0.03	0.03	0.05	0.47
b_{ACE}	1/d	0.03	0.03	0.06	0.003
μ_{MAC}	1/d	0.21	0.15	0.14	0.18
b_{MAC}	1/d	0.05	0.003	0.003	0.02
μ_{H2}	1/d	0.05	0.03	0.003	0.04
b_{H2}	1/d	0.10	0.01	0.01	0.06
μ_{SBR}	1/d	0.08	0.32	0.03	1.28
b_{SBR}	1/d	0.002	0.002	0.002	0.001

4. Conclusiones

La producción de metano en procesos de co-digestión anaerobia de purines de cerdo puede incrementarse de manera sustancial con el agregado de diversos co-sustratos. Particularmente *Spirogyra sp.* logró incrementar hasta tres veces la producción de metano respecto a la DA de purín con restos de poda de árbol de damasco, y duplicarla respecto a la mezcla de plantas acuáticas.

Resulta de particular interés haber demostrado que el modelo implementado, BNRM2, describe en forma adecuada la evolución del metano producido en los estudios de PBM. El uso de dicha herramienta permite complementar el desarrollo experimental, posibilitando profundizar en el conocimiento de cada proceso estudiado.

Finalmente, y considerando que tanto los purines de cerdo, como los co-sustratos evaluados, pueden encontrarse en las cercanías de la ciudad de Neuquén, se podría llevar a cabo la gestión de los efluentes porcinos mediante un proceso de co-digestion anaerobia, logrando no solo la producción eficiente de metano, si no que también un tratamiento integral del sustrato y co-sustratos, con posibilidad de un reuso de estos nuevos efluentes. Considerando las ventajas de incorporar *Spirogyra sp.* en los procesos de DA, es factible evaluar la conveniencia de desarrollar cultivos de macroalgas con fines energéticos, en cuyo caso la contribución a la reducción de la huella de carbono y mitigación de los GEI por el tratamiento del purín, se vería incrementada por los procesos de captura de CO_2 de las macroalgas durante su ciclo de vida. De esta manera, se plantea a la co-digestión anaerobia como un proceso sustentable y en armonía con el medio ambiente.

Abstract. Forest planning, based on mathematical optimization, makes it possible to model the complexity of a forest system. In this work, two approaches to forest plantation planning were evaluated. Firstly, the aim was to regulate produc-tion and, secondly, to maximise economic benefit. The models proposed give sat-isfactory results and allow different forest management scenarios to be explored efficiently.

Keywords: Strategic planning, Linear programming, Forest Management.

1 Introducción

En el sector forestal, la planificación estratégica de la producción es de gran importancia ya que busca regular la producción y aumentar los ingresos del bosque a fin de garantizar la competitividad [1]. La multidimensionalidad del sistema hace que este proceso sea complejo y el auxilio de modelos matemático algo necesario [2]. La programación lineal es una herramienta robusta para resolver este tipo de problemas. Los primeros modelos aplicados a las ciencias forestales se produjeron en los 60, de la mano de [3], [4] y [5]. Sin embargo, el enfoque de [6] define las bases de la planificación estratégica con el denominado Modelos Tipo I y II. En este trabajo se desarrolló un modelo de planificación forestal, basado en el Modelo Tipo I de [6], con el objeto de evaluar dos escenarios de producción, minimizar la fluctuación de la producción interanual y maximizar el valor actual neto (VAN).

2 Materiales y Métodos

El área de estudio consta de rodales de *Pinus taeda* (Pt), *Pinus elliottii var. elliottii x Pinus caribaea var. hondurensis* (Ph) y *Araucaria angustifolia* (Aa) pertenecientes a un patrimonio forestal ubicado en el norte de la provincia de Misiones. El escenario corresponde a un total de 162 rodales representando una superficie de 3.056 ha, con un rango etario de 1 hasta 36 años de edad.

El patrimonio cuenta con un esquema de manejo forestal típico, que se resume en la Tabla 1. Dentro de las actividades de manejo, se consideraron los siguientes costos: Plantación lograda: 951,51 USD/ha; Poda 1: 114,59 USD/ha; Poda 2: 117,1 USD/ha; Poda 3: 147,82 USD/ha; gastos administrativos: 50 USD/ha/año [7].

Tabla 1. Esquemas de manejo tradicional para las tres especies cultivadas.

Especie	Intervención	Intensidad (%)	Edad (años)
Araucaria angustifolia - Densidad Inicial 2.222 p/ha - 3 podas	1° raleo	50	8
	2° raleo	40	11
	3° raleo	40	15
	4° raleo	40	20
	Tala rasa	100	25
Pinus taeda - Densidad Inicial 1.667 p/ha - 2 podas	1° raleo	55	6
	2° raleo	40	9
	3° raleo	40	13
	Tala rasa	100	18
Pino híbrido - Densidad Inicial 1.333 p/ha - 2 podas	1° raleo	50	7
	2° raleo	40	10
	3° raleo	40	14
	Tala rasa	100	18

El esquema de manejo actual presenta una estructura rígida que no permite un adecuado balance de producción. Además, la empresa define, como nueva política, reemplazar rodales de Aa y Pt por pino hibrido (Ph), ya que este permite obtener aptitudes estructurales iguales o superiores con sus productos y remanufacturas.

Tabla 2. Productos forestales valorados en pie.

Producto (DPF en cm)	Longitud (ft)	Precio (USD/t)
Pt35a99	14	13,88
Pt29a35	14	8,23
Pt25a29	14	3,70
Pt18a25	10	2,37
Pt14a18	10	1,99
PtPul	8	1,21
Ph35a99	14	13,88
Ph29a35	14	8,23
Ph25a29	14	3,70
Ph18a25	10	2,37
Ph14a18	10	1,99
PhPul	8	1,21
Aa35a99	14	36,30
Aa29a35	14	20,68
Aa25a29	14	20,68

Aa18a25	10	9,33
Aa14a18	10	5,66
AaPul	8	1,21

La producción del patrimonio clasificada según sus diámetros en punta fina (DPF) se detalla en la Tabla 2, acompañada de sus valores en pie, calculados a partir de los precios puestos en la industria, menos costos promedio de raleos, cosecha y flete [7].

En la actualidad, la empresa realiza el proceso de planificación de forma empírica, con planilla de cálculo. A partir de la situación se plantea un modelo matemático de optimización y se evalúan dos funciones objetivo (F1 y F2) del mismo modo que [8]. Mediante F1 (1) se busca maximizar el VAN y con F2 (2) se pretende estabilizar la producción global del bosque. Estos modelos se evalúan en 5 escenarios, con un horizonte de planificación (PH) de 50 años, en los que se flexibiliza la edad de tala rasa (ETR), partiendo desde la edad de corta actual (escenario testigo), ± 1 (3 opciones de ETR) y ± 2 años (5 opciones de ETR). En cada uno se reemplaza con la implantación de Ph a los rodales de Aa y Pt al momento de su tala rasa. Además, para el cálculo de la rentabilidad, se utiliza una tasa de actualización del 10 %.

$$MaxVAN = \sum_{i=1}^{M} \sum_{j=1}^{N} VAN_{ij} \times X_{ij} \,; \forall k \tag{1}$$

$$MinDIF = Min(MinMax - MaxMin) \tag{2}$$

Inevitablemente, una función objetivo está ligada a un conjunto de restricciones. La restricción básica (3) se utilizó para indicar la disponibilidad del área máxima de cada rodal y para asegurar que la suma del área de un mismo rodal sea igual a su total, bajo diferentes alternativas de manejo, en ambas FO.

$$\sum_{j=1}^{N} X_{ij} \leq A_i; \forall i \tag{3}$$

Además de esta restricción, la F2 requiere de las restricciones (4) y (5), a fin de minimizar la diferencia entre la producción anual máxima y mínima de madera.

$$\sum_{i=1}^{M} \sum_{j=1}^{N} (VOL_{ijt} X_{ij}) \leq MinMax; \forall t \tag{4}$$

$$\sum_{i=1}^{M} \sum_{j=1}^{N} \left(VOL_{ijt} X_{ij}\right) \geq MaxMin; \forall t \tag{5}$$

Donde *PH* es el horizonte de planificación; VAN_{ij} es el valor actual neto (USD) de la i-ésima posición después de la j-ésima alternativa de gestión; VOL_{ijt} es el volumen (m3) producido en el puesto i-ésimo siguiendo la alternativa de gestión j-ésimo en el período t; *MinMax* es el volumen más bajo de la producción máxima posible en PH; *MaxMin* es el volumen más alto de la producción mínima posible en PH; X_{ij} es la fracción de área (ha) de la posición i-ésima siguiendo la alternativa de gestión j-ésima; A_i es el área total (ha) de la posición i-ésima al comienzo del PH; *M* es el número total de rodales; *N* es el número total de alternativas de gestión de i-ésimo rodal.

El software utilizado para realizar la planificación optimizada es Optimber-LP, desarrollado por la empresa brasileña Optimber Otimização e Informática Ltda. Ésta es una herramienta de planificación forestal estratégica con restricciones tácticas. Esta, a su vez, hace uso del software SIS Pinus, desarrollado por la Empresa Brasileira de Pesquisa Agropecuária (EMBRAPA), para la proyección del crecimiento de la masa forestal; y de LINGO, software desarrollado por Lindo Systems Inc., para la resolución del modelo mediante programación lineal. Los datos requeridos para modelar el patrimonio mediante Optimber-LP son: rodal, especie, edad, índice de sitio, superficie, año de plantación, densidad inicial, área basal, altura de poda y número de raleos. Estos fueron obtenidos por la empresa mediante inventarios forestales con fines comerciales. La implementación se llevó a cabo en un computador con Intel Core i5-2310M, CPU@ 2.10 GHz, 8 GB de RAM y SO de 64 bit.

3 Resultados

En la Fig. 1 se pueden ver los resultados de volumen obtenidos para cada uno de los 50 años de PH de cada uno de los productos detallados en la Tabla 2, en base al manejo actual del patrimonio (escenario testigo), es decir, sin flexibilizar la ETR, En este caso se observa una importante oscilación en la producción de rollos, entre 60.000 y 200.000 m^3/año. El principal problema de este manejo radica en la inestabilidad de su producción.

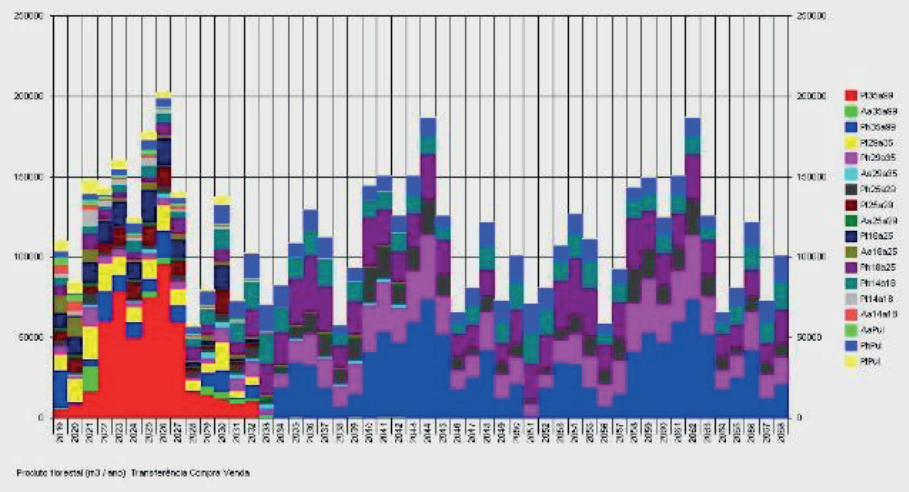

Fig. 1. Volúmenes globales del escenario testigo.

En Fig. 2 se observa que la variación volumétrica se encuentra entre 30.000 y 235.000 m3/año. Por su parte, en la Fig. 3, se observa una mayor variación volumétrica que se encuentra entre los 30.000 y los 300.000 m3/año. Esto se debe a que la F1 busca obtener el mayor rendimiento económico, sin importar la oscilación de su producción.

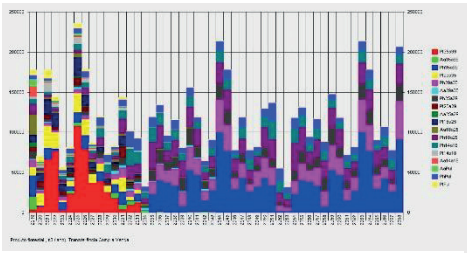

Fig. 2. Comportamiento del volumen aplicando modelo con F1 ± 1.

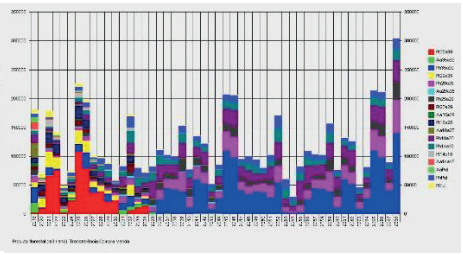

Fig. 3. Comportamiento del volumen aplicando modelo con F1 ± 2.

Por otro lado, la F2 busca estabilizar la producción, esto es, minimizar su variación interanual. Este resultado se aprecia en la Fig. 4, donde la producción de los primeros 10 años es de 135.000 m3/año, y de 105.000 m3/año en los siguientes años, con algunas oscilaciones que llegan a los 135.000 m3/año. También, en la Fig. 5, con una producción volumétrica de 125.000 m^3/año en los primeros 12 años, y 110.000 m3/año en los siguientes 38 años.

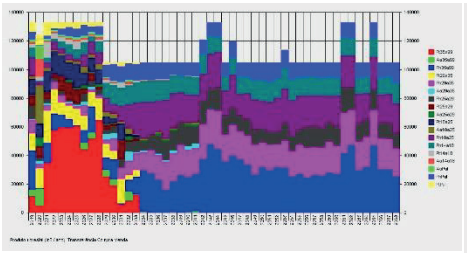

Fig. 4. Comportamiento del volumen aplicando modelo con F2 ± 1.

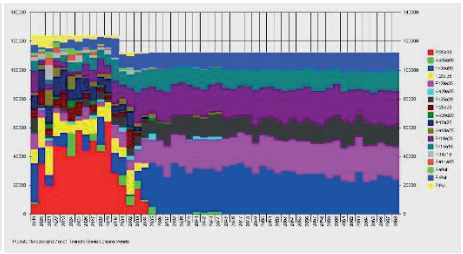

Fig. 5. Comportamiento del volumen aplicando modelo con F2 ± 2.

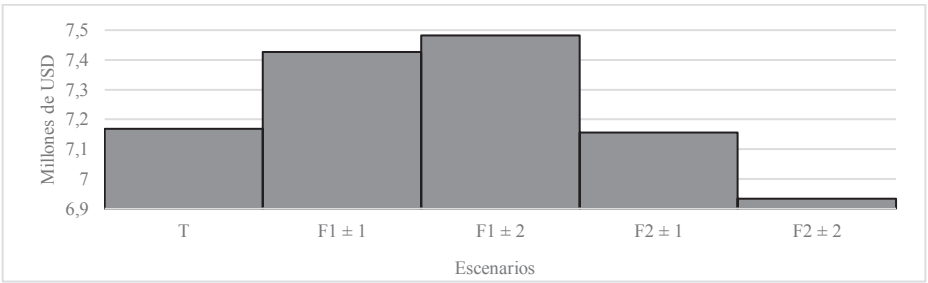

Fig. 6. VAN calculado por escenario.

Los rendimientos económicos de los escenarios simulados se presentan en el Fig. 6. El escenario T rindió 7,17 millones de USD. El escenario F1 ± 1 obtuvo un incremento del 3,5 %. A su vez, el escenario F2 ± 2 fue 4,2 % superior. Por otro lado, los escenarios F2 fueron 0,2 y 3,4 % inferiores a T para ± 1 y ± 2 respectivamente. Resultados lógicos teniendo en cuenta nuevamente el funcionamiento de las FO.

4 Conclusiones

La flexibilización de la ETR conlleva a una mayor estabilidad de la producción, principalmente cuando se utiliza F2; pero además a un mayor rendimiento económico en las simulaciones de F1. La utilización de una u otra dependerá del objetivo global de la organización. Respecto a la rentabilidad, los resultados de F2 fueron expuestos para determinar el costo de estabilizar la producción interanual y, en consecuencia, ordenar el bosque. Posiblemente, esta situación desencadene en una reducción significativa principalmente en los costos fijos operativos si se utilizara un esquema de costos más detallado. Por otro lado, es coherente encontrar mayores rendimientos económicos en la F1, donde el modelo apunta a turnos de corta más largos logrando con esto reducir la superficie afectada a actividades silvícolas, resultando por consecuencia en menores costos y mayores ingresos con productos de diámetros mayores, con mayor relación precio-volumen.

Abstract. In the forest supply chain, decisions related to bucking (cross sectional cuts) and distribution (vehicle routing) activities are usually considered separately and in different planning horizons. This separation between closely related problems gives rise to suboptimal solutions that, if they are simultaneously considered, could bring significant benefits. A tight coordination between the type and amount of material to be harvested and the actually material required to satisfy the daily demand would allow improvements in the efficiency of the production system (both in the forest and in the plant) and significant cost savings. To address this problem, in this work, a mixed integer linear programming (MILP) model that simultaneously considers both decisions is presented. Through a case study, the performance of the developed model is analyzed and the respective conclusions are detailed.

Keywords: Forest Industry, Bucking, Vehicle Routing, MILP.

1 Introduction

Forest supply chain management integrates different operations, such as harvesting, distribution, production, inventory management, among others, which are generally addressed in different planning horizons ([1], [2], [3]). In a context where decisions are made considering one activity, a negative impact can be obtained on another; therefore, it is essential to improve the efficiency of all operations as a whole. A tight coordination between the type and amount of material to be harvested and the actually material required to fulfill the daily demand will allow improvements in the efficiency of the production system and significant cost savings.

In the existing literature, harvesting and transportation problems are often treated with a decoupled approach. In general, harvesting decisions are first addressed in a tactical planning horizon and later, assuming a certain supply from each harvest area to each plant, transportation is organized ([4], [5]). There are situations where, during harvesting, transportation is considered as an additional cost (or a capacity constraint), without detailing how many vehicles will be required for transportation or how distribution will take place ([6], [7], [8]). Although most of these models are

developed for a tactical planning horizon, in daily operations it is generally unknown the effective availability of raw materials in the forests in that period.

The effective availability of raw material is determined through the bucking activity. This activity consists of the transverse cutting of a stem to produce logs of a certain length and diameter, and it can be performed at the destination of the wood (plant or temporary storage sector) or directly in the forest when the stem is harvested. The associated transport activities will then depend on the raw material being transported, stems or smaller logs. The first case is the simplest to address, where it is enough to determine the destination of the harvested stem, while the second case is more complex since transport decisions must necessarily consider aspects related to the load of each truck (logs of the same length must be transported on the same trip, although not necessarily the same diameter). The second approach is addressed in this work.

In this work, a mixed integer linear programming (MILP) model that considers both harvesting and transportation/distribution decisions is proposed. More precisely, it is determined for a weekly planning horizon: the working periods for the harvesting crews, the bucking patterns to be used in each harvest area and the number of logs of a given length and diameter to be obtained, decisions related to log storage in both harvest areas and plants, the truck fleet required to perform the distribution, the routes to be followed by each truck, as well as the composition of the load of each truck (i.e., length of logs to be transported on each trip and the total transported weight). To the best of our knowledge, this is the first time that transportation/distribution decisions and bucking decisions are jointly addressed.

In the following section the problem statement is presented, while in section 3 the proposed MILP model is detailed. In section 4 a case study to analyze the model performance is developed, and finally, in section 5 the final remarks are highlighted.

2 Problem statement

The main assumptions that are taken into account to model the considered problem are described below.

It is considered a set of plants I whose raw material requirements must be covered. It is assumed that at a higher level of planning (that is, annual harvesting planning) the set of harvest areas F to be exploited during the planning period T considered has already been defined.

2.1 Problem characteristics related to harvesting activities

The initial number of standing stems (trees) in each open harvest area f, $f \in F$, $qini_f$, is assumed to be known. In turn, the stems that belong to the same harvest area have identical characteristics (planted forest). It should be noted that the harvesting activities considered in this work are those related to stumpage: thinning activities are not included.

At the end of the planning horizon, there is a desired goal of standing stems in the harvest areas, $qend_f$, which depends on the objectives of the company; in other words, the target level for the harvesting activity at the end of the planning horizon.

The harvesting capacity in a certain period is given by the average productivity of the harvesting crews assigned to that area (previously determined in the annual harvesting planning), that is, the minimum and maximum number of stems that can be harvested in a period ($qcsmin_f$ and $qcsmax_f$, respectively) depends on the number harvesting crews assigned to that harvest area. The cost associated with harvesting crew is not considered because it is included in the annual harvest planning and does not depend on the decisions made in this formulation.

For each harvest area f, there is a set of applicable bucking patterns b, $b \in B$, which was previously determined. Each bucking pattern b is characterized by parameters $nu_{l,d,b}$, that correspond to the number of obtained logs of diameter d and length l when bucking pattern b is applied. Also, the level of losses generated when bucking pattern b is applied, $loss_b$, is considered, and it includes both stem fine tip (i.e. wood not suitable for use) and losses due to the taper of the log (see Fig. 1). These losses have an associated cost per ton of unused wood, $closs_b$.

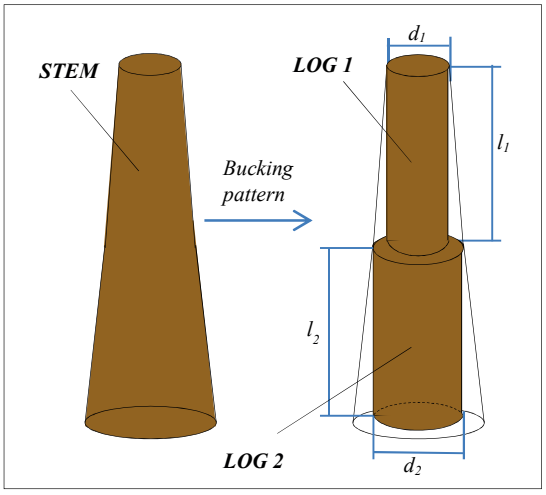

Fig. 1. Useful wood after applying bucking pattern. d: useful diameter, l: length.

Furthermore, it is assumed that if a bucking pattern is applied in a certain harvest area then it must be used at least a minimum number of times, $qminb_b$, in order to avoid setup times and costs. The types of logs that can be obtained by applying the bucking patterns are classified by length l, $l \in L$, and useful diameter d, $d \in D$.

Logs generated in a harvest area can remain on the roadside throughout the planning period without losing quality, in other words, there is no deterioration of the raw material during the planning horizon. However, logs generated in the harvest area f and not distributed at the end of the planning horizon are considered wasted material with an associated cost, $cqrl_{l,d,f}$.

2.2 Problem characteristics related to production activities

Each plant has associated a weekly demand for logs (by length and by diameter), $dtot_{l,d,i}$, which can be covered during any period of the planning horizon, as long as the maximum processing capacity in each plant is respected, $cap_{i,t}$. However, there is a minimum demand for logs of a certain length and diameter that must be satisfied in each period, $dmin_{l,d,i,t}$. This demand is related to the production commitments assumed by the plants. The minimum processing capacity of plants per period is closely related to the minimum demand for logs.

Each plant has a storage yard for logs. Each type of log has an assigned sector in the storage yard, with maximum capacity $maxstock_{l,d,i}$. Each log stored at the end of the planning horizon has an associated cost $cstock_{l,d,i}$ because they may not be required in the future and lose quality, or on the contrary, be used for the elaboration of products for which they were not intended, affecting the productivity levels of the plant. At the beginning of the planning horizon there is an initial inventory of logs available from previous planning periods, $stockini_{l,d,i}$.

2.3 Problem characteristics related to distribution activities

Regarding the distribution of the logs generated in the harvest areas, there is a heterogeneous truck fleet C to perform this activity. Each truck has a minimum and maximum load capacity ($capmin_c$ and $capmax_c$, respectively), therefore the quantity of logs to be transported will be limited by their corresponding weight, $weight_{l,d}$.

Each truck has a limited working day ($maxt_{c,t}$) and a maximum number of trips v, $v \in V$ to be completed in each period t. Each segment of the road network admits an average travel speed, which depends on whether the truck is loaded or unloaded. In turn, each truck has a stipulated loading and unloading time ($load_{c,f}$ and $unload_{c,i}$, respectively). Regarding the composition of the load, each truck can only transport logs of the same length per trip, allowing logs of different diameters to be loaded at the same time. Each truck is located at a regional base p, $p \in P$, from where its route begins and where it must end after completing all trips. The composition of routes presented in Bordón et al. (2018) [9] is considered in this work, where basically a route is made up of different types of movements.

The fixed cost for using a truck in a certain period is given by $ctruck_{c,p}$. The company cost policy considers a fixed cost (base) per use of trucks per period and a variable cost per kilometer traveled loaded and unloaded.

2.4 Optimization variables

The variables considered in this work are the following:

- The number of harvested stems and the number of stems left standing in each harvest area in each period, $Q^{CS}_{f,t}$ and $Q^{SS}_{f,t}$, respectively.
- The bucking patterns selection and the number of times they are used in each harvest area and in each period, $Y^{BP}_{b,f,t}$ and $Q^{BP}_{b,f,t}$, respectively.

- The number of generated logs of each type (length-diameter combination), per period, in each harvest area, $Q^{CL}_{l,d,f,t}$.
- The number of transported logs of each type, per period, from each harvest area to each plant, $Q^{TL}_{l,d,f,t}$.
- The inventory levels of logs of each type, per period, on the roadside in harvest areas, $Q^{RL}_{l,d,f,t}$.
- The number of processed logs of each type (above the minimum demand) in each plant in each period, $Q^{PL}_{l,d,i,t}$.
- The inventory levels of logs of each type, per period, in the storage yard of each plant, $Q^{SL}_{l,d,i,t}$.
- The truck selection in each period, $Y^{T}_{c,p,t}$.
- The type of loaded logs in each trip of each truck and the number of transported logs (of the same length but not necessarily the same diameter) on each trip of each truck from each harvest area to each plant in each period, $Y^{TT}_{l,c,v,f,i,t}$ and $Q^{TT}_{l,d,c,v,f,i,t}$, respectively.
- The route to be performed by each truck in each period, that is, its initial, loaded, unloaded and return movements, ($X^{D}_{c,p,f,t}$, $X^{L}_{c,v,f,i,t}$, $X^{U}_{c,v,i,f,t}$ and $X^{R}_{c,v,i,p,t}$, respectively).

The decisions listed above must be made seeking the minimization of the total costs (Z) related to harvesting and transport activities, guaranteeing the fulfillment of the demand of the plants and satisfying all the operative restrictions.

3 Mathematical model

The proposed MILP model is the following:

$$\min Z = CV^{Transp} + CF^{Transp} + CV^{Loss} + CV^{Stock} + CV^{Logs} \tag{1}$$

where,

$$CV^{Transp} = \sum_c \sum_{p \in PC_{p,c}} \sum_f \sum_t dpf_{p,f} cd_{p,f} X^{D}_{c,p,f,t} +$$
$$\sum_c \sum_v \sum_f \sum_i \sum_t dfi_{f,i} cl_{f,i} X^{L}_{c,v,f,i,t} +$$
$$\sum_c \sum_v \sum_i \sum_f \sum_t dif_{i,f} cu_{i,f} X^{U}_{c,v,i,f,t} +$$
$$\sum_c \sum_{p \in PC_{p,c}} \sum_v \sum_i \sum_t dip_{i,p} cr_{i,p} X^{R}_{c,v,i,p,t} \tag{2}$$

$$CF^{Transp} = \sum_c \sum_{p \in PC_{p,c}} \sum_t ctruck_{c,p} Y^{T}_{c,p,t} \tag{3}$$

$$CV^{Loss} = \sum_b \sum_{f \in BF_{b,f}} \sum_t closs_b loss_b Q^{BP}_{b,f,t} \tag{4}$$

$$CV^{Stock} = \sum_l \sum_d \sum_i cstock_{l,d,i} Q^{SL}_{l,d,i,t=|T|} \tag{5}$$

$$CV^{Logs} = \sum_l \sum_d \sum_f cqrl_{l,d,f} Q^{RL}_{l,d,f,t=|T|} \quad (6)$$

The objective function is given by the minimization of (1), where: (2) establishes the variable cost per traveled kilometer, (3) represents the fixed costs per use of trucks, (4) defines the cost for raw material loss when applying a certain bucking pattern, (5) sets the cost of keeping logs in plant storage yards at the end of the planning horizon, and (6) establishes the cost of not transported logs which remain on the roadside in the harvest areas at the end of the planning horizon.

The restrictions associated with the problem are the following:

$$qini_f = Q^{CS}_{f,t} + Q^{SS}_{f,t} \quad \forall f \in F, t = 1 \quad (7)$$

$$Q^{SS}_{f,t-1} = Q^{CS}_{f,t} + Q^{SS}_{f,t} \quad \forall f \in F, t > 1 \quad (8)$$

$$Q^{SS}_{f,t} \leq qend_t \quad \forall f \in F, t = |T| \quad (9)$$

$$Q^{CS}_{f,t} \geq qcsmin_f CUT_{f,t} \quad \forall f \in F, \forall t \in T \quad (10)$$

$$Q^{CS}_{f,t} \leq qcsmax_f CUT_{f,t} \quad \forall f \in F, \forall t \in T \quad (11)$$

$$Q^{CS}_{f,t} = \sum_{b \in BF_{b,f}} Q^{BP}_{b,f,t} \quad \forall f \in F, \forall t \in T \quad (12)$$

$$\sum_{b \in BF_{b,f}} nu_{l,d,b} Q^{BP}_{b,f,t} = Q^{CL}_{l,d,f,t} \quad \forall l \in L, \forall d \in D, \forall f \in F, \forall t \in T \quad (13)$$

$$Q^{BP}_{b,f,t} \geq qminb_b Y^{BP}_{b,f,t} \quad \forall (b,f) \in BF_{b,f}, \forall t \in T \quad (14)$$

$$Q^{BP}_{b,f,t} \leq qcsmax_f Y^{BP}_{b,f,t} \quad \forall (b,f) \in BF_{b,f}, \forall t \in T \quad (15)$$

$$Y^{BP}_{b,f,t} \leq CUT_{f,t} \quad \forall (b,f) \in BF_{b,f}, \forall t \in T \quad (16)$$

$$CUT_{f,t} \leq \sum_{b \in BF_{b,f}} Y^{BP}_{b,f,t} \quad \forall f \in F, \forall t \in T \quad (17)$$

$$CUT_{f,t} \leq CUT_{f,t+1} - CUT_{f,k} + 1 \quad \forall f \in F, \forall t \in T, k \geq t+2 \quad (18)$$

$$Q^{TL}_{l,d,f,t} + Q^{RL}_{l,d,f,t} = Q^{CL}_{l,d,f,t} \quad \forall l \in L, \forall d \in D, \forall f \in F, t = 1 \quad (19)$$

$$Q^{TL}_{l,d,f,t} + Q^{RL}_{l,d,f,t} = Q^{CL}_{l,d,f,t} + Q^{RL}_{l,d,f,t-1} \quad \forall l \in L, \forall d \in D, \forall f \in F, t > 1 \quad (20)$$

$$Q^{TL}_{l,d,f,t} = \sum_c \sum_v \sum_i Q^{TT}_{l,d,c,v,f,i,t} \quad \forall l \in L, \forall d \in D, \forall f \in F, \forall t \in T \quad (21)$$

$$Q^{TT}_{l,d,c,v,f,i,t} \leq qttup_{l,d,c,v,f,i,t} Y^{TT}_{l,c,v,f,i,t}$$
$$\forall l \in L, \forall d \in D, \forall c \in C, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (22)$$

$$\sum_l Y^{TT}_{l,c,v,f,i,t} = X^L_{c,v,f,i,t} \quad \forall c \in C, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (23)$$

$$\sum_l \sum_d weight_{l,d} Q^{TT}_{l,d,c,v,f,i,t} \geq capmin_c X^L_{c,v,f,i,t}$$

$$\forall c \in C, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (24)$$

$$\sum_l \sum_d weight_{l,d} Q^{TT}_{l,d,c,v,f,i,t} \leq capmax_c X^L_{c,v,f,i,t}$$

$$\forall c \in C, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (25)$$

$$\sum_c \sum_v \sum_f Q^{TT}_{l,d,c,v,f,i,t} + stockini_{l,d,i} = dmin_{l,d,i,t} + Q^{SL}_{l,d,i,t} + Q^{PL}_{l,d,i,t}$$

$$\forall l \in L, \forall d \in D, \forall i \in I, t = 1 \quad (26)$$

$$\sum_c \sum_v \sum_f Q^{TT}_{l,d,c,v,f,i,t} + Q^{SL}_{l,d,i,t-1} = dmin_{l,d,i,t} + Q^{SL}_{l,d,i,t} + Q^{PL}_{l,d,i,t}$$

$$\forall l \in L, \forall d \in D, \forall i \in I, t > 1 \quad (27)$$

$$Q^{SL}_{l,d,i,t} \leq maxstock_{l,d,i} \quad \forall l \in L, \forall d \in D, \forall i \in I, \forall t \in T \quad (28)$$

$$X^D_{c,p,f,t} = \sum_i X^L_{c,v,f,i,t} \quad \forall (c,p) \in PC_{p,c}, \forall f \in F, \forall t \in T, v = 1 \quad (33)$$

$$X^L_{c,v,f,i,t} \leq Y^T_{c,p,t} \quad \forall (c,p) \in PC_{p,c}, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (34)$$

$$X^U_{c,v,i,f,t} \leq Y^T_{c,p,t} \quad \forall (c,p) \in PC_{p,c}, \forall v \in V, \forall f \in F, \forall i \in I, \forall t \in T \quad (35)$$

$$Y^T_{c,p,t} \leq \sum_v \sum_f \sum_i X^L_{c,v,f,i,t} \quad \forall (c,p) \in PC_{p,c}, \forall t \in T \quad (36)$$

$$\sum_f X^U_{c,v,i,f,t} \leq \sum_f X^L_{c,v,f,i,t} \quad \forall c \in C, \forall v \in V, \forall i \in I, \forall t \in T \quad (37)$$

$$\sum_i X^U_{c,v-1,i,f,t} \leq \sum_i X^L_{c,v,f,i,t} \quad \forall c \in C, \forall f \in F, \forall t \in T, v > 1 \quad (38)$$

$$\sum_f X^L_{c,v,f,i,t} = \sum_f X^U_{c,v,i,f,t} + X^R_{c,v,i,p,t} \quad \forall (c,p) \in PC_{p,c}, \forall v \in V, \forall i \in I, \forall t \in T \quad (39)$$

$$\sum_f \left(\frac{dpf_{p,f}}{vd_{p,f}}\right) X^D_{c,p,f,t} + \sum_v \sum_f \sum_i \left(\frac{dfi_{f,i}}{vl_{f,i}}\right) X^L_{c,v,f,i,t} +$$

$$\sum_v \sum_i \sum_f \left(\frac{dif_{i,f}}{vu_{i,f}}\right) X^U_{c,v,i,f,t} + \sum_v \sum_i \left(\frac{dip_{i,p}}{vr_{i,p}}\right) X^R_{c,v,i,p,t} +$$

$$\sum_v \sum_f \sum_i \left(load_{c,f} + unload_{c,i}\right) X^L_{c,v,f,i,t} \leq maxt_{c,t} \quad \forall (c,p) \in PC_{p,c}, \forall t \in T \quad (40)$$

$$CUT_{f,t}, X^D_{c,p,f,t}, X^L_{c,v,f,i,t}, X^R_{c,v,i,p,t}, X^U_{c,v,i,f,t}, Y^{BP}_{b,f,t}, Y^T_{c,p,t}, Y^{TT}_{l,c,v,f,i,t} \in \{0,1\} \quad (41)$$

$$Q^{BP}_{b,f,t}, Q^{CL}_{l,d,f,t}, Q^{CS}_{f,t}, Q^{KT}_{c,t}, Q^{PL}_{l,d,i,t}, Q^{RL}_{l,d,f,t}, Q^{SL}_{l,d,i,t}, Q^{SS}_{f,t}, Q^{TL}_{l,d,f,t}, Q^{TT}_{l,d,c,v,f,i,t}, Z \geq 0 \quad (42)$$

Restrictions (7) and (8) establish the balance of stems in each harvest area in each period (the number of stems that are cut and left standing at the end of the period). Constraints (9) determine the maximum number of standing stems at the end of the planning horizon. Restrictions (10) and (11) establish the minimum and maximum quantities of stems to be cut, by period, where $CUT_{f,t}$ is the binary variable that indicates whether the harvesting crew is cutting stems in the harvest area or not. Constraints (12) state that the number of stems cut in a given harvest area is equal to the number of times all cutting patterns are applied. In Equations (13) the quantity of logs of each type that is generated by using the bucking patterns is determined. Constraints (14) and (15) determine the minimum and maximum number of times that the bucking patterns can be applied, respectively. Restrictions (16) and (17) establish that a bucking pattern must be used in a harvest area during a period if and only if a harvesting crew cuts stems in the harvest area during that period. Constraint (18) ensures that harvesting crew cuts in successive periods. Restrictions (19) and (20) establish the balance of logs in each harvest area in each period. Equation (21) states that the logs transported from a harvest area to the plants in a given period must match the number of logs loaded on trucks in the same period. Constraint (22) determines the maximum number of logs of a certain length that a truck can transport on a given trip, while constraints (23) state that only logs of the same length can be loaded in one trip at a time. Restrictions (24) and (25) establish that the load of a truck must satisfy the conditions of minimum and maximum load capacity, respectively. Constraints (26) and (27) set the inventory balances of logs of each type in each plant. Constraint (28) determines the maximum inventory capacity of logs of each type in each sector of the storage yard, while restrictions (29) establish the processing capacity limit of each plant in each period. Equation (30) forces the total demand for each plant to be covered. Through the restrictions (31) to (40) the routes that each truck must perform are built, these constraints are based on the work of Bordón et al. [9]. Finally, (41) and (42) establish the nature of the variables involved.

4 Case study

In order to assess the capabilities of the developed model, a case study consisting of a sawmill that requires a certain number of logs of different types is considered. In Table 1 the minimum and total demands for a planning horizon of 5 days are shown. In addition, the total weight of the raw material demanded (in tons) is also presented. Assuming a conversion factor of 0.8 tons/m^3 of pine, in this illustrative example a weekly supply of more than 1,800 m^3 of raw material to a sawmill is considered. According to the last National Census of Sawmills [10], the volume of transported raw material in this illustrative example is equivalent to that handled in large companies (annual production level greater than 23,585 m^3, which means 471.7 m^3 per week approximately).

There are 3 open harvest areas with different stem availabilities to obtain the required logs: 8,000 stems in f_1, 7,000 stems in f_2 and 6,500 stems in f_3. In each

harvest area there are 2 assigned harvesting crews, which can use the bucking patterns presented in Table 2, where the percentage of material lost after applying a certain pattern is also presented (this loss of material can be seen in Fig. 1). Since each harvesting crew can process a maximum of 50 stems per hour, the maximum harvesting capacity is set at 100 stems per hour. In a similar fashion, if the harvesting crew performs the cutting activity, then it must work at least 50% of its capacity.

There is a truck fleet composed of 100 trucks with minimum and maximum capacity of 18 and 27 tons each, respectively. The fleet is distributed in 3 regional bases

Each truck can perform at most 3 loaded trips in its route, as long as the working time limit is respected (8 hours). Both loading and unloading times of each truck are 30 minutes. The distances between each node of the network are given by Table 3. The rest of the parameters used are omitted due to space reasons.

Table 1. Minimum and total sawmill demands.

Type of logs	Minimum demand per period					Total demand	Total weight (tons)
	t_1	t_2	t_3	t_4	t_5		
$l_1 d_1$	50	100	75	50	50	450	8.55
$l_1 d_2$	100	80	50	50	20	600	36.6
$l_1 d_3$	0	150	150	150	0	900	81.9
$l_1 d_4$	100	100	80	75	50	600	102
$l_2 d_1$	0	100	180	150	90	1050	23.1
$l_2 d_2$	200	120	100	80	120	900	63.9
$l_2 d_3$	150	300	150	200	0	900	95.4
$l_2 d_4$	100	150	250	150	150	1200	237.6
$l_3 d_1$	100	100	250	50	0	750	20.25
$l_3 d_2$	0	0	80	270	350	900	77.4
$l_3 d_3$	200	200	200	80	0	1050	135.45
$l_3 d_4$	0	0	80	250	220	900	216
$l_4 d_1$	100	300	100	0	0	600	18.6
$l_4 d_2$	0	0	150	250	100	600	61.2
$l_4 d_3$	80	80	80	100	200	750	114
$l_4 d_4$	120	120	120	120	0	600	169.8

Table 2. Bucking patterns applicable to each harvest area.

Type of logs	Bucking pattern (harvest area)									
	b_1 (f_1)	b_2 (f_1)	b_3 (f_1)	b_4 (f_2)	b_5 (f_2)	b_6 (f_2)	b_7 (f_2)	b_8 (f_3)	b_9 (f_3)	b_{10} (f_3)
$l_1 d_1$	2				1		1

$l_4 d_4$				3	2					1
losses (%)	19	10	13	11	5	8	10	13	12	11

Table 3. Distances between the nodes (in kilometers).

	f_1	f_2	f_3	i_1
p_1	100	80	95	35
p_2	80	30	150	55
p_3	45	105	65	40
i_1	50	110	85	

The model is implemented and solved in GAMS [11] 24.7.3 version, with the CPLEX 12.6.3 solver, in an Intel(R) Core(TM) i7-8700, 3.20 GHz.

The size of the considered case study is 30,565 binary variables, 73,461 positive variables and 114,122 equations. Following, the main results obtained after 15 minutes, reaching 0.87% of optimality gap, are detailed. It is worth highlighting that the model gives a lot of detailed information about the harvesting and log transportation planning, but due to reduced space in this presentation they cannot be shown and it is available for interested readers.

Regarding to the harvest stage, the number of stems cut in harvest area f_1 is 610, 570 and 770 in periods t_1, t_2 and t_3, respectively, while for the same periods the number of stems cut in f_2 is 800, 664 and 636, respectively. In the harvest area f_3 the

number of cut stems in periods t_1 and t_2 is 700 and 800, respectively, while in period t_3 no tree is harvested. There are no harvest activities in periods t_4 and t_5 in any harvest area. The bucking patterns used (and the number of times they are applied) in each period are detailed in Table 4.

Table 4. Bucking patterns used.

Period	Bucking pattern (harvest area)									
	b_1 (f_1)	b_2 (f_1)	b_3 (f_1)	b_4 (f_2)	b_5 (f_2)	b_6 (f_2)	b_7 (f_2)	b_8 (f_3)	b_9 (f_3)	b_{10} (f_3)
t_1	150	100	360	147		509	144		700	
t_2		180	390	453		31	180		200	600
t_3		770				360	276			

In Table 5 the evolution of demand levels by period and by diameter for a particular log length (l_2) is shown. In this table the level of minimum committed demand per period ("$dmin_{l,d,i,t}$"), the level of covered demand above the committed demand per period ("$Q^{PL}_{l,d,i,t}$") and the accumulated covered demand ("ACD") are detailed.

Table 5. Demand satisfaction.

Diameter	*Period*	$dmin_{l,d,i,t}$	$Q^{PL}_{l,d,i,t}$	*ACD*
d_1	t_1	0	0	0
	t_2	100	0	100
	t_3	180	0	280
	t_4	150	0	430
	t_5	90	530	1050
d_2	t_1	200	160	360
	t_2	120	0	480
	t_3	100	0	580
	t_4	80	120	780
	t_5	120	0	900
d_3	t_1	150	0	150
	t_2	300	0	450
	t_3	150	100	700
	t_4	200	0	900
	t_5	0	0	900
d_4	t_1	100	0	100
	t_2	150	0	250
	t_3	250	0	500
	t_4	150	260	910
	t_5	150	140	1200

Regarding the use of trucks, 13 vehicles are used in period t_1 (9 from p_2 and 4 from p_3), 7 in period t_2 (4 from p_2 and 3 from p_3), 9 in period t_3 (5 from p_2 and 4 from p_3), 5 in period t_4 (all from p_3) and 8 trucks in period t_5 (1 from p_2 and 7 from p_3).

As an example, the load of two of the trucks used in one of the planning periods (t_1) is presented in Table 6. In this case, both trucks perform 2 trips between harvest area f_1 and the sawmill. In this table, the composition of each load can be seen: number of loaded logs of each diameter (of the same length) and total weight of the load.

Table 6. Truck loads.

Truck/trip	*Log length*	*Diameter/#Logs*			*Total weight (tons)*
$c_{71}\, v_1$	l_2	d_2 : 137			26.95
$c_{71}\, v_2$	l_3	d_1 : 180	d_4 : 92		26.94
$c_{72}\, v_1$	l_2	d_1 : 100	d_3 : 50	d_4 : 98	26.90
$c_{72}\, v_2$	l_1	d_3 : 180	d_4 : 62		26.92

Logs inventory levels (length l_2) in both the harvest areas and sawmill are presented in Fig. 2 and Fig. 3, respectively. In Fig. 2, the blue, red, and green bars represent the number of logs on the roadside in harvest areas f_1, f_2, and f_3, respectively.

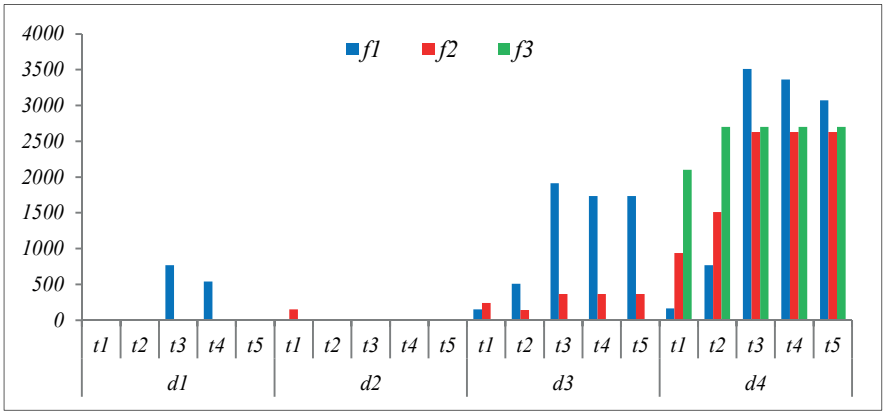

Fig. 2. Remaining logs of length l_2 on the roadside in harvest areas, by diameter.

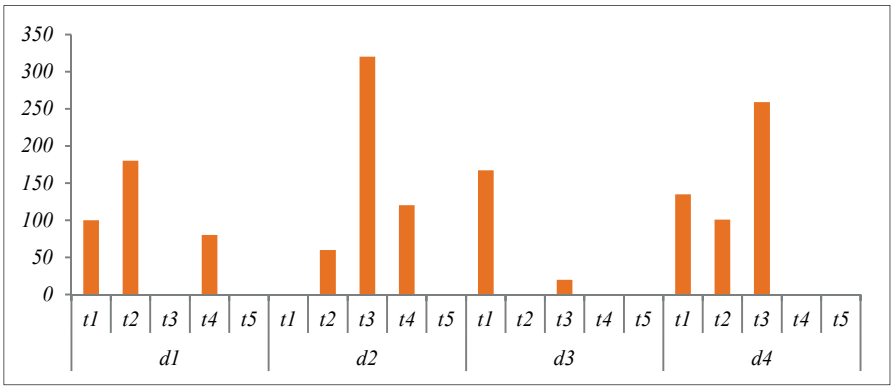

Fig. 3. Inventory level of logs of length l_2 in the sawmill, by diameter.

In Fig. 3 it can be seen that, since the logs stored in the plant at the end of the planning horizon are penalized, the model proposes a solution in which there are no logs (of any type) stored in period t_5.

Since the harvesting crews perform the logging activities during the first 3 periods in the harvest areas, in the last 2 periods the demand is satisfied with the logs stored (both in forests and plants). From the analysis of Fig. 2 and Fig. 3, it can be seen that in the last period, only logs that are required to fulfill total demand are transported, leaving the logs generated by excess on the roadside in harvest areas. This is mainly because, since more trucks will be required (at a higher cost), the model tends to use as few trucks as possible. Another factor influencing these decisions is that the cost of maintaining a log in the sawmill storage yard is slightly higher than the cost of maintaining the same log at the roadside in the harvest area.

5 Final remarks

In the forest industry, harvesting decisions are strongly related to plant production planning decisions. These plants, based on the commitments assumed with customers, plan detailed raw material supply programs to guarantee production. The harvesting crews receive these supply programs and harvest the raw material accordingly. Therefore, it is necessary to coordinate these efforts to avoid the generation of logs that will not be required by the plants and keep them in the storage yard at their respective cost. Transportation activities, in general, are not taken into account in this structure and have a great influence not only in the efficiency of the system but also in the cost structure.

The works found in the literature usually address these topics separately, which can lead to inefficient solutions. These inefficiencies are related to unnecessary logs inventory levels in both harvest areas and plants, and underutilization of truck loading capacity due to inefficient coordination, generating a high number of trips and a corresponding increase in the number of used trucks.

In this work, the proposed MILP model includes topics related to: vehicle routing, considering heterogeneous truck fleet, multiple periods, multiple plants and multiple depots; truck load composition; harvesting planning; and inventory management, both in harvest areas and plants.

The characteristics of the problem addressed and the solution time for the proposed example demonstrate the capabilities of the model to solve a problem in a weekly time horizon. Although the analyzed example was developed for illustrative purposes, it represents a situation in which more than 1,800 m^3 of raw material are transported, which in practice represents a situation related to large companies with a large supply flow. The model was solved with a CPU time limit of 15 minutes reaching a solution with an optimality gap equal to 0.87%.

Regarding the practical utility of the developed model, it can be used as a tool to support the planners' decisions, providing answers related to:: the periods in which the harvest teams must harvest, the level of forest production in each harvest area (number of generated logs of each type), the logs inventory levels, the number of trucks required to transport the harvested and the composition of each load, the route each truck perform in each period, the proportion of weekly demand covered in each period, among others. This solution capacity shows the potential of the developed MILP model when planning forestry activities.

Although the aim of this work is to present a mathematical model that jointly addresses issues that were not addressed before in the literature, key aspects emerge for improvement in future work, such as truck scheduling decisions to avoid or reduce waiting times that could be generated.

Resumen. La aplicación de fitosanitarios se ha vuelto una herramienta fundamental en el proceso actual de producción agropecuaria. La misma es compleja y dominada por muchos factores. A fin de ayudar a reducir las pérdidas y maximizar la eficiencia se decide realizar un ensayo con 3 pastillas de pulverización(3D-Defy-XR11002VP-TXA8002VK) a 2,6 bar de presión, con 50 litros de tasa de aplicación y 17 km/h de velocidad, circulando con el botalón a 0,75m sobre bancos que simulan objetivos tridimensionales donde se colocaron tarjetas hidrosensibles. Se evaluó Densidad de impactos, DV0,5 y Eficiencia. Se obtuvieron valores mayores de todos los parámetros en los objetivos horizontales. Las pastillas con algún tipo de angulación antero posterior mejoraron la uniformidad de aplicación entre objetivos verticales. Las pastillas anguladas no mejoran las características de aplicación en objetivos verticales en comparación con el resto de las pastillas.

Palabras clave: Pulverización, Pastillas angulados, Calidad de aplicación.

1 Introducción

El actual modelo de agricultura adoptado en los diversos sistemas de producción, especialmente los extensivos, como algodón, soja, maíz, entre otros, es muy dependiente del uso de productos fitosanitarios que actúan como importante componente en el manejo de los cultivos.

La tecnología de aplicación de agroquímicos es un área multidisciplinaria que estudia aspectos referentes a la llegada del producto químico al objetivo a controlar. Es una de las etapas más importantes del proceso de producción agrícola ya que debe realizarse de forma adecuada para que permita la correcta colocación del principio activo en el cultivo, en el momento oportuno, en cantidad necesaria, de forma económica y con mínimo de contaminación a otras áreas [1]. [2] afirman que se busca obtener la máxima eficiencia del producto fitosanitario con el menor volumen de

caldo posible, convirtiéndose en una variable de gran importancia al momento de seleccionar las pastillas de pulverización.

Para disminuir el volumen de caldo y al mismo tiempo proporcionar la cobertura deseada en el objetivo, se puede reducir el tamaño de gota de una pulverización. Pese a esto, gotas muy finas poseen dificultades para depositar una cantidad adecuada de producto en el objetivo por ser más vulnerables a la pérdida por deriva y evaporación, en consecuencia proporcionan un menor control [3].

Por lo tanto, el volumen de caldo influye directamente en el nivel de cobertura del objetivo biológico, pero su aumento resulta en un mayor gasto de tiempo para el reabastecimiento de las máquinas aplicadoras, entre otros aspectos [4]. En algunos casos, un menor volumen de aplicación puede aumentar tanto la cobertura como la eficacia [5]. Las gotas más pequeñas tienden a tener una mayor afinidad por las superficies de las plantas, especialmente en los pastos debido a su orientación principalmente vertical [6] [7] pero esto no parece afectar la eficacia de los herbicidas. En el 56% de los estudios examinados por [8], una disminución en la tasa de volumen de la aplicación condujo a una mejora o a ningún efecto sobre la eficacia de los herbicidas. Esto es consistente con otros estudios realizados por [9] y [10]. Cambiar el tamaño de la gota de pulverización afectó la deposición, pero el efecto sobre la cobertura no alcanzó similares niveles de correlación [11] [12]. [13] realizaron varios estudios sobre el tamaño de gota en relación a la deriva y la eficacia del producto a aplicar; concluyeron que las gotas de mayor tamaño reducen la deriva potencial un 85%, mientras se mantiene o mejora la eficacia de aplicación.

Aunque no existe un rango de tamaño de gota específico que sea propenso a la deriva en todas las condiciones, muchos investigadores han considerado que tamaños de gotas menores a 75 μm [14], 100 μm [15], 150 μm [16] o 200 μm [17] son más propensas a la deriva. Por otro lado [18], mencionan que tamaños de gotas mayores a 400 micras también significan un problema para la aplicación, ya que sostienen que gotas de este tamaño no se mantienen sobre la superficie de la planta, a la vez que proveen de una baja cobertura sobre el objetivo.

[19] trabajaron en la evaluación de la penetración del asperjado con diversas pastillas en el control de roya de la soja. Concluyeron que la densidad de impactos producida por la pastilla cono hueco y un volumen de aplicación de 150 l ha^{-1}, fue significativamente superior del resto de las pastillas tanto en el estrato superior como en el inferior. Combinaciones de pastillas y caudales mostraron un comportamiento similar en el estrato inferior, sin diferencias significativas entre ellas, sin embargo mostraron un comportamiento inferior respecto al cono hueco a 150 l ha^{-1}. Para el caso de doble abanico, no obtuvieron una mayor penetración por debajo de los 20 cm superiores del follaje del cultivo. Las únicas pastillas con las que obtuvieron un número aceptable de impactos y aún mayores (50 gotas cm^{-2}), fueron las de cono hueco a 120 y 150 l ha^{-1}. Destacan que un mayor volumen de aplicación por sí mismo, no es garantía de un alto número de impactos dentro del follaje, sino que está relacionado con las características de las pastillas en cuanto al modo de generación de gotas. En el caso del cono hueco, el DVM (diámetro volumétrico mediano) estuvo por debajo del valor ideal de 200-250 μm mencionado por [20]. Los resultados obtenidos por este equipo

de investigadores muestran que las gotas finas generadas por estas pastillas fueron las que mejor comportamiento presentaron con respecto a la penetración.

Distintos autores han mencionado que los parámetros de calidad de aplicación se hallan relacionados también a los ángulos de incidencia del chorro de pulverización [21] [22] [23], [24].

Se considera que el ángulo de pulverización de 90° en relación al suelo (posición vertical) es el más frecuentemente utilizado [24]. Pese a ello, las pastillas que presentan abanico simple con ángulos hacia adelante o hacia atrás, simétricos o asimétricos se utilizan tratando de buscar mayor penetración y uniformidad de deposición en el cultivo. Todos los trabajos se refieren a la angulación anteroposterior de la pastilla de manera diferente. Para tratar de aclarar y mejorar la comparación entre trabajos se ha decidido tomar 90° como la posición vertical más común y los ángulos con valor positivos tomados desde la posición vertical (90°) hacia la dirección de avance y los valores negativos desde la posición vertical en sentido contrario a la dirección de avance.

[25], evaluó el ángulo de incidencia del abanico de pulverización de tres diferentes pastillas de abanico plano y uno con doble abanico plano, y encontró incrementos en la deposición del caldo de pulverización cuando utilizó el ángulo de +45° en relación con la vertical.

[26], encontraron en un ensayo con cortina de aire que una velocidad de aire superior a 25 m s^{-1} acoplada con un ángulo de chorro de aire de +20° y una pulverización fina aumenta tanto la cobertura de partes ocultas de las plantas como la penetración del rociado hacia el fondo del dosel.

Las características de mayor interés en las aplicaciones hidráulicas son proporcionadas por las pastillas, siendo de gran importancia conocer las peculiaridades de cada una, a fin de seleccionar la mejor alternativa para cada ocasión. Las pastillas, son el órgano responsable de la emisión de las gotas y, por lo tanto, son consideradas el componente más importante del equipo pulverizador, ya que determinan diversos factores relacionados a la calidad de la aplicación, es decir, proporcionan una distribución relativamente homogénea a lo largo del botalón (calidad) [27] y logran eficacia biológica en función de la cantidad de impactos/cm^{-2} depositados en el objetivo, siendo necesarios de 20-30 para herbicidas sistémicos, 30-40 para herbicidas de contacto y 50-70 para fungicidas e insecticidas. [28]

[22] explican que el espectro de gotas dependerá del diámetro del orificio de salida, el ángulo de pulverización de la pastilla y la presión de funcionamiento, factores que inciden sobre la calidad de la pulverización. Por lo tanto, la correcta elección de la pastilla es esencial para garantizar que los plaguicidas se apliquen de manera efectiva a la velocidad correcta.

[2] mencionan que muchas veces los fabricantes informan solamente si un modelo de pastilla es adecuado para un herbicida, insecticida o fungicida, considerando los modos de acción de contacto o sistémico.

Una forma de estimar la cobertura del objetivo puede ser a través del número de impactos por unidad de área. Buena parte de las recomendaciones técnicas de aplicación son basadas en este criterio, informándose un rango o un número mínimo de

gotas necesarias para un buen control. La deposición y cobertura pueden ser analizadas de diferentes formas, utilizándose objetivos naturales o artificiales.

Las tarjetas hidrosensibles son una herramienta que permite lograr aplicaciones eficientes y responsables. Son de papel, muy sensible a la humedad, que al entrar en contacto con gotas de agua o líquido, se manchan de color azul, revelando el lugar donde han caído las gotas.

Por lo tanto, teniendo en cuenta los pocos estudios que han explorado el efecto del tipo de pastilla y la angulación anteroposterior en las tasas de recuperación de producto y la calidad de deposición de pulverización en condición de barbecho se realiza un ensayo con el propósito de determinar la uniformidad de distribución y calidad de aplicación de pastillas con diferentes características generales y diseños de angulación anteroposterior sobre distintos objetivos.

2 Materiales y métodos

El ensayo se llevó a cabo en la Estación Experimental Julio Hirschhörn perteneciente a la FCAyF de la Universidad Nacional de La Plata 34°35 S, 57°57 W.

Se utilizaron las pastillas descritas en la tabla 1 con diferentes características de pulverización. Se trabajó a una presión de 260 kPa, con previo control del caudal de las mismas mediante jarra graduada, cronómetro y un caudalímetro electrónico, en condiciones semicontroladas dentro de un galpón sin viento y sin accidentes topográficos.

La máquina utilizada fue una pulverizadora Hatsuta, vinculada al tractor a través del elevador hidráulico de tres puntos (montada), con un tanque de 400 l de capacidad y un botalón con separación entre pastillas de 0,525 m.

El botalón pasó por encima de los objetivos de pulverización a una altura de 0,75 m a fin de uniformar la distancia de las pastillas según recomendación de los fabricantes para cada una ([29] [30])

Tabla N°1: Descripción de pastillas utilizadas.

Pastillas	Ángulo Anteroposterior	Ángulo de apertura	caudal	Tipo	Marca	Siglas
3D Defy	30*	100	02	Abanico	Hypro	Defy-3D
XR11002VP	0	110	02	Abanico	Teejet	AP
TXA8002VK	0	80	02	Cono Hueco	Teejet	CC

*Intercalada hacia adelante y hacia atrás sobre el botalón según indicaciones del fabricante (Pentair, 2017).

La evaluación se realizó con tarjetas hidrosensibles [31] colocadas sobre estaciones de medición de 0,5 m de largo por 0,15 m de ancho con 2 prismas rectangulares de diferentes dimensiones que funcionaron como obstáculo de las gotas para llegar a los diferentes objetivos (Imagen 1). Se colocaron dos estaciones de muestreo distanciadas a 0,75 m entre si y dos más como repetición, distanciadas a 2 m en la dirección de avance respecto de los anteriores (Imagen 2). Las tarjetas fueron dispuestas sobre las

5 caras de los prismas y dos adicionales, una por delante y otra por detrás del objetivo en forma inmediata y horizontal, como se visualiza en la Imagen 2.

Se utilizó un diseño experimental factorial de 3x2x7 completamente aleatorizado con 4 repeticiones. El primer factor estuvo representado por 3 diseños diferentes de pastillas (Tabla 1), el segundo factor fueron las 2 estaciones de medición [(obstáculos de diferentes dimensiones, (ver Imagen 1)] y el tercer factor las 7 posibles ubicaciones de las tarjetas en cada estación de medición (Imagen 2).

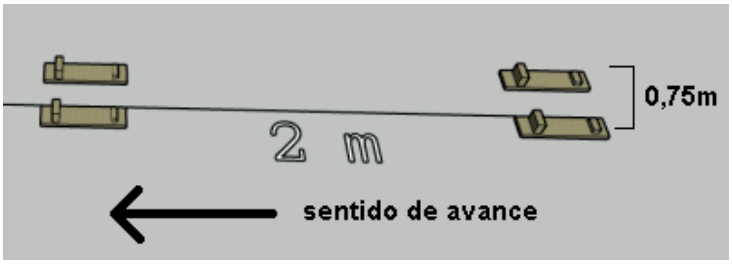

Imagen. 1. Distribución de las estaciones de evaluación.

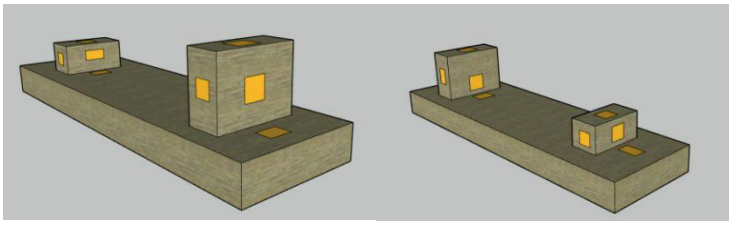

Imagen. 2. Disposición de las tarjetas hidrosensibles en el banco.

Luego del pasaje de la máquina pulverizadora se recogieron las tarjetas hidrosensibles y se colocaron en ambiente libre de humedad hasta su procesamiento. El mismo consistió en una digitalización de las tarjetas por medio de scanner cannon LIDE90 a 1200 d.p.i. y luego fueron analizadas con el programa CIR 1.5, obteniendo los siguientes parámetros que constituyeron las variables de respuesta:

- Densidad de impactos (N° de improntas cm^{-2}).
- Diámetro Volumétrico Mediano (DV 0,5 o DVM), (µm): Diámetro de gota que divide el volumen pulverizado a la mitad.
- Eficiencia (%): relación entre lo recogido en el objetivo y lo aplicado.

Para el análisis de uniformidad se procedió a dividir las tarjetas según cada posición, a fin de evaluar cuál de las pastillas consigue los mejores resultados en cada sector del objetivo y valorar de esa forma las características de la población de gotas que llegan a cada sitio.

Se realizó una segunda división de las tarjetas comparando los resultados de las que fueron colocadas en el objetivo más bajo del banco con las del objetivo más alto, analizando todas las pastillas en su conjunto con el fin de determinar la influencia de

la altura del objetivo. Asimismo, se analizó individualmente cada pastilla a fin de determinar la mejor alternativa frente a esta dificultad.

Esta forma de separación y análisis se realizó para objetivos verticales (V) y horizontales (H), objetivos delanteros (Ad) y traseros (Tr) y, por último, objetivos verticales laterales (D, I), verticales frontales y verticales traseros.

Debido a que las variables respuesta no responden a una distribución normal, los resultados fueron estudiados estadísticamente a través de un análisis de la varianza no paramétrico, mediante la prueba de Kruskal Wallis; y las medianas comparadas con un nivel de significancia ($p \leq 0.05$). Se utilizaron planillas Excel para el ordenamiento de los datos y para el análisis estadístico el programa INFOSTAT.

3 Resultados y discusión

Debido a que no se encontraron diferencias significativas entre los diferentes tamaños de obstáculos para ninguna de las variables estudiadas, se tomararon los resultados de ambos cubos como repeticiones.

3.1 Densidad de impactos

En la Fig. 1 se puede apreciar que la densidad de impactos que alcanza al objetivo tiene relación directa con su posición, los blancos horizontales siempre reciben mayor número de impactos independientemente de la pastilla utilizada, presentando como mínimo el triple de impactos respecto a los verticales. Esto puede deberse a su mayor superficie expuesta por su disposición perpendicular a la trayectoria teórica de las gotas tal como menciona [24]. La deposición por aspersión en objetivos verticales es difícil y varias investigaciones han demostrado que la misma disminuye cuando la orientación del objetivo cambia de horizontal a vertical [32] [33] [34].

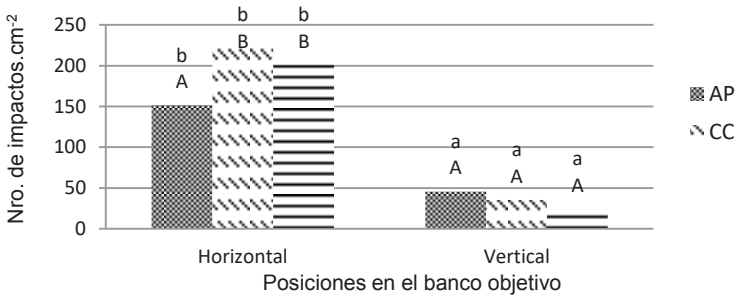

Fig. 1. Densidad de impactos cm^{-2} en función de los diferentes diseños de pastillas para las diferentes posiciones en el objetivo. Letras minúsculas diferentes sobre las columnas indican diferencias significativas entre posiciones y letras mayúsculas diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

CC y Defy-3D no presentaron diferencias significativas entre sí para las posiciones horizontales en ninguna de las ubicaciones (ver Fig. 2.) esto puede deberse al mayor número de gotas que generan estas pastillas en relación a AP ya qué las mismas generan gotas de tamaño fino en este rango de presiones mientras que AP genera gotas más gruesas (ver Fig. 6.).

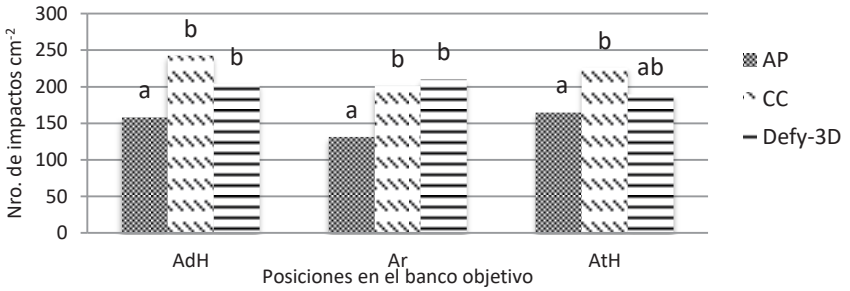

Fig. 2. Densidad de impactos.cm-2 para cada pastilla en función de la posición horizontal del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

Por lo tanto, podríamos suponer que la angulación de la pastilla tiene influencia en la proyección de las gotas tal como afirman [19] y [24]. Es decir, la angulación de la pastilla modifica la dirección con la cual la gota abandona la misma, y por consiguiente aumenta la posibilidad de alcanzar diferentes objetivos con disposición no horizontal, mejorando el comportamiento del abanico plano

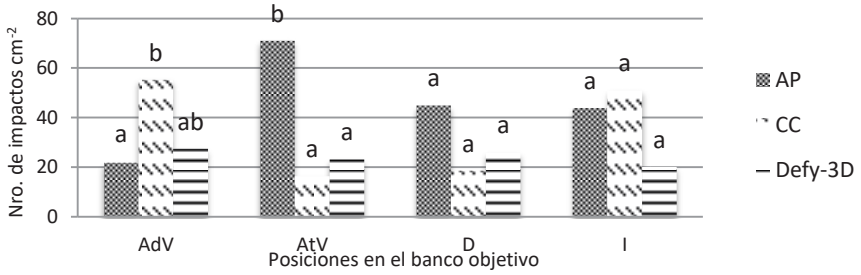

Fig. 3. Densidad de impactos.cm^{-2} para cada pastilla en función de la posición vertical del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

En las posiciones verticales, es interesante destacar el comportamiento de AP en la cara trasera vertical debido a que logro 300% más de impactos que las otras pastillas (Ver Fig. 3.). Esto puede deberse a la generación de un vórtice de viento por detrás del objetivo, lo que origina que las gotas cambien su trayectoria como consecuencia del aire circundante [35], las pastillas CC y Defy 3D al poseer una salida de gota angulada podrían sufrir menos este efecto.

En cuanto al CC fue notoria la cantidad de impactos alcanzados en la posición AdV, siendo ésta más del doble que las otras dos pastillas.

El comportamiento de Defy-3D fue regular en todas las posiciones verticales y nunca alcanzó el mayor número de impactos en relación a las otras dos pastillas, lo que puede deberse en parte, al efecto ejercido por la altura del botalón. [24] menciona, a partir de consideraciones teóricas, que la deposición sobre objetivos verticales se podría mejorar cambiando la trayectoria de pulverización desde la vertical estándar hacia un ángulo que sea más perpendicular al objetivo de pulverización. La aplicación de la teoría va a depender de si es posible retener tal ángulo desde la punta de la boquilla hasta el objetivo ya que a mayor ángulo mayor distancia debe recorrer la gota hasta el objetivo, siendo mayor el efecto de la gravedad sobre la misma y modificando de esta forma su angulación. [23] demuestran que a mayor altura del botalón, para todas las velocidades estudiadas, peor es la llegada de gotas a los objetivos verticales al igual que lo encontrado por [36].

Esto es de relativa importancia si se pretende realizar tratamientos con fungicidas o insecticidas ya que de utilizar el botalón demasiado alto seria dificultoso alcanzar el N° de impactos mínimos para control con pastillas anguladas, como se observa en el Fig. 3. Defy-3D no alcanzó los 30 impactos en ninguna de las posiciones verticals en tanto que, las demás pastillas no alcanzaron este N° de impactos en al menos una de las caras, lo que debería de ser considerado si el producto a aplicar posee una baja translocación en el vegetal. Esto nos permitiría afirmar que la angulación de la pastilla por sí sola no mejora el número de impactos obtenido en las posiciones verticales.

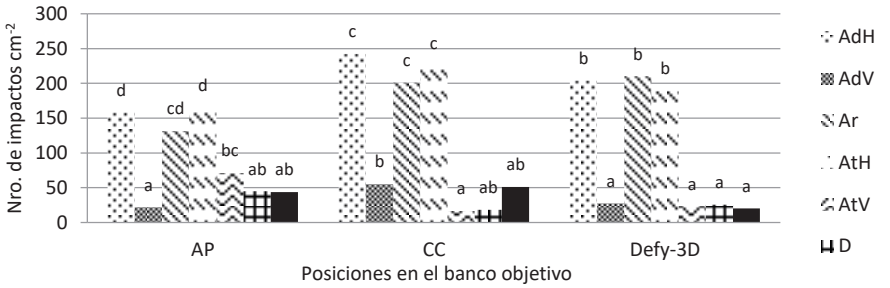

Fig. 4. Densidad de impactos en cada posición y ubicación del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre posición. Test de Kruskall-Wallis $p \leq 0,05$

En la Fig. 4, podemos observar el comportamiento de las pastillas en cada una de las caras del objetivo. Es posible apreciar a simple vista que los objetivos horizontales obtienen el mayor número de impactos independientemente de la pastilla utilizada, tal como se vienen mencionando. Por otro lado, es posible notar que ninguna pastilla logra una buena uniformidad en el número de impactos en todas las caras de los objetivos. Si se particionan los objetivos entre verticales y horizontales se observa que las pastillas Defy-3D son las de mayor uniformidad sin presentar diferencias estadísticas entre las posiciones verticales, al igual que con las horizontales. AP y CC son más variables y presentan diferencias estadísticas entre posiciones verticales pero no en las horizontales. Pese a esto, es posible apreciar una mayor uniformidad en las pastillas CC posiblemente pos su angulación tridimensional de salida de las gotas.

Esto nos permite concluir que la angulación de las pastillas posee un efecto positivo en la uniformidad de impactos para las diferentes caras de los objetivos pero sería recomendable ahondar en la investigación de esta variable para diferentes diseños y angulaciones de pastillas.

3.2 Diámetro volumétrico mediano (DV0,5)

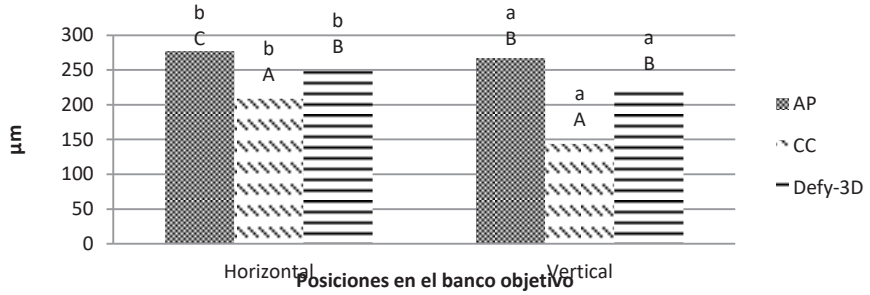

Fig. 5. DV0,5 en función de los diferentes diseños de pastillas para las diferentes posiciones en el objetivo. Letras minúsculas diferentes sobre las columnas indican diferencias significativas entre posiciones y letras mayúsculas diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

En la Fig. 5. se puede observar que en los objetivos verticales quedan retenidas gotas más finas respecto a los objetivos horizontales [26] [35].

[6] mencionan que las gotas más pequeñas parecerían tener más afinidad por los objetivos verticals, lo que se pueda deber a la menor influencia de la gravedad sobre ellas y su mayor tiempo de permanencia en el aire, lo que permite que pequeñas brisas las hagan impactar contra estos objetivos. En el caso de la pastilla CC es más notoria la tendencia, probablemente por ser la pastilla que genera las gotas más pequeñas.

Por otro lado, podemos observar que el tamaño de gotas que llega al objetivo mantiene una relación directa con el diseño de pastilla. Esto se puede deber a que diferentes diseños generan diferente tamaño de gota a una misma presión de trabajo pese a poseer idéntico caudal por minuto de erogación.

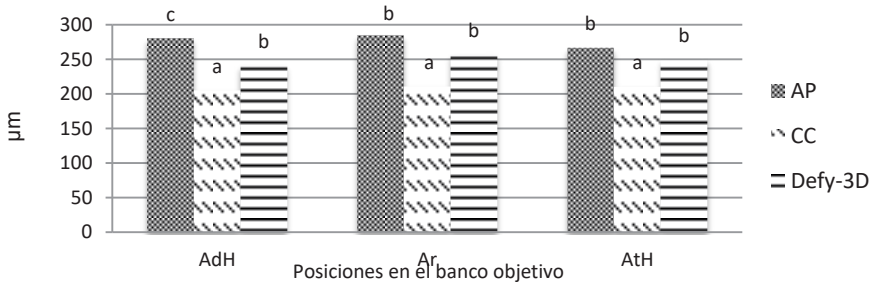

Fig. 6. Valores de DV0,5 para cada posición horizontal del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

A partir de los resultados mostrados en las Fig. 6. y 7. , se puede afirmar que AP es la pastilla que genera mayor tamaño de gotas sobre el objetivo, diferenciándose significativamente de CC en todas las posiciones, a excepción de AdV. Además, es de interés destacar que la pastilla Defy-3D nunca se diferenció significativamente de AP, lo que indica que el ángulo de proyección inicial de gotas tiene baja incidencia en el tamaño de gotas. Sólo en AdH e I la pastilla AP si se diferenció en el DVM que llega al objetivo, esto permitiría suponer que el tamaño de gota que llega a los objetivos horizontales está más relacionado con el tipo de pastilla y las condiciones ambientales que con la posición relativa del objetivo.

Las posiciones relativas verticales no son alcanzadas por el mismo tamaño de gota independientemente de la pastilla que lo genere, presentando diferencias de tamaño dentro de la pastilla y dentro de la posición. Para evaluar la homogeneidad de los DV0.5 en las diferentes posiciones y ubicaciones para cada diseño de pastilla, se calculó el coeficiente de variación (CV), donde AP obtuvo 23%, seguido por CC con 22% y Defy-3D con 18%. La pastilla Defy-3D presentó similar tamaño de gotas en las posiciones AdV y AtV y en las posiciones D e I, CC presentó la mayor desuniformidad en el tamaño de gotas para los objetivos verticales siendo que en las posiciones horizontales fue la pastilla con mayor similitud de tamaño de gotas. AP presentó diferencias marcadas entre AdV y AtV y similitud en sus posiciones D e I al igual que Defy-3D, pudiendo deberse a la angulación lateral de aproximadamente 5° para evitar que los abanicos se toquen en el botalón lo que genera que los mismos barran los objetivos D e I de forma similar.

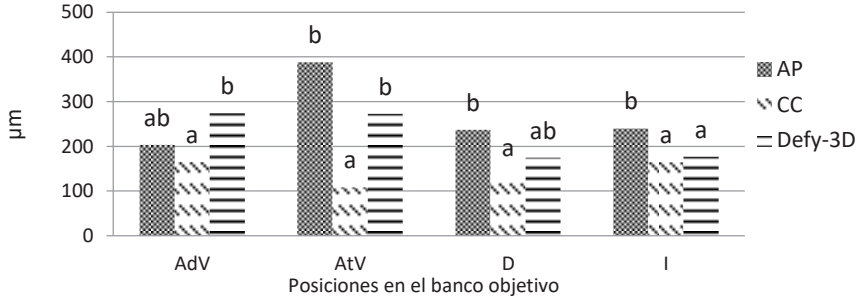

Fig. 7. valores del DV 0,5 para cada posición vertical del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

Por otra parte, se puede apreciar que generar gotas gruesas según [37], entre 340 µm y 403 µm, no significa producir bajo número de impactos en contra posición a lo expresado por [20]. Esto se obseva con la pastilla AP, que a pesar de generar gotas gruesas, logra un alto número de impactos en la posición AtV, obteniendo diferencias significativas respecto a CC y Defy-3D (Ver Fig. 7 y 3).

Según [37], tanto AP como Defy-3D, generan gotas medias y el CC gotas finas. Para CC se pudo observar en las posiciones verticales AtV y D un tamaño inferior a 150 µm que según [20], son más propensas a sufrir deriva. Mientras que AP y Defy-3D presentaron DVM por encima de los 170 µm en todas las posiciones y AP incluso

superiores a los 200 µm. Si consideramos que un adecuado balance se obtiene utilizando gotas entre 200-250 µm de diámetro estas pastillas podrían tener menores dificultades con la deriva en condiciones de campo con mayor viento

3.3 Eficiencia

La eficiencia es una variable de respuesta que depende del tamaño de la gota y del número de impactos que logran llegar al objetivo, esta se determina a partir de los litros ha^{-1} que llegan al blanco, respecto a los litros ha^{-1} erogados por el pulverizador. En el Fig. 8, se muestran los resultados de eficiencia para las distintas pastillas en las diferentes posiciones. Se puede visualizar que las mayores eficiencias se alcanzaron sobre las caras horizontales de los objetivos, independientemente del diseño de pastillas. Esto se debe a que las gotas tienen una mayor probabilidad de impactar sobre la mayor superficie expuesta en ese plano, logrando eficiencias mayores al 50% - 60 %. Esto además es acompañado por el mayor tamaño de los impactos que llegan a esta posición aumentando el valor de volumen recolectado (Ver Fig. 5).

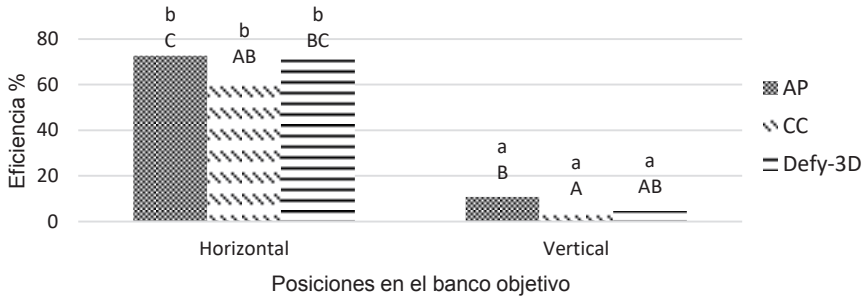

Fig. 8. Eficiencia en función de los diferentes diseños de pastillas para las diferentes posiciones en el objetivo. Letras minúsculas diferentes sobre las columnas indican diferencias significativas entre posiciones y letras mayúsculas diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

Como se observa en el Fig. 9., el comportamiento del CC fue homogéneo en todas las ubicaciones horizontales siendo la de menor eficiencia. La pastilla AP obtuvo un 20% más de eficiencia respecto al CC en las ubicaciones Ar y AtH, influenciado fundamentalmente por el DV0,5. Estos resultados concuerdan con lo determinado por [38] y [39], quienes afirman que aquellas pastillas que generan mayor tamaño de gota, generan mayores depósitos sobre el objetivo. Por otro lado, CC fue la pastilla que más uniformemente cubrió los objetivos llegando en forma similar a todas las ubicaciones a diferencia de AP y Defy-3D que en la posición AdH se asemejan a los valores de CC sin presentar diferencias estadísticas, pero que si se observan en Ar y AtH. Defy-3D nunca se diferenció de CC y AP permaneciendo en una posición intermedia entre ambas. Esto puede deberse en gran medida a que Defy-3D presenta un tamaño de gota

de llegada intermedio en casi todas las posiciones y una densidad de impactos también en una posición intermedia.

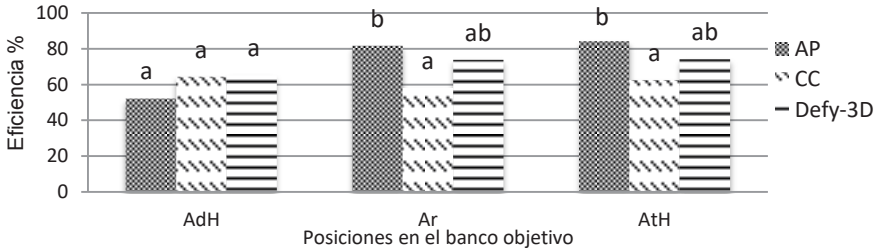

Fig. 9. Valores de Eficiencia para cada posición horizontal del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

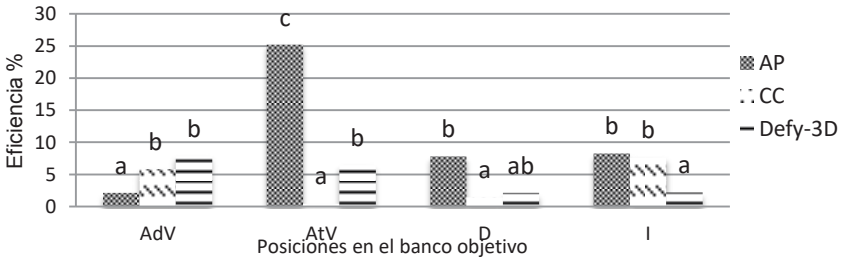

Fig. 10. Valores de eficiencia para cada posición vertical del objetivo. Letras diferentes sobre las columnas indican diferencias significativas entre pastillas. Test de Kruskall-Wallis $p \leq 0,05$.

Cuando los objetivos se disponían en forma verticals (Ver Fig. 10), solo la pastilla AP pudo superar el valores del 10%. Esto es importante de tener en cuanta ya que de ser necesario realizar controles sobre objetivos verticales será importante modificar parámetros de la aplicación que mejoren estos resultados.

4 Conclusiones

La angulación de las pastillas no mejora por si sola la calidad de aplicación en cuanto a Densidad de impactos y Eficiencia pero mejora la uniformidad de impactos entre las diferentes caras de los objetivos.

Conseguir la densidad de impactos para realizar controles biológicos en objetivos verticales reviste mayor complejidad que sobre objetivos horizontales.

Resumen. En el municipio de Villa del Rosario, Norte de Santander, empresas agroindustriales dedicadas al procesamiento de coco generan diferentes productos alimentarios, sin embargo el endocarpio del coco no es aprovechado, generando de 4 a 8 toneladas/semanales de residuo, ocasionando contaminación y proliferación de plagas. El Pleurotus ostreatus es un hongo comestible fácilmente cultivable a nivel mundial, rico en proteínas, vitaminas y minerales que crece en residuos con alto contenido ligno celulósico. Teniendo en cuenta la importancia nutricional del Pleurotus ostreatus y las condiciones ambientales favorables del municipio de Villa del Rosario, así como el alto contenido de compuestos ligno celulósicos que tiene el endocarpio de coco, se investigó el potencial de éste como sustrato para el crecimiento de Orellana (Pleurotus Ostreatus), evaluando las condiciones de crecimiento, variando el tamaño de partícula y los métodos de desinfección. Esta investigación se desarrolló en cuatro etapas, la primera consistió en determinar las características del endocarpio de coco; en la segunda se identificaron las condiciones óptimas de crecimiento de la Orellana (Pleurotus ostreatus); en la tercera se evaluó si el sustrato de coco proporciona las condiciones adecuadas para el crecimiento del hongo, en la última etapa se realizó el análisis de los resultados y la formulación de conclusiones. Con los resultados obtenidos, se demostró que bajo las condiciones ambientales de Villa Del Rosario, es posible cultivar el hongo Pleurotus ostreatus usando como sus-

trato el endocarpio de coco, realizando un tratamiento efectivo de desinfección y una reducción del tamaño de partícula al sustrato.

Palabras clave: Orellana, Endocarpio, Coco, Pleurotus ostreatus, Cocos, nucifera

1 Introducción

El coco es un fruto que se puede encontrar en la orilla de las playas tropicales arenosas del mar Caribe, océano indico y pacífico, este fruto tiene una demanda de uso agroindustrial para coco deshidratado, empleado en la panadería y repostería; del cual solo se aprovecha la pulpa que es la quinta parte de este y el resto de las capas fibrosas se desechan.[1]

En el área metropolitana de Cúcuta específicamente en el municipio de Villa del Rosario se encuentra ubicada la empresa Surticocos S.A.S, empresa dedicada a procesar 27.99 Toneladas/mes de coco, sin embargo, el endocarpio del coco no es aprovechado, generando de 4 a 8 Toneladas/semanal de residuo no aprovechados que ocasionan contaminación y proliferación de plagas.

El Pleurotus Ostreatus es un hongo fácilmente cultivable a nivel mundial encontrado en residuos lignocelulosicos, con altos componentes nutricionales. Teniendo en cuenta su importancia nutricional y sus requerimientos de crecimiento, se investigó si el endocarpio del coco es un sustrato adecuado para el crecimiento de Orellana (Pleurotus Ostreatus), evaluando sus condiciones de crecimiento, variando el tamaño de partícula del sustrato y el método de desinfección[2]

Esta investigación se llevó acabo en cuatro etapas, en la primera se determinó las características del endocarpio de coco; en la segunda etapa se identificaron las condiciones óptimas de crecimiento de la Orellana (Pleurotus Ostreatus); en la tercera etapa se evaluó si el sustrato de coco proporciona las condiciones adecuadas para el crecimiento del hongo y la cuarta etapa consistió en el análisis de los resultados y la formulación de conclusiones.

Demostrando que, bajo las condiciones ambientales de Villa Del Rosario, con un sustrato de endocarpio de coco, se puede cultivar el hongo Pleurotus Ostreatus realizando un tratamiento de desinfección del sustrato y una reducción del tamaño de partícula se permite obtener un cultivo de Pleurotus O. en endocarpio de coco.

2 Materiales y Métodos

El trabajo se enmarcó en una investigación cuantitativa con diseño cuasi-experimental con alcance descriptivo; debido a que se manipularon variables tales como el tamaño de partícula del sustrato de endocarpio de coco, métodos de desinfección del sustrato y se evaluó el crecimiento del hongo Pleurotus Ostreatus. [3]

2.1 Diseño experimental

Para la evaluación del crecimiento del hongo Orellana (Pleurotus Ostreatus), en un sustrato de endocarpio de coco (Cocos Nucifera). Se compararon las variables: método de desinfección respecto al tamaño de partícula, se realizaron 3 observaciones por tratamiento en un total de 12 tratamientos, en 3 ensayos realizados con las dos variables evaluadas. Para el ensayo 1 y 2 se evaluaron tres tamaños de partícula de (300, 600 y 118000 µm) versus tres métodos de desinfección (secado al sol, lavado en cal y choque térmico), finalmente el ensayo 3 se comprobó el crecimiento en sustrato de endocarpio sin triturar con tres tiempos de choque térmico.

2.2 Diseño metodológico.

Se pesó y separó la materia prima en cantidades de 10 kilos por tratamiento de desinfección, luego se realizó la adecuación de la materia prima para los procedimientos de pasteurización, lavado en cal y secado al sol, para los ensayos 1 y 2 evaluados. Más adelante se trasladó la materia prima a los laboratorios de operaciones unitarias en la sede de Campos Elíseos de la U.F.P.S. , el material se pasó por el molino de martillos de 5 hp y se tamizó consiguiendo tres tamaños de partícula (300µm, 600 µm, 118000 µm), se procedió a la adecuación del cuarto de cultivo, con lavado de pisos y paredes, se cubrió las entradas de luz y se realizó una aspersión para paredes con alcohol al 70% e hipoclorito al 10 %, se mezcló 700 ml de alcohol etílico (alcohol comercial de 96 °) con 300 ml de agua destilada o purificada, para la superficie de la mesa y lugar de inoculación, se mezcló 100 ml de cloro de uso casero con 900 ml de agua para los pisos y paredes del cuarto externo al del cultivo[4]; se realizó la inoculación del sustrato, más adelante se trasladó al cuarto del cultivo, controlando con termohigrómetro las condiciones ambientales de cada observación.

Reducción en los tamaños de partícula. Se realizó el diseño con base a las mallas de tamizador y a la potencia del molino de martillo de 5 hp, con tamaños de 300 micrómetros, 600 micrómetros y 118000 micrómetros además de los métodos de desinfección corresponden a un control, secado al sol, un choque térmico y lavado con cal como se puede evidenciar en tratamientos presentes de la Tabla 6. Tratamientos iníciales a evaluar, tamaño de partícula con método de desinfección.
Se agregó un tratamiento T10 en el ensayo 2 para determinar la necesidad de realizar una reducción de tamaño de partícula, y se planteó el ensayo 3, para determinar la necesidad de realizar una reducción de tamaño de partícula con un tratamiento térmico a diferentes temperaturas, como podemos ver en la Tabla 7. Tratamientos realizados en los ensayo 2 y 3.

Para la investigación se utilizó un arreglo factorial combinatorio (3 x 3), con trece tratamientos y tres repeticiones respectivamente evaluados en tres ensayos de cultivo. La inoculación se realizó en cada una de las bolsas de polipropileno de 0.5 kg, para los tratamientos del primer y segundo ensayo; en el tercer ensayo se utilizaron bolsas

de fique de 0.5 kg para permitir la aeración suministrando una sola vez durante todo el proceso 30 g de semilla por cada bolsa de 0.5 Kg de sustrato evaluado [5]

Tamizado. En este proceso se utilizó un tamiz de 300µm, 600µm y 118000 µm con un sistema de vibración por 3 minutos, a una itinerancia de 3segundos y una amplitud de 0.5mm. [10], con un tamizador ANALYSETTE 18 marca Fritsch GmbH.

Tratamiento de desinfección o esterilización de los sustratos. Para utilizar los sustratos en el cultivo del hongo seta, es necesario someterlos a un tratamiento previo, que consiste básicamente en aplicarles calor para disminuir la flora microbiana nociva que está presente en ellos y de esta manera evitar que los microorganismos compitan por espacio y nutrientes con el micelio de Pleurotus. [6]

Secado al sol. Todos los residuos fueron seleccionados y sometidos a un proceso de secado mediante la exposición directa al sol hasta que se observaran físicamente secos.

Tratamiento con choque térmico. El sustrato, se remojó en agua caliente y limpia, a 70-80°C, durante 15 minutos. Se realizó un par de aclarados o lavados más con agua caliente, hasta que los líquidos salientes fueron claros. Éste sistema es rápido, humedece y pasteuriza al mismo tiempo, no necesita vapor u otra manipulación por separado. Durante el remojado, el sustrato suele tomar 3 a 4 veces su peso en agua. [7]

Inmersión en agua alcalina. Esta es una de las técnicas más recientes que se practican en el cultivo de hongos. La desinfección con cal es un proceso propuesto como una alternativa, en la que se utiliza agua alcalinizada con cal comercial [Ca (OH)2], destruyendo de esta manera semillas, insectos, parásitos, hongos y bacterias, que pueden contaminar el sustrato y que pueden competir con el hongo de interés. Se trata de sumergir el sustrato en agua alcalinizada con cal comercial durante cierto tiempo dependiendo del sustrato y de las condiciones ambientales del lugar de cultivo. Según estudios realizados en México, la concentración y el tiempo adecuado para la preparación es de 0.5 % durante 24 horas respectivamente, en donde se alcanzó una alta eficiencia biológica. Esta técnica tiene una gran ventaja sobre las otras por ser un método en frío, alternativa para evitar el uso de altas temperaturas y por lo consiguiente un gasto energético. [8]

Traslado de la materia prima al área de siembra. La fase experimental se llevó a cabo en un cuarto cerrado, paredes de plástico y piso de tableta, con dimensiones de: 3m x 3 m y una altura de 2,10 m. Se lavaron las paredes y el piso con hipoclorito de sodio a 20 ppm. Para obtener las condiciones requeridas por el Pleurotus, se cubrió la ventana con plástico negro al 70%, manteniendo condiciones de luz y temperatura; para asegurar la humedad adecuada se realizaron riegos con una frecuencia de tres veces al día. Las variables fueron monitoreadas diariamente con un termohigrómetro.

Inoculación con la semilla de Orellana. Se realizó la inoculación de la semilla, en el municipio de Villa del Rosario Colombia, con los tres tipos de tratamientos de desinfección y tres repeticiones de cada tamaño de partícula. En el caso de los tratamientos para el endocarpio del coco se usó 0.5 kg de sustrato, implementado un inoculo de 20 g. de semilla por bolsa. La muestra de secado al sol se usó como muestra patrón vs las que llevan tratamiento de desinfección. La siembra se realizó en un lugar cerrado y aislado de plagas, con suelo en cemento y desinfectado, como se indica en la literatura. Para la desinfección de la sala de siembra y herramientas, se usó hipoclorito de sodio al 5 % diluido en agua (0.5 litros de hipoclorito en 20 litros de agua) [9]; se inocularon muestras de 500 gramos (g) peso húmedo de sustrato desinfectado de endocarpio de coco con 20 gramos semilla de Orellana, esta etapa de la investigación se realizó con elementos de protección como guantes de látex, tapabocas, cofia, lentes de seguridad, botas y overol, para disminuir la probabilidad de impactos negativos en inocuidad del hongo.[10]

Traslado al área de crecimiento. En esta etapa se realizó la adecuación del área para poder llevar las muestras inoculadas, al espacio conforme con los requerimientos técnicos para el crecimiento de Orellana. De acuerdo a las indicaciones, el principal requisito del área es ser anaerobia, por lo que no puede estar sometida a ningún tipo de alteración del ambiente del cuarto, como exposición a luz solar, humedad relativa y temperatura y la temperatura, la medición del ambiente se hizo con ayuda de un termohigrómetro que valoró en tiempo real los factores mencionados anteriormente. Además, se realizaron unos ligeros cortes en los costados de la bolsa que permitieron que los carpóforos crezcan de una manera uniforme, además de monitorear fácilmente la cantidad el tamaño, peso, color y tiempo de maduración que determina el rendimiento biológico del sustrato.[5]

Cuarto de fructificación. En esta etapa las muestras fueron dispuestas en un área limpia y desinfectada con sello de hermeticidad para impedir la entrada de plagas y así poder mantener controladas los factores de temperatura, humedad relativa y exposición a luz solar, en este paso se permitió el ingreso de luz solar de manera controlada y de forma indirecta con el propósito de posibilitar el crecimiento de la seta, ya que de exponer demasiado a esta luz puede afectar el cultivo y marchitarse.

3 Resultados.

3.1 Resultados de la caracterización físico-química del endocarpio de coco

Los resultados obtenidos de las pruebas de laboratorio del endocarpio de coco usado como sustrato en el cultivo de Pleurotus Ostreatus se presentan en la Tabla 1. (Pruebas Fisicoquímicas y Bromatológicas).

Tabla 1. Pruebas Fisicoquímicas y Bromatológicas.

Prueba	Método	Resultados
Humedad	A.O.A.C. 1925.10.- estufa	5.5%
Fibra detergente neutron	A.O.A.C. 15th Edition 1990. Gravimetría	79.67 %
Fibra detergente acida	A.O.A.C. 973.18. gravimetría	68.78 %
Hemicelulosa	Diferencia de FDN Y FDA	10.89%

3.2 Resultados para la identificar las condiciones adecuadas de crecimiento de la Orellana (Pleurotus ostreatus)

El cultivo de hongos de manera artesanal, a bajo costo (por sus características de austeridad), por lo general ejerce poco control sobre las condiciones del medio (Temperatura, humedad, ventilación, luz, oscuridad, etc.). Los cultivos son más estables y más productivos cuando el lugar de cultivo posee aire acondicionado. Sin embargo, las condiciones de cultivo caseras son baratas, dependientes de las condiciones del ambiente natural y son productivas a bajo nivel, suficiente para autoconsumo y comercialización del excedente. La temperatura se puede regular abriendo ventanas y puertas (si es que existen) para que la temperatura baje y permita además una ventilación.[11]

Los resultados obtenidos en la presente investigación, están descritos en la Tabla 2. Condiciones promedio de crecimiento de la investigación en el cultivo del Pleurotus Ostreatus, en un sustrato de endocarpio de coco en endocarpio de coco.

Tabla 2. Condiciones promedio de crecimiento de la investigación en el cultivo del Pleurotus Ostreatus en un sustrato de endocarpio de coco en endocarpio de coco.

Cultivo	Variables p				
	Temperatura °C	Humedad %	pH	Días de colonización	Días de aparición de carpoforos
Ensayo 1	27-34	63-98	6.41	12	14

La humedad se puede regular aplicando agua al suelo (esto permite también regular la temperatura), en cuanto a la humedad relativa del cuarto de fructificación debe estar entre el 80 y el 95%, dependiendo del desarrollo del cuerpo fructífero (por lo que se recomienda tener un termohigrómetro en el cuarto de cultivo para su monitoreo). La humedad en el cuarto puede ser ajustada mediante el riego con agua, durante algunas horas del día y así evitar que el sustrato se reseque. Al aparecer los primordios, la humedad relativa del cuarto de fructificación debe disminuirse a 85% - 90% y aumentarse la frecuencia de riego dependiendo de la tasa de fructificación. Durante el período de cosecha una humedad relativa entre el 80 y el 85% garantiza una calidad satisfactoria en el hongo.

3.3 Resultados de la evaluación el crecimiento del hongo (Pleurotus Ostreatus) en el endocarpio de coco (Cocos Nucifera), como sustrato para determinar la viabilidad de este nutriente en la producción de hongos comestibles

Se evaluaron las condiciones óptimas de crecimiento del hongo en los tres ensayos, para identificar que tratamiento presenta mayor viabilidad; sin embargo la producción de P. ostreatusse presentan pérdidas debido a contaminación en el sustrato mal desinfectado, causadas por hongos, bacterias, virus e insectos, que en su mayoría atacan en los primeros días del cultivo disminuyendo así la producción[7].

Resultados Ensayo 1, evaluación del cultivo de Orellana en dos tratamientos de desinfección vs tres tamaños de partícula. En las condiciones ambientales de Villa del Rosario se pude obtener un cultivo de Orellana con buena respuesta de crecimiento, se ve afectado por la contaminación de insectos que invade la muestra de la T1, T2 Y T3, que no muestra presencia de micelio o invasión del hongo ya que la cantidad de insectos en las muestras se propagaron a los otras tratamientos y repeticiones.

El tratamiento T4 con 4 repeticiones fue el de mejor aceptabilidad del hongo con un periodo de invasión de 12 días y de crecimiento en 17 días, las condiciones de humedad de este tratamiento fue de 8% y una temperatura de 31.5°C.

Comparados con los resultados de T4 las los tratamientos T1, T2 Y T3 con las condiciones ambientales de humedad (85-95%) y temperatura (26 – 32 °C), se evidencia que la plaga impide el crecimiento o propagación del hongo en el sustrato, por lo cual es necesario realizar un método de desinfección que destruya tanto larvas, pupas y mohos en el sustrato.

El resultado de la investigación para el primer ensayo demostró que el Pleurotus ostreatus crece en las condiciones ambientales de Villa el Rosario, con un tamaño de partícula de 0.600 mm, utilizando un tratamiento de desinfección de choque térmico correspondiente al tratamiento T4. El cuerpo fructífero murió con un tamaño aproximado a los 8 cm de largo y 5 cm de ancho.

Resultados Ensayo 2, evaluación de 3 métodos de desinfección: secado al sol, choque térmico e inmersión alcalina. Para el ensayo 2, se evaluaron tres métodos de desinfección del sustrato: secado al sol, choque térmico e inmersión alcalina, con una variación del tratamiento secado al sol en el que no se trituró el sustrato (T10) y los tratamientos de T4 a T9 se realizaron con 3 tamaños de partícula, para realizar el montaje, se trasladó el cuarto de cultivo a otro sitio en Villa del Rosario donde la temperatura ambiente fue de 23°C y una humedad de 87%.En este ensayo se encontró una invasión del micelio en un tiempo de 5 a 6 días.

Pese a las condiciones del cultivo para el ensayo dos, las muestras compitieron por el sustrato (Trichoderma spp., Penicillium spp., etc. Según la literatura) impidiendo que posteriormente el desarrollo del Pleurotus Ostreatus. La pasteurización así realizada no proporciona una protección natural del substrato contra las contaminaciones fúngicas, especialmente si se trata de Trichoderma spp.[12]

Los tratamientos de T4 A T10, presentaron contaminación a las dos semanas de la inoculación y la presencia de hongos competentes por el sustrato separamos las muestras contaminadas para obtener una hipótesis alternativa.

Se observó presencia de moho contaminante en el tratamiento T6 del ensayo 2. Los primordios empezaron a crecer, el tratamiento y sus repeticiones se separaron, se dejó

aislado para observar su crecimiento y compararlo con las muestras aun no contaminadas, luego de 51 días los carpoforos alcanzaron tamaños de 5 a 7 cm. De altura y 5cm de ancho.

Se realizó un Ensayo 3, en el que se evaluó el crecimiento del hongo en el endocarpio de coco sin triturar, desinfectado con el método de choque térmico durante 20, 30 y 40 minutos, las condiciones ambientales de crecimiento fueron de 17°C y humedad de 99%.

4. Análisis de Resultados

4.1 Caracterización del sustrato

Resultados de celulosa. Todo material ligno-celulósico está constituido por tres componentes: celulosa, lignina y hemicelulosa [13]. Se conocen más de 200 sustratos posibles para el cultivo de Pleurotus ostreatus, estos están principalmente compuestos por celulosa (45 a 60%) hemicelulosa (15 a 20%) y lignina de (10 a 30%).

Comparado con la cantidad de celulosa con 24.37% es el compuesto que más degrada el hongo para su desarrollo al presentarse en menor cantidad puede afectar los resultados de la investigación.

Una de las mejores fuentes de carbono para el crecimiento miceliares es la celulosa para el desarrollo óptimo del hongo [14].

Lignina. El porcentaje de lignina encontrado en el endocarpio de coco mostro que su cantidad 44.41% está en mayor presencia que la celulosa 24.37%, como muestran otros estudios donde el nivel de lignina no supera el 15% tomando lo descrito.

La degradación de componentes estructurales está estrechamente relacionada con la naturaleza química de los sustratos y la capacidad de degradación enzimática del hongo [15]. Lo anterior coincide con estudios similares, donde los mejores resultados, están asociados a sustratos que tienen un alto contenido de lignina [16].

La cantidad de hemicelulosa y celulosa en los resultados de la presente investigación, son 10% menor a la de Bledzki (2010) [17], con respecto a la fibra la cantidad de FDN la presente investigación solo tuvo una diferencia de 2.33% .El FDA de éste estudio es menor a un 7.78% comparada con la de autores.

En la investigación de Rivera (2013) [14] se sustenta que el hongo en su fase de crecimiento micelial (fase de incubación), consume preferiblemente carbohidratos solubles y hemicelulosa respecto de la celulosa y lignina. Con base en esto, el sustrato de endocarpio de coco no proporciona suficientes carbohidratos solubles, asimilables por el hongo en su fase de crecimiento en cuanto al contenido de hemicelulosa pero si en cantidades de lignina.

El resultado de nitrógeno de 0,29%, puede considerarse bajo para la obtención de una mayor eficiencia biológica y el contenido de proteína en el hongo. Se considera que para el cultivo del hongo Pleurotus el contenido de nitrógeno puede estar entre 0,7-0,9 % en peso seco [12].

Todos los alimentos, cualquiera que sea el método de industrialización al que hayan sido sometidos, contienen agua. La determinación del contenido de humedad, es uno de los análisis más importante y ampliamente usados en el proceso y control de

los residuos, ya que indica la cantidad de agua involucrada en la composición de los mismos [18]. Según el contenido de humedad de la biomasa es la relación de la masa de agua contenida por kilogramo de masa seca, el polvo de coco es altamente higroscópico, tiene una capacidad de retención de agua de hasta cuatro veces su peso, elevada capacidad de retención de agua facilita tener disponible el agua necesaria para el cultivo, suficiente suministro de aire, distribución del tamaño de las partículas adecuado para mantener las condiciones anteriores [19], esta capacidad de retener agua en el sustrato asegura que el ambiente de crecimiento para el hongo sea adecuado con un porcentaje de 5.5% en base seca.

En cuanto al efecto del tamaño de partícula sobre la capacidad de aireación y el agua total disponible, se estudiaron sustratos preparados con diferentes proporciones de partículas menores de 1 mm de diámetro; se determinó que conforme se incrementa el porcentaje de partículas menores de 1 mm, la capacidad de aireación disminuye. Por esto el sustrato con un rango de tamaño de partícula en los tratamientos de 0.300 y 0.600 μm, se compactó, debido a la cantidad de humedad en el sustrato por la formulación aplicada.

4.2 Identificación de condiciones de crecimiento del hongo

Comparado con los estudios de Bejarano (2016) [18], la temperatura óptima para el cultivo de Orellana es de 20-28°C y humedad de 70 a 80%, valores en los cuales el hongo alcanza sus mejores valores de crecimiento y fructificación. Las condiciones de crecimiento fueron las adecuadas durante el cultivo con parámetros ambientales de la región, Con temperaturas promedio de 26-28°C, estos parámetros indican que en temperaturas ambiente de 25 a 28°-C se pueden obtener resultados positivos para la siembra de pleurotus ostreatus.
Según Fernandez (2004) [20], no existe una única fórmula para la producción de Orellanas, esto es determinado por el mercado a quien va dirigida y la biomasa presente en el lugar donde se plantarán. De los tantos sustratos utilizados se tienen datos de que mientras más rico sea el sustrato más susceptible es para contaminarse por estas razones asegurar un método de desinfección adecuado y buenas prácticas de manejo. Las condiciones de cultivo de este estudio fueron 23-26°C y humedad de 90-99%, con una producción a los 15dias para el bagazo de caña, 23 días para el heno, luego a los 18 días en el tratamiento de cacao y seguidamente aparecieron los primordios de la combinación de cacao, maracuyá y bagazo de caña a los 20 días. El tratamiento que pasados 20 días no mostro ninguna respuesta en relación con el hongo Pleurotus ostreatus es el de cáscara de maracuyá.

Las condiciones de temperatura fueron de 26-28°C y una humedad de un 70-80%, las muestras correspondientes a los sustratos de pajilla de frijol y rastrojo de maíz, no desarrollaron fructificaciones en este periodo, sus estadios requirieron más de 28 días de incubación y 3 días más para su etapa adulta. El periodo de producción total más corto fue de 63 días en el sustrato de paja de trigo, en cebada fue de 68 días, en el sustrato de la hoja de plátano fue de 72 días, en el rastrojo de maíz 84 días y el mayor periodo de producción lo obtuvo la pajilla de frijol con 95 días, con un total de 3 co-

sechas por sustrato. Indicando que la producción del hongo se ve afectada en el desarrollo por las temperaturas, pero que si llega a una etapa de fructificación.

De acuerdo con Donado (2014) [21], las especies de Pleurotus tienen fototropismo positivo, ya que la luz (intensidad luminosa, fotoperiodo y tipo de radiación), es uno de los factores necesarios para el desarrollo de los primordios. En condiciones de total oscuridad se diferencian escasos basidiocarpos que suelen ser deformes, racimos, de forma coraloide, color blanco y sabor amargo, en los que no se distingue el pie y el sombrero. En condiciones de escasez de luz, se asiste a la producción de cuerpos fructíferos con forma de corneta, sombrero muy reducido y pie alargado y débil.

4.3 Evaluación de las condiciones de crecimiento del hongo

Aunque las condiciones de crecimiento estuvieron dentro de los valores de la literatura las variables de temperatura para el cultivo del hongo no pueden dejarse al azar, deben controlarse lo más posible para asegurar una estabilidad en el cultivo, ya sea por medio de instrumentos básicos como atomizadores o instalando sistemas de riego y así evitando la contaminación cruzada por parte de los operarios del cultivo.

Otro factor importante en las condiciones de crecimiento es una semilla que asegura un rendimiento de propagación mayor al 90%, se recomienda inocular in vitro para posteriormente inocular el sustrato de estudio.

Para evitar problemas de contaminación en el cultivo del hongo ostra, es necesario trabajar en condiciones asépticas, realizando una buena esterilización y pasteurización de los sustratos, desinfección de los cuartos de incubación y fructificación, esto ayuda a evitar la proliferación de plagas y enfermedades que pueden dañar la producción. Alrededor del módulo debe mantenerse muy limpio, siempre con el objetivo de no permitir el acercamiento e ingreso de ningún patógeno [11]. Realizando todos los medios para evitar la contaminación del cultivo.

Para el control de colémbolos y de dípteros se recomiendan medidas preventivas como colocación de filtros junto a los ventiladores, eliminación de residuos, tratamiento térmico de los sustratos para eliminar huevos y larvas, etc.

5. Conclusiones

El endocarpio de coco puede ser usado como sustrato en el cultivo de pleurotus ostreatus, si se utiliza un tratamiento de desinfección de choque térmico y una reducción de partícula menor a 1 mm.

No se puede descartar el uso de endocarpio de coco su composición, ya que su bromatológica está constituida por carbohidratos estructurales que favorecen el desarrollo del hongo.

Los resultados concuerdan con otras investigaciones de P. ostreatus, que indican que el cultivo de orellanas puede ser rentable económicamente y aportaría en la mitigación de la problemática ambiental que generan los residuos agroindustriales.

El porcentaje de lignina, celulosa y hemicelulosa (compuestos Lignocelulósicos), presentes en el endocarpio usado en el cultivo de Orellana, presentan una relación de

celulosa 24.37%. < lignina 44.41%. Para un porcentaje alto en la lignina, se debe considerar una formulación para aumentar el contenido de lignina ya que esta determina la dureza de las maderas e interfiere con el desarrollo adecuado para la fijación y absorción de nutrientes, por esta razón es necesario realizar la reducción del tamaño de partícula.

La cantidad de nitrógeno presente en el endocarpio de Coco (0.29%), según la literatura consultada y los resultados obtenidos, es un determinante importante en el crecimiento del hongo.

Para el cultivo de pleurotus Ostreatus cultivado en sustrato de endocarpio de coco, se debe considerar una formulación con dos o más componentes, para obtener la cantidad de nutrientes necesarios en el crecimiento y fructificación del hongo.

Para evitar la contaminación del sustrato, el ambiente debe ser inocuo, y generar las condiciones ambientales adecuadas para el crecimiento del hongo, y evitar que otros hongos compitan con el Pleurotus Ostreatus, sin retardar el crecimiento o la invasión micelar, asegurando la mejor eficiencia biológica posible.

1 Introducción

Las enfermedades, plagas y malezas son cada vez más comunes y agresivas en los sisemas productivos, por lo que se requiere del uso de tecnologías de control apropiadas a cada situación. La eficiencia de las mismas influye en la cantidad de producto que llega al objetivo, mejorando la calidad de las aplicaciones y permitiendo la reducción en el uso de principios activos y contaminaciones indeseadas. La calidad de las aplicaciónes es evaluada por medio de colectores artificiales que a su vez son procesados con diversos programas informáticos [1];[2]. Estos colectores y programas pueden diferir en sus resultados. Se evaluó la calidad de aplicación con dos colectores artificiales diferentes, tarjetas Amarillas (papel hidrosensible Syngenta®) y tarjetas Blancas (papel fotográfico Glosy de 230 gr m^{-2}) y dos programas de procesamiento (CIR-1.5 y Gotas-PC). El ensayo se realizó en condiciones semicontroladas, sin viento y sin desuniformidades de la superficie del terreno. Se sutilizaron 2 pastillas diferentes, de igual caudal por minuto y separadas 0,52 m, trabajando a 2,5 bares (250 kpa) de presión y con una velocidad de trabajo del equipo de 17 km h^{-1} para erogar 50 l ha^{-1} (Ver Tabla 1).

Table 1. Pastillas características descripción

Pastillas	Ángulo	caudal	Tipo	Marca	Siglas
XR11002VP	110	02	Abanico	Teejet	AP
TXA8002VK	80	02	Cono Hueco	Teejet	CC

El botalón circuló a 0,75 m por encima de objetivos artificiales que poseian prismas cúbicos donde se colocaron los colectores en posición horizontal, arriba (Ar), adelante (AdH) y atrás (AtH) y en posicion vertical adelante (AdV) y atras (AtV). Los mismos se digitalizaron con scanner a 1200 dpi, para ser procesadas con los programas CIR-1.5 y Gotas-PC, obteniendo los siguientes parámetros:

- Densidad de impactos (N° de improntas cm^{-2}).
- Eficiencia (%), relación entre lo recogido en el objetivo y lo aplicado.

También se trabajó con trazador colorimétrico (Azul Brillante FD&CNº1) recolectado con papel de filtro el cual fue lavado con agua para cuantificar el trazador mediante espectrofotometría, y comparar con la eficiencia obtenida por los programas.

2 Resultados y discusión

El programa CIR es el más sensible en la detección de las gotas y distingue superposición de las mismas, presentando un mejor desempeño para la cuantificación de Impactos cm^{-2}. No se observaronn diferencias estadisticas entre tipos de colectores (Ver Fig.1).

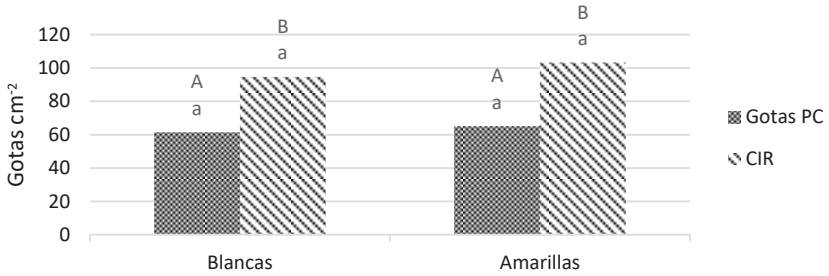

Fig. 1. Densidad de impactos por cm^{-2}. Comparación entre el cuantificado por los software CIR-1.5 y Gotas-PC utilizando los dos colectores, tarjetas blancas (papel Glosy) y tarjetas amarillas (papel hidrosensible). Letras mayúsculas diferentes significan diferencias estadísticamente significativas ($p \leq 0.05$) para el test de Ranks de Kruskal Wallis entre programas. Letras minúsculas diferentes significan diferencias estadísticamente significativas ($p \leq 0.05$) para el test de Ranks de Kruskal Wallis entre colectores

Los resultados demuestran que los colectores artificiales ubicados en las posiciones horizontales presentan mayor número de impactos que las verticales, ya que estas últimas son de mayor dificultad de alcance durante la pulverización, coincidiendo con [3–6]. Por otro lado, el programa CIR-1.5 contabiliza mayor número de gotas, con respecto al software Gotas-PC en todos los tratamientos realizados, sin importar el tipo de pastilla y tarjeta colectora, presentando las mismas tendencias de comportamiento en todas las posiciones; esto puede deberse a que Gotas-PC presenta dificultades para determinar superposiciones de impactos (propias de las gotas de mayor tamaño) y para reconocer gotas muy pequeñas lo que conlleva a un menor número de improntas cm^{-2} coincidiendo con [7] (Ver Fig.2 y Fig.3).

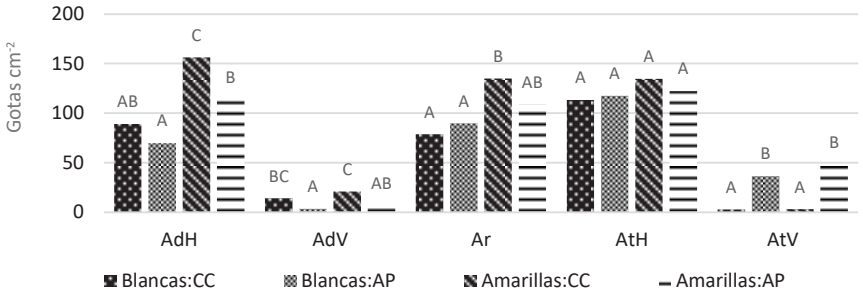

Fig. 2. Densidad de impactos cm^{-2} contabilizadas por el software Gotas-PC en las diferentes posiciones particionadas por colector tarjetas blancas (papel Glosy) y tarjetas amarillas (papel hidrosensible) y por pastilla AP y CC. Letras diferentes significan diferencias estadísticamente significativas ($p \leq 0.05$) para el test de Ranks de Kruskal Wallis dentro de cada posición.

Se pueden observar diferencias entre los colectores pero variables entre las posiciones y los programas. Esto probablemente se deba auna interaccion entre la capacidad de los programas de detectar diferentes tamaños de gotas y superposiciones de las mismas cuando alcanzan las distintas posiciones [7] [2]. Sumado a esto, los colectores de papel fotográfico disminuyen la expansión de las gotas generando diferentes tamaños de impronta que las tarjetas hidrosensibles, lo que colaboraría con estas diferencias tan variables [8].

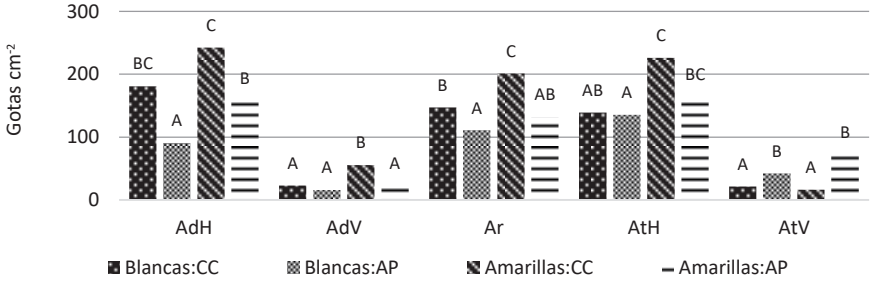

Fig. 3. Densidad de impactos cm^{-2} contabilizadas por el software CIR 1.5 en las diferentes posiciones particionadas por collector tarjetas blancas (papel Glosy) y tarjetas amarillas (papel hidrosensible) y por pastille AP y CC. Letras diferentes significan diferencias estadísticamente significativas ($p \leq 0.05$) para el test de Ranks de Kruskal Wallis dentro de cada posición.

Al estudiar la Eficiencia (%) a través de colectores fotográficos, tanto el software Gotas-PC como el CIR-1.5 arrojaron valores menores sin diferencias significativas con la metodología de trazador, demostrando un buen comportamiento por parte de los mismos. Mientras que, cuando se utilizaron colectores hidrosensibles, ambos software sobreestimaron la eficiencia de aplicación con relación al trazador. Esto puede deberse a que no todos los programas calculan el área de la gota de la misma forma, utilizando diferentes fórmulas de transformación de improntas en volumen [9], lo que seguramente genera errores entre programas. Los factores de corrección que utilizan los programas para calcular el volumen de la gota a partir de su impronta en el papel, están dados para trabajar con colectores hidrosensibles y no fotográficos (Ver Fig.4)

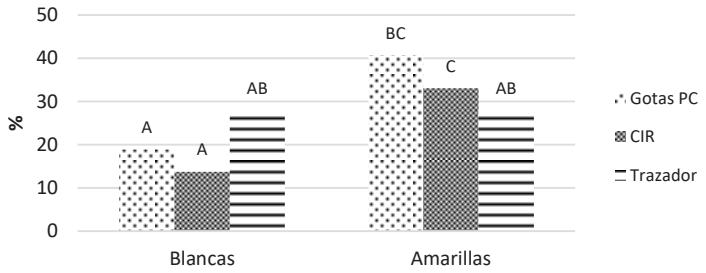

Fig. 4. Comparación de la eficiencia de aplicación cuantificada por los softwares CIR 1.5 y Gotas para pc con dos tipos de colectores, tarjetas blancas (papel Glosy) y tarjetas amarillas (papel hidrosensible) con respecto al trazador colorimétrico. Letras diferentes indican diferencias estadísticamente significativas ($p \leq 0.05$) para el test de Ranks de Kruskal Wallis.

Con el papel fotografico, el CIR 1.5 presenta diferencias con el trazador, aún siendo el del resultado más certero (sobreestima sólo un 18%). Gotas-PC no presenta diferencias significativas con el CIR 1.5 y el trazador, pudiendo deberse este comportamiento a la metodología estadística utilizada y a la gran variabilidad. Por otro lado, el programa Gotas-PC sobreestimó en un 45,9% la eficiencia cuando se emplearon colectores amarillos, probablemente por dificultades en transformar improntas en volumen. En este sentido, los propios fabricantes del software remarcan la necesidad de que la tarjeta hidrosensible presenten una baja densidad de impactos [10] [11].

Los diferentes colectores siguen la misma tendencia en todos los tratamientos, por consiguiente podrían utilizarse ambos para analizar la calidad de aplicación a campo, teniendo en cuenta que los porcentajes de eficiencia variarán según el colector utilizado.
