Abstract— Water needs energy and energy needs water. In this context, the optimization of the use of each of these variables is a fundamental goal to tackle climate change and achieve sustainable development. The water-energy nexus has gained relevance in the literature through the study of their dependencies, with the objective of increasing their synergies and reducing their trade-offs. Moreover, the nexus approach has proven to be a useful methodology to evaluate the impact of a variable (or group of variables) in a specific system or network, as for example, the intricate network of the Sustainable Development Goals (SDG). The main purpose of this study is to improve the understanding of the water-energy nexus through a comprehensive literature review, based on the influence of the publications (citation-based approach). The methodology allows the identification of the top 50 most influential papers related to the water-energy nexus, based on the number of citations that it has, since its publication in a scientific journal. Additionally, it has been analyzed the main journals in this topic, the context and characteristics of the publications (geographical locations and study design), most cited authors, the timeline and evolution of the literature. Finally, the study seeks to improve the comprehension of the relevance of the dependencies and interactions between these variables, added to their fundamental roles in the whole system.

Keywords: Water-Energy Nexus, Nexus Approach, SDG, Sustainability.

1 Introducción

La era del antropoceno, con la actividad humana como principal responsable de la presión sobre los recursos naturales y el medioambiente. En ese sentido, en las últimas décadas, las estadísticas reflejan un rápido crecimiento del consumo y demanda mundial del agua y la energía.

Las proyecciones realizadas por agencias internacionales indican que el consumo de agua para generación de energía aumentará en 60% al 2040 [1]. De la misma manera, estudios independientes indican que el consumo mundial de agua fresca y energía podrían aumentar en 50% en el año 2050 (año base 2015) [2].

En este contexto, acompañados de situaciones climáticas más intensas (sequías más prolongadas, olas de calor, escasez de agua, etc.), la tendencia es un aumento de la presión sobre los recursos hídricos y los sistemas energéticos, los cuales ya pueden ser observados en algunas de las regiones más vulnerables. En algunos casos, estas situaciones pueden incluso propiciar tensiones geopolíticas, como los que se observan por ejemplo en la construcción de la Gran Represa del Renacimiento, sobre el río Nilo azul y que impacta directamente en el potencial consumo de agua de 3 países (Etiopía, Egipto y Sudán).

Adicionalmente, también existen preocupaciones por el impacto en el medioambiente, suponiendo el riesgo global de someter a una gran presión sobre estos 2 recursos fundamentales para la vida humana: el agua y la energía ([3] & [4]). Así, en ambos sentidos de la interacción agua-energía, se ha buscado optimizar la utilización del recurso, con el objetivo de aliviar la presión sobre los recursos agua y/o energía, reducir las emisiones de gases de efecto invernadero e impulsar el desarrollo sostenible ([1],[5],[6] & [7]).

Como lo menciona [1], el agua depende de la energía y la energía depende del agua. En lo que se refiere al estudio del impacto del agua sobre los sistemas energéticos, en análisis generalmente se orienta a la optimización del consumo de agua en la generación de energía, además de cuestiones de seguridad energética en contexto de políticas de racionamiento de consumo de agua ([8],[9],[10],[11],[12] & [13]). En sentido contrario, el estudio del impacto de la energía en los sistemas hídricos, se encuentra en la literatura que los mismos se orientan a mejorar la eficiencia energética de los sistemas de irrigación, sistemas de bombeo y extracción, sistemas de desalinización de agua, entre otras ([15],[16],[17],[18] &[19]).

El Foro Económico Mundial del 2008 es normalmente mencionado como el origen del concepto de análisis a través del nexo agua-energía, a pesar de que existen algunos estudios previos que ya mencionaban este enfoque ([4] & [14]). De la misma manera, es innegable, que el enfoque de nexos agua-energía también ha ganado tracción en la literatura a partir del año 2015, con la Agenda 2030 y sus Objetivos de Desarrollo Sostenible (ODS), los cuales identifican al agua (ODS6) y la energía (ODS7) como fundamentales para el desarrollo sostenible ([20],[21] & [22]). En este sentido existen muchos estudios analizando nexos entre los ODS, abarcando diversas combinaciones, como nexos agua-energía-alimentos, nexo agua-energía-cambio climático, entre muchas otras [20].

Esta investigación tiene como objetivo proveer una visión holística de la producción científica en el área del nexo agua-energía, comprender la evolución de la literatura en dentro de las ciencias, identificar tópicos y publicaciones de tendencia dentro de la misma área, mediante el análisis de diversos indicadores bibliométricos.

El artículo está organizado de la siguiente manera: primero, en la Sección II se detalla la caracterización del problema de investigación; en la Sección III se explica la metodología implementada para la revisión sistemática de la literatura del nexo agua-energía; en la Sección IV se procede a presentar los resultados obtenidos; y finalmente en la Sección V se presentan las conclusiones de la investigación.

2 Caracterización del problema

2.1 Interacciones y enfoque de nexos entre los ODS

El compromiso asumido por los países miembros de las Naciones Unidas en el año 2015, a través de la Agenda 2030 y sus Objetivos de Desarrollo Sostenible (ODS) para el período 2015-2030, ha sido un tema de gran interés en la producción científica ([23],[24] & [25]).

No obstante, a pesar del gran volumen de publicaciones en las diversas áreas de los ODS, aún existen brechas en la comprensión sobre el impacto (sinergias y trade-offs) de las interacciones de los ODS, aumentando en complejidad a medida que se avanza en el nivel de análisis (objetivos, metas e indicadores) ([26],[27],[28],[29],[30],[31],[32],[33],[34], [35],[36] & [37]).

En este sentido, el análisis de las interacciones a través del enfoque de nexos ha permitido evaluar simultáneamente las interacciones entre distintos sectores [20]. Así, la literatura de enfoque de nexos ha permitido evaluar el impacto de un grupo de ODS sobre otro objetivo particular o grupo de objetivos, de manera a identificar y/o comprender las relaciones de sinergia, trade-off o neutralidad entre los mismos. Algunos de los enfoques de nexos más estudiados incluyen: agua-energía-alimentos, agua-alimentos-clima, alimentos-energía, agua-energía, energía-crecimiento económico-clima, entre muchas otras ([20],[22],[38] & [39]).

En lo que se refiere al enfoque de nexos agua-energía, según [1] las interdependencias entre ambas tenderán a intensificarse rápidamente en el futuro. Los distintos escenarios de [1] subrayan la necesidad de optimizar el consumo y gestión del agua en los sistemas de generación de energía, de lo contrario podría incrementar las posibilidades de estrés hídrico en distintas regiones del mundo, en donde el consumo de energía está aumentando rápidamente. De la misma manera, la mejora en eficiencia energética y la optimización de los sistemas de irrigación, son temas ampliamente abordados por el enfoque de nexos agua-energía ([12], [15], [40], [41]).

3 Metodología

3.1 Criterios de selección de artículos

Esta etapa se ha realizado mediante búsqueda sucesivas, estructuradas y lógicas de palabras clave. Estas búsquedas se han orientado exclusivamente en artículos, a través de la identificación de palabras claves, las cuales en este caso particular han sido "nexo agua-energía", las cuales debían encontrarse presentes en el título del artículo.

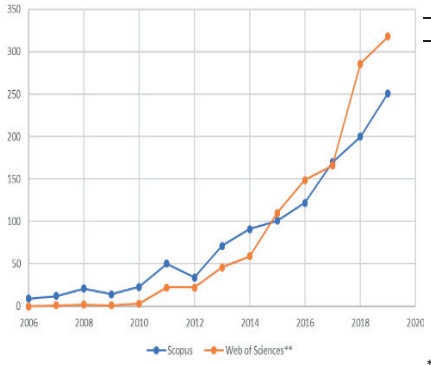
En este sentido, la búsqueda ha sido realizada a través de la base de datos bibliográfica Scopus, la cual agrupa principalmente publicaciones de las revistas indexadas a la editorial Elsevier. Así también, la búsqueda ha sido realizada en idioma inglés (water-energy nexus), teniendo en cuenta que la mayoría de las publicaciones científicas, presentes en dicha base de datos bibliográfica, se encuentran publicadas en ese idioma.

Adicionalmente, se ha podido incorporar al análisis el trabajo de [1], el cual permite tener una visión más amplia de artículos, los cuales se encuentran publicados en otras bases de datos bibliográficas (Web of Science), distintas de Scopus.

En lo que se refiere a la búsqueda propia, se han realizado primeramente las búsquedas que se identifican en la Tabla 1.

Table 1. Palabras claves utilizadas en las búsquedas

1º Búsqueda	(TITLE-ABS-KEY("water-energy nexus" OR "WEN" OR "sustainable development" OR "sustainability" OR "Sustainable Development Goals" OR "SDG" OR "SDG7" OR "SDG6" OR "SDG synergy" OR "Water-Energy Development" OR "water-energy co-benefits" OR "nexus approach" OR "nexus development" OR "water for energy" OR "energy for water"))
2º Búsqueda	(TITLE-ABS-KEY("water-energy nexus" OR "SDG7" OR "SDG6" OR "water-energy co-benefits" OR "nexus approach" OR "water for energy" OR "energy for water"))
3º Búsqueda	(TITLE-ABS-KEY("water-energy nexus" OR "nexus approach" OR "water for energy" OR "energy for water"))
4º Búsqueda	TITLE ("water-energy nexus") AND DOCTYPE (ar)



Como se observa en la Tabla 1, se ha realizado una búsqueda en 4 etapas, primeramente, se realizó la 1° búsqueda por palabras claves a partir del cual se obtuvieron 217.124 resultados. Teniendo en cuenta la gran cantidad de resultados, incluyéndose varias investigaciones no relevantes con el tema central de investigación, se ajustaron los parámetros de búsqueda en una 2° búsqueda, a partir del cual se obtuvieron 1.607 resultados. Luego, en la 3° búsqueda, considerando únicamente el enfoque de nexos, arrojó 1.169 resultados, aún así la cantidad de artículos no relevantes continuaba siendo elevada. Finalmente, se optó por ajustar los parámetros de búsqueda, orientándola exclusivamente a artículos con las palabras claves "water-energy nexus" en el título, con lo cual se pudo depurar la muestra y reducir la misma a 147 artículos (ver Material Complementario 1).

Se debe resaltar que, de acuerdo a los resultados de la búsqueda, la mayor parte de la literatura basada en el enfoque agua-energía ha sido principalmente publicada en la última década, siendo un tema relativamente reciente y que ha ganado mayor relevancia a través de su vinculación con los Objetivos de Desarrollo Sostenible (ODS6 y ODS7).

4 Resultados

4.1 Análisis de publicaciones

La distribución anual de publicaciones sobre el nexo agua-energía, como se ha mencionado previamente, ha crecido vertiginosamente a partir del año 2010. De hecho, el top 50 de los artículos más influyentes sobre este tema son prácticamente en su totalidad (a excepción de 1 artículo) del período 2011-2020 (ver Material Complementario 2).

Número de Publicaciones		
Año	Scopus	Web of Sciences**
2019	251	318
2018	200	286
2017	170	166
2016	122	149
2015	101	110
2014	91	59
2013	71	46
2012	34	22
2011	50	22
2010	23	3
2009	14	1
2008	21	2
2007	12	1
2006	9	-
Total	**1169**	**1185**

* Datos de Ding et al. (2020)

Fig. 1. Nº de publicaciones anuales en base al nexo agua-energía (3º filtrado)

Así también, vemos en la Fig. 1, que las publicaciones indexadas a las bases de datos de Web of Sciences (WoS) han crecido rápidamente, superando a las de la base de datos Scopus a partir del año 2015.

Los datos preliminares del año 2020 tienden a reforzar la tendencia, resaltando el creciente interés en este tópico en la literatura internacional.

4.2 Análisis de citaciones

En la presente sección se presenta el análisis de la revisión de la literatura en base a la evaluación del número de citaciones encontradas en la muestra de los artículos que han aplicado el enfoque de nexos agua-energía. Así también se identifica el top 50 de los artículos científicos más influyentes (de acuerdo al nº de citaciones) en este tópico, pudiendo observar la evolución del tema en la ciencia, sus ramificaciones en distintos sectores y disciplinas.

En la Tabla 2 se pueden observar los 10 artículos más citados, en base la metodología descrita previamente, aplicando el enfoque de nexos agua-energía.

Table 2. Lista de artículos con más citaciones (Top 10) *

Ranking	Título del Artículo	Autor/es	Nº Citaciones
1	The water-energy nexus in Middle East and North Africa	Siddiqi, A., Anadon, L.D.	295
2	Policy and institutional dimensions of the water-energy nexus	Scott, C.A., Pierce, S.A., Pasqualetti, M.J., (...), Montz, B.E., Hoover, J.H.	237
3	Linkage analysis for the water–energy nexus of city	Fang, D., Chen, B.	116
4	Optimal design and operations of supply chain networks for water management in shale gas production: MILFP model and algorithms for the water-energy nexus	Gao, J., You, F.	111
5	Water-energy nexus: A review of methods and tools for macro-assessment	Dai, J., Wu, S., Han, G., (...), Xue, W., Yang, Q.	97
6	Gaining perspective on the water-energy nexus at the community scale	Perrone, D., Murphy, J., Hornberger, G.M.	88
7	Evaluation of Spain's water-energy nexus	Hardy, L., Garrido, A., Juana, L.	84
8	Is there a water-energy nexus in electricity generation? Long-term scenarios for the western United States	Ackerman, F., Fisher, J.	83
9	Water-energy Nexus: A case of biogas production from energy crops evaluated by Water Footprint and Life Cycle Assessment (LCA) methods	Pacetti, T., Lombardi, L., Federici, G.	69
10	Drought and the water-energy nexus in Texas	Scanlon, B.R., Duncan, I., Reedy, R.C.	63

*Citaciones en indexadas en base de datos bibliográficos de Scopus.

Es interesante destacar que, si bien se esperaría que los artículos más antiguos corran con ventaja por el tiempo que han estado disponibles para acumular citaciones, en la realidad se observa que esto no necesariamente se cumple. En el top 50 de los artículos más influyentes identificados previamente, la mayor cantidad de artículos corresponden al año 2018 (13 publicaciones), y el 80% de las publicaciones corresponden al período 2015-2019 (40 publicaciones), todo ello en correspondencia con la adopción de la

Agenda 2030 y los Objetivos de Desarrollo Sostenible a partir del año 2015 y su consecuente impacto en el análisis del enfoque de nexos para la medición del impacto e interacciones de los objetivos relativos al agua (ODS6) y energía (ODS7).

4.3 Revistas más influyentes relacionadas con el análisis del nexo agua-energía

En la Fig. 2 se pueden distinguir las revistas con mayor número de artículos publicados en referencia al nexo agua-energía, destacándose principalmente: Applied Energy y el Journal of Cleaner Production.

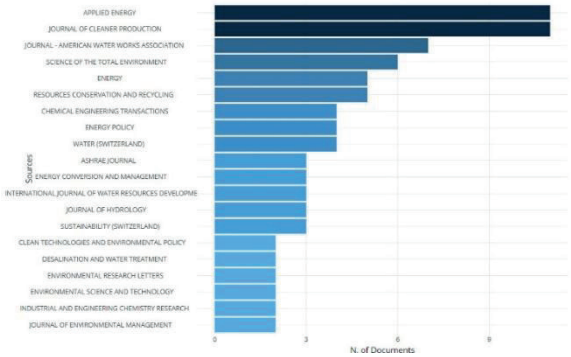


Fig. 2. Revistas con mayor nº de publicaciones (nexo agua-energía)

Luego, analizando únicamente el top 50 de publicaciones más influyentes, de acuerdo al número de citaciones, se observa que el 39% de las mismas se encuentran publicadas en 4 revistas: Applied Energy, Journal of Cleaner Production, Science of the Total Environment y Energy Policy.

No obstante, se debe resaltar que, de manera general, la distribución de publicaciones entre las distintas revistas científicas es bastante variada y diversificada, pudiéndose observar, en la muestra total de 147 publicaciones, un total de 80 revistas con publicaciones relacionadas al enfoque de nexos agua-energía.

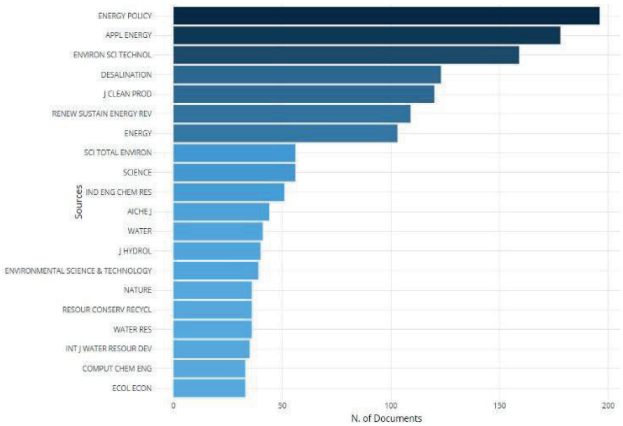

Fig. 3. Revistas con mayor nº de citaciones

Así también, se ha podido identificar en la Fig. 3, que no necesariamente revistas con mayor cantidad artículos publicados son los que acumulan más citaciones en la literatura del enfoque de nexos agua-energía (por ej. Energy Policy).

4.4 Autores más prolíficos

La literatura referente al nexo agua-energía es una literatura relativamente reciente, la cual ha ganado tracción principalmente en la última década (2010-2020). En ese sentido, como parte de los resultados obtenidos se observa que los autores más productivos en este tópico han acumulado entre 1 a 4 artículos publicados en diversas revistas científicas (Fig.4).

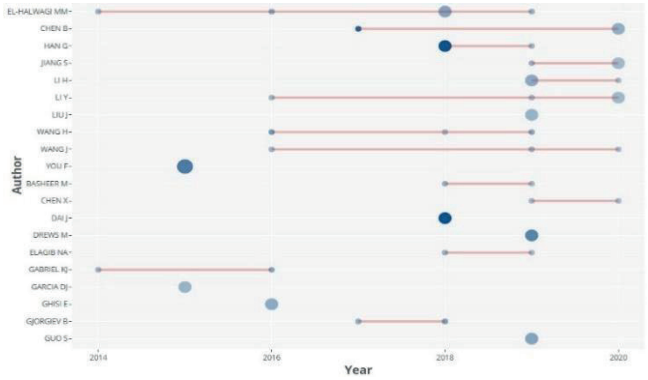

Fig. 4. Evolución de publicaciones de autores prolíficos

De la misma manera, se puede observar en la Fig. 5, que no existe una correlación relevante entre la cantidad de artículos publicados y la cantidad de citaciones acumuladas localmente por autor. La cantidad acumulada de citaciones locales de un autor indica su nivel actividad en una determinada área de estudio.

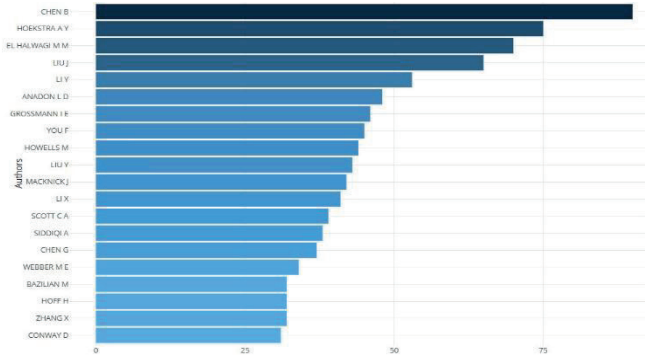

Fig. 5. Autores con mayor nº de citaciones locales

En lo que se refiere a la autoría principal de los trabajos publicados dentro del top 50 de los artículos más influyentes, no se observa ninguna brecha o predominancia de algún autor en particular. En este sentido, la mayoría de los autores principales en este grupo posee una única publicación, a excepción de 2 autores (K.J. Gabriel y B. Gjorgiev) quienes poseen 2 publicaciones cada uno, los cuales se enfocaron en la optimización del uso del agua en la industria y en la generación de energía.

En lo que se refiere al análisis geográfico de las publicaciones, en función a las afiliaciones de los autores, es importante destacar que el enfoque de nexos agua-energía es un tópico de tendencia principalmente en universidades y centros de investigación de China y EEUU, como se puede observar en la Fig. 6. En ese sentido, también se ha analizado en la muestra, la cantidad de veces que han sido citados los distintos países estudiados en los artículos publicados, observándose que EEUU acumula 806 citaciones, seguido por China con 169 citaciones y luego España con 143 citaciones

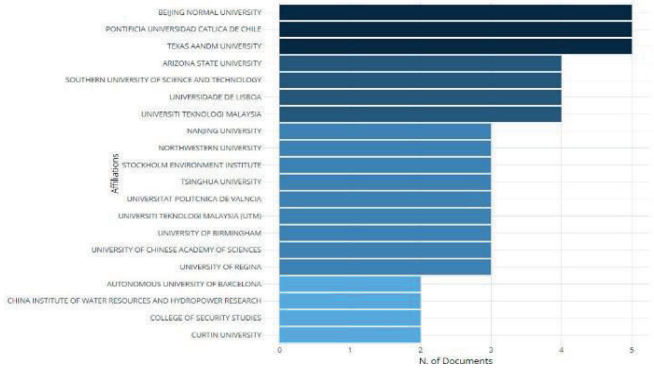

Fig. 6. Nº de publicaciones por afiliación

4.5 Análisis detallado de contenido del top 50 de artículos más influyentes

La literatura referente al enfoque de nexos agua-energía abarca una vasta diversidad de sectores y ciencias, lo que se refleja consecuentemente en los distintos tipos de publicaciones y objetivos perseguidos por cada uno de los mismos.

En este sentido, como resultado de la metodología implementada para la revisión bibliográfica, se puede distinguir que la mayor parte de los artículos en el top 50 en este tópico, se enfocan en el sentido de interacción agua → energía (43%), es decir, mejorar la comprensión del impacto del agua (i.e. escasez, políticas públicas, sistemas de bombeo, etc.) en la generación de energía.

No obstante, es importante resaltar que también existen otras alternativas al momento de realizar el análisis, como ser el sentido de interacción energía → agua, en donde el objetivo es cuantificar o comprender el impacto de la energía en el consumo de agua y/o en el servicio de tratamiento de aguas residuales. Así también, existen estudios más amplios, que realizan simultáneamente el análisis del nexo agua-energía en ambos sentidos de interacción. En la Tabla 3 se identifica el tipo de interacción analizada en cada uno de los artículos dentro del top 50 más influyentes seleccionados previamente.

Table 3. Top 50 artículos nexo agua-energía según tipo de interacción analizada

Agua → Energía	Energía → Agua	Agua←→Energía
[8] [9] [10] [11] [12] [13] [14] [44] [46] [47] [48] [49] [52] [53] [54] [57] [60] [66] [67] [71] [73] [75]	[15] [16] [17] [18] [19] [40] [41] [56] [58] [59] [61] [63] [65] [69] [70] [72]	[5] [6] [7] [42] [43] [45] [50] [51] [55] [62] [64] [68] [74]

Así también, se han analizados los resúmenes de los artículos seleccionados previamente, y a través del conteo de palabras claves, se han identificado tópicos de tendencia dentro de la misma área de estudio (enfoque de nexos agua-energía). Así, en la Fig. 7, se pueden distinguir todas aquellas palabras claves, identificadas en los resúmenes de los artículos, que han acumulado una frecuencia de 5 o más citaciones en el período de estudio.

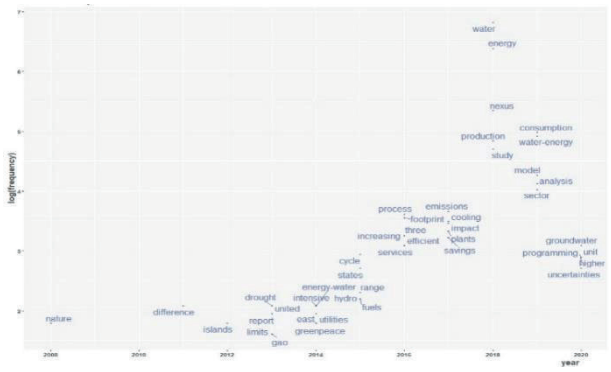

Fig. 7. Análisis de tópicos de tendencia (palabras claves)

Luego, se observa que algunas de las palabras claves, además de aquellas principales (agua, energía y nexo), incluyen: producción, consumo, estudio, modelización y análisis. De hecho, el consumo y la producción de agua y/o energía, son algunos de los elementos de estudio más recurrentes en el análisis del nexo agua-energía.

De la misma manera, se observa en la Fig. 8, que dentro de la intrincada red de coincidencias de la literatura de enfoque de nexos agua-energía, analizada a partir de los resúmenes de los artículos previamente seleccionados (n=147), que los nodos con mayor número de conexiones son: agua, agua-energía, nexo y energía. También, el algoritmo utilizado para la clusterización, distingue 3 grandes clústeres.

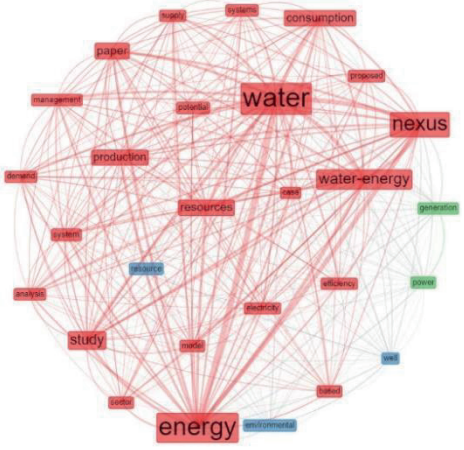

Fig. 8. Red de coincidencias en artículos de enfoque de nexos agua-energía

Así, se observa que variables que previamente ya habían sido identificadas como relevantes en el estudio del nexo agua-energía, efectivamente tienen un rol fundamental en la red de interacciones del tema analizado, como son: producción, consumo, recursos, demanda, electricidad, entre otras.

Como ya lo han identificado otros autores, la mayoría de los estudios con enfoque de nexos agua-energía son eminentemente cuantitativos, existiendo por el momento, una muy baja producción científica orientada a los aspectos de vinculación del análisis del nexo agua-energía para el diseño de políticas públicas y de administración eficiente de recursos naturales [1].

5 Conclusiones

La relación de dependencia, cada vez más intensa, entre el agua y la energía es innegable e inevitable, como lo han demostrado diversos autores. Esta relación entre 2 recursos fundamentales para la vida humana, y que han sido identificados como parte de los Objetivos de Desarrollo Sostenible (ODS6 y ODS7), tienen un impacto relevante en otros sistemas y sectores, como la producción de alimentos, cambio climático, emisiones de gases de efecto invernadero, crecimiento económico, entre otras.

Este trabajo ha realizado una revisión bibliográfica estructurada, mediante indicadores bibliométricos, de la literatura más influyente acerca del nexo agua-energía. En ese sentido, el principal aporte de la investigación ha sido la identificación de tendencias e influencias en la literatura del enfoque de nexos agua-energía, permitiendo una mejor comprensión de la evolución de la misma en la ciencia y su relevancia en distintos sectores y desde variadas perspectivas.

Los resultados demuestran un creciente interés en el nexo agua-energía, principalmente a partir del año 2010 en adelante, situación que ha reforzada a partir del año 2015 con la adopción de la Agenda 2030 de las Naciones Unidas. De la misma manera, se observa una gran representatividad de estudios orientados a la problemática en China y Estados Unidos, abarcando estudios a nivel urbano, local, regional, nacional o transnacional. Así también, se ha encontrado que los artículos identificados y relacionados al nexo agua-energía han sido publicados en una gran variedad (aproximadamente en 80 revistas) de revistas científicas, sin embargo, son 2 las que se destacan claramente sobre las demás: Applied Energy y el Journal of Cleaner Production.

Se observa una tendencia hacia un análisis del enfoque de nexos agua-energía orientados hacia la modelización y optimización del consumo y/o producción (generación) de estos recursos, teniendo en cuenta las proyecciones al alza de la demanda de ambos en el largo plazo, considerando los riesgos del cambio climático y la relevancia de la seguridad energética. Luego, alineados con estas tendencias, se observa en el mapa de relaciones que además de las palabras claves (agua, energía y nexos), existe un importante número de conexiones en la red entre otras variables ya identificadas previamente como: consumo, producción, electricidad y recursos.

Es importante tener en cuenta las limitaciones propias de la metodología implementada, considerando el limitado número de artículos analizados y su inscripción dentro de una única base de datos bibliográficos. No obstante, los resultados ofrecen un panorama global del enfoque de nexos agua-energía en la literatura y permiten establecer un marco conceptual más estructurado para futuras investigaciones orientadas a algunas de los tópicos de tendencia identificados en la investigación.

Finalmente, en relación a perspectivas futuras de investigación, se recomienda profundizar la comprensión del enfoque de nexos agua-energía, a nivel de metas y/o indicadores, de manera a identificar las sinergias y trade-off que aceleren el desarrollo sostenible de empresas, industrias, ciudades y/o países. Así también, existe un campo bastante fértil para la investigación del nexo agua-energía y su impacto en sistemas más amplios y dinámicos, como la generación de alimentos, crecimiento económico y/o cambio climático.

Resumen. Las enfermedades fúngicas en el cultivo de trigo (Triticum aestivum) ocasionan pérdidas importantes en rendimiento y calidad de los granos. Los coadyuvantes deben considerarse como herramientas de manejo que mejoran el nivel de desempeño de los fitosanitarios. Se realizaron ensayos sobre espigas de un cultivo de trigo en antesis temprana (estado Z61) para evaluar el efecto de la adición de coadyuvante sobre la prestación de diferentes pastillas. El ensayo fue conducido en un esquema factorial de 4x2 con 10 repeticiones. Los factores fueron cuatro pastillas: abanico plano (XR11002), doble abanico asimétrico con aire inducido (AI3070), doble abanico simétrico con aire inducido (AI3030), cono hueco (TXA8002), y la adición de un codyuvante polifuncional. Se utilizaron tarjetas hidrosensibles y el programa CIR 1.5® para la determinación de densidad de impactos (imp cm^{-2}) y el Diámetro Volumétrico Mediano (µm), y mediante el uso del trazador Azul Brillante se determinó la deposición (%). Se realizó análisis de la varianza y las medias fueron comparadas por el test de Tukey ($p \leq 0,05$). La inclinación en 70º hacia atrás, mejora la cantidad de depósito sobre la espiga respecto a ángulos menores. La utilización de gotas finas y direcciones múltiples como las de la boquilla de cono hueco aumentan la deposición. El efecto del coadyuvante sobre las boquillas, no es concluyente y no se encontraron beneficios significativos en el uso de los mismos. La utilización de este tipo de coadyuvante provocó que la vena líquida se rompiera en un mayor número de impactos de menor diámetro.

Keywords: Palabras clave: Deposición, doble abanico; aire inducido.

1 Introducción

El trigo (Triticum aestivum) es el cereal de invierno más importante de la Argentina. Una de las principales problemáticas asociadas a este cultivo, es el manejo sanitario. La presencia de enfermedades foliares y de la espiga provocan grandes reducciones en el rendimiento y en la calidad de los granos. Para lograr disminuir el desarrollo de las mismas, se hace hincapié en la aplicación de fungicidas en el momento oportuno. En el caso de la fusariosis de la espiga(Fusarium graminearum), la aplicación debe ser en forma preventiva, con productos fungicidas que actúen principalmente como de contacto, por lo cual deben ser aplicados inmediatamente antes de la ocurrencia de la infección. [1] menciona que el momento óptimo para realizar el control es aproximadamente una semana después del inicio de la floración, máxima exposición de las anteras, pero generalmente las dificultades operativas para la aplicación condicionan

un tratamiento tardío. Este hecho pone de manifiesto que los resultados poco satisfactorios en el control químico a campo radican en la dificultad en alcanzar las anteras con la aspersión por la estructura de la espiga, en las técnicas de aplicación y en las condiciones ambientales al momento de la aplicación.

Experiencias usando fungicidas demuestran un amplio rango de eficiencia de acuerdo a múltiples factores tales como la elección del fungicida, el momento y método de aplicación, considerando los tipos de picos pulverizadores y las condiciones climáticas presentes durante el momento de aplicación como determinantes del éxito de la aplicación [2]. [3], establece que el éxito o fracaso de un tratamiento fitosanitario depende de cuatro factores básicos: buena calidad del agua, correcta elección de producto y dosis, momento oportuno de control y calidad de la aplicación. [4] citan que una buena aplicación implica una correcta distribución del fitosanitario, con mínimas pérdidas. Todas aquellas gotas que no lleguen al blanco, o que aun habiéndolo alcanzado no permanezcan retenidas sobre él, constituyen una pérdida de producto que reduce la eficiencia de la aplicación y se conoce genéricamente como deriva. La tecnología ha desarrollado dispositivos para disminuir las pérdidas por deriva, con la creación de nuevas boquillas, ya sean dotadas de pre-orificio o con inducción de aire, aumenta así el diámetro de gotas y disminuye la proporción de aquellas más propensas a la deriva. Sin embargo, existen opiniones encontradas en cuanto a la eficacia de las mismas. Al aumentar el tamaño de gota manteniendo constante el volumen de aplicación necesariamente se estará disminuyendo la cantidad de gotas formadas [5].

Para que la aplicación de agroquímicos sea adecuada, es necesario seleccionar el tamaño de gotas conforme a las condiciones climáticas imperantes durante el momento de la aplicación [6]. En este sentido, las gotas formadas por las boquillas de pulverización pueden tener su tamaño alterado por la presión de trabajo, formulación del producto utilizado, tipo y conformación de la boquilla. Estos últimos son los responsables de la calidad de la aplicación e interferirán sobre el caudal, cobertura del blanco y en la uniformidad de distribución del caldo.

La eficiencia de una pulverizadora puede estar afectada por la mala elección de las boquillas o estado avanzado de desgaste, mala ubicación en el botalón, altura inadecuada o por la presión de trabajo no aconsejada. Las boquillas son elementos básicos para una correcta uniformidad de distribución del producto sobre el cultivo y/o el suelo. Se debe elegir el tipo y modelo de boquilla de acuerdo al volumen que se va a pulverizar por hectárea, el producto, la plaga y el cultivo a tratar [7].

Al respecto, [8] sugiere para aplicaciones de fungicidas sistémicos una cobertura mínima de 30 a 40 gotas cm-2, mientras que, [9] establece un mínimo de 20 a 30 impactos cm-2 como norma general para productos sistémicos. [10] recomienda una densidad de al menos 50 a 70 impactos cm-2 para proporcionar resultados satisfactorios en la aplicación de fungicidas. En tanto que, [11] y [12] acuerdan que 60 impactos cm-2 son necesarios cuando se realizan tratamientos fúngicos para alcanzar eficacia biológica, dejando de lado los efectos de cobertura, características de la población de gotas, tamaño de gotas, amplitud relativa, uniformidad de distribución y recuperación de la solución aplicada sobre el objeto de aplicación. La amplitud relativa da una referencia de la homogeneidad de la clase de gotas que llegan al objetivo, cuanto más chico sea el número, más homogéneo es el espectro de gotas.

Sin embargo, además de la densidad de impactos, también es importante el diámetro de gotas para este tipo de productos. [13], recomiendan un diámetro de gotas (diámetro volumétrico mediano - DVM) entre 200 μm y 300 μm (gotas finas a medianas, según norma ASABE S572.1) como ideales para aplicaciones de fungicidas

sistémicos, relacionando el tamaño de la gota con la capacidad de deposición de las mismas, siendo que gotas finas (entre 106 µm y 235 µm, según ASABE S572.1) propician mayor cobertura pero presentan mayor riesgo de deriva. [14] encontraron menor diámetro de las gotas, mayor densidad y cobertura para las boquillas de cono hueco respecto a boquillas de abanico plano, bajo condiciones controladas. Sin embargo, estas últimas presentaron mayor uniformidad, atribuible, en principio, al perfil de distribución. Similares resultados presentaron [15], sobre un cultivo de soja (Glycine max (L) Merr) en R5, asociando la mejor distribución en el canopeo de las boquillas de cono hueco con la mayor cantidad de impactos de menor DVM, tanto en el estrato superior como en el inferior; las boquillas de doble abanico, en cambio, con un espectro de gotas de finas a medianas (entre 106 µm y 340 µm, según norma ASABE S572.1), no tuvieron mayor penetración después de los 0,20 m. Por su parte, [16] obtuvieron mejores porcentajes de cobertura, tanto en la espiga como en la hoja bandera de un cultivo de trigo, cuando pulverizaron con gotas finas (entre 106 µm y 235 µm, según norma ASABE S572.1).

Conforme a lo mencionado hasta aquí, la aplicación eficiente requiere una cobertura adecuada de la superficie objetivo con gotas de tamaño apropiado. La elección del patrón de gotas es muy difícil de definir, ya que depende de una serie de interacciones en la cual interviene el tipo de producto fitosanitario, su modo de acción, su formulación, la ubicación de la plaga, el tamaño de la plaga, las características de la superficie de la plaga y las condiciones ambientales [17]. Además de estar afectado por el diseño de la punta de pulverización, el patrón de gotas producido también sufre influencia de la presión de trabajo y de las características físicas del caldo que varían de acuerdo con la formulación del producto y el tipo de adyuvante que se utiliza. Debido a que la utilización de estos aditivos se ha incrementado notablemente en los últimos tiempos, es importante evaluar las características físicas que estas sustancias le confieren al caldo de pulverización y las posibles variaciones que pueden presentarse en el espectro de distribución. De hecho, el rendimiento de las boquillas pulverizadoras puede ser sustancialmente modificado a causa de los coadyuvantes, afectando tanto el proceso de formación de las gotas como el comportamiento de estas en contacto con el blanco, alterando el riesgo potencial de deriva de la aplicación [18].

Los coadyuvantes deben considerarse como herramientas de manejo que mejoran el nivel de desempeño de los fitosanitarios y la consistencia de los resultados. En este sentido, [19] encontraron una disminución de la capacidad antiderivante al evaluar la interacción de dos coadyuvantes comerciales, un tensioactivo y un antiderivante, utilizados conjuntamente durante el proceso de aplicación de agroquímicos. Por su parte, [20] evaluaron la influencia de diferentes adyuvantes multifuncionales asociados a cuatro formulaciones de glifosato en el control de Digitaria insularis L. La maleza mostró una alta sensibilidad a las diferentes formulaciones de glifosato, aunque la adición de los adyuvantes al caldo de pulverización, independientemente del tipo de sal, no tuvo beneficios significativos en el control de la misma, sin un aumento en la velocidad de acción del herbicida. [21] evaluaron el efecto de la adición de coadyuvantes (surfactantes) a los fungicidas en el control de enfermedades foliares y de la espiga en trigo. Los resultados demostraron que la adición de adyuvantes al caldo de pulverización interfirió positivamente en el desempeño de los fungicidas y afectó significativamente la severidad de enfermedades, el número de granos por espigas, la productividad y el retorno económico. De la misma manera, [22] estudiaron la combinación de adyuvantes y fungicidas sobre las características fisicoquímicas del caldo de pulverización y el control de enfermedades foliares en los cultivos de trigo y soja. Los mismos concluyeron que la adición de coadyuvantes al caldo de pulverización

redujo significativamente la tensión superficial de la mezcla respecto al fungicida sin aditivos, atribuyendo a esta característica la menor severidad e incidencia de enfermedades.

[23] evaluaron la interacción de dos boquillas, abanico plano inclinado y abanico plano con inducción de aire, con diferentes adyuvantes de uso agrícola en la estimación del riesgo potencial de deriva. Los resultados determinaron que la boquilla con aire inducido obtuvo el mayor DVM, menor porcentaje de gotas ≤ 100 µm, menor riesgo potencial de deriva y espectro de gotas más uniforme en comparación a la de abanico plano inclinado. La adición de adyuvantes, independientemente de sus propiedades, minimizó los riesgos potenciales de deriva en la boquilla de abanico plano inclinado en tanto que, en la de aire inducido, únicamente el polímero vegetal tuvo este efecto, siendo el más eficiente. [24] estudiaron la influencia de diferentes aditivos y boquillas en la deriva de glifosato. Los autores concluyeron que la reducción de la deriva de glifosato está relacionada con la selección correcta de la boquilla de pulverización. Las boquillas con aire inducido proporcionaron menor deriva que la boquilla de abanico plano convencional, así como menor densidad de impactos y mayor DVM en el objeto de aplicación. El comportamiento de los adyuvantes fue dispar, NP-10® y Emultec R® aumentaron la deriva mientras que Grap 'Oil®, Grap Super Gun®, Iharol® y Dash HC® disminuyeron la densidad de gotas derivadas cuando se utilizaron con la boquilla XR, en comparación con el testigo sin coadyuvantes. [25] evaluaron la incidencia de dos tensioactivos sobre el grado de cobertura, tanto en tarjetas hidrosensibles como en hojas de cultivo de soja, mediante el empleo una boquilla de abanico plano 80015 a 300 kPa de presión. El agregado de tensioactivos al caldo de pulverización incrementó el grado de cobertura, dado principalmente por un aumento en el DVM de los impactos que alcanzaron los objetivos. El nivel de cobertura logrado estuvo afectado por las características superficiales del blanco. [26] encontraron una tendencia al aumento en la densidad de impactos con el uso de tensioactivos. Los mismos mencionan que los adyuvantes con tensioactivos se usan con la finalidad de disminuir la tensión superficial e incrementar la adherencia por una mayor superficie de contacto, contrariamente a lo que ocurre cuando se utiliza agua como dispersante que produce efectos de alta tensión superficial lo que provoca que las gotas adopten la forma esférica, con poca superficie de contacto y con tendencia al escurrimiento. Del mismo modo, [27] indican que la reducción de la tensión superficial de las gotas aumenta las posibilidades de retención de las mismas, mientras que [23] encontraron que la adición de adyuvantes minimizó los riesgos potenciales de deriva en boquillas de abanico plano inclinado y abanico plano con inducción de aire. En tanto, [28] trabajaron con dos tipos de coadyuvante, aceite agrícola metilado y ésteres metílicos de ácidos grasos de aceites vegetales, para la aplicación de herbicidas en el control de malezas de hoja ancha. Encontraron que el uso de ésteres generó mayor cantidad de gotas finas a muy finas, probablementepor una mayor reducción de la tensión superficial del agua, con la consecuente pérdida de gotas en el ambiente de trabajo. A este efecto también le adjudicaron el "corrimiento" del DVM, observándose una diferencia entre la lectura del software y la clasificación de la tabla que aporta la marca de boquillas utilizadas.

[29] demostraron que las gotas gruesas (entre 341 µm y 403 µm, según norma ASABE S572.1) generadas por boquillas con aire inducido y la disposición de dos boquillas (una hacia adelante y otra hacia atrás), aumentan la deposición en objetivos verticales y horizontales de un cultivo de cereal. Los mismos aseguran que al aumentar el ángulo entre las dos boquillas, también aumentan los depósitos en dichos objetivos. También [30] sugieren, para un control eficiente de las enfermedades en

espiga, utilizar boquillas anguladas hacia atrás y una población de gotas medianas (entre 236 µm y 340 µm, según norma ASABE S572.1) o con aire inducido. Además, encontraron una tendencia hacia una mayor deposición sobre la cara trasera de las espigas respecto a la delantera, para todas las boquillas utilizadas. Sin embargo, el abanico con aire inducido y con una inclinación de 10° hacia atrás presentó la mayor deposición en ambas caras, mientras que el abanico convencional la menor. Por su parte, [31] recomiendan trabajar con boquillas de abanico plano orientadas en la dirección de avance, con una inclinación respecto a la horizontal de 30° hacia abajo y asistidas con una corriente de aire, asegurando una mayor deposición y cobertura sobre las caras de la espiga. En este sentido, [32] demostraron que los depósitos sobre espigas de trigo aumentaron a medida que la inclinación de la boquilla de abanico plano variaba de 10° a 40°.

En razón de lo expuesto, la pulverización es la forma de aplicación más común y difundida de fitoterápicos, pero sus resultados son variables y complejos, lo que hace importante su evaluación.

Teniendo en cuenta lo antes mencionado, el presente trabajo tiene por objetivos evaluar el efecto del agregado de coadyuvante en la prestación de distintas boquillas sobre el cultivo de trigo.

2 Materiales y métodos

Los ensayos tuvieron lugar en la Estación Experimental Julio Hirschhorn de la Facultad de Ciencias Agrarias y Forestales de la Universidad Nacional de La Plata (34° 59' S, 57° 59' W), situada en la localidad de Los Hornos de la ciudad de La Plata, Argentina. Las aplicaciones se efectuaron sobre un cultivo de trigo (Triticum aestivum) en la etapa de antesis temprana, estado Z61 según escala de Zadocks et al., (1974), correspondiente al período de cultivo de mayor susceptibilidad a la infección por Fusarium graminearum. Para realizar las aplicaciones, se utilizó un equipo pulverizador hidráulico montado con un tanque de 400 l de capacidad, ancho de labor de 8,4 m, portapicos múltiples distanciados a 0,525 m y altura de botalón respecto a la espiga de 0,35 m. La velocidad de desplazamiento del conjunto fue de 2,45 m s-1, la presión de trabajo de 300 kPa y la tasa de aplicación para todos los tratamientos de 103 l ha-1, en correlación con los volúmenes que se utilizan para tratamientos de fungicidas. Para las aplicaciones se utilizó agua y se agregó un trazador de tipo alimenticio, Azul Brillante (FD&C Azul No. 1) en una dilución de 13,073 g l-1. Con el objetivo de evaluar el efecto de la adición de un aditivo a la mezcla, se incorporó un coadyuvante polifuncional marca Rino® en una dosis de 30 ml hl-1. El mismo es un nonilfenol polietilenglicol éter que tiene las propiedades de ser adherente, dispersante, emulsionante, humectante y tensioactivo.

Las condiciones meteorológicas promedio durante el ensayo fueron de cielo descubierto, temperatura media de 29,4 ºC, humedad relativa del 42% y velocidad del viento de 4,5 km h-1 con ráfagas de hasta 11,3 km h-1.

Se utilizó un diseño factorial de 4x2 con diez repeticiones distribuidas completamente al azar. Se evaluaron cuatro diseños de boquillas, abanico plano 11002 (AP11002), cono hueco 8002 (TXA8002), doble abanico simétrico con inducción de aire 11002 (AI3030) y doble abanico asimétrico con inducción de aire 11002 (AI3070) que definieron los tratamientos. Cada uno de ellos fue evaluado con agua y con la mezcla de agua y coadyuvante, estableciéndose así dos subtratamientos para cada uno (Tabla 1).

*clases de gotas de las boquillas de acuerdo a ASABE S572.1 (ASABE, 2009)
**Inclinaciones con respecto al plano vertical central de la boquilla

Se estableció como objetivo de medición la espiga. La misma fue evaluada a través de dos metodologías. Por un lado, se determinó la deposición del caldo por medio de la cuantificación del trazador adicionado al mismo (Azul Brillante, FD&C Azul No. 1), conforme a la metodología propuesta por [33]. Para ello, luego de realizada la aplicación y del secado del pulverizado sobre el cultivo, se recolectaron diez espigas por repetición y se colocaron en recipientes individuales y herméticos. En el laboratorio, las muestras de material se lavaron con 30 ml de agua destilada y mediante un espectrofotómetro se realizó la lectura de fluorescencia del residuo recolectado. Con la medida de fluorescencia y a partir de curvas de calibración realizadas con concentraciones conocidas de trazador, se determinó la cantidad de pulverizado por espiga.

Por otro lado, se utilizaron tarjetas hidrosensibles Syngenta® de 3" x 1" a fin de caracterizar la población de gotas que alcanzó el objetivo. Para esto, mediante un tubo cilíndrico apoyado sobre la espiga, se colocaron cuatro tarjetas hidrosensibles simulando las caras de la misma: anterior, posterior, derecha e izquierda. Las tarjetas fueron digitalizadas con una resolución de 1200 dpi y procesadas por medio del programa CIR 1.5. Se realizó el conteo y cálculo de las variables repuesta sobre el promedio de cinco ventanas de medición. Las mismas fueron: Densidad de impactos (DI, imp. cm^{-2}) y Diámetro Volumétrico Mediano (DVM, µm).

Los datos obtenidos se analizaron mediante un ANOVA factorial y los promedios se compararon mediante la prueba de comparaciones múltiples de Tukey, con un nivel de significancia de α=0,05.

3 Resultados y discusión

3.1 Densidad de Impactos (DI)

En la Figura 1 se presenta el promedio de densidad de impactos sobre la espiga para cada tratamiento, con y sin el agregado de coadyuvante. En un análisis general de los valores, la boquilla TXA8002 tiene los mayores valores en tanto que, AI3030 y

AI3070 las menores densidades de impactos y AP11002 un comportamiento intermedio. No obstante esto, únicamente TXA8002 se diferencia significativamente de los demás tratamientos, mientras que AP11002 lo hace solamente de AI3070. La mayor densidad de impactos de la boquilla TXA8002 fue en parte informada por [14] y [16], quienes atribuyeron estos resultados al espectro de gotas de menor tamaño de las boquillas de cono hueco respecto a las demás. Relacionado a esto es que las gotas pequeñas tienen mayores probabilidades de depositarse que un mismo volumen representado por gotas más grandes, lo que explica el bajo rendimiento de AI3030 y AI3070. Estos resultados se corresponden con los de [24] quienes encontraron menor porcentaje de deriva y menor densidad de impactos con las boquillas con aire inducido respecto a la boquilla de abanico plano convencional.

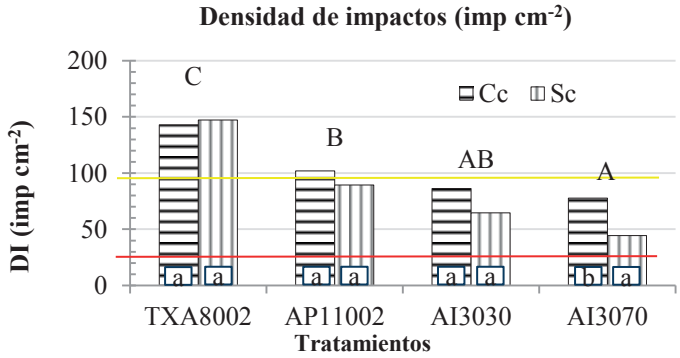

Fig. 1. Densidad de impactos sobre la espiga para cada tratamiento y subtratamiento. AP11002: abanico plano 11002; TXA8002: cono hueco 8002; AI3030: doble abanico simétrico con aire inducido 11002; AI3070: doble abanico asimétrico con aire inducido 11002; Cc: con el agregado del coadyuvante; Sc: sin el agregado del coadyuvante. Letras minúsculas diferentes en las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre subtratamientos para cada boquilla. Letras mayúsculas diferentes sobre las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre tratamientos

Los resultados corroboran las dificultades de las gotas para alcanzar el objetivo vertical, vinculadas a la propia estructura de la espiga y su orientación, siendo relativamente más fácil que las mismas alcancen las partes orientadas horizontalmente, como la hoja bandera. El bajo desempeño de las boquillas AI3030 y AI3070 no condice con las recomendaciones de [30] respecto a la utilización de boquillas anguladas hacia atrás y una población de gotas medianas o inducidas con aire para un control eficiente de las enfermedades en espiga. No obstante esto, todas las boquillas alcanzaron el mínimo de 20 a 30 impactos cm^{-2} que establece [9] para productos sistémicos, como así también las 30 a 40 gotas cm^{-2} recomendadas por [8] para alcanzar eficiencia biológica en tratamientos fúngicos con productos sistémicos. Sin embargo, en este tipo de cultivo, la estructura y fisiología de la espiga hacen que los productos fungicidas actúen principalmente como de contacto y no sistémicos [1], requiriendo para su control un mínimo de 60 impactos cm^{-2} recomendados por [11] y [12] y hasta 70 impactos cm^{-2} de acuerdo a [10]. La boquilla AI3070 es la que registra los menores valores, por lo que en este parámetro no alcanza una mayor aptitud con respecto a las demás. En este sentido, esta alternativa sería la más complicada en alcanzar el número de impactos requerido ya que la densidad de impactos promedio sobre la espiga fue de 61 gotas cm^{-2}, en tanto que las demás opciones (AI3030, AP11002 y TXA8002) lo superan, sin comprometer la aplicación. Sin embargo, AI3030 con 76 impactos cm^{-2}

sobre la espiga, apenas logran los requerimientos anteriormente mencionados, siendo probable que se ponga en riesgo la eficacia de la aplicación si las condiciones ambientales empeoran.

En cuanto al efecto de la adición del coadyuvante Rino® sobre la variable densidad de impactos, únicamente el tratamiento AI3070 presentó significativamente mayor número de impactos con el agregado del aditivo al caldo de pulverización. No obstante esto, se manifiesta en los tratamientos una tendencia hacia una mayor densidad de impactos con la adición del coadyuvante salvo para la boquilla TXA8002. La mayor DI, por la incorporación del coadyuvante, puede deberse a la menor tensión superficial de las gotas lo que permite que las mismas se aplanen más y reboten menos y se adhieran más al objetivo, aumentando la densidad de impactos en el mismo. En coincidencia con esto, [26] encontraron una tendencia al aumento de la DI con el uso de adyuvantes. Los mismos mencionan que los adyuvantes con tensioactivos se usan con la finalidad de disminuir la tensión superficial e incrementar la adherencia por una mayor superficie de contacto, contrariamente a lo que ocurre cuando se utiliza agua como dispersante que produce efectos de alta tensión superficial lo que provoca que las gotas adopten la forma esférica, con poca superficie de contacto y con tendencia al escurrimiento. Del mismo modo, [27] indican que la reducción de la tensión superficial de las gotas aumenta las posibilidades de retención de las mismas, mientras que [23] encontraron que la adición de adyuvantes minimizó los riesgos potenciales de deriva en boquillas de abanico plano inclinado y abanico plano con inducción de aire.

Si bien las diferencias son insignificantes, el menor número de impactos de la boquilla de cono hueco ante la incorporación del aditivo pudo deberse a la conjunción de gotas de tamaño fino y condiciones ambientales de 29,4 ºC y 42% de HR registradas al momento de la aplicación. Estas variables pudieron predisponer a una mayor termoderiva de las gotas y consecuentemente un menor número de impactos en los objetivos cuando se utilizó el coadyuvante. La disminución de la tensión superficial del líquido por el agregado del coadyuvante pudo ocasionar un rompimiento de la vena líquida en un mayor número de gotas de menor tamaño, resultando en un diámetro de gota menor al mencionado por el fabricante y susceptible de ser derivado. Estos factores podrían reducir la mejora producto del efecto de una mayor retención de las gotas en el objetivo por una menor tensión superficial. No obstante la explicación dada anteriormente, el comportamiento de XRA8002 coincide con lo mencionado por [19] quienes encontraron que el uso de tensioactivo puro incrementó significativamente la cantidad de líquido derivado.

3.2 Diámetro Volumétrico mediano (DVM)

El Diámetro Volumétrico Mediano (DVM o DV0.5) es el diámetro de la gota que separa la población de gotas ordenadas de menor a mayor en dos mitades de igual volumen de líquido [6]. En la Figura 2 se grafican los valores promedio de esta variable sobre la espiga para cada tratamiento y subtratamiento. En un análisis general, TXA8002 presentó significativamente los menores DVM, mientras que AI3070 tuvo significativamente los mayores diámetros y AP11002 y AI3030 un comportamiento intermedio sin diferenciarse estadísticamente entre sí.

Los resultados, fueron consecuentes con los tamaños de gotas que caracterizan a las boquillas, TXA8002 y AP11002 tuvieron los menores diámetros, mientras que AI3030 y AI3070 los mayores valores. Estas diferencias fueron en parte informadas por [23] y [24] quienes además hicieron hincapié en los menores riesgos potenciales

de deriva de las boquillas con aire inducido respecto a las convencionales. Los menores DVM de la boquilla de cono hueco respecto al abanico plano convencional, coinciden con lo informado por [14] y [15] al evaluar similares boquillas bajo condiciones controladas y sobre un cultivo de soja respectivamente. Sin embargo, los menores diámetros de TXA8002, 150 µm aproximadamente en promedio, no entran dentro de las recomendaciones de [13] para aplicaciones de fungicidas sistémicos, ya que las mismas propician mayor riesgo de deriva. Los mismos autores sugieren gotas entre 200 µm y 300 µm como ideales para este tipo de aplicaciones, siendo el abanico plano convencional y AI3030 las que mejor se ajustan a estos diámetros, con un DVM de 205 µm y 214 µm, respectivamente. La boquilla de doble abanico asimétrico alcanzó valores de DVM de 330 µm, lo que supone que las gotas difícilmente puedan atravesar el canopeo y por lo tanto queden retenidas en los estratos superiores. Similares resultados fueron obtenidos por [15] sobre un cultivo de soja en R5 donde las boquillas de doble abanico con un espectro de gotas de finas a medianas no tuvieron mayor penetración de los 0,20 m.

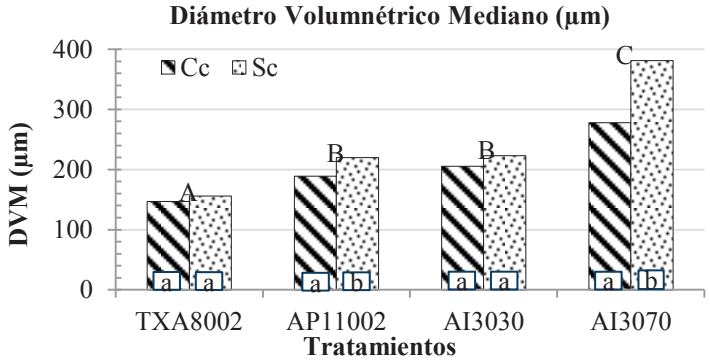

Fig. 2. Diámetro Volumétrico Mediano (DVM) sobre la espiga para cada tratamiento y subtratamiento. AP11002: abanico plano 11002; TXA8002: cono hueco 8002; AI3030: doble abanico simétrico con aire inducido 11002; AI3070: doble abanico asimétrico con aire inducido 11002; Cc: con el agregado del coadyuvante; Sc: sin el agregado del coadyuvante. Letras minúsculas diferentes en las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre subtratamientos para cada boquilla. Letras mayúsculas diferentes sobre las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre tratamientos

Un análisis diferente se puede realizar cuando se comparan los DVM de las poblaciones de gotas que alcanzaron el objetivo con el informado por los fabricantes para cada boquilla, de acuerdo a la presión de trabajo y caudal de las mismas. En este sentido, TXA8002, AP11002 y AI3030 presentan como DVM de referencia valores de 193 µ, 219 µ y 333 µ (Dowling, 2017*) respectivamente, mientras que las poblaciones de gotas que alcanzaron las espigas presentaron valores de DVM menores a los citados. Estos resultados reafirman que las gotas de menor tamaño, independientemente del DVM de la boquilla, alcanzan una menor velocidad final de caída y quedan suspendidas por más tiempo en el aire lo que las deja expuestas a condiciones de evaporación y a ser arrastradas por el viento y depositarse en la espiga. En cambio, las gotas de mayor tamaño por su peso y velocidad de caída, tienden a quedar retenidas en superficies horizontales de los estratos superiores, como sucede con la hoja bandera en el cultivo de trigo.

Al analizar los DV0.1 de referencia (diámetro de gota por debajo del cual se encuentra el 10% del volumen total del líquido pulverizado), los mismos tienen la misma tendencia que se observó para los DVM, la boquilla TXA8002 con 97 µ es la de menor DV0.1, seguido por AP11002 con 108 µ y AI3030 con 166 µ (Dowling, 2017[1]). Si bien las diferencias entre diseños de boquillas son chicas, principalmente entre las convencionales, los valores demuestran la gran proporción de gotas finas que se generan cuando se trabaja con pulverizaciones hidráulicas, independientemente del diseño de boquilla utilizado.

De acuerdo a la ficha de datos de AI3070, la misma posee un DV0.5 de 270 µ, valor menor al que se encontró en la espiga. Esto estaría indicando que la población de gotas que alcanzó el objetivo es más gruesa que la población de gotas que salió de la boquilla, lo que puede deberse a las condiciones atmosféricas de temperatura y humedad relativa, que pudieron disminuir por evaporación el tamaño de las gotas, afectando en mayor medida a las más chicas. Además, se puede adjudicar estos mayores DV0.5 a una inexactitud de la metodología , siendo que algunas gotas visualizadas en el papel podrían ser el resultado del solapamiento de varias gotas, por lo que el diámetro de las gotas tomado por el programa sería la combinación del diámetro de varias gotas pequeñas y no de una grande.

Estos resultados concuerdan con lo señalado por [28] quienes en la evaluación de diferentes boquillas hallaron discrepancia en el tamaño de las gotas (DVM) entre la lectura del software y la clasificación de la tabla que aporta la marca de las boquillas utilizadas.

En el análisis del efecto de la adición del coadyuvante al caldo de aplicación sobre la variable Diámetro Volumétrico Mediano, los resultados no fueron los esperados. Todos los tratamientos obtuvieron un DVM menor cuando se incorporó el aditivo a la mezcla, siendo las diferencias significativas en los tratamientos AP11002 y AI3070. De acuerdo a las propiedades del aditivo utilizado (adherente, dispersante, emulsionante, humectante y tensioactivo) se hubiese esperado un aumento del DVM por una disminución de la tensión superficial de las gotas. En acuerdo con esto, [25] obtuvieron un incremento del grado de cobertura, dado principalmente por un aumento en el DVM con el agregado de tensioactivo al caldo. La menor tensión superficial del caldo de aplicación provoca que las gotas cuando impactan en el objetivo de aplicación se expanden y disminuya el ángulo de contacto con la superficie, aumentando así su mojabilidad. Estas características se traducen en una mayor impronta de las gotas sobre las tarjetas hidrosensibles y consecuentemente un mayor diámetro. Contrariamente, las boquillas presentaron un menor diámetro volumétrico mediano con el coadyuvante, lo que implica una población de gotas de menor tamaño y consecuentemente mayores riesgos de deriva. Existen antecedentes que avalan una disminución en el DVM por la incorporación de un tensioactivo al caldo de aplicación. En este sentido, [18] obtuvieron una disminución del DVM cuando utilizaron un surfactante como coadyuvante respecto al agua como testigo. Estos resultados permiten acordar con la hipótesis ad hoc de [28] quienes adjudican al uso de ésteres metílicos de ácidos grasos de aceites vegetales la capacidad de una mayor reducción de la tensión superficial del agua, con la consecuente pérdida de gotas en el ambiente de trabajo por una mayor producción de gotas finas y muy finas, lo que traería aparejado un corrimiento del DVM. En este sentido, y en coincidencia con los resultados, [19] encontraron un incremento significativo de líquido derivado cuando utilizaron tensioactivo puro en relación con el agua. Del mismo modo, [17] menciona que la dis-

[1] Dowling, L. 2017. Pesticide Application Technology Laboratory de la Universidad de Nebraska para Pentair. Comunicación Personal

minución de la tensión superficial del caldo produce una disminución en el tamaño de las gotas y un aumento en el ángulo de aspersión.

De acuerdo a los resultados, los efectos del aditivo pueden ser contrapuestos. Por un lado, la utilización de este tipo de coadyuvante en la mezcla provocó que la vena líquida se rompiera en un mayor número de impactos de menor diámetro que si las condiciones ambientales son favorables, el DVM de la población de gotas que alcanza el objetivo disminuye. Si las condiciones ambientales favorecen a una evaporación y exoderiva, las gotas de menor tamaño no alcanzan el objetivo y consecuentemente el DVM de esa población aumenta.

Conforme a lo analizado hasta aquí, los resultados no fueron lo suficientemente decisivos como para concluir respecto al efecto del coadyuvante. Esto podría deberse a la complejidad del proceso de aplicación donde confluyen distintos factores como tamaño de boquilla, presión de trabajo, velocidad de avance, altura de botalón, características del caldo, condiciones ambientales al momento de la aplicación y características de la superficie objetivo que interactúan de manera diferente según el diseño de la boquilla, afectando directa e indirectamente a la población de gotas. En este sentido, [17] menciona que los coadyuvantes pueden generar interacciones entre la densidad, viscosidad y tensión superficial y pueden afectar de manera diferente a una boquilla de abanico plano que a una del tipo cono hueco.

3.3 Deposición (%)

En lo referente a la recuperación del producto sobre la espiga, independientemente de la incorporación o no del coadyuvante al caldo (Figura 3), la boquilla TXA8002 registró los mayores valores, cercanos al 55%, diferenciándose significativamente de los demás tratamientos, en tanto que AP11002 y AI3030 presentaron los menores porcentajes, cercanos al 30%, pero sin diferenciarse entre sí. En tanto, AI3070 con un porcentaje de depósito de 41,5% tuvo un comportamiento intermedio, significativamente diferente a las demás boquillas. Estos resultados ponen en discusión las dificultades para las recomendaciones de la dosis de producto, dadas las diferencias de deposición que se alcanzan. No existe una tendencia clara y los resultados no permiten asociarlos a una única variables que pueda explicar los diferentes comportamientos. Esto implicaría que el tamaño reducido de las de la población de gotas de la boquilla de cono hueco convencional favoreció en mayor medida la retención del caldo sobre la estructura vertical. La proyección angulada de AI3070 mejoró significativamente la deposición sobre la espiga con respecto a los demás abanicos planos, pero fue significativamente inferior a TXA8002. Estos resultados parecen indicar que a pesar de la intrincada e irregular superficie de la espiga, no se alcanza una adecuada captación y retención de la solución asperjada cuando aumenta el DVM de la población de la población de gotas.

Los resultados concuerdan con lo mencionado por con [13] quienes asocian la deposición con el tamaño de gotas, siendo que gotas finas resultan en mejor cobertura y penetración. Sin embargo, difieren en parte con lo mencionado por [29] quienes demostraron que las gotas gruesas aumentan la deposición en objetivos verticales y horizontales, corroborándose con el mayor DVM de AI3070. Estos últimos autores también aseguran que, al aumentar el ángulo entre las boquillas dobles, aumentan los depósitos en los objetivos, lo que fue ratificado en este trabajo por los mayores porcentajes de deposición de AI3070 respecto a AI3030. Esto mismo fue informado por [31] adjudicando a la angulación de 60º hacia adelante (inclinación respecto a la horizontal de 30º hacia abajo) una mayor deposición y cobertura sobre las caras de la

espiga. Del mismo modo, [29] mejoraron significativamente la deposición total sobre objetivos verticales cuando utilizaron la boquilla AI3070 11003 respecto a AIXR 11003 y AITTJ60 11003, adjudicando principalmente este comportamiento a un incremento del depósito en la cara posterior del objetivo.

En el análisis comparativo de las boquillas doble abanico respecto al abanico convencional, AI3070 alcanzó un 37% más de deposición respecto a AP11002 en tanto que AI3030 produjo un 7% menos de deposición. En parte estos valores acuerdan con [32] respecto a un incremento en la deposición a medida que la inclinación de la boquilla aumenta de 10º a 40º. Sin embargo, y de acuerdo a los resultados del ensayo, la inclinación en 30º de la alternativa AI3030 no fue suficiente para mejorar los depósitos, siendo necesaria una mayor angulación para incrementar los mismos. Del mismo modo, [5] encontraron un 73% más de deposición sobre la espiga cuando trabajaron con boquillas doble abanico TJ608002 en comparación con un abanico plano, atribuyendo esta mejoría al doble perfil de pulverizado.

De los resultados obtenidos se desprende que el diseño de la boquilla afecta significativamente los volúmenes recogidos en el objetivo, en coincidencia con [29] La combinación de una pulverización dirigida hacia el objetivo junto con un tamaño de gota reducido, pareciera ser la mejor alternativa para lograr una mayor tasa de recuperación sobre objetivos verticales, en condiciones atmosféricas compatibles con dicho tamaño, escasa velocidad de viento, temperaturas no demasiado altas y alta humedad relativa.

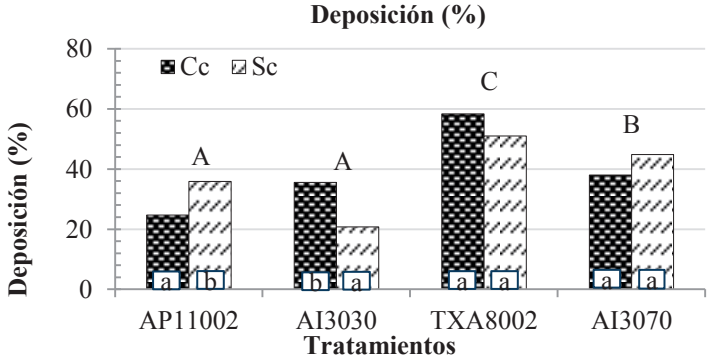

Fig. 3. Deposición (%) sobre la espiga para cada tratamiento y subtratamiento. AP11002: abanico plano 11002; TXA8002: cono hueco 8002; AI3030: doble abanico simétrico con aire inducido 11002; AI3070: doble abanico asimétrico con aire inducido 11002; Cc: con el agregado del coadyuvante; Sc: sin el agregado del coadyuvante. Letras minúsculas diferentes en las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre subtratamientos para cada boquilla. Letras mayúsculas diferentes sobre las columnas indican diferencias significativas ($p \leq 0,05$) según el test de LSD Fisher entre tratamientos

Las metodologías de evaluación utilizadas presentan ventajas y desventajas que resultan complementarias al momento de realizar un análisis completo de los parámetros de caracterización de la aplicación. Por un lado, el análisis digital de las tarjetas hidrosensibles permite de manera rápida y sencilla caracterizar el espectro de gotas con el que se está aplicando. Por otro lado, la utilización de trazadores posibilita realizar estudios de deposición en objetivos naturales, siendo una técnica de fácil manipulación, confiable y económica, en acuerdo con [33].

En lo que respecta al efecto del coadyuvante sobre el porcentaje de líquido recogido, únicamente se observaron diferencias significativas sobre la espiga con las boqui-

llas AP11002 y AI3030, aunque el resultado no fue el mismo para los dos tratamientos. Con la boquilla AI3030 se logró significativamente mayor deposición cuando se agregó el coadyuvante al caldo, mientras que con AP11002 se observó lo opuesto.

El comportamiento diferencial de los tratamientos ante la adición del coadyuvante, permite agrupar a las boquillas en dos grupos. Por un lado, los picos de tipo abanico convencional y doble abanico asimétrico que tuvieron una respuesta negativa a la incorporación del coadyuvante al caldo y, por otro lado, el cono hueco convencional y el doble abanico simétrico que se mostraron favorecidos por el agregado del coadyuvante. Estos resultados exponen nuevamente que el efecto del coadyuvante sobre las boquillas no es concluyente y coincide con lo observado por [20] quienes no encontraron beneficios significativos en el uso de aditivos, luego de evaluar diferentes coadyuvantes multifuncionales. Contrario a estos resultados, [21] demostraron que la adición de adyuvantes al caldo de pulverización interfirió positivamente en el desempeño de los fungicidas. Del mismo modo, [22] concluyeron que la adición de coadyuvantes al caldo redujo significativamente la tensión superficial de la mezcla, atribuyendo a esta característica la menor severidad e incidencia de enfermedades. Si bien en el ensayo no se evaluó la acción de un fungicida y su interacción con el coadyuvante, lo observado hasta aquí indicaría que no hubo modificaciones contundentes en la aplicación que permitan adjudicarle al aditivo un efecto positivo sobre las características del caldo.

4 Conclusiones

De los resultados, se desprende la importancia de la selección de las boquillas acorde al objetivo de aplicación y a las condiciones climáticas al momento de la misma. La inclinación en 70º hacia atrás, mejora la cantidad de depósito sobre la espiga respecto a ángulos menores. La utilización de gotas finas y direcciones múltiples como las de la boquilla de cono hueco aumentan la deposición en el objetivo vertical. Respecto al efecto del coadyuvante sobre las boquillas, no es concluyente y no se encontraron beneficios significativos en el uso de los mismos. La utilización de este tipo de coadyuvante en la mezcla provocó que la vena líquida se rompiera en un mayor número de impactos de menor diámetro que si las condiciones ambientales son favorables, el DVM de la población de gotas que alcanza el objetivo disminuye. Si las condiciones ambientales favorecen a una evaporación y exoderiva, las gotas de menor tamaño no alcanzan el objetivo y consecuentemente el DVM de esa población aumenta.

Abstract. Dos de las decisiones más importantes en la gestión de los servicios de salud son el número y la ubicación de las instalaciones que se crearán. Ambas decisiones tendrán una influencia decisiva en los gastos del sistema de salud y en el uso efectivo de dichos servicios por parte de sus beneficiarios. El objetivo de este trabajo consiste en evaluar la eficiencia espacial de la red de centros de atención primaria de la salud (CAPS) de la ciudad de Bahía Blanca (Argentina). Para ello, se comparan las distancias que los usuarios deben recorrer para asistir a un CAPS en la actualidad, con las distancias que deberían recorrer si su localización fuera óptima. La localización óptima se determinó utilizando un modelo P-media con restricciones de capacidad. La demanda anual de consultas médicas de cada nodo de demanda se estimó multiplicando el número de habitantes de dicho nodo por un índice socioeconómico. Los resultados obtenidos ponen en duda la eficiencia espacial de la red de CAPS de la ciudad de Bahía Blanca. En todos los escenarios estudiados, solo el 11% de los CAPS actualmente abiertos se colocan en sus ubicaciones óptimas. Una reorganización de la red de atención (manteniendo la misma capacidad y cantidad de CAPS abiertos que en la situación actual) podría disminuir las distancias de viaje (tanto del sistema total como el promedio por consulta) en un 36%. Además, la distancia recorrida por los usuarios que viven más lejos del CAPS abierto más cercano podría reducirse a casi la mitad.

Keywords: Primary health care centers; Spatial Efficiency; Optimal location; Bahía Blanca (Buenos Aires, Argentina)

1 Introducción

La gestión de los servicios de salud públicos es una de las mayores preocupaciones de los estados modernos, debido en parte a la gran cantidad de recursos monetarios que implica el cuidado de la salud. Una de las decisiones más importantes relativas a la provisión de servicios médicos sanitarios es la referida a la localización de los centros de salud, ya que tanto la cantidad de instalaciones a establecer como su ubicación influyen en los costos del sistema y en la utilización efectiva de los servicios por parte de los usuarios [1]. Asimismo, es necesario tener en cuenta que toda la población debería tener un fácil acceso a los servicios de atención primaria de la salud, y que un acceso deficiente está asociado a resultados negativos en salud [2].

A pesar de ello, en Argentina, y en Bahía Blanca en particular, en la práctica esta red es el producto del devenir histórico. En efecto, la decisión de apertura de muchos de los centros actualmente en funcionamiento puede ser atribuida en muchos casos al accionar de grupos de presión (como asociaciones vecinales) o a decisiones fortuitas, sin consideración alguna de las características, problemas y necesidades sanitarias de la población usuaria. Esta situación se debe a que muchas administraciones públicas no han aplicado metodologías y técnicas para localizar nuevos equipamientos o para expandir los existentes que consideren mínimos criterios de eficiencia y equidad [3].

Numerosos autores han establecido criterios que deben regir la planificación de la localización y distribución de los centros de salud. Por un lado, la red asistencial debe ser eficiente desde el punto de vista espacial, es decir, que el costo que afrontado por el conjunto de la población para encontrar atención médica (medido en distancia o en tiempo de traslado) sea el menor posible. Por otro lado, dicha red puede ser evaluada desde el punto de vista de la equidad espacial. Esta regla se refiere a la accesibilidad diferencial de un servicio por parte de los distintos grupos de población según su necesidad, y depende de la facilidad de acceso, de la variabilidad de las distancias que separan a cada individuo del centro de salud más cercano, de las características de dicho centro (especialidades brindadas, horario de atención, entre otros) y de las distintas necesidades de la población potencialmente usuaria [4].

Los denominados modelos matemáticos de localización-asignación constituyen herramientas que permiten a los tomadores de decisión aplicar los criterios de eficiencia y equidad a la planificación de una red de centros de salud. En particular, los modelos P-media suponen que, cuando la demanda no es sensible a la magnitud o calidad de los servicios suministrados en cada centro de oferta (con lo cual se puede suponer que los demandantes concurrirán al centro más cercano), la eficacia de su ubicación puede medirse a partir de la suma de las distancias de viaje entre todos los nodos de demanda y de oferta ponderada por la población de cada nodo de demanda [5].

Un problema que se inscribe en el contexto antes descripto es la asignación óptima de las localizaciones de los Centros de Atención Primaria de la Salud (CAPS) encargados de la atención primaria de la salud (APS) en Argentina. En particular, en la ciudad de Bahía Blanca (Provincia de Buenos Aires, Argentina) funcionan 49 CAPS dependientes del municipio, 45 de las cuales cuentan con atención de al menos un médico clínico y pediatra o un médico de familia. Las restantes unidades sanitarias solo cuentan con el servicio de enfermería.

A partir de lo expuesto, el objetivo general del presente trabajo consiste en evaluar la eficiencia espacial de la localización de la red actual de CAPS de la ciudad de Bahía Blanca, a partir de la comparación de las distancias estimadas en que deben incurrir actualmente el conjunto de los usuarios de los servicios de APS versus las que resultan de una asignación espacial óptima estimada utilizando un modelo de localización de tipo P-media.

2 Metodología

Para determinar la localización óptima de los centros de salud en la ciudad de Bahía Blanca se utilizó un modelo P-media con restricciones de capacidad que permite establecer cuál debería ser la ubicación de los distintos centros de oferta para minimizar la distancia total que el conjunto de la población debe recorrer para acceder a la atención médica. De esta manera, este tipo de modelo asegura que la distribución espacial de los centros de oferta cumplirá el criterio de eficiencia espacial mencionado anteriormente [6]. Luego, dado que no se dispone de información relativa a la distancia que recorre actualmente la población para acceder a los CAPS, se utilizó el mismo modelo para simular el funcionamiento del sistema, bajo el supuesto que la población acudirá siempre al CAPS más cercano.

La nomenclatura utilizada en la exposición formal del modelo se indica a continuación:

Conjuntos
- I, conjunto de nodos de demanda i
- J, conjunto de posibles localizaciones de los nodos de oferta j

Parámetros
- d_{ij}, distancia entre el nodo de demanda i y el nodo de oferta j, medido en km.
- h_i, demanda en el nodo i, medido consultas anuales.
- P, número de instalaciones a ubicar.
- $W_{máx}$, capacidad instalada de cada centro de salud abierto, medido en consultas por año.

Variables de decisión (de tipo binarias, toman valores 0 o 1)
- Y_j, toma valor 1 si el centro de oferta j se abre y 0 si el centro j no se abre.
- X_{ij} , toma valor 1 si el nodo de demanda i es asignado al centro de oferta j y 0 en caso contrario.

El modelo P-media para la determinación de la localización óptima de la red de CAPS queda determinado por las siguientes ecuaciones:

$$Min \ \sum_i \sum_j h_i d_{ij} X_{ij} \tag{1}$$

Sujeto a

$$\sum_j Y_j = P \tag{2}$$

$$\sum_j X_{ij} = 1 \qquad \forall i \tag{3}$$

$$X_{ij} - Y_j \leq 0 \quad \forall i,j \tag{4}$$

$$\sum_i h_i X_{ij} \leq W_{máx} \, y_j \qquad \forall j \tag{5}$$

$$Y_j \in \{0,1\} \quad \forall j \tag{6}$$

$$X_{ij} \in \{0,1\} \quad \forall i,j \tag{7}$$

La Ec. (1) o función objetivo, establece que se minimiza la distancia total ponderada que recorre la población de cada nodo de demanda para asistir al nodo de oferta que le es asignado. La restricción definida por la Ec. (2) determina que sólo se ubiquen P centros de oferta. La Ec. (3) asegura que cada centro de demanda i se asigna a un único centro de oferta j, mientras que la Ec. (4) establece que un nodo de demanda i será atendido por un centro de oferta j sólo si se ubica una instalación en el nodo j. La Ec. (5) impone a cada centro de salud instalado una capacidad máxima de atención. Las Ec. (6) y (7) aseguran la integrabilidad y continuidad de la solución.

2.1 Definición de conjuntos y parámetros

Los conjuntos I y J están compuestos por los 354 radios censales[1] urbanos delimitados por el Instituto Nacional de Estadísticas y Censos (INDEC) en el Censo Nacional de Población, Hogares y Viviendas del año 2010 [7]. Esto implica que cada radio censal no solo alberga un nodo de demanda, sino que también es un sitio potencial para localizar un CAPS.

La distancia d_{ij} entre cada nodo de demanda i y cada potencial sitio de radicación de un centro de oferta j se estimó utilizando *Google Maps*, considerando que la población se moviliza en automóvil o moto (con lo cual se debe respetar el sentido de circulación de las calles) y que recorre el trayecto más corto expresado en km[2]. Para estimar la distancia, se supone que toda la población está ubicada en el centroide geográfico del radio censal. En el caso de la ubicación de los centros de salud, se adoptaron dos criterios: si en el radio censal está funcionando un CAPS, se respeta la ubicación real actual; mientras que en el resto de los casos (radios censales que no albergan ningún CAPS en la actualidad) la ubicación potencial de los centros se considera dada por su centroide geográfico.

La información estadística referida a las consultas históricas realizadas en cada CAPS puede no reflejar la verdadera necesidad de los habitantes de cada radio censal, ya que no toda necesidad se traduce en una demanda efectiva al sistema de salud debido a diversas barreras al acceso [8]. Por lo tanto, la utilización de dicha información en el modelo podría perpetuar las desigualdades preexistentes en el acceso a los servicios de APS. Además, si bien se cuenta con información de las consultas atendidas por cada CAPS existente, no se dispone de datos respecto del radio censal de procedencia de los usuarios atendidos. En vista de estas restricciones, la demanda de consultas de cada radio censal, h_i, se determinó ponderando el número de residentes de cada radio por un índice de nivel socioeconómico[3] estimado para cada nodo de demanda [7]. Más específicamente, se asumió que las puntuaciones del índice socioeconómico calculado para cada radio censal reflejan la demanda normativa (promedio) de las consultas médicas anuales por habitante. De esta forma, la población que habita en

[1] El radio censal es la unidad censal más pequeña utilizada por el INDEC en el CENSO 2010

[2] Para esta estimación se programó una macro en Excel donde se cargaron las coordenadas de cada elemento de los conjuntos *I* y *J* y que se vinculaba automáticamente a G*oogle Maps* para el cálculo de las distancias.

[3] El índice se construyó aplicando análisis factorial a la información estadística relativa a las características habitacionales, del hogar y de la población relevada en el CENSO 2010. Para mayor detalle consultar Arnaudo [11].

aquellas áreas geográficas con mayores niveles de desventaja presenta mayores necesidades de atención de la salud [9, 10]. El objetivo de este procedimiento es estimar una demanda *potencial* de consultas médicas, y no la demanda real, introduciendo en el análisis un criterio de equidad en el acceso a la atención médica al priorizar (en términos de facilidad en el acceso a los CAPS) a la población con mayor necesidad de atención médica. Por último, dado que la información relativa a la cantidad de habitantes de cada radio censal data del Censo 2010, el número de habitantes de cada radio censal utilizado en los cálculos se actualizó teniendo en cuenta la tasa de crecimiento poblacional informada por INDEC y suponiendo que la misma se distribuye uniformemente por toda la ciudad.

Con el objetivo de poder comparar la localización óptima que resulta de cada uno de los modelos con la situación actual se considera que se instalarán 45 (P=45) centros de oferta (no se consideran los 4 CAPS que cuentan solo con atención de enfermería). Esto implica suponer que todos los centros de salud a instalar cuentan con la atención de un médico de familia o la combinación de un médico clínico y un pediatra.

La capacidad máxima de atención de cada CAPS se estima en 5.000 consultas por año. Tal capacidad máxima se determinó asumiendo que los centros funcionan 5 horas diarias, igual que los CAPS que actualmente se encuentran funcionado y que cada consulta médica insume 20 minutos [12].

2.2 Escenarios de Estudio

Además del caso base, el modelo se utiliza para analizar distintos escenarios, construidos a partir de valores alternativos para dos parámetros: i) el número de centros de salud a instalar (P) y ii) la capacidad máxima de atención de los CAPS ($W_{máx}$) (Tabla 1). Para la elaboración de estos escenarios se consideraron diversas manifestaciones públicas por parte de representantes del gobierno local a cargo de su gestión al momento de desarrollar esta investigación, en las cuales afirmaron su intención de reforzar la dotación de recursos humanos de algunos centros de salud estratégicamente ubicados, y de cerrar aquellos centros que presentan alta capacidad ociosa.

Tabla 1. Escenarios Propuestos. Valores de la capacidad máxima de atención de cada CAPS ($W_{máx}$) y Número de CAPS a instalar (P)

	$W_{máx}$ (cant. de consultas)	P (Núm. de CAPS)
Caso Base	5.000	45
Escenario 1	5.000	44
Escenario 2	5.000	43
Escenario 3	7.500	45
Escenario 4	7.500	44
Escenario 5	7.500	43

Fuente: Elaboración propia

Todos los escenarios se construyen con el fin de evaluar el efecto de cambios en los parámetros sobre la distancia óptima recorrida por la población para acceder a un centro de salud. Los escenarios Caso Base, 1 y 2 analizan el impacto de la disminución en la cantidad de CAPS. Mientras que, los escenarios 3-5 mantienen abierta la

misma cantidad de centros que los primeros escenarios y al mismo tiempo aumentan la cantidad de consultas que se pueden atender.

En la actualidad no existen datos respecto de las distancias efectivamente recorridas por los residentes de cada radio censal de la ciudad de Bahía Blanca para recibir atención en un CAPS. Dado que tal información resulta necesaria para comparar la performance de la red actual de CAPS en relación a las soluciones óptimas propuestas por el modelo, la misma se estimó utilizando el mismo modelo y considerando como dadas las localizaciones de los CAPS. En este caso, el modelo se limita a asignar la población de cada nodo de demanda a un centro de salud, cumpliendo con las restricciones impuestas y minimizando la distancia recorrida. En este mismo sentido, dado que tampoco se cuenta con información acerca de la capacidad máxima de atención de cada centro de salud, y con el fin de que la comparación de la situación actual con los escenarios óptimos sea consistente, se supone que cada CAPS instalado en la actualidad atiende como máximo 5.000 consultas al año. Este supuesto se sustenta en las horas de atención de los CAPS que actualmente están funcionando.

Para el análisis de los resultados, cómo medida de la eficiencia espacial de cada solución se considera, la distancia total recorrida en el sistema (valor de la función objetivo), entendiendo que a medida que esta distancia disminuye la distribución de los centros de oferta mejora la eficiencia espacial. Además, en cada solución se tiene en cuenta dos indicadores de desempeño adicionales: la distancia que en promedio se debe recorrer para acceder a una consulta médica y la distancia máxima que debe recorrer un usuario para arribar a un CAPS.

3 Resultados

El modelo de localización óptima se implementó y resolvió en GAMS [13] con el *solver* CPLEX*,* ejecutado en una computadora portátil con procesador Core i5 (4° generación) de 1.2GHz y 6GB de memoria DDR3. Los tamaños de las diferentes instancias del modelo, en todos los escenarios, fueron de 126.025 variables (todas binarias), 355 restricciones de igualdad y 126.025 restricciones de desigualdad. Además, todos los escenarios se resolvieron en menos de 90 segundos.

En la Figura 1 se muestran los resultados del cálculo del índice socioeconómico de por radio censal y la ubicación actual de los CAPS. Para facilitar la exposición de los resultados, se dividió a los radios censales en cuartiles, donde el primer cuartil comprende al 25% de los radios censales analizados con mayor nivel socioeconómico en términos relativos y el cuarto cuartil incluye al 25% de los radios censales con menores valores de dicho índice. Se aprecia que los radios censales con menor nivel socioeconómico son los situados en la periferia de la ciudad, lo cual parece corresponderse con la mayor oferta de CAPS existentes en los mismos. Sin embargo, esta correspondencia que a simple vista pareciera presentarse entre la ubicación actual de los CAPS y las necesidades de atención sanitaria (estimadas a partir del índice de nivel socioeconómico) no necesariamente implica que la distribución actual de la red de centros de atención primaria resulte eficiente desde el punto de vista espacial. Para poder ser concluyentes al respecto, a continuación, se exponen los resultados de la simulación de la situación actual, así como de la resolución del modelo matemático de localización óptima bajo los escenarios planteados.

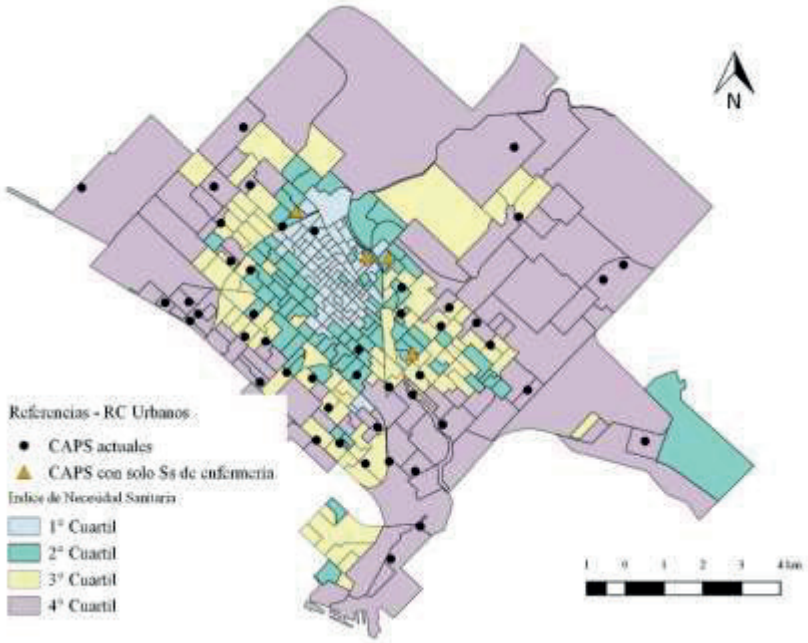

Fig 1. Bahía Blanca. Radios Censales agrupados por cuartiles del índice de necesidad sanitaria y distribución actual de CAPS (Fuente: Elaboración propia en el software QGIS [14])

Un primer resultado a resaltar es que cuando se simula la situación actual, el modelo no asigna población a uno de los CAPS en funcionamiento. Es decir, el modelo infiere que con los parámetros usados en esta corrida el mismo no es necesario. Por otra parte, en todos los escenarios posibles no hay diferencias significativas en las soluciones encontradas en cuanto a la localización de los CAPS instalados. Además, si bien existe correspondencia entre las necesidades de salud y la ubicación actual de los CAPS, de acuerdo con las soluciones óptimas encontradas en cada escenario solo el 12% de los CAPS actuales está situado óptimamente (Figura 2).

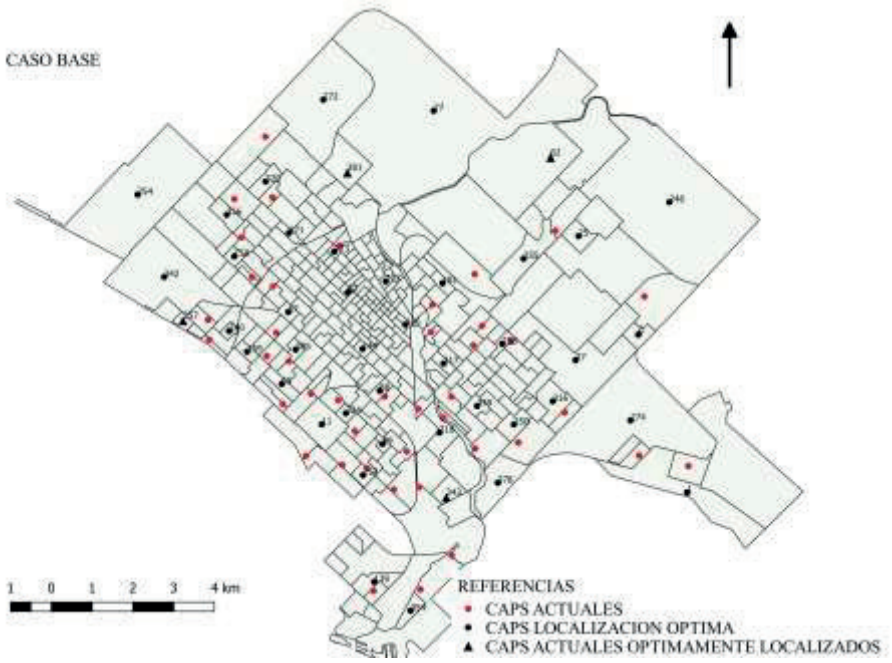

Fig 2. Bahía Blanca. Localización óptima de los CAPS (caso base) versus localización actual (Fuente: Elaboración propia en el software QGIS [14])

Como se mencionó anteriormente, para evaluar las distintas soluciones desde el punto de vista de la eficiencia espacial, es necesario comparar para cada uno de los escenarios propuestos la distancia recorrida por la población para acceder a un CAPS. En la Tabla 2 se observa que cuando se compara la situación actual simulada con el caso base, se observa que una reorganización de la red asistencial podría reducir las distancias recorridas, tanto la distancia total recorrida en el sistema como la distancia promedio por consulta, aproximadamente un 36%. Además, la distancia máxima que debe recorrer quien vive más alejado de un CAPS se reduce en un 50%.

Tabla 2. Distancias recorridas para concurrir a un CAPS (en km)

	Total Sistema	**Promedio**	**Máxima**
Situación Actual	157.674	1,04	4,18
Caso Base	100.733	0,66	2,10

Fuente: Elaboración propia.

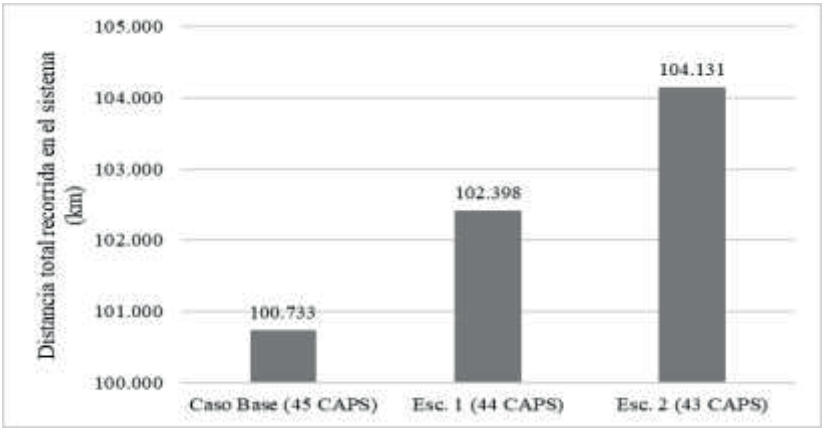

Fig 3. Análisis de escenarios. Distancia total recorrida (km). Máxima capacidad de atención 5.000 consultas por año (Fuente: Elaboración propia).

Un resultado esperable se verifica en el resto de los escenarios. Si disminuye el número de CAPS abiertos (manteniendo la capacidad de atención en 5.000 consultas anuales) aumenta la distancia total recorrida del sistema, pero por una cantidad muy pequeña (3,5% al cerrar dos centros de salud en relación con el caso base) (Figura 3). Del mismo modo, aumentar la capacidad de atención de los CAPS en un 50% reducirá las distancias de viaje (Figura 4). Sin embargo, comparando las Figuras 2 y 3 se aprecia que la reducción en los tiempos de viaje atribuible al aumento de la capacidad es de una magnitud no significativa. Es decir, que aumentar los costos de funcionamiento de los CAPS no representaría una mejora sustancial en términos de eficiencia espacial.

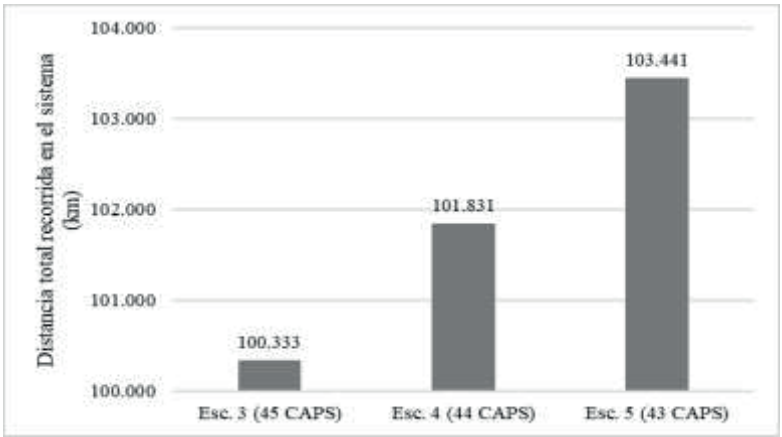

Fig 4. Análisis de escenarios. Distancia total recorrida (km). Máxima capacidad de atención 7.500 consultas por año (Fuente: Elaboración propia).

4 Discusión y conclusión

El presente trabajo se propuso analizar la eficiencia de la disposición espacial de la red de CAPS del subsector público de la salud de la ciudad de Bahía Blanca. La relevancia de este análisis se justifica por la existencia de numerosos estudios que han demostrado que las distancias que deben recorrer los potenciales usuarios puede ser decisiva al momento de facilitar (y asegurar) su concurrencia a los centros de salud. En este sentido, una asignación espacial incorrecta puede disminuir la efectividad de las políticas de APS, lo cual en última instancia se traduce en un menor estatus de salud poblacional y/o en mayores costos para el sistema de salud, dado la necesidad de atender situaciones de enfermedad que podrían haber sido prevenidas o atenuadas en sus consecuencias.

Los resultados del modelo indican que una relocalización de la red de CAPS redundaría en una disminución del 36% de las distancias recorridas por la población, tomando como referencia el caso base que es uno de son los que arroja los mejores resultados. De esta manera una reorganización de la red prestacional implicaría una mejora en términos de eficiencia espacial. Así, con igual presupuesto operativo se mejoraría la situación de la población. Asimismo, comparando la situación actual con los escenarios en los que se instalan una menor cantidad de CAPS y se supone igual capacidad máxima de atención que en actualidad (escenario 1 y 2), se evidencian que se podrían lograr mejoras en la eficiencia espacial del sistema con menores costos de funcionamiento para el sistema de salud. Por otro lado, los escenarios que implican un aumento de la capacidad máxima de atención y por lo tantos mayores costos de funcionamiento generan resultados similares a los escenarios de bajos costos. Cabe mencionar que este análisis no tiene en cuenta los costos asociados a la relocalización de los centros de salud.

Si bien el eje del trabajo es la eficiencia espacial, el análisis realizado también incorporó implícitamente un objetivo de equidad en el acceso a los servicios de salud, en la medida que se dio mayor ponderación a los nodos de demanda con más alto porcentaje de población en condiciones de vulnerabilidad socioeconómica. En efecto, el procedimiento utilizado para estimar la demanda, al intentar captar la necesidad de consultas médicas y no las consultas efectivamente registradas introduce un elemento de equidad en el análisis. Este enfoque, aunque discutible (como todo aporte de carácter normativo) cuenta con antecedentes en la literatura (Australian Institute of Health and Welfare [9]). Una restricción adicional derivada de este enfoque es la imposibilidad de validar las estimaciones de demanda (ya que estas no necesariamente se corresponderán con los datos observados, y de hecho no se espera que sea así). Sin embargo, los resultados obtenidos son similares a los encontrados por Elorza et al [15] a través de una metodología diferente también aplicada a la ciudad de Bahía Blanca.

Otros autores han utilizado los modelos P-media para determinar la localización óptima de CAPS. Las principales diferencias de estos estudios con el que se presenta en este trabajo radican en i) la forma de estimar la demanda de los CAPS y ii) en que estos autores implementaron sus problemas en diversos *softwares* pertenecientes a los denominado sistemas de información geográficos (SIG) [1,16]. Respecto de la estimación de demanda, Fo y Mota [1] estiman la cantidad necesaria de CAPS suponiendo que debe existir un centro cada 12.000 habitantes. Mientras que Ramírez [16] su-

pone que la población que acude a los CAPS es solo aquella que no cuenta con cobertura de salud por parte de una obra social o una empresa de medicina prepaga.

Al momento de valorar las conclusiones, las limitaciones del análisis deben ser tenidas en cuenta. En primer lugar, las distintas soluciones del modelo suponen la posibilidad de relocalizar todos los CAPS actuales, situación que difícilmente se verifique en la realidad. En segundo lugar, las distancias recorridas actualmente por la población para acceder a los centros de salud tuvieron que ser simuladas, bajo el supuesto de que siempre se acude al CAPS más cercano. Evidentemente esto no necesariamente es un fiel reflejo de la realidad, en la medida que los habitantes tengan la posibilidad de elegir libremente el centro donde se desean atender. Sin embargo, se optó por esta vía dado que la información de las distancias efectivamente recorridas no se encuentra disponible. En tercer lugar, debe considerarse que implícitamente se asumió que la calidad de atención ofrecida por cada CAPS, así como los horarios de atención es idéntica, de forma tal que la elección del centro de oferta por parte de los usuarios solo dependerá de la distancia a recorrer. Por último, solo se considera que la población se traslada en un vehículo particular siendo deseable incorporar la posibilidad de que se desplace en transporte público o peatonalmente.

El trabajo puede ser ampliado en diversas direcciones. Una alternativa evidente sería estimar las distancias recorridas en la actualidad a partir de un estudio de campo, tomando una muestra de la población que concurre a los CAPS de la ciudad y registrando su lugar de residencia. Otra posibilidad consiste en postular una función de probabilidad de concurrencia a los CAPS en función de la distancia que debe recorrer los residentes de cada nodo, donde mayores distancias estarían asociadas a menores probabilidades de concurrencia. Por último, el modelo podría ser modificado para incluir la probabilidad que la población utilice medios de transporte alternativos.

Resumen Ante la necesidad de las organizaciones de afrontar diversos problemas de gestión, la toma de decisiones multi–criterio grupal ha crecido como campo de estudio. Aún así, existen dificultades no resueltas en la aplicación de estas metodologías relacionadas con la valoración del nivel de consenso alcanzado y el tratamiento de las formas de ignorancia sobre la información disponible (imprecisión, incertidumbre y falta de datos). En consecuencia, el presente trabajo evalúa y compara, al considerar las cuestiones antes mencionadas, dos métodos de toma de decisiones multi–criterio grupales: uno denominado Procesos DRV (Decisión con Reducción de Variabilidad) y otro conocido como AHP grupal (proceso analítico jerárquico grupal). La propuesta se aplicó a un caso real referido al problema de selección de proveedores para la gestión de residuos patógenos en una institución pública. En las conclusiones se reconocen las principales diferencias entre las dos metodologías analizadas, se indican las limitaciones del caso y se anticipan futuras líneas de investigación.

Keywords: Métodos multi–criterio grupales, PROCESOS DRV, AHP GRUPAL, Gestión de residuos patógenos

1. Introducción

Con el traslado y transferencia de los métodos de investigación operativa al campo industrial y de los negocios, se presentaron variedad de nuevas cuestiones a investigar. El campo de la decisión multi–criterio discreta no fue la excepción,

ya que del estudio de métodos individuales, se desprendió el interés por estudiar los métodos grupales [1].

Uno de los espacios de aplicación, que ha crecido junto con las población mundial es el uso de herramientas multi–criterio para la adecuada gestión de los residuos que se generan en el diagnóstico, tratamiento e inmunización de seres humanos o animales [2]. De hecho, la literatura especializada remarca que aunque el valor de los estudios de gestión de residuos patógenos en los países en desarrollo es claro, unos pocos estudios abordan directamente el problema en el contexto Latinoamericano [3]. En particular, la gestión de este tipo de residuos, no es carente de dificultades y es afectada por una multiplicidad de factores y actores que la administran. Kharat et. al. [4] señala que la gestión involucra un proceso complejo debido a que interactúan diversas dimensiones como: medioambiente, presupuesto, gestión pública, diversidad de actores, por mencionar algunos.

El proceso de asistencia para la toma de decisiones de por sí es complejo porque debe considerar la naturaleza del problema, su campo de aplicación y obtiene las preferencias del tomador de decisiones [5]. Desde que se formaliza el estudio de los métodos que soportan las decisiones en problemas grupales se señala que la complejidad es creciente porque es necesario considerar las preferencias de los diferentes grupos de interés [6].

En un análisis bibliométrico sobre los métodos grupales Kabak y Ervural [7], resaltan que el estudio de tales métodos ha crecido en los últimos años y que a pesar de su crecimiento pocos trabajos se ocupan de analizar el grado de consenso alcanzado. Más aún, la comparación entre métodos que trabajan con medidas de consenso es menos abordada todavía por la literatura.

Paralelamente, la aplicación de estas metodologías no está exenta de ciertas dificultades sobre la información disponible conocidas como formas de ignorancia. Entre las formas de ignorancia se encuentra la incertidumbre o datos que inducen alguna forma de conocimiento parcial o creencia por parte del observador, la imprecisión o error de medición y falta de disponibilidad sobre ciertos datos [8; 9]

Las consideraciones conjuntas sobre el nivel de consenso logrado y la contemplación de los efectos sobre las formas de ignorancia no ha sido documentada. Con el objetivo de superar estas dificultades, este trabajo estudia compara el grado de consenso alcanzado y el tratamiento sobre las formas de ignorancia de dos métodos de toma de decisiones multicriterio grupales: uno denominado Procesos DRV (Decisión con Reducción de Variabilidad)(Zanazzi, 2016 [10]) y otro conocido como AHP (Proceso Analítico Jerárquico) grupal (el cual es uno de los más populares métodos multi–criterio) [11]. Para la comparación ambos métodos se trabaja sobre un caso real referido a la gestión de residuos patógenos.

En cuanto a la estructura de este documento, se continúa con un apartado de referencias teóricas relevantes, donde se recorren tanto metodologías multicriterio para la toma de decisiones en grupo comparadas en este trabajo. A continuación, se presentan los resultados obtenidos y se discuten los hallazgos. El trabajo cierra con las conclusiones obtenidas, además de especificar limitaciones y líneas de investigación futuras.

2. Referencias relevantes

2.1. Procesos DRV en la literatura

El método Procesos DRV (Decisión con Reducción de Variabilidad)es una aproximación que busca reducir las dificultades en la información que afectan a los procesos de decisión grupal (incertidumbre, imprecisión, datos inexistentes) [10].
El método Procesos DRV puede aplicarse con problemas que requieren elegir un objeto entre una cantidad finita de alternativas. Además se supone que los miembros del grupo comparten objetivos en cuanto al problema analizado, es decir que no se trata de situaciones de negociación o de conflicto [12; 13].
El método se desarrolla en tres etapas: Estabilización; Agregación y Ordenamiento. La secuencia de operaciones es la siguiente:

- Fase Estabilización: permite que el grupo analice en plenario los diferentes sub–problemas que integran el proceso decisorio y se establezca un nivel de consenso básico. Incluye:
  - Estructuración del problema: Se esquematiza el problema en un diagrama tipo árbol, y que puede dividirse en sub–problemas: asignación de prioridades a los criterios, asignación de utilidades a las alternativas según el primer criterio, asignación de utilidades según el segundo criterio y así sucesivamente.
  - Estudio de un sub–problema: es necesario analizar uno por uno, los distintos subproblemas. Respecto de cada subproblema, las percepciones de los integrantes pueden ser completamente distintas, porque cada persona filtra la realidad de forma selectiva en función de su área de conocimiento y experiencias anteriores [14].
  - Análisis grupal del sub–problema: se realizaron ejercicios para la reducción de diferencias de posturas que permiten definir los elementos a comparar en el sub–problema e intercambiar conocimientos.
  - Asignación de utilidades a los elementos comparados: se realiza una actividad destinada a valorar si el consenso es real o es solo aparente. Para ello, se solicita que los miembros del grupo asignen, de manera individual y con absoluta independencia unos de otros, utilidades de tipo subjetivo a los elementos comparados [15].
  - Análisis de las utilidades: El método supone que si el grupo mantiene diferencias importantes, las utilidades deben ser muy diferentes y están representadas por la Distribución Uniforme. El trabajo grupal debe contribuir a reducir las diferencias, por lo que la dispersión observada debe mostrar una tendencia sostenida a la reducción. De este modo, para verificar la estabilidad y el consenso se trabaja con el Indicador IVR (Índice de Variabilidad Remanente, ver expresión 1[5]) y el análisis de normalidad

[5] El IVR compara a través de un cociente la variabilidad de las utilidades asignadas por el grupo en relación a las utilidades representadas por la distribución uniforme. Aquí, k representa el elemento comparado, u^*_{kn} muestra la utilidad asignada por el

de los datos mediante el test de Shapiro-Wilks modificado por Rahman y Govindarajulu [16].

$$IVR = \frac{\sum_{k=1}^{K}\sum_{n=1}^{N}(u_{kn}^{*} - \bar{u_k^{*}})^2}{\frac{N-1}{3k}} * 100\,\% \tag{1}$$

- Verificación de consenso: cuando todas las utilidades asignadas a cada uno de los elementos comparados, pudieron ser representadas con una Distribución Normal, fue posible presumir consenso y pasar a un nuevo su–problema (Segundo ítem).

- Fase Agregación permite obtener valores globales para cada alternativa de decisión. Para la obtención de coeficientes globales se trabaja con la ponderación lineal. Así, W_j es la variable aleatoria que representa los pesos de los criterios, y las U_{ij} son variables aleatorias que simbolizan las utilidades asignadas a los candidatos al evaluar la alternativa genérica i bajo el criterio j. La contribución parcial a la prioridad asignada se obtiene como el producto de las dos variables aleatorias mencionadas conforme a la expresión 2.

$$Z_{ij} = W_j * U_{ij} \tag{2}$$

Asimismo, los valores globales de una alternativa genérica V_i, se obtienen como se indica en 3.

$$V_i = \sum_{i=1}^{J} W_j * U_{ij} = \sum_{i=1}^{J} Z_{ij} \tag{3}$$

- Fase ordenamiento permite ordenar las alternativas, desde la mayor a la menor preferencia. La comparación de los promedios de las valoraciones V_i permite establecer un primer ordenamiento de la mayor a la menor preferencia. Sin embargo, dado que los valores observados pueden estar afectados por el error muestral, es posible que esta modalidad conduzca a identificar relaciones de preferencia que no son reales. Para distinguir estas situaciones el método aplica pruebas repetidas de comparación de variables dependientes y controla la tendencia a cometer errores de tipo I, con la tasa de descubrimiento falso propuesta por Benjamini y Yekutieli [17].

2.2. AHP grupal en la literatura

Existen múltiples antecedentes de adaptación de AHP a la toma de decisiones grupales [11]. Un artículo seminal es el presentado por Forman y Peniwati [18] donde dos métodos son propuestos para sustanciar las modalidades grupales de trabajo: la primera consiste en la Agregación de juicios individuales (AIJ) y la segunda plantea la Agregación de prioridades individuales (AIP).

participante n al comparar el elemento genérico k, $\bar{u_k^{*}}$ es la utilidad promedio considerada por el grupo al considerar el elemento k y N expresa el total de participantes del grupo.

La literatura acuerda que la estrategia AIP transforma las matrices de comparación por pares individuales por medio del método de la media geométrica en una matriz de comparación grupal y asume el grupo como una unidad sinérgica. La estrategia AIJ se aplica cuando los miembros del grupo tienen diferentes sistemas de valores y la agregación de prioridades individuales se puede calcular al utilizar una media geométrica o media aritmética para que el vector de prioridades individual se transforme en un vector de prioridad grupal [18].
Dong y Saaty [19] hacen una propuesta superadora basada en un modelo de búsqueda de consenso asistido por un moderador. En este enfoque, agregan los juicios individuales con la estrategia AIJ e introducen una medida llamada Índice de consenso grupal (GCI) que refleja la compatibilidad de la matriz propuesta por un participante genérico p en relación con la matriz grupal. Si el GCI no identifica la compatibilidad deseada del participante en relación con el grupo, el moderador sugiere al experto más discordante para acercar su posición al grupo. En una contribución más reciente, Dong y Cooper [20] introduce una innovación para estimar los pesos que se asignarán a cada miembro del grupo a través de las cadenas de Markov. Además, se incorpora un mecanismo de retroalimentación como sustituto de las sugerencias del moderador para minimizar el sesgo de subjetividad en el momento en que aconseja a los expertos sobre cómo revisar o actualizar sus opiniones.

De ahora en adelante, la propuesta de Dong y Saaty [19] se utilizará para comparar con el método de procesos DRV. La justificación de esta elección radica en que los procesos DRV utilizan la figura de un facilitador.

El procedimiento de Dong y Saaty [19] toma las matrices de todos los tomadores de decisiones con una consistencia aceptable para construir una matriz grupal. Cada una de las valoraciones grupales es obtenida a través de la expresión 4.

$$a_{ij(g)} = \prod_{p=1}^{N} (a_{ij_{(p)}})^{\rho_p} \tag{4}$$

dónde N es el número total de participantes, ρ_p es el pero de la opinión de cada experto y se verifica que $\sum_{p=1}^{N}(\rho_p) = 1$.

Luego, se calcula el índice GCI (que la compatibilidad de cada decisor individual en relación al grupo) para cada uno de los N participantes. La ecuación que refleja el GCI para cada participante p es introducida en 5.

$$GCI_k = \frac{1}{k^2} \sum_{i=1}^{I} \sum_{j=1}^{J} a_{ij_{(p)}} a_{ji(g)} \tag{5}$$

dónde k es el número de elementos comparados cada vez, $a_{ij_{(p)}}$ es cada una de las valoraciones de la alternativa i bajo el criterio j de un participante genérico p, and $a_{ji_{(g)}}$ corresponde a la valoración del criterio j bajo la alternativa i para el grupo.

Si el GCI de cada uno de los N participantes es menor o igual a ϵ (ϵ puede fijarse en un 1.01); se puede decir que el decisor genérico p tiene un aceptable

consenso y entonces el proceso se detiene. Por el contrario, si el GCI excede el umbral, el método calcula la media geométrica entre la posición del tomador de decisión más discordante (máximo GCI) y la matriz grupal. Luego, el moderador propone al tomador de decisión, una nueva valoración que surge del cálculo anterior para acercarlo a la posición del grupo que puede ser representada por la expresión 6.

$$a_{ij(p)}^{t+1} = {a_{ij(p)}^{t}}^{\alpha^t} \cdot {a_{ij(q)}^{t}}^{(1-\alpha^t)} \tag{6}$$

(Aquí, el α es sugerido por el moderador, mide el grado en que el decisor mantiene su postura y puede variar en el rango entre 0 y 1. Paralelamente, su complemento $(1-\alpha)$ representa el nivel de acercamiento de la posición del decisor a la posición grupal).

Si el tomador de decisiones más alejado rechaza la propuesta, no puede actualizar sus juicios en cualquiera de las siguientes iteraciones. De esta manera, su evaluación en las próximas iteraciones, tendrá resultados obtenidos a través de la expresión 7.

$$a_{ij(p)}^{t+1} = a_{ij(p)}^{t} \tag{7}$$

El proceso antes mencionado se repite con las nuevas valoraciones del participante más discordante en la ronda t + 1 y se construye la nueva matriz de grupo. Nuevamente, el GCI de cada participante se evalúa de forma iterativa hasta que se den alguna de las siguientes condiciones:

- el GCI de cada participante es menor que el umbral de 1.01.
- se da una situación dónde todos los expertos se han negado a actualizar sus valoraciones.
- o se ha alcanzado el número máximo de iteraciones. Cabe señalar que el moderador sugiere subjetivamente el número límite de iteraciones permitidas.

3. Resultados y discusión

Se analiza el caso de la selección de proveedores para el recolección, tratamiento y disposición final de los residuos patógenos en una institución universitaria pública. El caso fue resuelto con el método procesos DRV en su aplicación original.

Para valorar a los tres candidatos que se presentaron para prestar el servicio (Oferente 1, Oferente 2 y Oferente 3), las actividades de estructuración permitieron adoptar los siguientes criterios: modalidad operativa y logística (MO), mejora del servicio (MS), costo (CO), tratamiento y disposición final de los residuos (TR), experiencia (EXP), flota de vehículos (FLO) y condiciones de higiene y seguridad (HyS). La figura 1 representa el diagrama de árbol del problema

En la aplicación inicial el estudio del sub–problema referido a determinar los pesos criterios y los subproblemas MO, CO y EXP requirieron dos iteraciones de análisis. Adicionalmente, el análisis del subproblema FL requirió 3 iteraciones

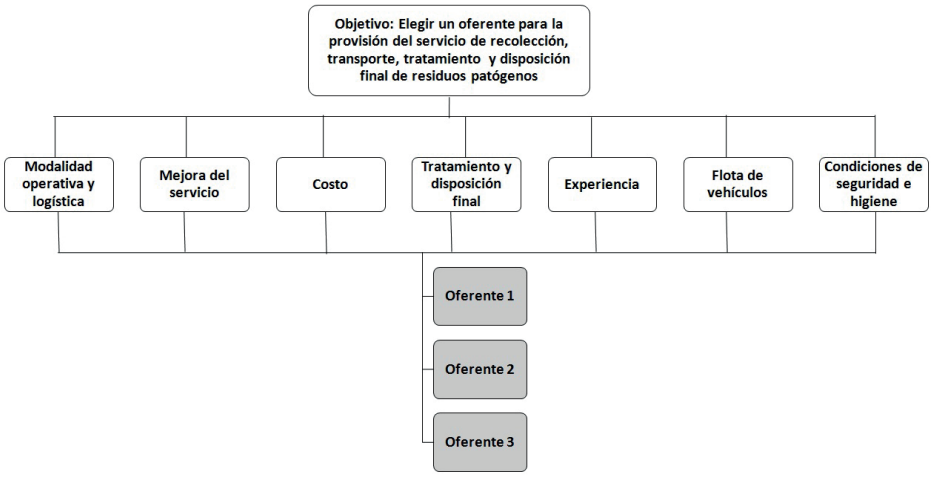

Figura 1. Diagrama de árbol del problema

de análisis y los restantes sub–problemas (MS,HyS y TR) requirieron sólo una iteración.

En los casos donde se precisaron varias iteraciones, se observa que la suma de cuadrados refleja los niveles de incertidumbre e imprecisión que afectan al proceso de decisión. Es decir, en la medida que el IVR decrece, la suma de cuadrados observada (numerador del IVR) decrece y en las diversas iteraciones se aprecia cómo se controlan las dificultades sobre la información. Es pertinente destacar en este punto, que cuando el acuerdo era aparente y aún quedan pendientes nuevas iteraciones, la información se presenta a los miembros del grupo a través de diagramas de caja de las utilidades estandarizadas con lo que es sumamente dificultoso dilucidar quién es el actor en desacuerdo.

Luego, cuando el IVR estuvo por debajo del umbral permisible para todos los sub–problemas, las pruebas de normalidad resultaron aceptables. Lograda la estabilidad, los pesos resultantes fueron de: $0,302$, $0,224$, $0,136$, $0,117$, $0,079$, $0,076$ y $0,066$ para los criterios MO, CO, EXP, FLO, MS, HyS y TR, respectivamente.

Los valores promedio globales para cada alternativa, fueron $0,44$, $0,38$ y $0,18$ para los oferentes uno, dos y tres respectivamente. Como las diferencias entre los oferentes uno y dos pueden originarse en el error muestral, se aplicaron pruebas de comparación de medias, arrojando los resultados que se presentan en el cuadro 1. Allí se obtienen diferencias significativas entre los oferentes.

En la tabla 1, el valor p de contraste se obtiene mediante la aplicación del algoritmo de Benjamini y Yekutieli [17]. Cuando el valor p observado en la prueba es menor que el valor de contraste la diferencia se considera significativa. En este caso hay preferencia estricta de la alternativa uno con las restantes.

Los datos recopilados de la primera evaluación realizada por los participantes

Tabla 1. Ordenamiento final.

Oferentes comparado	Valor t	Valor p observado	Valor p de contraste	Decisión
1 con 2	4,68	0,00545	0,00909	Hay Diferencia
1 con 3	19,4	0,00001	0,01819	Hay Diferencia
2 con 3	16,07	0,00002	0,02728	Hay Diferencia

al aplicar los procesos DRV son adaptados para trabajar con AHP grupal en la versión propuesta por Dong y Saaty. Así, las utilidades asignadas en la primera iteración por los participantes fueron tomadas para calcular cocientes de modo que las valoraciones se transformen en una comparación por pares. De este modo, se obtienen matrices triangulares y con ellos se aplica el modelo de consenso propuesto por Dong y Saaty [19].
Se simularon dos situaciones: una en la que la sugerencia del moderador de acercarse a la postura más discordante a la posición del grupo se acepta la mayor parte del tiempo y otra, en la que en la primera iteración el participante más discordante rechaza la sugerencia del moderador para acercarse a la posición global.
Adicionalmente, Dong y Saaty [19] proponen que α indica qué tan detallado será el análisis grupal en la búsqueda de consenso. Se trabajará en todas las iteraciones con un α de 0,5. El método citado permite trabajar con pesos diferenciales para los diferentes tomadores de decisiones. En esta línea, la posibilidad de asignar diferentes pesos a cada participante puede acentuar el efecto de la presión de grupo y considera una posición más fuerte que otra. En este ejemplo, para fines de comparabilidad con los procesos DRV, se utilizaron pesos idénticos para todos los tomadores de decisiones en todas las iteraciones.
Los resultados que se refieren a la aceptación mayoritaria de la sugerencia del moderador se resumen en la Tabla 2 y la Tabla 3. En contraste, los resultados vinculados a la segunda situación simulada de rechazo de la sugerencia del moderador en la primera ronda se resumen en la Tabla 4 y la Tabla 5

Del análisis de la Tabla 2 preparada con el método AHP y con un nivel α de 0.5 puede apreciarse que 58 iteraciones son necesarias para obtener la matriz grupal. En paralelo, la tabla 4 elaborada con un nivel α de 0,5 muestra 68 iteraciones. De este modo, se destaca que el número de iteraciones aumenta a medida que el tomador de decisiones más discordante se niega a actualizar sus valoraciones en las primeras rondas. Este aumento en el número de intercambios puede ser valorado por el grupo como una instancia negativa y, por lo tanto, condiciona futuras aplicaciones. Asimismo, se observa que el método facilita mejorar el nivel de consenso al aumentar el número de rondas.

En el procedimiento AHP, aunque la actividad es grupal, no se indica en el artículo de Dong y Saaty [19] que se tomen precauciones para recopilar las evaluaciones subjetivas de manera independiente, con lo cual el impacto del la presión grupal puede imponer sesgos. Además, la sugerencia del moderador sobre el participante más discordante puede aumentar esa desviación y condicionar su posición para avanzar y finalizar la actividad.

Tabla 2. Índice de consenso grupal (GCI) y la elección del tomador de decisiones más discordante para cada subproblema en la situación I

Sub-problema	Iteración	Índice de consenso grupal (GCI)	Decisor más discordante (DM_P)	Elección
Peso del criterio	0	$GCI_0 = (1{,}0596; 1{,}009; 1{,}0221; 1{,}0163; 1{,}0012; \mathbf{1.0744})$	DM6	Acepta
	1	$GCI_1 = (\mathbf{1.0539}; 1{,}0085; 1{,}0225; 1{,}0146; 1{,}0038; 1{,}0227)$	DM1	Acepta
	2	$GCI_2 = (1{,}0167; 1{,}0073; 1{,}02; 1{,}0185; 1{,}0029; \mathbf{1.0209})$	DM6	Acepta
	3	$GCI_3 = (1{,}0152; 1{,}0061; \mathbf{1.0193}; 1{,}0171; 1{,}0036; 1{,}0048)$	DM3	Acepta
	4	$GCI_4 = (1{,}0132; 1{,}0076; 1{,}0043; \mathbf{1.0141}; 1{,}0031; 1{,}0045)$	DM4	Rechaza
	5	$GCI_4 = (\mathbf{1.0132}; 1{,}0076; 1{,}0043; \mathbf{1.0141}; 1{,}0031; 1{,}0045)$	DM1	Rechaza
Criterio Modalidad Operativa	0	$GCI_0 = (1{,}0458; 1{,}3479; 1{,}0212; 1{,}0543; 1{,}037; \mathbf{1.7183})$	DM6	Acepta
	1	$GCI_1 = (1{,}0574; \mathbf{1.269}; 1{,}0363; 1{,}0289; 1{,}024; 1{,}2117)$	DM2	Acepta
	2	$GCI_2 = (1{,}0449; 1{,}0862; 1{,}0236; 1{,}045; 1{,}0343; \mathbf{1.1732})$	DM6	Acepta
	3	$GCI_3 = (1{,}0513; \mathbf{1.0677}; 1{,}032; 1{,}0322; 1{,}0282; 1{,}0566)$	DM2	Acepta

Tabla 3. Resultados finales de la estrategia AHP grupal en la situación simulada I

	Modalidad Operativa	Costo	Experiencia	Flete	Mejora del Servicio	Higiene y Seguridad	Tratamiento	Puntaje
Peso	0.303	0.244	0.135	0.114	0.074	0.071	0.062	
Oferente 1	0.517	0.394	0.536	0.421	0.462	0.448	0.532	0.4705
Oferente 2	0.362	0.320	0.301	0.410	0.376	0.419	0.256	0.3478
Oferente 3	0.121	0.286	0.163	0.151	0.162	0.133	0.212	0.1797

En relación a esta cuestión, procesos DRV incorpora un paso fundamental en la fase de estabilización correspondiente a la utilización de alguna herramienta grupal que permita la estructuración del problema y la formación de un lenguaje común. Durante esta actividad el grupo discute, verbaliza y define en forma conjunta los criterios y alternativas. Otra cuestión importante en esta fase, es que la asignación de juicios se realiza en forma individual a los fines de mitigar el efecto de la presión grupal.

Con la modalidad de trabajo propuesta en AHP donde el moderador opera sobre el participante más discordante, se pueden perder instancias de intercambio de opiniones y experiencias entre los tomadores de decisiones en la estructuración del problema. Estos problemas asociados con la necesidad de cumplir con la medida de consenso objetiva pueden afectar la posibilidad de construir conocimiento conjunto.

En relación con la imprecisión o error de medición, la versión grupal de AHP recopila los datos solo una vez. Esta situación genera una dificultad para las operaciones posteriores, porque puede arrastrarse el error si existe. En este sentido, antes de un cambio en la información, se pierde flexibilidad para posibles adaptaciones.

En resumen, la estrategia AHP adoptada detecta la falta de consenso y ayuda al grupo a alcanzar un grado predefinido de consenso, al tiempo que reduce los niveles de incertidumbre. Se observa una mejora continua de la medida de consenso en las iteraciones presentadas en el ejemplo al aumentar el número de rondas. Aun así, la estrategia puede incorporar mejoras que consideren los efectos de la presión de grupo y arbitrar medios para trabajar en el error de medición.

4. Conclusiones

Ha sido posible comparar dos métodos grupales considerando sus respuestas en la búsqueda del consenso y el tratamiento que hacen sobre las formas de ignorancia. Ambos métodos tienen mecanismos para tratar ambos factores y han facilitado la decisión final en el caso de aplicación referido a la gestión de residuos patógenos .

En el caso de procesos DRV en particular se resaltan los recaudos del método en la etapa de estructuración del problema, los cuales se orientan a la formación de un lenguaje común. Es más, las actividades de estructuración acompañadas

Tabla 4. Índice de consenso grupal GCI y la elección del tomador de decisiones más discordante para cada subproblema en la situación II

de formas de recolección independiente y la presentación de la información con medidas indirectas obstaculizan la adaptación del grupo al pensamiento dominante y así se reduce la presión de los pares. Adicionalmente, es posible trabajar con herramientas potentes en la fase de estabilización (IVR y normalidad de los datos) que permiten disminuir los efectos de las dificultades sobre la información no relacionados a la imprecisión y la incertidumbre.
En el caso del método grupal de AHP en la versión de Dong y Saaty, hay una etapa de estructuración de problemas a través del diagrama de árbol, aún así en la instancia grupal no se indica en qué forma se llevan adelante los intercambios en esta actividad de estructuración. En cuanto a la presión grupal, la no indicación de recolección de utilidades de tipo subjetivo de forma individual e independiente acompañada de la sugerencia del moderador sobre el participante más discordante pueden acelerar la búsqueda de una solución de cierre que favorezca la opinión de algunos, con la pérdida de instancias de intercambio de las restantes opiniones. Adicionalmente, el gran número de iteraciones que deben efectuarse puede llevar a cansancio de los participantes y del analista en el procesamiento. En cuanto a la imprecisión o error de medición, la versión grupal de AHP recopila los datos solo una vez lo que en las operaciones posteriores puede arrastrar el error si existe, y en relación a la incertidumbre, esta se ve reducida.
En cuanto a las limitaciones de este trabajo, se encuentra el hecho de que los datos se recolectaron a partir de un método y debieron ser adaptados al otro para mostrar la comparación y las formas de trabajo. Debido a ser el caso de aplicación real por cuestiones de agenda del grupo de trabajo no fue posible aplicar ambos métodos en forma completa.
Por último, quedan líneas abiertas de investigación para trabajar con la comparación de otros métodos grupales. Adicionalmente, pueden analizarse qué otras métricas pueden ser pertinentes para la comparación de métodos, como por ejemplo la reversión de rangos, el análisis de sensibilidad, por sólo mencionar algunas.

Abstract. COVID-19 has placed stress on all national health systems worldwide. Recent studies of the disease have evaluated different variables, quarantine models, mitigation efforts, damage to the mental health, mortality of the population with chronic diseases, diagnosis of the disease, use of masks and social distancing, or mortality regarding different age groups. This study focuses on the capacity of the four National Health System recognized by the WHO. These systems are: (1) The Beveridge model, (2) the Bismarck model, (3) the National Health insurance model, and (4) the "Out of pocket" model. The capacity to respond to the pandemic is analyzed through the days where the mortality doubles by comparing the medians of the doubling mortality variables using the Mood's median test method. The results obtained show similar medians between the study groups. The COVID-19 pandemic saturates health systems regardless of their management structures and the result measured with the variable 'days with double the mortality' is similar among the 4 national health systems.

Keywords: COVID-19, coronavirus, National Health Systems, death rate, non-parametric test.

1 Introduction

Over the last 10 months COVID-19 has spread from China to the rest of the world. National health systems have implemented different strategies to control the disease [1–10] to reduce the rate of infection and mortality. Different authorities have identified different factors associated with the distinctive dynamic system of the disease: climatic factors [11–15], pre-existing disease conditions [16], mental illnesses [17–23], prediction models [24, 25], social distancing [26], and mask, among others [27–31].

Currently, the pandemic has more than 20 million confirmed cases worldwide with 750,000 deaths. America is the continent with the most active cases; Europe is on alert

for outbreaks or a "second wave" of infections. There are currently several studies in the search for a cure that are in the phase of clinical trials in humans [32].

Regarding health systems, there are four national health systems: (1) The Beveridge model, this model is financed by direct taxes, where the person being treated does not pay for care. Also in this model, most of the clinics and hospitals are owned by the government and most of the employees are government employees. This system is implemented in countries such as Great Britain and Spain. (2) The Bismarck model, is financed by private health insurance. This system is jointly financed by employers as employees through payroll deduction, medical care is paid for and reimbursed by insurance, and health centers and doctors are generally private. This system is applied in Germany, France, and Japan. (3) The National Health insurance model, is financed through payroll and tax deductions. These payments are turned over to the national health insurance program, which is administered by the government. The health service is provided by private hospitals and doctors. Some countries only allow the provision of health services to non-profit Private Foundations to achieve cost containment. This system is applied in countries like Canada and South Korea, among others. The last health system corresponds to the so-called (4) “out-of-pocket” system, which is based on the lack of universal health coverage, the patient must pay for their health expenses. In this system, those with the highest income will be able to take care of themselves and the poor will continue to be ill or die. This system is applied in countries within Latin America, Africa, Eastern Europe, and Asia [33–35]. Each system has its characteristics and different approaches and they are heterogeneously distributed in different countries.

The study evaluated the relationship between National Health Systems and the doubling time of the COVID-19 death by country, to evaluate the performance of the different health systems in their response to the pandemic.

2 The Four National Health Systems

The Beveridge model was founded in 1948 by William Beveridge. In this system, health coverage is universal, the health care system is available to all citizens without direct payment, and it is financed by the government through taxes. Most hospitals and clinics are owned by the government and the officials are public employees. The state pays the health care, managing to regulate prices, and define the quality and costs of health care. Private clinics are also financed by the state, which defines health care and the value of each health benefit. The greatest weakness of the system is the long waiting times for medical attention. This system is known globally as the National Health Service (NHS).

The Bismarck model was established by the Prussian Chancellor Otto von Bismarck during the German unification in the 19th century, this system uses an insurance system, called sickness funds. These insurances are jointly financed between employers and employees under payroll discounts. In this case, all members contribute to a defined insurance fund and this provides defined benefits. Private insurance companies must be non-profit; They exist for self-employed citizens and for those who wish to receive

elective services that are not covered by sickness funds. This model has a multi-payer system, where each country has a different number of insurers to choose from. This system has universal coverage and very strict regulations with the sole objective of reaching the entire population and being a non-profit entity.

The National Health Insurance (NHI) model is based on the existence of a universal and unique health insurance system defined in a geographic area and financed by the Government through different sources such as taxes and social security contributions. The NHI model maintains strict independence between the universal insurance system provided by the Government and the medical providers made up by foundations or private companies. The benefits are regulated by a general benefit contract. This contract allows (1) to limit an increase of providers, (2) to share the risk of diseases among the entire population, (3) to ensure the universal availability for all citizens, (4) a general regulation for all providers, and (5) ensures adequate and timely provision of medical services. The fundamental difference between the NHS and the NHI is the separation between universal government insurance and the provision of medical services. In the NHI system, the Government negotiates prices and benefits with private companies and foundations; the government delegates all medical provision services to independent entities. This health care system has been adopted by the governments of Canada, Taiwan, and South Korea. Finally, the model based on universality does not require advertising expenses, reduces the cost of uncertainty by sharing risk, has no financial incentives for denial of service, does not cause bankruptcies in the population, and generates savings for the population due to its public nature.

The Out of Pocket model corresponds to health systems in very poor and disorganized nations where the provision of medical services is not universal and corresponds to an economic transaction between the citizen and private medical service. Large areas of China, India, and rural Africa do not have adequate medical services for their population. About 40 industrialized countries maintain robust national health systems. The United States has a health system where each citizen based on their social and economic position can be classified in one of the 4 national health systems.

3 Methodology

We reviewed the literature regarding the mortality associated with the COVID-19 disease in different countries; however, the analysis was limited to 57 nations representing 70% of the global population. The characteristics of these nations are described in Table 1, with an analysis of mortality up to the 1st of July, 2020. Subsequently, the countries were classified into one of the four national health system models. The information for classification was obtained from the WHO, and the reports associated with each country. Subsequently, the statistical analysis of the comparison of medians of the doubling mortality time variable (Ec. 1) was performed with the Mood technique; using different cut-off dates to see the impact of the pandemic on each health system.

$$Dt = Period / Log^2 (D1 / D0) \quad (1)$$

Where *D0* is the first day with accumulated deaths equal to 10 and *D1* is day i with n accumulated deaths.

3.1 Results

The analysis dates correspond to 60, 75, and 90 days post day 1 with a cumulative number of 10 deaths. Box charts in figure 1 show similar medians for each national health system.

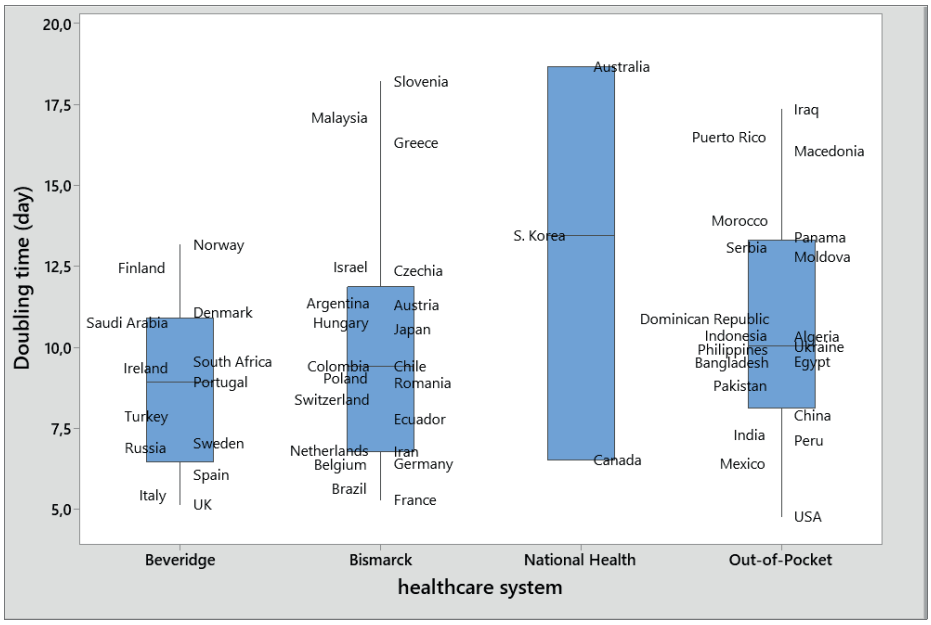

Fig. 1. Box Graph of day 90

To determine whether or not there are significant differences in the information, the Mood median test was performed for each date of the study. Based on a MOOD non-parametric test, the distributions of these four groups were not significantly different when using a significance value of 0.05 (p-value = 0.361 for 60 days, p-value = 0.361 for 75 days, p-value = 0.117 for 90 days). As seen in Table 1, the P-value for each date shows the absence of statistical differences between the different health systems regarding their capacity to respond to the COVID-19 pandemic.

4 Conclusions

The COVID-19 pandemic has been studied from numerous aspects: climatic factors, pre-existing disease conditions, mental illnesses, quarantine models, social distancing, age, use of mask among others.

This study evaluated the relationship between National Health Systems and the doubling time of the COVID-19 death by country to evaluate their performance during the pandemic.

The 4 national health insurance models compared in this study were: (1) The Beveridge model, (2) the Bismarck model, (3) the National Health Insurance model, and (4) the "Out of Pocket" model. The classification of each model in different countries has been studied by international organizations such as the WHO.

The P-values of the different time periods (60, 75, and 90 days) show no significant difference in the doubling mortality time between the different health systems.
Finally, the study establishes no difference in the performance of the different health systems during the COVID-19 pandemic. However, multidimensional modeling must be carried out to know the causes of the doubling mortality time.

Abstract. Se aborda la modelación del proceso de selección y priorización de pacientes en listas de espera quirúrgicas electivas en un hospital público en Chile en base a información histórica con fines de elaborar un modelo de simulación que permita analizar diferentes políticas de configuración y operación del sistema de pabellones quirúrgicos y listas de espera. Se cuenta con datos de un año con aproximadamente 15.000 intervenciones en más de 600 patologías, 8.000 pacientes en la lista de espera inicial, 15 pabellones, 150 cirujanos, cuatro periodos horarios diarios y consideración de fines de semana. Con ellos se modelan procesos clave del sistema de pabellones quirúrgicos. Se utiliza conocimiento experto sobre los procesos de planificación y ejecución de intervenciones quirúrgicas que representan la operación del sistema. Se modela la priorización de pacientes a través de un ranking de selección en cada clúster, representado como una distribución de posición relativa en la lista de espera.
Se usan múltiples indicadores para validar la representatividad del modelo de simulación elaborado, concluyéndose que la modelación del proceso de priorización de pacientes refleja eficientemente el desempeño del sistema, constituyéndose en una herramienta útil y fácil de implementar en el contexto de la simulación del sistema de pabellones quirúrgicos.

Keywords: Pabellones Quirúrgicos, Gestión hospitalaria, Listas de espera quirúrgicas, Priorización de Cirugías.

1 Introducción

Proporcionar una buena calidad de atención es un objetivo primordial, de hecho, una prioridad y un deber de las instituciones de salud en todo el mundo. (Barbagallo et al., 2015). Sin embargo, los recursos estructurales del Sistema Nacional de Salud son limitados y no se pueden intervenir quirúrgicamente a todos los pacientes oportunamente. En la espera quirúrgica los pacientes soportan dolor creciente, limitaciones funcionales y pérdida de calidad de vida relacionada con la salud, llegando incluso a la muerte del paciente a la falta de atención (Desmeules et al., 2012). Además de la poca disponibilidad de recursos escasos de los hospitales (Durán et al., 2017) se presentan problemas de gestión de los mismos, que afectan el rendimiento general de cada pabellón (Garbey

et al., 2017). Existe evidencia que demuestra la optimización de utilización de pabellones por entre un 10 y un 15% respecto a métodos de programación manuales (Durán et al., 2017).

Las listas de espera y los tiempos de espera son un motivo de preocupación en el mundo (Rojas et al., 2017). Los autores además se refieren a que "en las últimas dos décadas se han desarrollado múltiples estrategias enfocadas a reducir el tamaño o a disminuir el tiempo de espera, o simplemente, orientadas a racionalizar la lista". Tradicionalmente el tiempo de espera ha sido el criterio más utilizado para el manejo de dichas listas, pero se discute cada vez más su pertinencia, bajo el argumento de que no siempre el paciente que más tiempo lleva esperando es el que más necesita la intervención (Escobar et al., 2005).

Por otro lado, el movimiento quirúrgico "es considerado una variable que interfiere en los indicadores de calidad y productividad de las instituciones hospitalarias. Se constituye en parámetros de evaluación de la productividad en la sala de cirugía, o sea, tasa de ocupación, tiempo de permanencia, recuperación anestésica, intervalo de tiempo entre cirugías, tasa de retraso y suspensión de cirugía" (Abeldaño & Coca, 2016).

En ese contexto, se modela los procesos de priorización de pacientes en lista de espera en el Hospital Público Puerto Montt, con fines de elaborar un modelo de simulación que permita analizar diferentes estrategias de configuración y operación del sistema de pabellones quirúrgicos. Se utilizan datos de operación del año 2017 con 15.000 intervenciones en más de 600 patologías, 8.000 pacientes en la lista de espera inicial, 15 pabellones, 150 cirujanos, cuatro periodos horarios diarios y consideración de fines de semana. Los datos incluyen tipo de intervención realizada, tipo y fecha de ingreso al sistema, equipo clínico y pabellón asignado, tiempos de ejecución de cada etapa del proceso en el pabellón quirúrgico. No se incluye información clínica detallada del paciente.

2 Modelo del Sistema de Priorización

A continuación se describe los aspectos más relevantes del sistema y el modelo construido:

Caracterización de patologías. Se consideran 633 patologías diferentes, en 10 especialidades médicas y 35 subespecialidades. Por facilidad se realizó un análisis de conglomerado jerárquico resultando en 47 grupos según las variables determinantes.

Ingreso de pacientes. Existe 3 fuentes de pacientes para los pabellones quirúrgicos: Listas de Espera para intervenciones electivas, Urgencias desde el servicio de atención regular y Otras entradas (pacientes del sistema de Garantías Explícitas de Salud GES). A su vez, los pacientes en Lista de Espera provienen de un listado histórico más los ingresos que ocurren diariamente en las diferentes patologías. Cada uno de estos flujos ocurre a diferentes tasas, diferenciados por patología. Se utiliza tablas de frecuencia para modelar las tasas de ingreso.

Resolutividad quirúrgica y no quirúrgica. Aproximadamente un 75% de los pacientes en lista de espera al comienzo del año constituyen pacientes efectivos, en tanto el 25% restante recibe una resolución no quirúrgica, descargándose del sistema.

Tiempos de proceso para intervenciones quirúrgicas. Se consideran 5 etapas en el proceso quirúrgico: preparación del paciente, aplicación de anestesia, intervención quirúrgica, recuperación en pabellón, descarga a sala de recuperación. Para los 47 clúster definidos se establecen las distribuciones correspondientes a sus duraciones y sus parámetros.

Selección de patologías. Los ingresos de urgencia y otros son asignados inmediatamente para intervención teniendo prioridad por sobre los pacientes en lista de espera. La capacidad remanente de los pabellones se asigna a patologías de acuerdo a la frecuencia de ocurrencia correspondiente al clúster respectivo.

Priorización de pacientes. Se establece una función de ranking relativo histórico para la selección de pacientes en lista de espera. Éste se calcula para un paciente como la posición porcentual dentro de la lista correspondiente al momento de ser seleccionado. La forma general de esta función es de tipo U, mostrando una tendencia a seleccionar con mayor probabilidad a pacientes más antiguos, pero también a otros más recientes con menor probabilidad. En algunos casos la forma de la curva es aplanada, mostrando que la priorización para esos clústeres es más bien uniforme.

Selección de equipo quirúrgico. 133 cirujanos se clasifican según sus especialidades y las intervenciones que realizan habitualmente con mayor frecuencia. Se establece las frecuencias de asistencia y producción para cada cirujano en cada día de la semana y periodo horario. Por simplicidad, los valores de muy baja frecuencia anual (menos de 5 intervenciones) se asignan a cirujanos-cluster de mayor presencia.

Selección de pabellón quirúrgico. Se determinan las frecuencias de uso de los diferentes pabellones para cada clúster, representando la dedicación preferente de las instalaciones sin hacer distinción en la fuente de ingreso.

Suspensiones de cirugías. Debido a que no se cuenta con información detallada de las causas de suspensiones, éstas se modelan de acuerdo a su frecuencia histórica para cada clúster.

3 Validación del Modelo

Se elaboró un modelo de simulación y se definen más de 15 indicadores de desempeño del sistema para su validación: las cantidades de intervenciones quirúrgicas realizadas:

totales, electivas, de urgencia y de otras entradas diferenciadas según horario, clúster, pabellón y cirujano. Además, se verificaron los tiempos de duración de los procesos dentro de las intervenciones quirúrgicas, los tiempos de permanencia en las listas de espera, el tamaño de la lista de espera final, y ranking de priorización de pacientes según clúster. Se utilizan herramientas de estadística descriptiva, análisis de correlación, intervalos de confianza, histogramas y pruebas de inferencia para verificar la validez de las estimaciones.

4 Conclusiones

Se concluye que la modelación del proceso de priorización de pacientes en lista de espera utilizando distribuciones de ranking según clúster de patologías así como las relaciones de cirujanos a patologías y horarios de desempeño reflejan eficientemente el desempeño del sistema y constituyen una herramienta útil y fácil de implementar en el contexto de la simulación del sistema de pabellones quirúrgicos. El modelo permite implementar y evaluar diferentes políticas de operación y configuración del sistema conformado por los pabellones quirúrgicos y las listas de espera de pacientes en un contexto de simulación de procesos por lo que se constituye en un enfoque poderoso y sencillo para el análisis y mejora en la calidad de servicio a los pacientes en espera de intervenciones.

Abstract. Los sistemas de jubilación y pensión en el mundo han sufrido cambios importantes, debido a las imposiciones gubernamentales en varios aspectos. En esta investigación desarrollamos un modelo de optimización lineal para determinar los porcentajes óptimos de aportaciones en un sistema de jubilación diseñado para apoyar a los docentes de una institución de educación superior. Los parámetros que considera el modelo, el cual es desarrollado en el lenguaje LINGO son: la tasa de interés que genera la inversión, la tasa de inflación, los años ahorrados, los años en que se desea tener cobertura, y los salarios de los trabajadores. Los resultados arrojan los porcentajes óptimos de inversión con respecto al salario del trabajador, suponiendo que se desea tener cobertura durante cierta cantidad de años en el futuro y se ha ahorrado durante un periodo de tiempo, al final mostramos un análisis de sensibilidad haciendo que los parámetros antes mencionados tomen valores en ciertos rangos razonables.

1 Introducción

Los sistemas de pensión tienen el objetivo de dotar a los trabajadores de un ingreso económico durante su vida post laboral, para que pueda hacer frente tanto a sus gastos de vida, como a diferentes situaciones que se le pueden presentar. Un plan de pensiones, consiste de un arreglo de pagos regulares, generalmente durante la vida laboral de un trabajador, que le permitirá garantizar un ahorro para la edad avanzada (Blanchard and Fischer (1989); Rofman (2005)).

Mientras los países de todo el mundo se encuentran experimentando incrementos nunca antes visto en la esperanza de vida y las tasas de fertilidad, paralelamente se presentan cambios en las normas contables, reducciones de contribuciones y bajos rendimientos financieros. Aunado a lo anterior se suma una alta volatilidad en los mercados financieros lo que impacta de manera directa el poder adquisitivo de los trabajadores. Todos estos elementos han llevado a una caída en los sistemas financieros y a un aumento en las tasas de interés. Los fondos de pensiones del Reino Unido y USA, que tradicionalmente habían tenido asignaciones de capital relativamente altas, han sido duramente afectados (Marco, M., Gregoriou, G. N. and Masala, G. (2010)).

En México, tanto el Instituto Mexicano del Seguro Social (IMSS) como el Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado (ISSSTE) abordan la seguridad social estableciendo dos regímenes claramente diferenciados: el régimen obligatorio y el régimen voluntario. Tradicionalmente creados para brindar un retiro digno a los trabajadores, los sistemas de pensiones en México enfrentan retos enormes, producto de un escenario complejo. En las leyes de ambas instituciones se establece que la seguridad social en el régimen obligatorio debe atender el retiro, cesantía en edad avanzada y vejez de los trabajadores. Puede apreciarse entonces la importancia que históricamente ha otorgado el estado mexicano a los planes de pensiones en nuestro país. No obstante, el modelo tradicional de pensiones ha sufrido diversos cambios debidos a múltiples problemáticas que se han presentado tanto a nivel global como local. El modelo de liberalización financiera imperante en México, desde hace varias décadas, generó que se modificara el sistema de pensiones. En México se reformó el sistema de pensiones para el retiro del IMSS, que desde el año 1997 cambió (IMSS(1997)), de un sistema público, a un sistema privado de aportaciones individuales. Paralelamente, en 2007, se reformó la ley del ISSSTE, (ISSSTE(2007)), de tal manera que la nueva ley permite la creación de un sistema de pensiones que actualmente funciona como una Administradora de Fondo para el Retiro (AFORE).

Como puede verse, la creación de fondos de ahorro para el retiro tiene una importancia enorme desde cualquier perspectiva: social, económica, política y finalmente, humana. El garantizar un nivel de vida digno para los trabajadores pensionados que aportaron su fuerza laboral durante una vida de trabajo, es un problema de la mayor relevancia. La mejoría en los tratamientos médicos para atender enfermedades crónico degenerativas que aquejan de manera importante a los adultos mayores, ha favorecido que la esperanza de vida se incremente de manera significativa, con el consecuente impacto en la calidad de vida de los mismos. Es decir, la longevidad puede tener consecuencias importantes en el plan de pensiones de los trabajadores. Este es un tema en el que tanto legisladores, actuarios e ingenieros financieros tienen que abordar desde sus respectivas disciplinas.

De acuerdo con los datos proporcionados por el IMSS, el ISSSTE y el Instituto Nacional de Estadística Geografía e Informática (INEGI), la proporción de trabajadores activos cotizantes en los sistemas de pensión respecto a la población económicamente activa (PEA) ocupada fluctuó alrededor de 37 por ciento entre 2000 y 2009 (Murillo, S., and Venegas, F. (2011)). Actualmente, cerca del 60 por ciento de la PEA ocupada no está cotizando para acceder a una pensión por jubilación o retiro al llegar a la vejez. Esto, desde luego, conduce a diferentes cuestionamientos sobre las funciones sociales y económicas que los sistemas de pensiones deberían cumplir (Murillo, S., and Venegas, F. (2011)).

Por todo lo anterior, resulta indispensable abordar el tema del ahorro para el retiro con el objetivo de mitigar las condiciones de desamparo en que se encuentra una enorme parte de la población en México al llegar a una edad avanzada. A más de veinte años de la reforma a la Ley del IMSS, es necesario proveer alternativas viables que permitan que los trabajadores puedan contar con un plan de pensión para el retiro.
(Lin C, et al., 2014) hacen uso de un proceso estocástico de Ito, considerando tres variables de estado: la tasa de crédito, la tasa interés libre de riesgo, y la tasa de crecimiento del salario, dicho proceso es estudiado a través de un modelo de simulación tipo Mínimos Cuadrados Monte Carlo (LMS) para fijar los precios de las opciones y en donde el beneficio obtenido se toma del máximo entre los beneficios definidos y las contribuciones definidas. En el modelo se toma como supuesto que la edad máxima para permanecer en el sistema de pensión es de 65 años, sin embargo, también considera que existen dos posibilidades en donde el trabajador se pueda retirar con menos de esa edad: (1) El trabajador tiene más de 15 años de experiencia y más de 55 de edad y (2) el trabajador tiene más de 25 años de experiencia.
En este trabajo se desarrolla un modelo de ahorro para el retiro de los trabajadores académicos de una institución de educación superior pública en México, cuyo objetivo es mitigar las consecuencias económicas que los planes de retiro vigentes (AFORES) con seguridad no van a cubrir. El estudio se plantea desde dos perspectivas: (1) El primero hace un análisis de la cobertura en tiempo que los ahorros alcanzan a cubrir haciendo uso de las aportaciones sugerida por la institución educativa, y (2) Bajo una perspectiva de optimización se determina el mínimo porcentaje del salario que se recomienda aportar para tener determinada cobertura en años, bajo ciertos años de trabajo.

2. Materiales y Métodos

2.1 Descripción del problema.

En el año de 1997 el Instituto Mexicano del Seguro Social (IMSS(2019) publicó una nueva ley para reglamentar las jubilaciones, esta nueva ley surge por diferentes razones, entre ellas podemos encontrar el incremento promedio de la esperanza de vida de los Mexicanos, según el (INEGI (2019)) la esperanza de vida ha aumentado considerablemente; en 1930 las personas vivían en promedio 34 años; 40 años después en 1970 este indicador se ubicó en 61; en el año 2000 fue de 74, en 2016 fue de 75.2 años y especialmente para el año 2016 en el estado de Hidalgo la esperanza de vida fue de 74.6 años. Otro aspecto importante es el origen del recurso económico que se obtiene para las jubilaciones, pues en la antigua ley del Seguro Social, el recurso otorgado a los jubilados provenía de las personas económicamente activas. Si observamos datos proporcionados por el (INEGI(2019)) veremos que el índice de natalidad se redujo en

un 50% entre los años 1970 y 1990, esto ocasiona que si no existen personas económicamente activas para poder subsidiar la jubilación de las personas retiradas se tendría un problema económico de grandes dimensiones al intentar otorgar este recurso.

En dicha ley se menciona que las personas que cuenten con un trabajo formal y que comiencen a trabajar después de julio de 1997 sólo recibirán el dinero ahorrado por ellos mismos en su fondo de retiro (Afore), el cual se otorgara en parcialidades de acuerdo a la esperanza de vida en ese momento. Tomando en cuenta que las recompensas económicas dadas por esos esquemas de retiro (Afores) son bajas, por ejemplo (https://app.finauta.com/retiro/res/fc4af1a0#News), una persona de 43 años en la actualidad, con un salario mensual 20,000 MXN y un ahorro acumulado de 100,000 MXN hasta este momento , estaría recibiendo aproximadamente 3,600 MXN mensuales a los 60 años de edad, casi una quinta parte de su salario actual, además, sin considerar inflación. A la luz de ese escenario, no tan favorable, algunas instituciones han optado por crear su propio sistema de jubilación con el fin apoyar al trabajador. En este trabajo se desarrolló un modelo de optimización que pudiera apoyar la toma de decisiones en una institución de educación superior para implementar un sistema interno de ahorro para el retiro. En concreto nuestro modelo determina el porcentaje del salario del trabajador que debería invertir en un fideicomiso para alcanzar determinados niveles de calidad de vida económica futura. En las siguientes secciones se desarrolla el modelo de optimización, así como los datos de entrada usados en su análisis.

El proceso de ahorro y retiro consiste en el ingreso de docentes que cuentan con edades y salarios diferentes y que deseen ahorrar un porcentaje de su salario para un fondo de retiro que, a lo largo de un tiempo determinado por ellos, dicho dinero es incrementado por los intereses bancarios producidos por un fideicomiso en alguna institución bancaria. Cuando el docente decide retirarse se otorgará el dinero recaudado a lo largo de los años de ahorro para que pueda disfrutar de su vejez.

Fig 1. Proceso general de ahorro y retiro

2.2 Recopilación de datos.

La institución educativa en donde recabamos información estableció que los profesores beneficiados deberían contar con algunas características importantes para poder ingresar a su programa de jubilación.

Como característica primordial el trabajador deberá pertenecer al sindicato de académicos, esto con el fin de que reciba de manera justa y legal todos los beneficios que establece su contrato colectivo de trabajo. Un elemento importante en el modelo es el salario del trabajador, pues estos no son iguales para todos los profesores, porque en las instituciones educativas de nivel superior existen diferentes tipos de plaza con el que es contratado el personal, debido a su experiencia, nivel de estudios, publicaciones realizadas, etc., entre otros factores que definen su categoría de contratación.

Una parte importante en el modelo de optimización es el porcentaje del salario que tanto los docentes, como la institución misma aportarían al sistema de jubilación, en un principio se creyó que un 5% del salario mensual no significaría una reducción considerable en su nivel de vida. Dado que el dinero aportado por los trabajadores e institución se invertiría en algún instrumento financiero, se considera que estos dan una tasa de interés aproximada del 6% anual (Comunicación personal).

También, nuestro modelo toma en cuenta la inflación, el cual es manejado como un parámetro más, pues si una persona planea vivir durante 10 años después de su retiro, con el dinero que puede vivir hoy, se necesita inflar su salario actual para llevarlo a valor futuro. Para este caso se considera una inflación de 3.33% ya que en promedio según el Banco de México (Banxico (2020)) es la inflación anual que sufre el país. Como parte de este razonamiento, y en pro de mejorar los salarios, la institución otorga un incremento aproximado salarial del 3% anual tratando de contrarrestar dicha inflación.

2.3 Formulación del Modelo

A continuación, definimos por medio de la siguiente notación las variables y parámetros del modelo de optimización:

Conjuntos:

i: Conjunto de años ahorrando, i={1,…,N}
j: Conjunto de años con cobertura, j= {N+1,…,n}

Parámetros

N: Número de años que la persona ahorra
n: Número de años que la persona recibe pensión (cobertura)
α: Tasa de incremento salarial
β: Tasa de inflación
κ: Tasas de interés que paga el fideicomiso
θ: Tasa de interés en cuenta de ahorro bancaria
S_0 : Salario inicial

Variables:

γ: Porcentaje de aportación (variable de decisión)
R_i : Retiro en el año j
A_i : Aportación en el año i
S_i : Salario en el año i
B_i : Balance en el año i
B_j : Balance en el año j

Con dichas definiciones, el modelo matemático queda como:

Min $Z= \gamma$

S.A.

$$A_i=S_i(2*\gamma) \text{ , } i=1,..., N \quad (1)$$

$$A_j=0 \text{ , } j=N+1,..., N+n \quad (2)$$

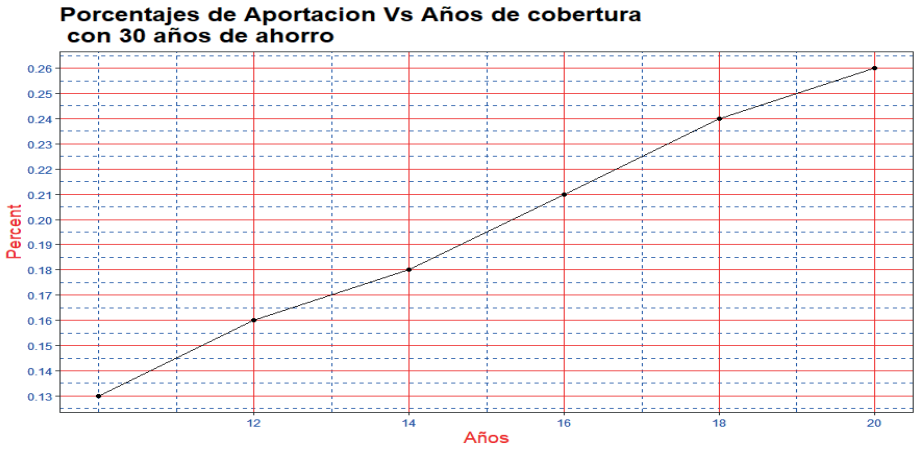
$$S_i= S_{i-1} (1+\alpha), \; i=1,...,N \quad (3)$$

$$S_j=0 \text{ , } j=N+1,..., N+n \quad (4)$$

$$B_i= (B_{i-1} +A_i)(1+\kappa), \; i=1,...,N \quad (5)$$

$$R_j=S_0 \; (1 + \beta)^j, \; j=N+1,..., N+n \quad (6)$$

$$B_j = (B_{j-1} - R_j)(1 + \theta), \quad j=N+1,..., N+n \quad (7)$$



$$R_i=0, \; i=1,..., N \quad (8)$$

$$B_{N+n} \geq 0 \quad (9)$$

$$\gamma \geq 0 \quad (9)$$

3. Resultados y análisis de sensibilidad

El modelo fue ejecutado con los valores de los parámetros siguientes, los cuales fueron explicados en la sección de 2.2:
N=30, n=10, α=3%, β=3.3%, κ=6%, θ=3%, S_0= 240,000.
El porcentaje de aportación obtenido fue de γ=13%, el cual dista por más del doble que se ha propuesto (5%).
Con la finalidad de que los trabajadores y la Institución percibieran el comportamiento del porcentaje de aportación, analizamos dos escenarios, considerando los años trabajados o ahorrados (N) y los años de vida después del retiro que se desean cubrir (n). El primer escenario considera que la persona ahorra un tiempo total de 30 y desea vivir entre 10 y 20 años con el dinero recaudado después del retiro (ver Fig. 2).

Gráfica 2: Porcentajes de aportación según los años de cobertura al momento de retiro

Como se puede observar en la Fig. 2, existe una relación aproximadamente lineal entre los años de cobertura después de la jubilación y los porcentajes de aportación, pues si se desea vivir más años con el dinero generado, el porcentaje de aportación anual deberá ser mayor.
En el escenario número dos se analizó el caso de un profesor retirado que pretende o espera vivir 10 años con el dinero recaudado, pero en esta ocasión el tiempo de ahorro se consideró como variable independiente. En este escenario variamos el tiempo de ahorro desde los 16 años hasta los 30 años, obteniendo los siguientes resultados (véase la Fig. 3).

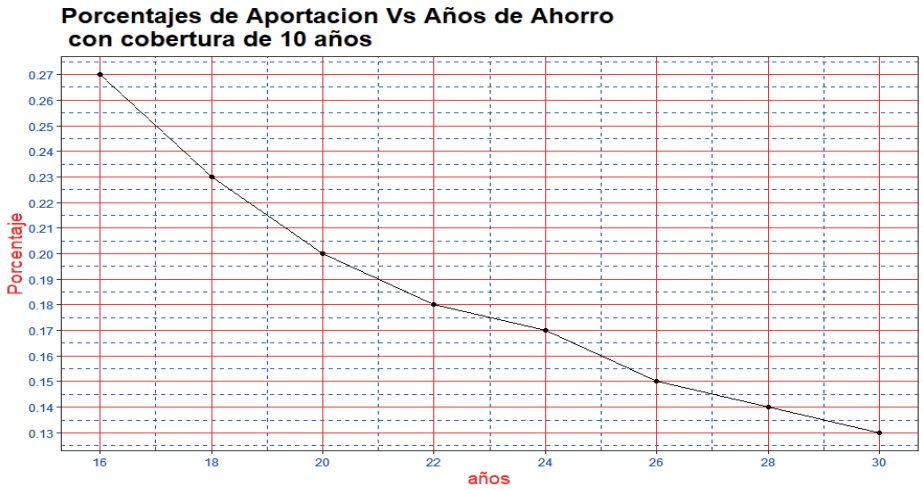


Fig. 3: Relación de años de ahorro y porcentajes de aportación para un retiro con 10 años de cobertura económica

En la Fig. 3, podemos observar que la curva es descendente, por lo tanto, a medida que ahorramos más tiempo el porcentaje de aportación es menor para vivir diez años de jubilación.
Por el momento este modelo no incorpora el efecto que tiene la esperanza de vida del docente, ya que es evidente, en cualquier caso, que, aunque se desee disfrutar del ahorro una cierta cantidad de años, esto puede ser truncado por la muerte del individuo. Estudios futuros podrían incluir un tipo de modelo de programación estocástica, para incluir el factor del tiempo de vida o la aleatoriedad de las tasas de interés, incluso cambiar el enfoque por un modelo de simulación.

4. Conclusiones

El modelo desarrollado permitió a la Institución Educativa definir el mejor porcentaje de aportación salarial, considerando las opiniones de los profesores después de que ellos fueron informados del análisis generado con el modelo. Lo que fue evidente de este análisis es que un porcentaje del 5% de aportación salarial, es insuficiente para cubrir los gastos de vida futuros de la mayoría de los trabajadores. El modelo resulta ser útil para todas aquellas empresas que requieran hacer de una manera cuantitativa un análisis de sus distintos escenarios en sus planes de jubilación. Actualmente se está trabajando por los autores un modelo estocástico de simulación para explorar escenarios más reales en el comportamiento del sistema.

Abstract. Four yeast strains (*Candida tropicalis, C. krusei, C. kefyr* and *Rodhotorula mucilaginosa*) isolated from an apple juice plant were evaluated for their ability to form monospecies biofilms on ultrafiltration membranes. Yeast attachment and biofilm formation was estimated at different contact times 2, 6, 24, 48, 72 h and one week using apple juice as food matrix and polyvinylidene fluoride membrane as contact surface. The highest counts recorded after one week trial were for *C. tropicalis* and *C. krusei* (9.02 ± 0.30 and 9.30 ± 0.29 log CFU cm^{-2} respectively), followed by *C. kefyr* (8.63 log CFU cm^{-2}) and *R. mucilaginosa* with the lowest adhesion (7.68 log CFU cm^{-2}). The present study supports the importance to examine the interactions among members of resident microbiota on surfaces commonly used for juice clarification processes and should alert about improving and adopting better cleaning and disinfection protocols as they can represent a serious hygienic-sanitary problem.

Keywords: Biofilms, Yeast, *Candida* spp., Ultrafiltration membranes, Apple juice.

1 Introduction

Microorganisms form microbial aggregates called biofilms able to adhere to different surfaces. Microbial cells are enclosed in an extracellular polymeric matrix that they produce and this determines the microenvironment of the resulting microbial community. Biofilms, represent a perpetual hazard for food industries as they contaminate different stages along the production lines leading to potential equipment damage and/or product contamination [1-2]. Membrane technologies are widely used in food industries for many separation processes such as juice clarification. Ultrafiltration (UF) membranes are characterized by a pore size of 0.001–0.05 μm and molecular weight cut-off (MWCO) between 1 and 300 kDa, retaining most of the suspended solids and microorganisms [3]. One of the major setbacks of filtration technologies is

membrane biofouling, which significantly reduces the filtration flux, shortens the lifespan of membrane and increases energy consumption with the consequent losses of product yield [4-6]. Yeasts are the predominant microorganisms associated with the spoilage of acid fruits and acid food products and so they represent the principal microbial group associated to biofilm formation in related industrial facilities [5]. Taking into account the aforementioned, the present study describes the dynamics of monospecies adhesion and biofilm formation of *C. krusei*, *C. tropicalis*, *C. kefyr* and *R. mucilaginosa* on UF membranes under conditions of industrial relevance.

2 Materials and methods

2.1 Culture conditions.

C. tropicalis, C. krusei, C. kefyr and *R. mucilaginosa* were previously isolated from the surfaces of polyvinylidene fluoride (PVDF) UF membranes, of an apple juice processing industry located in the Alto Valle de Río Negro, Argentina [6]. Stock cultures of each yeast strain were stored at -70°C until use in yeast extract glucose chloramphenicol (YGC; Biokar diagnostics, Beauvais, France) broth supplemented with 20% v/v glycerol. Before use, a loop of frozen cells was suspended in YGC broth at 25 ± 1°C until reaching the stationary phase (48 h). Cultures were then harvested by centrifugation at 1200 x *g* for 5 min (Labofuge 200, Kendro, Germany) and washed twice with phosphate-buffered saline. Pellets were subsequently re-suspended in sterile clarified 12°Brix apple juice and the suspensions were adjusted by optical density at 550 nm to 0.125 (~ 10^6 cells ml^{-1}) using a spectrophotometer (Thermo Spectronic Genesys 20, Thermo Electron Corporation, Waltham, MA, USA).

2.2 Food soiling system (culture media) and biofilm formation

The 12° Brix apple juice used in the successive assays was prepared from 72° Brix concentrated apple juice provided by a national producer/exporter company. Assays were carried out on PVDF-UF membranes (Synder Filtration, Vacaville, CA, USA), with a MWCO of 100 kDa and operation characteristics resembling the ones seen in juice processing industries [3]. According to the supplier's recommendations, before use the membranes were immersed for 15 min in sterile distilled water to eliminate possible antibiotic residues. For the assays sections of 1 x 2 cm of PVDF membranes were cut with sterile scissors and the sections were placed into each well of a sterile 6-well plate (Jet Biofil, Argentina). To test monospecies biofilm formation, 4 ml of each yeast adjusted suspension was put in contact with surfaces for 2, 6, 24, 48, 72 h and 1 week at 25 ± 1 °C under static conditions. Initially, yeast cells were allowed to deposit on the membranes for 2 h at 25 ± 1°C. Afterwards, the food matrix was replaced every 48 h with sterile juice in order to provide fresh nutrients for the cells.

2.3 Quantification of cells and statistical analysis

After each incubation period membranes were carefully removed using sterile forceps and rinsed by immersing in sterile water for 1 min to remove loosely attached cells. The remaining cells were detached following Trampuz [7] with some modifications Briefly, surfaces were transferred to tubes with sterile beads and 9 ml of water and placed in a bath ultrasound (Digital Ultrasonic Cleaner, PS-10A); this was filled with deionized water and specific holders were used to place two tubes on the corner locations. The samples were sonicated for 2 min at 20°C, at a frequency of 40 KHz. Then each tube was vortexed at full speed for 1 min. After that, samples were serially diluted and counts determined by spread plate technique on YGC agar after 24– 48 h incubation. The results were expressed as log CFU cm^{-2}. In all cases, triplicate tests were performed under identical conditions and the results expressed as means and standard deviations (mean± SD). When appropriate, Student's t-test was used for comparison of means. Confidence level equal or higher than 95% was considered statistically significant (*$P < 0.05$, **$P < 0.01$, ***$P < 0.001$).

3 Results and discussion

Yeast attachment and biofilm formation on PVDF UF membranes was evaluated at six time interval (2, 6, 24, 48, 72 h and one week), is shown in **Table 1**. After one-week trial, *C. krusei* and *C. tropicalis* were the strains that presented the highest counts. The trend was observed along the different times intervals assayed. Comparing the start point (2 h) with final point (1 week) it was observed that *C. krusei*, *C. tropicalis, C. kefyr* increased 2.09, 2.08 and 1.44 log units respectively while *R. mucilaginosa* increased 0.89 log units at the end of the trial. *C. krusei* represented the majority of the isolates from UF membrane samples and this show the adaptive advantage of this species in this environment [6-9]. *C. tropicalis* is capable of producing multicellular, filamentous forms of growth; it was suggested that the condition to switch their morphology modifies the ability to invade different surfaces to form biofilms [1-2, 8]. These yeasts are able to form a dense network on inert surfaces, forming biofilms resistant to removal. Previously, Tarifa [9] described and characterized the multispecies biofilm formation under a flowing system and observed that the four yeasts species adhere to active part of the membrane and to the fibers. In this work, it was observed that the yeasts strains studied were able to strongly adhere and form mono-species biofilm on the PVDF membrane surface and increased their viable cell counts. Testing different conditions contribute to understand the behavior of theses yeast in diverse environments and conditions.

Table 1. Cells numbers of *R. mucilaginosa, C. tropicalis, C. krusei and C. kefyr* expressed as mean log CFU cm^{-2} ± SD in mono-species biofilms on PVDF-membranes surfaces at different times at 25º C.

4 Conclusion

Research on biofilms has focused on understanding the mechanisms and factors governing biofilm formation in mono- or dual-species biofilm models and in the design of strategies to control them at lab scale. The results of this study should alert to the presence of complex communities that could affect the effectiveness of sanitation procedures and the microbiological stability of juice-producing plants. Future studies will focus multispecies biofilm formation on membranes under static conditions and the interactions between common spoilage yeast and bacterial pathogens pertinent to juice safety.

Resumen. Se estudió el efecto del calentamiento sobre la degradación de color y biocompuestos como ácido L-ascórbico *(AA)* y licopeno *(L)* en tomate triturado a 70, 80, 90 y 100 ºC durante 2 h. Los cambios la coordenada *a** de color (rojo-verde), siguieron una reacción de primer orden con una energía de activación de 64,54 kJ/mol. La degradación de *AA* y *L* también siguieron una cinética de primer orden con energías de activación de 25,69 y 45,96 kJ/mol, respectivamente. Las energías de activación obtenidas revelaron que *a** fue el parámetro de calidad más sensible a los cambios de temperatura, mientras que las constantes de la velocidad de reacción (*k*) mostraron que *L* presenta la mayor velocidad de degradación en comparación con los demás parámetros estudiados. Por otra parte, la relación entre el contenido de licopeno y el color (coordenada *a**) en el tomate triturado, mostró una correlación positiva, la cual se evaluó mediante el coeficiente de Pearson (r = 0,88). Los resultados obtenidos en este estudio podrían ser útiles para optimizar el procesamiento térmico de tomate triturado, minimizando las pérdidas de componentes de calidad nutricional y sensorial del producto.

Keywords: Tomate Triturado, Cinética de Degradación Térmica, Calidad.

1 Introducción

El tomate (*Solanum lycopersicum*) es un fruto climatérico de un color rojo intenso característico. Además de ser uno de los cultivos más significativos del mundo y de gran importancia económica [1], presenta un elevado valor nutricional debido al contenido de biocompuestos como el ácido L-ascórbico y licopeno que le confieren una importante capacidad antioxidante. Estos biocompuestos son beneficiosos para la salud, varios estudios epidemiológicos han informado que la ingesta de estos compuestos en la dieta reduce la incidencia de las enfermedades degenerativas, carcinogénicas y cardiovasculares [2-3]. Particularmente, el licopeno tiene una doble función

en la calidad del tomate ya que pertenece al grupo de pigmentos responsables del color, por lo que además de su propiedad antioxidante influye en la percepción de frescura del tomate que, junto con el color, son los atributos de calidad sensorial más importantes [3]. Por su parte, el tomate representa una de las principales fuentes de vitamina C, la cual posee también propiedades antioxidantes con una función protectora del organismo humano [4]. Como contrapartida, el tomate es un producto altamente perecedero, con una corta vida útil poscosecha, lo que limita su distribución y comercialización.

El tomate triturado como subproducto resulta una alternativa que permite el aprovechamiento integral del fruto y generación de valor. El aprovechamiento de piel, pulpa y semillas del tomate, enriquece el perfil nutricional del producto debido a la contribución de todas las partes constitutivas del fruto. Se informó [2] que además de la pulpa donde se concentra el mayor porcentaje de compuestos antioxidantes, la piel aporta hasta un 28% del contenido de licopeno y un 13% de ácido-L ascórbico y las semillas el 22% y 18% para licopeno y acido L-ascórbico, respectivamente. La producción de tomate triturado requiere del procesamiento térmico, el cual es el principal tratamiento en productos a base de tomate [5]; estos procesos (esterilización, pasteurización y deshidratación) permiten generar productos alimenticios inocuos, de mayor estabilidad y vida útil [6]. Sin embargo, durante el tratamiento térmico, las propiedades nutricionales y sensoriales se ven afectadas por el calor. Debido a la importancia de los atributos de calidad y los beneficios asociados a la salud por parte de los biocompuestos presentes en el tomate, resulta importante la optimización del procesamiento térmico basado en modelos cinéticos de degradación apropiados que permitan asegurar la inocuidad y preservar la calidad.

A pesar de que existe una amplia literatura asociada al estudio de componentes de calidad en tomate y subproductos como pasta, puré, jugos y salsa, no se han encontrado estudios cinéticos en tomate triturado. El conocimiento de los parámetros cinéticos y la energía de activación asociada al proceso térmico son esenciales para poder predecir los cambios de calidad que ocurren durante el procesamiento térmico y optimizar dicho proceso.

En base a lo anterior, el presente trabajo tuvo como objetivo desarrollar las cinéticas de degradación térmica de los componentes de calidad del tomate triturado que podrían ser de utilidad en la optimización del procesamiento térmico para asegurar la inocuidad y minimizar las pérdidas de componentes de calidad. Por otra parte, se buscó desarrollar una relación entre los parámetros de color y el contenido de licopeno en tomate triturado para determinar la reducción de este componente durante el proceso térmico mediante una medición rápida de color en línea.

2 Materiales y Métodos

2.1 Materia Prima y Preparación de Tomate Triturado

Se utilizaron tomates (*Solanum lycopersicum*) obtenidos del mercado local de Villa María, Córdoba (Argentina). Los frutos fueron almacenados a 4 °C hasta su utilización (dentro de las 24 h). Los tomates fueron lavados con agua de grifo para eliminar

la suciedad superficial y posteriormente seccionados en cuartos y triturados mediante multiprocesadora (Smartchef, Peabody, Argentina) para obtener tomate triturado.

2.2 Tratamiento Térmico

Muestras de 3 mL de tomate triturado fueron colocadas en tubos de vidrio con tapa a rosca y sometidas a calentamiento en baño de agua termostatizado con agitación a temperaturas de 70, 80, 90 y 100 ºC, con una precisión de ± 1°C, a diferentes tiempos (0-120 min). Se colocaron termopares en 3 tubos a través de la tapa para monitorear la temperatura dentro de los mismos durante el calentamiento. El tiempo necesario para alcanzar la temperatura de calentamiento requerida (tiempo de subida) fue inferior a un minuto y este período de tiempo se excluyó del análisis de los parámetros cinéticos. Finalmente, los tubos se enfriaron rápidamente en un baño de agua hielo para detener la degradación térmica.

2.3 Determinación de Color

Las muestras de pulpa tratada térmicamente se homogeneizaron mediante vortex y fueron colocadas en una celda de cerámica (3 cm de diámetro) para la determinación del color; la cual se llevó a cabo mediante colorímetro triestímulo (Konica Minoltta CR-400, Tokio, Japón) con una superficie de medición de 8 mm de diámetro y provisto de un observador estándar de 10° y un iluminador estándar D65. La determinación se basó en el espacio de color CIELab, compuesto por tres coordenadas colorimétricas, L^* que representa la luminosidad (0 para el negro y 100 para el blanco), a^* (valores negativos para el verde, valores positivos para el rojo) y b^* (valores negativos para el azul, valores positivos para el amarillo). El instrumento se calibró con una placa blanca estándar (sY=93,2, sx=0,3133, y sy=0,3192) y cada determinación de color se realizó por triplicado.

2.4 Contenido de Licopeno

La determinación de licopeno (L) se realizó mediante espectrofotometría. Primero, 0,5 gramos de tomate triturado fueron extraídos con 5 mL de hexano: acetona: etanol en proporción 2:1:1. La mezcla fue sometida a agitación mediante vortex durante 3 minutos, al resguardo del aire y de la luz y finalmente se agregó 1 mL de agua bidestilada. Posteriormente se extrajo cuidadosamente la fase superior y se medió la absorbancia por espectrofotometría a 503 nm; se utilizó un espectrofotómetro UV-VIS con arreglo de diodos (Analitik jena specord S600, Jena, Alemania) y una cubeta de vidrio con una trayectoria óptica de 1 cm (l). Para el cálculo del contenido de Licopeno se empleó el coeficiente de extinción molar $\varepsilon = 172.000$ L $mol^{-1}cm^{-1}$ [7]. Las muestras se analizaron por triplicado. Los resultados se expresaron como mg L/100 g peso fresco.

2.5 Contenido de Acido L-ascórbico

La determinación de ácido L-ascórbico (*AA*) se realizó mediante HPLC según el procedimiento descripto por Tiwari et al. [8] con pequeñas modificaciones. Primero, se mezcló 1 g de tomate triturado en un tubo centrífugo de 15 mL con 5 mL de ácido metafosfórico al 2,5% (p/v) (Merck, Darmstadt, Alemania), luego se mezcló durante 3 minutos mediante vortex al resguardo del aire y de la luz. Se centrifugó a 5.338,78 RCF durante 10 min a 4 °C, y luego el sobrenadante se filtró a través de un filtro de nylon de 45 µm (GVS Filter Technology, EUA.) y se colocó en un tubo eppendorf de 1 mL protegido de la luz. Finalmente, se inyectaron 20 µl de extracto filtrado en el HPLC. El sistema cromatográfico utilizado se basó en un HPLC (Thermo Scientific ULTIMATE 3000, USA) con bomba cuaternaria y columna C18 (150 x 4,6 mm, 5 µm, PRONTOSIL SPHERIBOND ODS2, Alemania). Se utilizó un detector DAD a una longitud de onda de 245 nm. La fase móvil fue una mezcla 93:7 de 0,5% p/v de ácido metafosfórico y acetonitrilo (ACN) (pH:2), la cual fue bombeada isocráticamente a 1 mL min^{-1}. Los cromatogramas fueron procesados usando el software del Sistema de Datos de Cromatografía Termo Científica (CDS). Los resultados fueron calculados mediante la curva estándar del ácido L-ascórbico (Sigma-Aldrich, San Luis, EUA) y las áreas obtenidas en los cromatogramas. Todas las muestras se analizaron por triplicado y los resultados se expresaron como mg *AA*/100 g peso fresco.

2.6 Modelo Cinético

La cinética de degradación del cambio en las coordenadas de color, el contenido de *AA* y *L* se evaluaron mediante modelos cinéticos de orden cero (Ec.(1)) y primer orden (Ec.(2)).

$$C = C_0 - kt \tag{1}$$

$$C/C_0 = exp\ (-kt) \tag{2}$$

Donde C es el parámetro a estimar, C_0 indica el valor del parámetro en la condición inicial, t es el tiempo de procesamiento térmico, y k es la constante de velocidad a la temperatura T.

La dependencia de k con la temperatura se modeló utilizando la Ecuación de Arrhenius (Ec.(3)).

$$k = k_0\ exp\ (-E_a/RT) \tag{3}$$

Donde k_0 es el factor de pre-exponencial, E_a es la energía de activación, R es la constante universal de los gases (0,00831 kJ mol^{-1} K^{-1}), y T es la temperatura absoluta.

Para estimar los parámetros se utilizaron los valores medios de las determinaciones realizadas por triplicado.

2.7 Análisis Estadístico

Las experiencias se realizaron por triplicado. Los resultados se expresaron como valores medios ± desviación estándar. Los análisis de correlación y el cálculo de las respectivas constantes se realizaron utilizando el programa Microsoft Excel® 2010.

3 Resultados y Discusión

3.1 Características físicas y químicas

Las características físico-químicas del tomate triturado utilizado en el estudio cinético de color y biocompuestos fueron (± desvío estándar): °Brix (20 °C) = 3,78±0,03; humedad (%) = 95,63±0,12; acidez (% ácido cítrico) = 0,53±0,05; pH = 4,48±0,01; Licopeno (mg *L*/100 g peso fresco) = 5,31±1,51; acido L-ascórbico (mg *AA*/100 g peso fresco) = 19,25±3,86. Los valores obtenidos se encuentran dentro del rango reportado en la literatura de tomate [1-9-10].

3.2 Efecto del Procesamiento Térmico en el Color

El tomate presentó un color rojo característico, el cual se determinó por colorimetría CIELab con valores de a^* = 16,32±0,55; b^* = *11,55*±0,41 y L^* =*37,84*±0,85. El calentamiento a las diferentes temperaturas de estudio provocó un efecto adverso sobre las coordenadas colorimétricas a^*, b^* y L^*. En la Fig. 1 se puede observar la evolución de a^* por efecto del calentamiento, este valor colorimétrico es de gran importancia para evaluar la evolución del color del tomate triturado durante el tratamiento térmico ya que representa el color rojo, propio del producto. Los resultados obtenidos para las variaciones de coordenada colorimétrica a^* fueron modelados mediante cinéticas de orden cero (Ec. (1)) y primer orden (Ec. (2)), presentando el modelo cinético de primer orden un mejor ajuste (R^2 =0,93-0,98). Sin embrago, para los cambios en L^* y b^* no se encontraron modelos cinéticos que describan satisfactoriamente la evolución para las diferentes temperaturas y tiempos de estudio (datos no mostrados).

La constante cinética de velocidad (k) fue calculada a partir de las curvas de a^*/a^*_0 en función del tiempo (Fig. 1) y se describe en la Tabla 1.

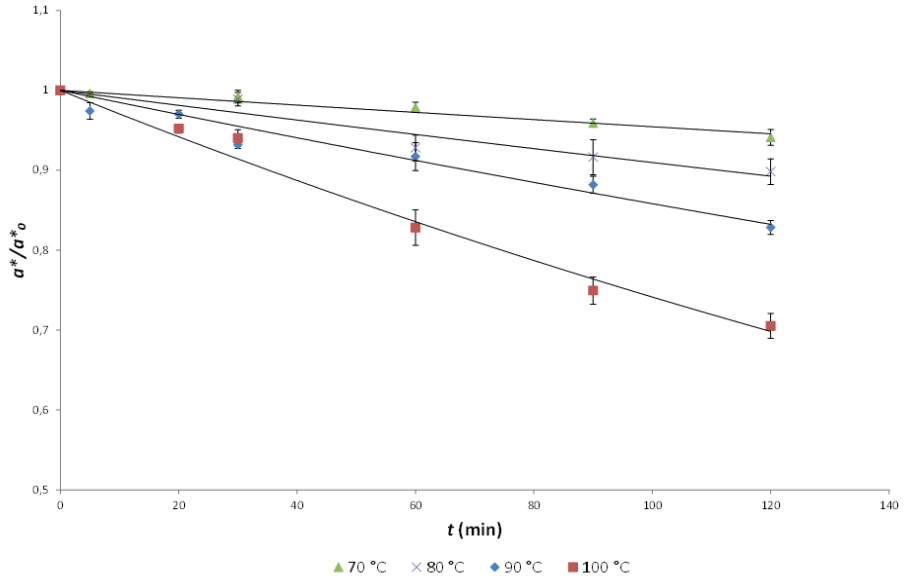

Fig.1. Degradación isotérmica de la coordenada colorimétrica a^* en tomate triturado tratado a diferentes temperaturas. Las líneas representan los ajustes del modelo (Ec. (2)) a los datos experimentales. Las barras representan la media ± desviación estándar.

Se observó que los valores de k aumentaron con la temperatura, lo que indica que la degradación es mayor a temperaturas de procesamiento más elevadas. Los valores de k para los cambios de la coordenada a^* durante el calentamiento se incrementaron con la temperatura, tomando valores de entre 0,5-3,0 x 10-3 min-^{1}. En correspondencia con el presente estudio se informaron cinéticas de primer orden de la coordenada a^* para puré de tomate [11] y pasta de tomate procesados térmicamente [12]. Asimismo, se reportó un modelo cinético de primer orden para los cambios de color en piel de tomate a temperaturas entre 50-100 °C [13].

El valor de a^* para tomate triturado tratado térmicamente a 70, 80, 90 y 100 °C durante 120 min mostró reducciones de 5,89; 10,18; 17,17 y 29,48%, respectivamente. Para evaluar el efecto de la temperatura sobre las constantes cinéticas, los datos mostrados en la Tabla 2 se ajustaron a la ecuación de Arrhenius (Ec. (3)). La energía de activación (E_a) obtenida por Arrhenius es una medida del efecto de la temperatura sobre cada uno de los procesos, de manera que, para un mismo incremento de temperatura, cuanto mayor sea el valor de la energía de activación, mayor será el efecto que produzca; para la coordenada a^* se obtuvo un E_a = 64,54 kJ/mol (Tabla 2). Ganje et al. [12] reportaron un valor similar de energía de activación (65,22 kJ/mol) para el valor de a^* en pasta de tomate tratada térmicamente. A su vez para pasta de tomate doblemente concentrada [14] se reportó un valor de 40,96 kJ/mol. Sin embargo, se informó para piel de tomate tratada térmicamente [13] un valor de E_a = 29,07 kJ/mol, significativamente menor al obtenido en este estudio, lo que podría indicar menor sensibilidad a los cambios de temperatura para la piel de tomate respecto al tomate triturado.

3.3 Degradación Térmica de Licopeno

La concentración inicial promedio de licopeno en el tomate triturado fue de 5,31±1,51 (mg 100 g^{-1} peso fresco), valor que disminuyó con el calentamiento. Se informaron en la literatura contenidos de licopeno similares para piel y pulpa de tomate [2] con valores de 8,7±1,12 y 2,8±0,14 (mg 100 g^{-1} peso fresco), respectivamente. A su vez se obtuvo un contenido de 6,62±0,32 (mg 100 g^{-1} peso fresco) para puré de tomate fresco [5], mientras que para una emulsión de tomate en aceite de oliva [10] se obtuvieron valores de 6,07±0,24 (mg 100 g^{-1} peso fresco). Sin embargo, para tomates frescos variedad Río Grande [15] se reportó un contenido de 50 (mg 100 g^{-1} peso fresco). Esto muestra que se observa una amplia gama de contenidos de licopeno para tomate, lo que puede estar relacionado con la variedad, la madurez y el procedimiento de extracción.

Los resultados mostraron que el calentamiento produjo una disminución del contenido de L para todas las condiciones de estudio, 70, 80, 90 y 100 °C, con pérdidas de 23,94; 30,17; 45,05 y 55,24%, respectivamente para 120 min de tratamiento, indicando una importante pérdida nutricional. A medida que el tiempo del proceso aumentó, la concentración de dicho componente disminuyó (Fig. 2), siendo mayor dicha reducción al incrementar la temperatura de tratamiento.

Se evaluó el ajuste de los modelos cinéticos de orden cero y primer orden y se obtuvo el mejor ajuste para el modelo cinético de primer orden (Ec. (2)), representando adecuadamente el efecto del tratamiento térmico sobre la degradación de *L* en tomate triturado como se muestra en la Fig. 3. El coeficiente de determinación R^2 presentó valores entre 0,91 y 0,98, indicando un buen grado de ajuste del modelo cinético de primer orden a los datos experimentales.

Otros estudios en tomates y frutas reportaron una cinética de primer orden para la degradación de *L*, en pulpa de tomate durante el secado [16], en subproductos del tomate durante el almacenamiento [17]. Una cinética de primer orden también se reportó para la degradación de licopeno en pulpa de tomate [18] y para una variedad de frutos, tal como se informó para el fruto de Guayaba liofilizado durante el almacenamiento a 30°C [19], entre otros.

El efecto de la temperatura sobre las constantes cinéticas (Tabla 1) se evaluó mediante la ecuación de Arrhenius (Ec. (3)). La Tabla 2 muestra los parámetros de Arrhenius, presentando una energía de activación de 45,96 kJ/mol (con un $R^2 = 0,98$). Este resultado indica que la sensibilidad de la variación del contenido de licopeno a los cambios de temperatura es menor que la que presenta la coordenada *a** de color (ya que es 64,54 kJ/mol). Sin embargo, *L* mostró una mayor velocidad de degradación que el parámetro de color, con valores de *k* entre 2,4-8,2 x 10-3 min^{-1}.

Valores similares de energía de activación fueron reportados en la literatura; para tomate secado por aire caliente se informó un valor de E_a = 46,96 kJ/mol [15], para una emulsión de tomate en aceite de Oliva tratada térmicamente [10] se reportó un valor levemente menor al obtenido en el presente estudio de 28 kJ/mol, al igual que en pulpa de tomate almacenada a diferentes condiciones de temperatura se informó valores de entre 19,87-27,74 kJ/mol [18].

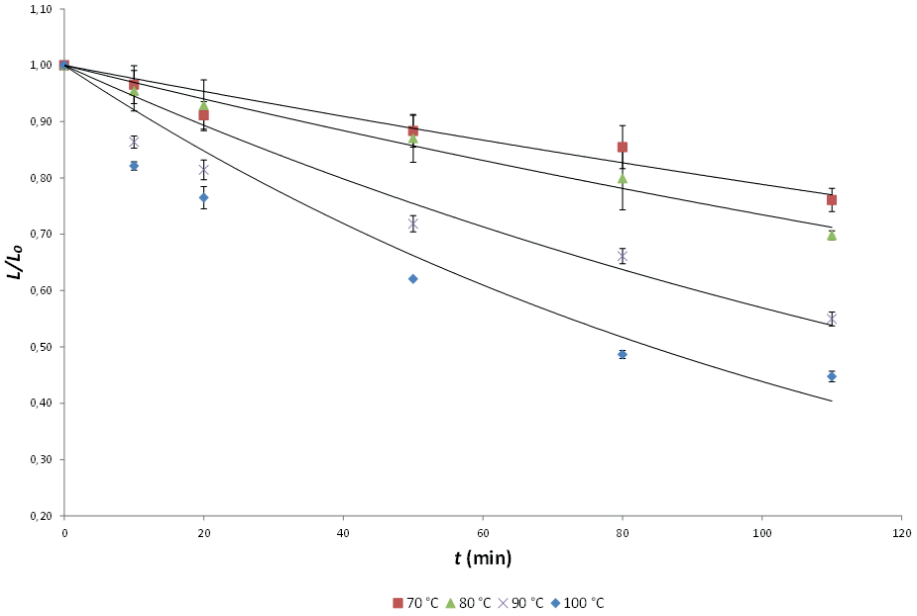

Fig. 2. Degradación isotérmica de *L* en tomate triturado tratado a diferentes temperaturas. Las líneas representan los ajustes del modelo (Ec. (2)) a los datos experimentales. Las barras representan la media ± desviación estándar.

3.4 Degradación Térmica de Acido L-ascórbico

El contenido inicial promedio de ácido L-ascórbico en tomate triturado fue de 19,25±3,86 (mg AA/100 g peso fresco), y se observó una disminución con el calentamiento. Valores similares fueron informados para el contenido de *AA* en piel de tomate [2] reportándose 16,9±0,89 (mg AA/100 g peso fresco), mientras que para piel y pulpa de tomate, de una amplia variedad de cultivares [20], se obtuvieron valores de entre 8,55-56,0 y 8,40-32,4 (mg AA/100 g peso fresco), respectivamente. Dichos autores [20] indicaron que el contenido de ácido L-ascórbico depende de la variedad de cultivares y los factores ambientales. Los resultados obtenidos de los tratamientos térmicos a 70, 80, 90 y 100 °C indicaron una reducción del contenido de ácido L-ascórbico con el procesamiento térmico. Dicha reducción aumentó con el tiempo de tratamiento llegando a valores de 16,43; 17,00; 24,71 y 29,86 % a los 120 min, respectivamente. La degradación térmica del ácido L-ascórbico, para diferentes temperaturas y tiempos de proceso, se evaluaron mediante modelos cinéticos de orden cero y de primer orden, siendo este último el más adecuado para representar esta variación, como se muestra en la Fig. 3. Otros estudios en tomate y frutas también obtuvieron cinéticas de primer orden para representar el efecto del tratamiento térmico sobre el ácido L-ascórbico, este mecanismo de degradación se reportó para tomate secado por aire caliente [15], en tomate para diferentes condiciones de secado y temperaturas [21], para jugo concentrado de tomate durante el calentamiento [22] y pulpa de tomate tratada térmicamente a diferentes temperaturas y tiempos [23]. Además el

modelo cinético de primer orden se reportó para modelar la cinética de degradación térmica de *AA* en una amplia variedad de frutos, en manzanas molidas a altas temperaturas [24], en fruto de Amla durante la cocción a temperaturas entre 50-120 °C [25], entre otros.

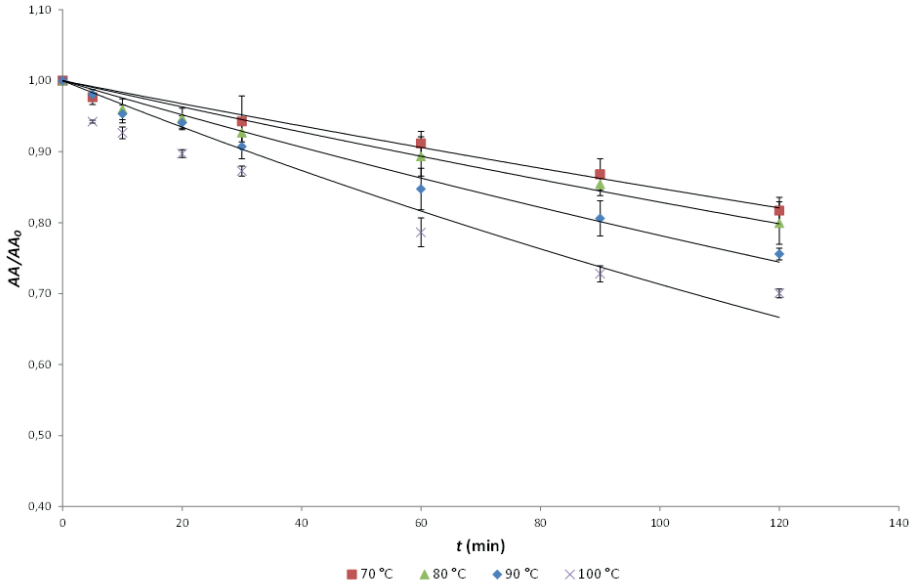

Fig. 3. Degradación isotérmica de *AA* en tomate triturado tratado a diferentes temperaturas. Las líneas representan los ajustes del modelo (Ec. (2)) a los datos experimentales. Las barras representan la media ± desviación estándar.

Como se muestra en la Fig. 3, la degradación térmica del ácido L-ascórbico siguió una cinética de reacción de primer orden, obteniéndose una alta correlación (R^2=0,91-0,99) entre los valores experimentales y los predichos por el modelo para las cuatro temperaturas de estudio, lo que indica la idoneidad del mismo.

El efecto de la temperatura sobre las constantes cinéticas se evaluó mediante la ecuación de Arrhenius (Ec. (3)). En la Tabla 2 se muestran los parámetros del modelo de Arrhenius obtenidos con un alto coeficiente de determinación (R^2 = 0,96). La energía de activación obtenida fue de 25,69 kJ/mol, inferior a la energía de activación obtenida para la coordenada a^* y licopeno, lo que indica una menor sensibilidad a los cambios de temperatura para el ácido L-ascórbico en comparación con los otros parámetros estudiados bajo las mismas condiciones de tiempo y temperatura. Otros estudios informaron energías de activación similares, para jugo de tomate concentrado secado por aire caliente se reportó 28,75 kJ/mol [22], para pulpa de fresa [26] y marula [27] tratadas térmicamente con valores de energías de activación de 21,36 y 29 (kJ/mol), respectivamente. Por otro lado, en un trabajo donde se evaluó la variación de ácido L-ascórbico en tomate durante el secado por aire caliente [15], se obtuvo una E_a de 40 kJ/mol, siendo este valor superior al obtenido en este estudio.

Tabla 1. Parámetros cinéticos y coeficiente de determinación (R^2) para color (*a**), Licopeno (*L*) y acido L-ascórbico (*AA*), en tomate triturado tratado a diferentes temperaturas.

	***T* (°C)**	***k x 10*$^{-3}$ (min^{-1})**	**R^2**
*a**	70	0,47±0,04	0,96
	80	0,94±0,21	0,93
	90	1,53±0,13	0,95
	100	2,99±0,06	0,98
L	70	2,38±0,39	0,93
	80	3,09±0,40	0,98
	90	5,63±0,17	0,91
	100	8,24±0,16	0,91
AA	70	1,65±0,17	0,99
	80	1,88±0,29	0,96
	90	2,46±0,14	0,97
	100	3,38±0,12	0,91

Tabla 2. Parámetros de Arrhenius y coeficiente de determinación (R^2) para color (*a**), Licopeno (*L*) y acido L-ascórbico (*AA*) en tomate triturado.

	***ln* k_0 (min^{-1})**	**E_a (kJ mol^{-1})**	**R^2**
*a**	14,96	64,54	0,99
L	10,00	45,96	0,98
AA	2,54	25,69	0,96

3.5 Relación entre la Coordenada *a** y el Contenido de Licopeno

El color rojo característico del tomate maduro representado por el coordenada *a** está relacionado con el contenido de licopeno, siendo uno de los pigmentos más abundante en el tomate [3-28]. Debido a esta relación, se revelaron cambios de color al evaluar la disminución de *a** durante el procesamiento térmico, e indirectamente esto sugiere que se producen cambios de composición en el tomate triturado, esta relación también

se observó en piel de tomate tratada térmicamente [13]. La Fig. 4 muestra una correlación positiva entre el contenido de licopeno y el valor de la coordenada *a**, durante el tratamiento térmico. Esta relación se evaluó mediante el coeficiente de Pearson, obteniéndose un valor de r = 0,88. A fin de obtener un índice predictivo para estimar las pérdidas por degradación térmica de licopeno midiendo el valor de *a**, la relación entre ambos parámetros se ajustó mediante una regresión lineal, y se obtuvo la siguiente ecuación:

$$y = 0{,}35\ x - 2{,}02 \tag{4}$$

Donde *y* es el contenido de licopeno y *x* la coordenada *a**, durante el tratamiento térmico. Estos resultados sugieren que la coordenada colorimétrica *a** puede utilizarse como un buen indicador de la degradación de licopeno en tomate triturado durante el tratamiento térmico.

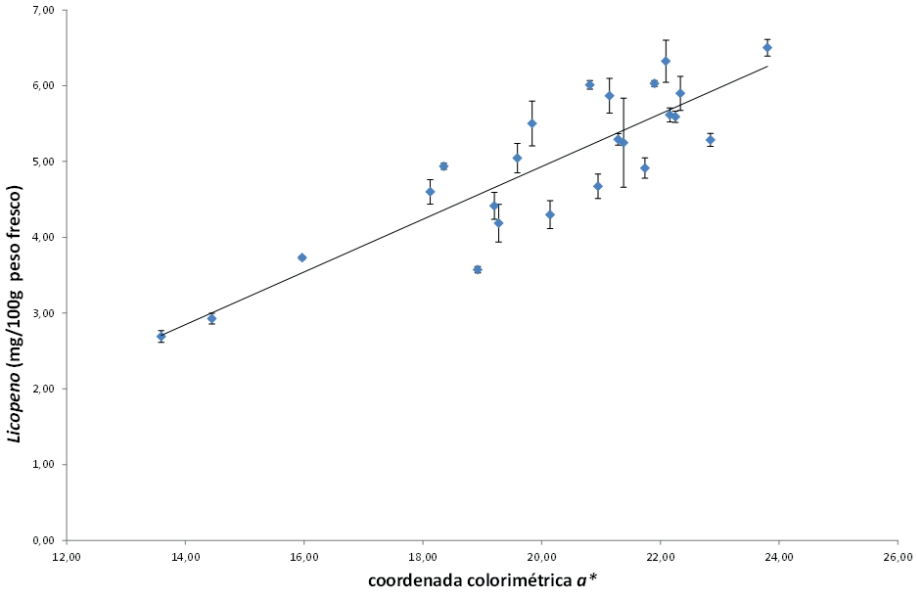

Fig. 4. Relación entre el contenido de licopeno y la coordenada colorimétrica *a**, durante el tratamiento térmico. La línea representa el comportamiento predicho por el modelo lineal (Ec.(4)). Las barras representan la media ± desviación estándar.

4 Conclusión

Este estudio tuvo como objetivo determinar la cinética de degradación térmica de parámetros de calidad como el color y los compuestos bioactivos en tomate triturado como producto que permite un aprovechamiento integral del fruto. El modelo cinético de primer orden fue el que mejor se ajustó a la degradación de color, licopeno y ácido

L-ascórbico. Las variaciones de las constantes de velocidad de degradación con la temperatura se correspondieron en alto grado con la relación de Arrhenius. Las energías de activación obtenidas revelaron que el color, mediante el estudio de la coordenada a^*, fue el parámetro más sensible a los cambios de temperatura, mientras que los valores de las constantes de la velocidad de reacción (k) mostraron que el licopeno tiene la mayor tasa de degradación en comparación con los otros parámetros estudiados. Por otra parte, la relación entre el contenido de licopeno y el valor de la coordenada a^*, por medio de un ajuste lineal, presentó una correlación positiva. Los resultados obtenidos en este trabajo podrían ser útiles para optimizar el proceso de pasteurización de tomate triturado, con la finalidad de reducir al mínimo la pérdida de color y biocompuestos. Por otra parte, la relación entre licopeno y color podría ser de utilidad para obtener, con un buen grado de estimación, el contenido de licopeno en línea mediante una rápida medición de color.

Abstract. En este trabajo se analizaron los perfiles reológicos y térmicos de oleogeles formulados con aceite de girasol alto oleico. Se utilizaron ceras de girasol recuperadas de fondos de tanque de almacenamiento (CP) y ceras de girasol comerciales (CC) como agentes organogelantes. La concentración de las ceras (C) y la temperatura de enfriamiento (T) en base a las cuales fueron formulados los oleogeles se obtuvieron a partir de un diseño de experimentos del tipo factorial de tres niveles con dos variables (3^2), siendo 1,5% y 3,5% la mínima y máxima C, y 5 °C y 25 °C las mínimas y máximas T permitidas. Las propiedades reológicas fueron estudiadas mediante ensayos oscilatorios (barridos de deformación y frecuencia). Todas las muestras presentaron comportamiento del tipo gel, en donde el módulo de almacenamiento fue predominante frente al módulo de pérdida. El oleogel más fuerte y con mayor viscosidad fue obtenido con C = 3,5% y T = 5 °C, siendo indistinto el tipo de cera utilizado. Del análisis de los resultados se determinó que un aumento en la concentración de las ceras provocó un incremento en la propiedad analizada. El mismo efecto fue generado por el descenso de la temperatura de enfriamiento. Las propiedades térmicas fueron analizadas mediante barridos de temperatura y calorimetría diferencial de barrido. En base a los resultados obtenidos se pudo concluir que los oleogeles formulados con CP presentaron propiedades reológicas y térmicas muy similares a las de los oleogeles desarrollados con CC.

Keywords: Oleogel, ceras de girasol, reología.

1 Introducción

Muchos son los riesgos asociados con el consumo de grasas trans y grasas saturadas [1]. Sin embargo, el reemplazo de estas grasas ha demostrado ser un difícil desafío para la industria alimentaria debido a las propiedades sensoriales y fisicoquímicas que éstas le otorgan a los alimentos procesados. Por esta razón, es de suma importancia encontrar reemplazos para las grasas saturadas y trans que posean propiedades organolépticas similares. Una de las alternativas que ha sido ampliamente estudiada es la

generación de oleogeles. Los oleogeles son sistemas conformados por aceites líquidos que son estructurados por agentes gelificantes. En este tipo de compuestos, el aceite líquido permanece inmovilizado dentro de los poros de la red tridimensional que se forma debido al auto ensamblado de los cristales del agente gelificante. Entre las diferentes opciones que se han estudiado, el uso de ceras capaces de estructurar aceites vegetales ha demostrado ser muy prometedor [2].

Los oleogeles de cera se han estudiado como miméticos de grasas en una variedad de productos de la industria alimentaria, incluyendo carne, panadería y productos lácteos entre otros [3, 4]. Específicamente, los oleogeles de cera de girasol se estudiaron como un posible reemplazo para la margarina y los productos para untar [5–7]. Más recientemente, los oleogeles de cera de girasol comenzaron a usarse como un reemplazo total o parcial de las grasas en productos horneados, como galletas y hojaldres [8–10]. Sin embargo, todas estas investigaciones se realizaron a partir cera de girasol comercial como agente organogelante. Los sedimentos del tanque de almacenamiento de aceite de girasol fueron estudiados como una nueva fuente potencial de ceras por Redondas et al. [11]. En base a los resultados obtenidos en ese trabajo, se decidió investigar más a fondo las posibles aplicaciones de este tipo de ceras en la industria alimentaria, específicamente su función como agente gelificante.

Por lo tanto, el objetivo de este trabajo fue estudiar el potencial reemplazo de las ceras de girasol comerciales por las ceras recuperadas de los sedimentos de tanque de almacenamiento de aceite de girasol mediante la comparación de sus propiedades reológicas y térmicas. Con el uso de un diseño experimental factorial de tres niveles con dos variables (3^2), se analizó el efecto de la concentración de las ceras y la temperatura de enfriamiento sobre dichas propiedades de los oleogeles. El comportamiento viscoelástico de los oleogeles fue determinado mediante pruebas oscilatorias (barridos de deformación y frecuencia angular), mientras que su temperatura de gelificación fue medida de manera reológica mediante barridos de temperatura. Finalmente, los perfiles térmicos fueron determinados mediante calorimetría diferencial de barrido.

2 Materiales y métodos

2.1 Materiales

Las ceras de girasol fueron recuperadas de fondos de tanque de almacenamiento de girasol y posteriormente fueron purificadas de acuerdo con el procedimiento desarrollado por Redondas et al. [11]. Las ceras de girasol recuperadas mediante esta técnica serán identificadas con la sigla CP. CP (punto de fusión: 75,13 ± 1,05 °C) se compone de ésteres de cera en el rango de 40 - 60 átomos de carbono (75,9% en peso del total de la muestra cerosa). Las ceras de girasol comerciales (CC) fueron proporcionadas por Koster Keunen Inc. El aceite de girasol alto oleico (GAO) utilizado para desarrollar los oleogeles fue adquirido en un supermercado local.

2.2 Diseño experimental

Con el fin de evaluar la influencia de la concentración de las ceras de girasol (C) y la temperatura de enfriamiento (T) sobre las propiedades reológicas de los oleogeles, se realizó un diseño de experimentos del tipo factorial de tres niveles con dos variables (3^2). Como resultado, se obtuvieron 9 experimentos, los cuales se encuentran reportados en la Tabla 1.

El diseño experimental se llevó a cabo con el software STATGRAPHICS Centurion XVI (prueba LSD de Fisher, $\alpha = 0,05$; versión 16.1.03; StatPoint Technologies, Inc.) [12]. Las concentraciones mínimas y máximas seleccionadas fueron 1,5% y 3,5% en peso respectivamente. El valor mínimo de C (1,5%) se seleccionó en base en los resultados obtenidos en Redondas et al. [11]. En ese trabajo de investigación, los autores encontraron que 1,5% en peso era la concentración mínima de CP necesaria para estructurar completamente GAO. Las ceras de girasol son buenos agentes organogelantes, pero el mayor problema que presenta su uso es que pueden otorgarle a los oleogeles una sensación cerosa en la boca a concentraciones medias y altas [9, 13, 14]. Este problema puede evitarse con el uso de bajas concentraciones de ceras. Es por este motivo que se determinó que 3,5% sea la concentración máxima permitida en el diseño experimental de modo tal de que los oleogeles generados no presentaran dicha sensación cerosa y a su vez tener un buen rango de concentraciones disponibles para evaluar.

Los oleogeles han sido ampliamente estudiados como posibles sustitutos de grasas como la manteca y la margarina. Dado que estos productos se almacenan en heladera a 5 °C, esa temperatura se seleccionó como la temperatura mínima de enfriamiento para el diseño experimental. Además, se propuso el análisis de las propiedades de los oleogeles a 25 °C, también conocido como temperatura ambiente, siendo ésta la máxima temperatura de enfriamiento permitida en este diseño de experimentos.

Tabla 1. Diseño de experimentos utilizado para el desarrollo de los oleogeles

Experimento	C (% peso)	T (°C)
1	1,5	15
2	3,5	5
3	1,5	25
4	3,5	15
5	2,5	5
6	1,5	5
7	2,5	15
8	3,5	25
9	2,5	25

C: concentración de ceras, T: temperatura de enfriamiento

2.3 Desarrollo de oleogeles

Para el desarrollo de los oleogeles (peso final = 50 g), se calentó una determinada cantidad de GAO en un baño de agua hasta alcanzar 80 °C. Se añadió la cantidad correspondiente de ceras, y se mantuvo a la mezcla cera - GAO a 80 °C con agitación magnética constante durante 5 minutos, asegurando la completa disolución de las ceras y la homogeneidad de la mezcla. Posteriormente, los oleogeles fundidos se depositaron en recipientes adecuados para los distintos análisis (recipientes cilíndricos de plástico y cápsulas DSC) y se almacenaron a la temperatura de enfriamiento seleccionada durante 24 h. Finalmente, los oleogeles se mantuvieron a 5 °C durante otras 24 h antes del análisis. Los oleogeles desarrollados con ceras de girasol recuperadas se identificarán con la sigla OCP, mientras que los oleogeles desarrollados con ceras de girasol comerciales se representarán con el acrónimo OCC. Para indicar un experimento específico, el acrónimo (OCP o OCC) irá seguido del número de experimento correspondiente (por ejemplo, OCP1, OCC1, etc.).

2.4 Comportamiento reológico

Las propiedades reológicas de los oleogeles se determinaron mediante un análisis oscilatorio, de acuerdo con el procedimiento descrito por Redondas et al. [11]. Se utilizó el reómetro Paar Physica (MCR 301, Anton Paar Gmbh, Austria) con un sistema de control de temperatura Peltier. Las mediciones se realizaron utilizando la geometría de placa paralela (diámetro = 50 mm, PP50, Anton Paar) con un gap de 1 mm.

Para determinar la región viscoelástica lineal (RVL) de los oleogeles, se realizaron barridos de deformación (γ) en el rango de 0,001 - 100%, a una frecuencia fija de 10 rad/s y a una temperatura de 5 °C. Para investigar el comportamiento de los oleogeles en función del tiempo, se realizaron barridos de frecuencia angular (ω), entre 0,01 - 100 rad/s y un valor fijo de deformación seleccionado dentro del RVL. Finalmente, la temperatura de gelificación de los oleogeles se determinó mediante barridos de temperatura entre 90 y 5 °C con una velocidad de enfriamiento de 2 °C/min, a una frecuencia fija de 6,28 rad/s y un valor de esfuerzo de corte de 0,5 Pa, de acuerdo con el procedimiento descrito por Doan et al. [15].

2.5 Comportamiento térmico

Para determinar el efecto de la concentración de las ceras sobre el comportamiento térmico de los oleogeles, muestras con 1,5%, 2,5% y 3,5% en peso de ceras desarrollados a T = 5 °C fueron analizadas mediante calorimetría diferencial de barrido (DSC). Los procesos de fusión y cristalización de las muestras se estudiaron utilizando un aparato Discovery DSC (TA Instruments, EE. UU.). Las muestras se prepararon colocando entre 8 y 10 mg de oleogel en recipientes de aluminio, que se sellaron herméticamente con una tapa de aluminio y luego se colocaron en la cámara DSC. Para eliminar la historia cristalina de los oleogeles, las muestras fueron equilibradas a 90 °C durante 10 minutos. Luego, las muestras se enfriaron hasta 5 °C a una veloci-

dad de 5 °C/min, manteniendo esta temperatura durante 20 minutos para asegurar la completa cristalización de las ceras. Finalmente, los oleogeles se calentaron hasta 90 °C a una velocidad de 5 °C/min. Se realizaron tres medidas independientes.

La temperatura de fusión (T_f), la temperatura de cristalización (T_c) y sus correspondientes temperaturas de inicio (T_{on}), al igual que la entalpía de fusión (ΔH_f) y la entalpía de cristalización (ΔH_c) se determinaron a partir de los termogramas utilizando el software suministrado con el instrumento (TA Instruments' Universal Analysis Software). Para eliminar la interferencia del ruido en las curvas de cristalización, las mismas fueron suavizadas con el software Origin Pro (OriginLab Corporation) [16]. La entropía de fusión (ΔS_f) se calculó de acuerdo con la ecuación:

$$\Delta S_f = \frac{\Delta H_f}{T_f} \quad (1)$$

2.6 Análisis estadístico

El análisis estadístico de las muestras fue realizado a través de una prueba ANOVA de dos vías y el test LSD Fisher (α = 0,05) con el software de análisis estadístico InfoStat (Versión 2018, Grupo InfoStat, FCA, Universidad Nacional de Córdoba, Argentina) [17].

3 Resultados y discusión

3.1 Módulos de almacenamiento y pérdida

En primer lugar, se determinó el rango viscoelástico lineal (RVL), y para ello los oleogeles fueron sometidos a barridos de deformación. En la Fig. 1 se muestran las curvas representativas de los módulos de almacenamiento (G´) y pérdida (G´´) obtenidas luego de dicho análisis, tanto para OCP (Fig. 1a, 1b y 1c) como para OCC (Fig. 1d, 1e y 1f). En las curvas de G´ se pudieron distinguir dos regiones. La primera región, a bajos porcentajes de deformación, se caracteriza por ser una zona en donde G´ permanece relativamente constante. Esta región, también conocida como "plateau", constituye lo que se conoce como región viscoelástica lineal (RVL). A continuación, se observa una segunda zona en donde G´ disminuye en función del aumento de la deformación aplicado. Esto se debe a que luego de superar el umbral máximo de tolerancia a las deformaciones que las muestras poseen, la estructura cristalina se destruyó y las muestras dejaron de comportarse como un sólido blando para transformarse en un compuesto viscoelástico que fluye.

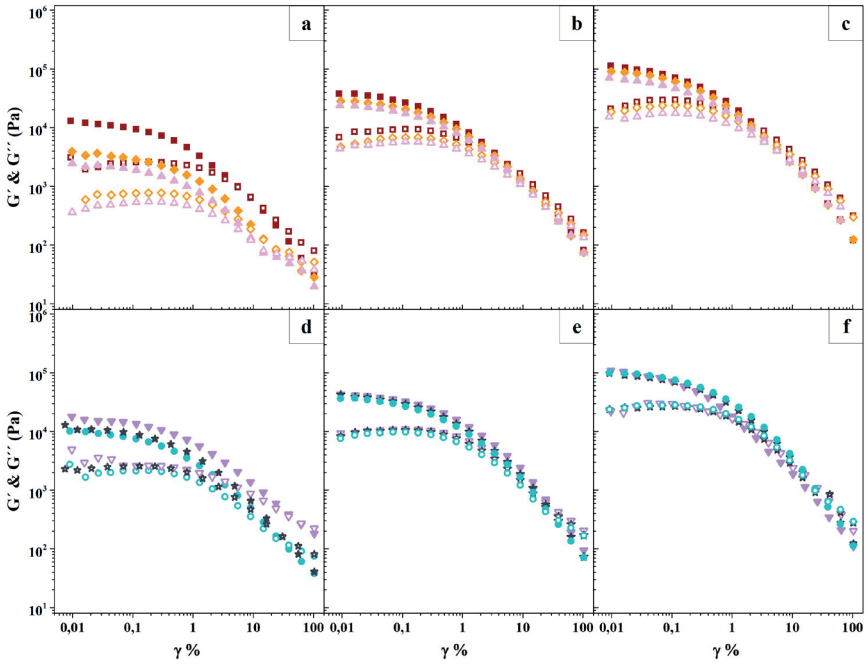

Fig. 1. Variación del módulo de almacenamiento (G´, símbolo lleno) y del módulo de pérdida (G´´, símbolo vacío) en función del barrido de deformación (γ) a ω = 10 rad/s. Los oleogeles fueron desarrollados con 1,5% (a y d), 2,5% (b y e) y 3,5% (c y f) de la correspondiente cera. ■ OCP T = 5 °C, ◆ OCP T = 15 °C, ▲ OCP T = 25 °C, ▼ OCC T = 5 °C, ★ OCC T = 15 °C, ● OCC T = 25 °C. OCP: oleogeles desarrollados con cera de girasol purificada. OCC: oleogeles desarrollados con cera de girasol comercial.

A continuación, se realizaron ensayos de barrido de frecuencia de todas las muestras. Para asegurar la linealidad de la medida, los mismos se realizaron a deformaciones de 0,05%, ya que este valor se encontraba dentro del RVL (Fig. 2). Al analizar los resultados, se pudo confirmar que todas las muestras presentaron un comportamiento del tipo gel con un carácter predominantemente elástico ($G'_{LVR} > G''_{LVR}$). La ausencia de un punto de intersección entre las dos curvas sugiere que las redes cristalinas de los oleogeles toleraron las deformaciones a las que fueron sometidas sin sufrir una ruptura irreparable.

En los reogramas se observó una baja dependencia de ambos módulos con la ω dentro de los límites de la prueba, estando esto indicado por la pendiente ligeramente positiva que las curvas poseen en la Fig. 2. Esto sugiere que los cristales de las ceras se organizan generando estructuras tridimensionales con una alta elasticidad. Malkin e Isayev [18] definieron a los "geles fuertes" como aquellos donde tan δ (ω) ≤ 0,1. Ninguno de los oleogeles analizados en este trabajo satisfizo esta condición (información no mostrada), lo cual indicó que los oleogeles generados en este trabajo se comportaron como "geles débiles".

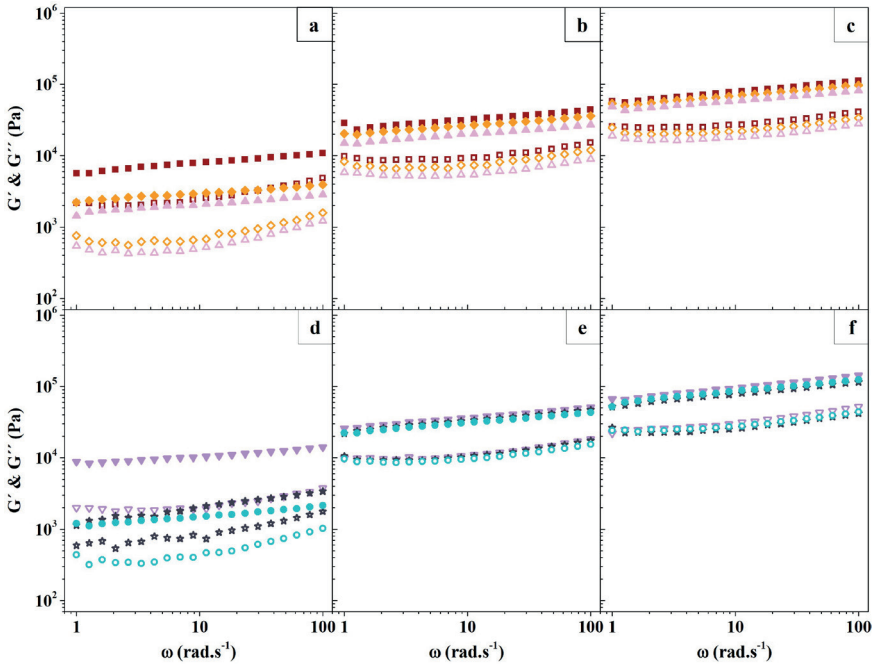

Fig. 2. Variación del módulo de almacenamiento (G´, símbolo lleno) y del módulo de pérdida (G´´, símbolo vacío) en función del barrido de frecuencia angular (ω) a γ = 0,05%. Los oleogeles fueron desarrollados con 1,5% (a y d), 2,5% (b y e) y 3,5% (c y f) de la correspondiente cera. ■ OCP T = 5 °C, ◆ OCP T = 15 °C, ▲ OCP T = 25 °C, ▼ OCC T = 5 °C, ★ OCC T = 15 °C, ● OCC T = 25 °C. OCP: oleogeles desarrollados con cera de girasol purificada. OCC: oleogeles desarrollados con cera de girasol comercial.

Tanto G´ como G´´ aumentaron con el incremento de la concentración, aunque este cambio fue menor en los oleogeles formulados con 2,5% y 3,5% de ceras (OCP: Fig. 2a 2b y 2c; OCC: Fig. 2d, 2e y 2f). Los valores más altos de G´ fueron obtenidos usando 3,5% de ceras. Este hallazgo sugiere que las muestras con la concentración de cera más alta poseían estructuras cristalinas significativamente más elásticas que las estructuras de los oleogeles formulados con concentraciones de cera más bajas, específicamente 1,5%. Esto podría atribuirse a una mayor densidad de cristales. Del análisis de las curvas también se observó una disminución en las propiedades elástica con el incremento de la temperatura de enfriamiento, siendo esta diferencia considerablemente mayor en los oleogeles formulados con 1,5% de OCP y OCC (Fig. 2a y 2d, respectivamente).

En los oleogeles desarrollados bajo las mismas condiciones OCC presentó G´ levemente mayor que OCP, siendo esta diferencia más notoria en los oleogeles formulados con 1,5% de ceras. A pesar de esto, los módulos de OCP y OCC resultaron ser comparables. La composición de ambos agentes gelificantes fue estudiada previamen-

te, determinando que, aunque la distribución de los ésteres de cera era similar, CC presentaba una cantidad ligeramente mayor de ésteres de cera totales [11]. Esto podría explicar las diferencias encontradas durante este análisis reológico.

3.2 Módulo complejo

En los análisis oscilatorios como el barrido de frecuencia angular, G* es una medida de la resistencia total de la muestra a las pequeñas deformaciones aplicadas durante el análisis. En las Fig. 3 se muestran los perfiles de G* a diferentes temperaturas de enfriamiento (5, 15 y 25 °C) y concentración del agente gelificante (1,5; 2,5 y 3,5% peso) en función la frecuencia angular. Todas las curvas resultaron ser lineales y presentaron un leve aumento de G* con el aumento de la frecuencia. Del análisis de los resultados se observó que OCP2 y OCC2 (C = 3,5% de ceras y T = 5 °C) presentaron los mayores valores de G*.

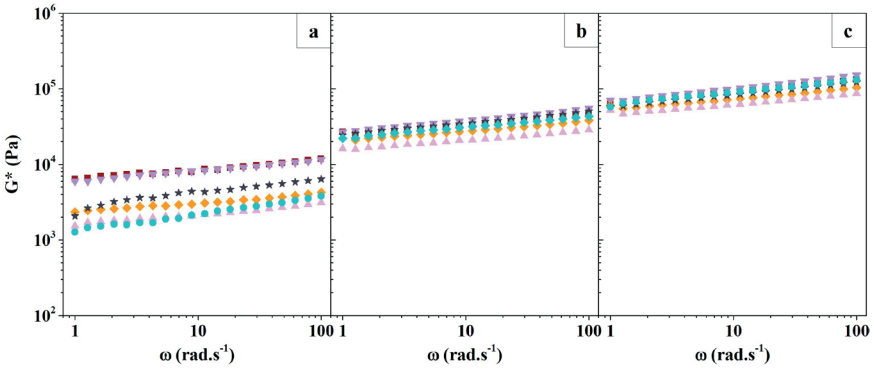

Fig. 3. Variación del módulo complejo (G*) en función del barrido de frecuencia angular (ω) a γ = 0,05%. Los oleogeles fueron desarrollados con (a) 1,5%, (b) 2,5% y (c) 3,5% de la correspondiente cera. ■ OCP T = 5 °C, ◆ OCP T = 15 °C, ▲ OCP T = 25 °C, ▼ OCC T = 5 °C, ★ OCC T = 15 °C, ● OCC T = 25 °C. OCP: oleogeles desarrollados con cera de girasol purificada. OCC: oleogeles desarrollados con cera de girasol comercial.

En la Fig. 3a se puede observar que los oleogeles desarrollados a T = 5 °C presentaron valores de G* considerablemente mayores que aquellos desarrollados a T = 15 °C y T = 25 °C. Este hallazgo indicó que un aumento en la temperatura de enfriamiento generó oleogeles menos resistentes, expresados por menores valores de G*. En cambio, en los oleogeles formulados con 2,5% y 3,5% de ceras el efecto de la temperatura de enfriamiento no fue tan significativo (Fig. 3b y 3c, respectivamente), siendo esto más notorio en los oleogeles con CC como agente gelificante.

3.3 Viscosidad compleja

La viscosidad compleja (η*) provee una medida de la resistencia que poseen las muestras a fluir cuando son sometidas las fuerzas de corte [10]. En todas las muestras se observó una disminución de η* con el incremento de la ω, lo que demostró que η* poseía una gran dependencia de ω (Fig. 4). Este hallazgo es el resultado del reordenamiento microestructural que sufren los oleogeles durante este tipo de ensayos [10]. Patel sugiere que esto se debe a la ruptura de los agregados cristalinos para generar nuevos agregados de menor tamaño que pueden reorientarse en el espacio a lo largo del plano en el cual se aplica la fuerza [19]. De la misma manera que para G´, G´´ y G*, η* aumentó con el incremento en la concentración de las ceras y la disminución de la temperatura de enfriamiento (Fig. 4), siendo esto último más evidente en los oleogeles formulados con 1,5% de ceras (Fig. 4a). Al comparar los oleogeles desarrollados bajo las mismas condiciones, OCC presentó valores de η* levemente mayores que OCP, aunque estas diferencias fueron menos notorias en los oleogeles formulados con 2,5% y 3,5% de ceras, lo que indicó que a estas concentraciones la η*, y por lo tanto la resistencia a fluir, de OCP y OCC fue prácticamente la misma.

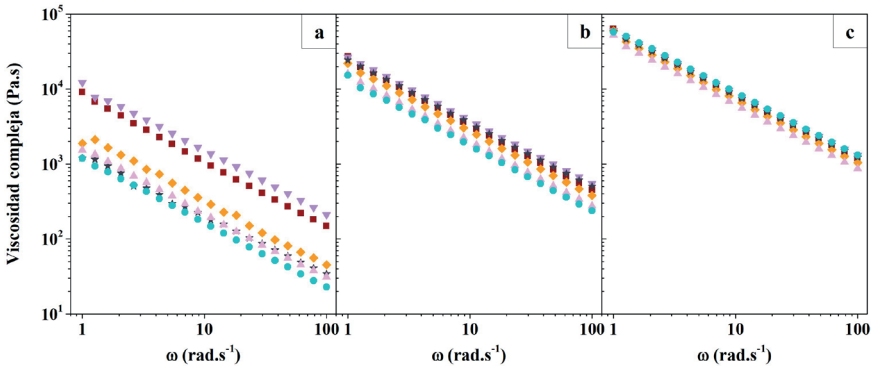

Fig. 4. Variación de la viscosidad compleja (η*) en función del barrido de frecuencia angular (ω) a γ = 0,05%. Los oleogeles fueron desarrollados con (a) 1,5%, (b) 2,5% y (c) 3,5% de la correspondiente cera. ■ OCP T = 5 °C, ◆ OCP T = 15 °C, ▲ OCP T = 25 °C, ▼ OCC T = 5 °C, ★ OCC T = 15 °C, ● OCC T = 25 °C. OCP: oleogeles desarrollados con cera de girasol purificada. OCC: oleogeles desarrollados con cera de girasol comercial.

3.4 Comportamiento térmico

El último análisis reológico realizado fue el barrido de temperatura entre 90 y 5 °C. A 90 °C los oleogeles presentaron un comportamiento líquido, en donde el predominio estaba dado por G´´. Durante el enfriamiento de las muestras se observó un cambio drástico en la pendiente de la curva. Este punto fue definido como $T_{gel\ onset}$ y correspondió a la transición de mezcla líquida a solución viscosa. Al enfriarse por debajo de $T_{gel\ onset}$, la solubilidad de las ceras en GAO comenzó a disminuir, lo que condujo a la nucleación y, finalmente, al crecimiento de los cristales de las ceras. Como resultado,

G´´ y G´ comenzaron a aumentar, hasta alcanzar en punto en donde G´ = G´´. Es en este punto en donde la red tridimensional de los oleogeles se forma debido a la interacción de los cristales. La temperatura en donde ocurre dicho cambio en las propiedades es definida como la temperatura de gelificación (T_{gel}). A temperaturas inferiores a T_{gel}, G´ es mayor que G´´, indicando el carácter predominantemente elástico de los oleogeles.

Los valores de T_{gel} y $T_{gel\ onset}$ de OCP y OCC se encuentran reportados en la Tabla 2. Un aumento en la concentración de CP dio como resultado un aumento de T_{gel} y $T_{gel\ onset}$. En cambio, en OCC se observó que los oleogeles formulados con 2,5% y 3,5% de ceras no presentaron diferencias significativas en sus correspondientes valores de T_{gel} y $T_{gel\ onset}$. Los oleogeles formulados con 2,5% y 3,5% de CP presentaron valores de T_{gel} entre 1 °C y 3 °C mayores que en los oleogeles formulados con CC bajo las mismas condiciones. Este hallazgo sugiere una formación tardía de la red tridimensional de OCC frente a OCP, probablemente debido a las diferencias entre la composición de CP y CC previamente estudiadas [11].

Table 2. Temperatura de gelificación obtenida a partir de análisis reológicos de barridos de temperatura.

	OCP		**OCC**	
C (% peso)	**T_{gel}**	**$T_{gel\ onset}$**	**T_{gel}**	**$T_{gel\ onset}$**
1,5	$47,82 \pm 2,84^{a}$	$51,29 \pm 1,82^{a}$	$48,35 \pm 1,57^{a}$	$50,64 \pm 0,56^{a}$
2,5	$53,30 \pm 0,85^{b}$	$55,12 \pm 0,91^{b}$	$52,19 \pm 0,39^{b}$	$54,21 \pm 0,39^{b}$
3,5	$55,22 \pm 1,13^{c}$	$56,96 \pm 0,72^{c}$	$52,21 \pm 0,49^{b}$	$53,87 \pm 0,58^{b}$

Los valores se reportan como el promedio ± intervalo de confianza (n = 3). Los valores en la misma columna seguidos por diferentes letras (a - c) son estadísticamente diferentes ($p < 0,05$) de acuerdo al test de Fisher. C: concentración de ceras, T_{gel}: temperatura de gelificación, $T_{gel\ onset}$: temperatura inicial de gelificación.

A continuación, se evaluó el efecto generado por la concentración sobre el perfil térmico de los oleogeles, analizados mediante DSC. Para ello, tres muestras de los oleogeles formulados con las concentraciones utilizadas en este trabajo y 5 °C fueron analizados (1,5%: OCP2 y OCC2, 2,5%: OCP5 y OCC5 y 3,5%: OCP6 y OCC6). La temperatura de fusión (T_f) y de cristalización (T_c), así como la entropía de fusión y de cristalización (ΔH_f y ΔH_c, respectivamente) y sus respectivas temperaturas de inicio (T_{on}) se encuentran reportados en la Tabla 3.

Todas las muestras analizadas presentaron un solo pico correspondiente a la fusión de los ésteres que conforman a las ceras de girasol (Fig. 5a). En un trabajo publicado anteriormente, se estudió el comportamiento térmico de las ceras, y se descubrió que en los termogramas de fusión las mismas presentaban picos largos y estrechos debido a su gran homogeneidad química [11]. Durante el proceso de cristalización, los ésteres de cera de las muestras cristalizaban a una T_c ligeramente diferente, generando lo que podría describirse como picos superpuestos. Los oleogeles formulados con CP y

CC presentaron este mismo patrón de cristalización, siendo esto más notorio a medida que aumentaba la concentración de las ceras (Fig. 5b). Doan et al. [20] definió a los oleogeles como disoluciones compuestas por ceras diluidas en aceite. Por lo tanto, es esperable la presencia de múltiples picos superpuestos en los termogramas de cristalización de los oleogeles.

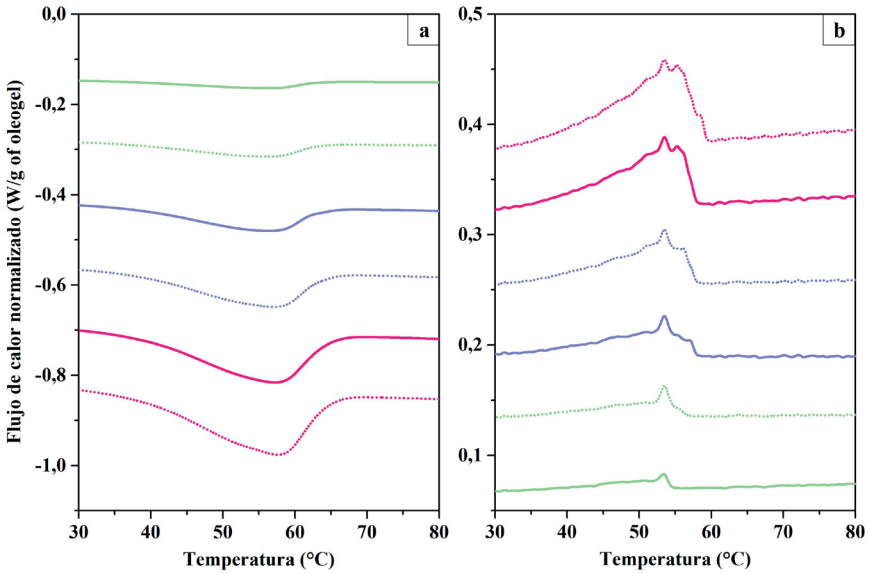

Fig. 5. Perfiles de fusión (a) y cristalización (b) de OCP (línea continua) y OCC (línea punteada) a C = 1,5% (—), C = 2,5% (—) y C = 3,5% (—) de la correspondiente cera de girasol.

Los picos de fusión y cristalización de OCP y OCC fueron más bajos y anchos que los de CP y CC, respectivamente. La temperatura de fusión de los oleogeles fue menor que la reportada para CP y CC (75,13 ± 1,05 °C y 76,86 ± 0,54 °C, respectivamente) [11], debido a la dilución de las ceras en el aceite. De manera similar, la temperatura de cristalización también se ubicó a menores valores que los de CP y CC (72,12 ± 0,56 °C y 70,96 ± 0,57 °C, respectivamente). T_m y T_c aumentaron con el incremento en la concentración de ceras, debido a la presencia de una mayor cantidad de componentes cristalinos (Tabla 3). El mismo comportamiento fue reportado por Blake et al. [21] en oleogeles desarrollados con CC en aceite de canola, Yilmaz y Öğütcü [22] en oleogeles formulados con CC y aceite de oliva y Doan et al. [23] en oleogeles de CC y aceite de salvado de arroz.

3,5	55,80±1,94^{a}	5,12±0,68^{b}	57,31±1,74^{a}	58,32±1,86^{b}	7,08±0,72^{c}	39,42±1,50^{b}	21,34 ±2,05^{c}

Los valores se reportan como el promedio ± intervalo de confianza (n = 3). Para cada sección de la tabla, los valores en la misma columna seguidos por diferentes letras (a - c) son estadísticamente diferentes ($p < 0,05$) de acuerdo al test de Fisher. C_{CP}: concentración de CP, C_{CC}: concentración de CC, T_c: temperatura de cristalización, ΔH_c: entalpía de cristalización, $T_{on\ c}$: temperatura inicial de cristalización, T_f: temperatura de fusión, ΔH_f: entalpía de fusión, $T_{on\ f}$: temperatura inicial de fusión.

En general, OCC presentó una mayor entalpía de fusión que OCP (Tabla 3). Este hallazgo estuvo en concordancia con ΔH_f de CP (167,71 ± 9,05 J/g de cera) y CC (213,98 ± 16,79 J/g de cera) previamente reportado en Redondas et al. [11]. ΔH_f es considerado como un indicador de la cantidad de material organogelante y de la interacción entre los cristales de las ceras. Como se mencionó previamente, CP y CC presentaban cantidades similares de ésteres de ceras, por lo tanto, un valor más alto de ΔH_f sugiere que OCC presentaba una red tridimensional con una mayor cantidad de interacciones entre los cristales de las ceras y una mejor organización espacial.

Blake et al. mencionó en su trabajo que la entropía de fusión (ΔS_f) proporciona una visión más precisa acerca del orden cristalino, ya que valores más altos de entropía fueron encontrados en oleogeles que presentaban redes con un mayor orden cristalino [21]. Los oleogeles desarrollados con 1,5% de ceras presentaron los ΔS_f más bajos, mientras que los oleogeles con 3,5% de ceras presentaron los valores más altos (Tabla 3). No se observaron diferencias significativas entre los valores de entropía de OCP y OCC formulados con 1,5% y 2,5% de ceras, pero sí existieron diferencias en los oleogeles formulados con 3,5% de ceras, confirmando que, para esta concentración, la red tridimensional de OCC poseía un mayor grado de orden cristalino.

4 Conclusiones

Todas las muestras presentaron un comportamiento de sólido viscoso, con un carácter predominantemente elástico y valores de G´ > G´´ a lo largo de los límites de frecuencias analizado. Se pudo comprobar que, en las muestras desarrolladas bajo las mismas condiciones, OCP presentaba propiedades similares a OCC. En los casos en donde se observaron diferencias, las mismas fueron mínimas, siendo OCC el que poseía el mayor valor. En base a los resultados, se determinó que la concentración de ceras fue el parámetro que más afectó a las características reológicas (G´, G´´, G* y η*) y térmicas (T_{gel}, T_f, ΔH_f, T_c y ΔH_c) de los oleogeles. Se estableció que un incremento en la concentración de ceras produjo un aumento en el parámetro reológico o térmico analizado. También, se pudo establecer que la temperatura de enfriamiento ejerció un efecto del tipo negativo (un incremento en la temperatura provocó una disminución en el valor del parámetro evaluado), siendo este efecto más notorio en los oleogeles formulados con 1,5% de ceras de girasol. Los oleogeles desarrollados con 3,5% de ceras y 5 °C fueron los que presentaron mayores valores reológicos y térmicos.

Resumen. En este trabajo se evaluaron y compararon las propiedades sensoriales de un queso Port Salut, con sustitución de un 50% de NaCl con KCl y dos muestras del mismo queso sin sustituir (uno elaborado idénticamente al sustituido, pero de concentración estándar de NaCl, y el otro de una marca comercial líder). Las características sensoriales más distintivas de ambos tipos de quesos fueron evaluadas mediante un panel no entrenado, a partir de una prueba de ordenamiento de atributos. También se determinó la aceptabilidad del queso reducido, en comparación con su versión no reducida, cuando las muestras no fueron identificadas y también cuando lo estaban. Además, en este último caso, a la muestra reducida se le asocio una promesa nutricional. Los evaluadores detectaron diferencias en cuanto al sabor salado y amargo, al compararlo con las muestras no reducidas. La aceptabilidad del queso reducido fue mayor que su versión sin reducción, y la misma aumentó cuando a los evaluadores se le presentó la muestra identificada y con una promesa nutricional de impacto positivo para la salud.

Palabras clave: Queso Port Salut, Cloruro de Sodio, Evaluación Sensorial.

1 Introducción

El cloruro de sodio (NaCl) cumple diversas funciones en los alimentos, como facilitar su procesado, desarrollo y potenciación del sabor, y su conservación; estas características sumadas a que es un ingrediente relativamente de bajo costo, han llevado a su gran utilización [1]. Sin embargo, el consumo excesivo de sal se ha relacionado con la hipertensión arterial (HA) y un mayor riesgo de padecer enfermedades cardiovasculares. Es por esto, que el contenido de sodio de los alimentos procesados es considerado un problema de salud pública; actualmente la ingesta de NaCl en países desarrollados varía entre 8 a 13 g por día, que es muy superior a los 5 g recomendados por la Organización Mundial de la Salud (OMS) [2].

La sal en el queso participa en la formación del sabor, conservación, propiedades funcionales (capacidad de fusión, estiramiento y flujo), reología y textura [3]. Por este

motivo, una reducción en el contenido de la misma implica también mantener las propiedades inherentes al queso. El NaCl puede ser sustituido parcialmente por otros compuestos como cloruro de potasio (KCl), cloruro de calcio ($CaCl_2$) o cloruro de magnesio ($MgCl_2$), siendo el KCl, quien presenta mejores características para la sustitución, debido a la similitud entre los cationes potasio y sodio [4]. Además, numerosos estudios han demostrado que una ingesta de potasio en la dieta puede disminuir el efecto de la HA inducida por el sodio, al disminuir la presión arterial y reducir la excreción urinaria de calcio [5].

En base a lo anterior, los objetivos del presente trabajo fueron evaluar y comparar sensorialmente un queso Port Salut con sustitución de un 50% NaCl con KCl y dos muestras del mismo queso sin sustituir (uno elaborado idénticamente al sustituido, pero de concentración estándar de NaCl y el otro, de una marca comercial líder)

2 Materiales y Métodos

Para las pruebas, se elaboró un queso Port Salut sustituido en un 50% su contenido de NaCl por KCl y otro sin reducción. También se utilizó una muestra de queso Port Salut de una marca líder de la región (NOALSA), con el objetivo de evaluar los atributos sensoriales. Las muestras presentaban un estadio de maduración similar.

2.1 Análisis sensorial

2.1.1 Prueba de ordenamiento por atributos

Un panel conformado por 32 evaluadores (no entrenados), recibieron tres muestras de queso Port Salut ordenadas al azar y codificadas con un número de tres cifras. En esta prueba los atributos evaluados fueron: resistencia al corte, sabor salado, sabor amargo, persistencia del sabor y retrogusto.

2.1.2 Prueba de aceptabilidad

Cuarenta personas que consumían queso Port Salut con una frecuencia mayor a una vez cada dos semanas fueron reclutadas. En esta prueba se evaluaron únicamente los quesos Port Salut elaborados con sustitución en un 50% su contenido de NaCl por KCl y sin reducción (no se consideró el queso de marca comercial).

Los evaluadores fueron divididos en dos grupos de 20. Una mitad realizó la prueba a “ciegas”, sin saber de qué muestras se trataba, mientras que el resto efectuó la prueba con las muestras identificadas y además la reducida en sodio presentaba la siguiente promesa nutricional: “menos sodio más salud”. Cada evaluador recibió, una muestra de queso Port Salut concentración estándar de sodio y otra reducida en sodio, y evaluó la aceptabilidad de cada queso mediante una escala hedónica del 1 al 10, donde 1 representaba la menor aceptabilidad y 10 la mayor aceptabilidad

2.2 Análisis estadístico

Se realizó el test de Friedman para los datos de la prueba de ordenamiento por atributos, tomando como referencia el estadístico *ji-cuadrado* de 4.61 y un valor de significación del 0.1. Aquellos atributos donde se observó diferencia, se evaluaron a partir de un ensayo de múltiple comparación.
El Análisis de Varianza (*ANDEVA*) para dos factores con varias muestras por grupo se realizó para el ensayo de aceptabilidad; en cada uno hubo 20 repeticiones. Los dos factores considerados fueron el tipo de queso Port Salut (reducido o no) y si las muestras estaban identificadas o no. Se empleo el programa informático Excel (Microsoft Office Profesional Plus 2019) para el análisis de datos.

3 Resultados

3.1 Prueba de ordenamiento por atributos

La Tabla 1, muestra la suma de los ordenamientos que le otorgaron los evaluadores a cada muestra de quesos Port Salut, frente a cada atributo. Donde aquella muestra que presento menor sabor salado, los evaluadores le daban el primer orden, mientras que la más salada el tercero. El mismo procedimiento fue aplicada a los demás atributos.

Tabla 1. Valores de la suma de los ordenamientos.

Atributo	PS no reducido	PS reducido	PS marca líder	F experimental
Resistencia al corte	74[b]	62[a, b]	56[a]	5.25
Sabor salado	55[a]	76[b]	61[a]	7.31
Sabor amargo	68[a]	52[b]	72[a]	7.00
Persistencia del sabor	64 [a]	72 [a]	56 [a]	4.00
Retrogusto	60 [a]	72 [a]	60 [a]	3.00

PS: queso Port Salut.
[*]Para un mismo atributo, valores con una letra en común no son significativamente diferentes (p>0.1).

Tal como lo indica la Tabla 1, la muestra reducida en su contenido de sodio se diferenció de las otras dos en cuanto al sabor salado, comportamiento que era esperado. Por su parte, los quesos sin reducción no lograron diferenciarse tras el análisis. El mismo comportamiento se obtuvo para el sabor amargo. Lo anterior indica que el porcentaje de reducción de NaCl y sustitución por KCl es percibido y diferenciado sensorialmente.

3.2 Prueba de aceptabilidad

El queso Port Salut reducido en sodio obtuvo una mayor aceptabilidad, tanto cuando la prueba fue realizada a ciegas como cuando las muestras estaban rotuladas (Ver Fig.1). Los resultados obtenidos indican que tanto en la evaluación de las muestras a ciegas

como cuando estaban identificadas, el queso Port Salut reducido en sodio obtuvo la mayor aceptabilidad.

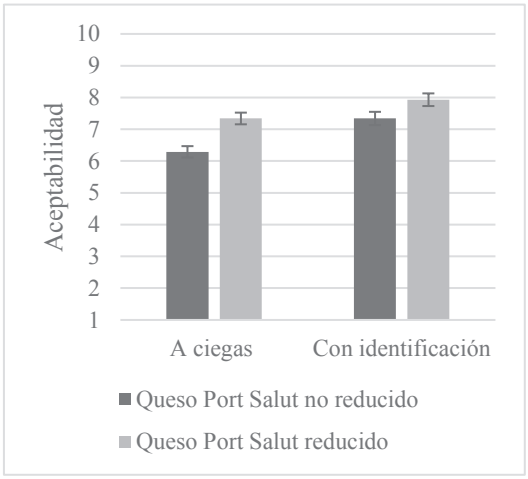

Fig. 1. Aceptabilidad queso Port Salut con y sin reducción de sodio.

4 Conclusión

La sustitución del 50% de NaCl por KCl en queso Port Salut, que fue comprobado al determinar el contenido de sodio en la masa, fue percibida por el panel sensorial a través de la diferencia percibida en el sabor salado y amargo, en comparación al queso no reducido. El reemplazo impactó positivamente en la aceptabilidad del producto, viéndose incrementada cuando se le asociaba a la muestra un efecto positivo a la salud.

Resumen. El bagazo de cerveza, mayor subproducto de la producción de cerveza, constituye actualmente un residuo que se descarta o destina a alimentación animal. Sin embargo, su contenido relativamente elevado de compuestos fenólicos lo posiciona como una fuente interesante de estos compuestos bioactivos a ser explotada. En el presente trabajo se estudió el efecto del tiempo de secado al que se sometió al bagazo, cuyo contenido de humedad inicial al egresar del proceso es extremadamente elevado, sobre la bioactividad de los extractos obtenidos posteriormente a partir de dicho material. Se encontró que la extensión del tiempo de secado de 5 a 20 horas produjo una disminución en la calidad de dichos extractos, determinada por el contenido de fenoles totales, la actividad antioxidante y la capacidad antirradicalaria.

Palabras clave: Bagazo de Cerveza, Compuestos Bioactivos, Actividad Antioxidante.

1 Introducción

El bagazo de cerveza (en adelante BSG, por su sigla en inglés 'brewer's spent grain') es el subproducto sólido que se obtiene en la etapa de generación del mosto a partir de la malta de cebada en el proceso de elaboración de la cerveza. Constituye el mayor subproducto de la industria cervecera, representando el 85 % del total de los productos secundarios generados [1]. Se compone principalmente por la cáscara de la cebada, las plántulas, parte del pericarpio y otros materiales que no fueron solubilizados o precipitados en los procesos a los que se sometió previamente. Este material representa aproximadamente el 30 % (p/p) del material de partida. Su composición mayoritaria es variable pero generalmente incluye en materia seca hasta 20 % de proteína, 70 % de fibra y 1,2 % de compuestos fenólicos, principalmente flavonoides y ácidos fenólicos [2]. Existe evidencia científica de la capacidad de estos últimos compuestos para exhibir actividad anticarcinogénica, antiinflamatoria y antioxidante [3].

El contenido de humedad del BSG apenas egresa del proceso varía entre 70 y 80 %. Debido a su alto contenido en agua, polisacáridos y proteínas, éste es particularmente susceptible a sufrir degradación microbiana, constituyendo un subproducto altamente contaminante. Actualmente, el BSG se descarta o comercializa como alimento para ganado; sin embargo, podría ser considerado como materia prima para elaboración de alimentos para consumo humano debido no sólo a su alto poder nutritivo, sino también a su naturaleza de grado alimentario.

En el presente trabajo, se caracterizaron extractos de BSG provenientes de la elaboración de cerveza provistos por un fabricante local. Se estudió el efecto del tiempo de secado del BSG sobre la bioactividad de sus extractos obtenidos posteriormente.

2 Materiales y métodos

2.1 Materiales

El BSG, correspondiente al estilo de cerveza "Dorada Pampeana", fue provisto por la cervecería "Tres Hileras", ubicada en la ciudad de Bahía Blanca. Las muestras se recogieron hasta dos horas después de generadas y fueron procesadas inmediatamente.

2.2 Métodos

Deshidratación del BSG. El BSG utilizado contaba con aproximadamente un 76 % de humedad al momento de egresar del proceso de producción de la cerveza. Con el fin de reducirlo y evitar su degradación, se procedió a prensarlo en una prensa neumática a 4 bar para luego finalizar el proceso en una estufa de circulación forzada a 60 ºC. El tiempo necesario para alcanzar peso constante fue de 5 h. Se decidió estudiar el efecto del tiempo de secado evaluando luego los extractos obtenidos a 5 y 20 h de secado.

Obtención de los extractos de BSG. Las muestras deshidratadas fueron pulverizadas y se seleccionó la fracción pasante por tamiz ASTM 14 (1410 μm). Para la extracción se utilizó una relación de sólido a solvente (etanol/agua (60:40, v/v)) de 1:20 (p/v), estableciéndose las siguientes condiciones operativas: 60 ºC – 30 min – agitación magnética. El sólido residual se separó mediante centrifugación a 7000 rpm durante 10 minutos y el sobrenadante se filtró con membrana de nylon de 0,45 μm de tamaño de poro.

Caracterización de los extractos de BSG. Los extractos fueron caracterizados en cuanto a su bioactividad de acuerdo con la siguiente metodología:
Contenido total de compuestos fenólicos (TPC). La determinación del TPC se realizó según el método colorimétrico de Folin-Ciocalteu siguiendo la metodología reportada por Pacheco et al. [4]. Los resultados fueron expresados como mg de equivalentes de ácido gálico por kg de sólido seco (mg GAE/kg ss).
Poder reductor de iones férricos (FRAP). Se aplicó el método de FRAP, según Pacheco et al. [4]. Los resultados se expresaron en mmol Trolox/kg sólido seco.

Actividad antirradicalaria (AAR, método de decoloración de $ABTS^{+\bullet}$): Se preparó una solución de $ABTS^{+}$ 7 mM y persulfato de potasio 2,45 mM (1:1), mantenida a temperatura de refrigeración y al abrigo de la luz durante 12 h, condiciones necesarias para la formación del radical catiónico $ABTS^{+\bullet}$. Antes de iniciar el ensayo, se realizó una dilución de la solución de $ABTS^{+\bullet}$ en etanol, hasta alcanzar una absorbancia de 0,7. Se mezcló 1 ml de la solución con 10 µl de alícuota de extracto para leer la absorbancia a 734 nm a los 10 min. Los resultados se expresan como %AAR, definida como:

$$\% AAR = \left(1 - \frac{A_{10\,min}}{A_0}\right) 100\,\% \quad (1)$$

A_0: absorbancia antes del agregado de la alícuota.
$A_{10\,min}$: absorbancia a tiempo 10 min.

3 Resultados y discusión

La Fig. 1 muestra los resultados correspondientes al TPC de los extractos obtenidos por secado del BSG por 5 y 20 h. Se puede observar que la extensión del tiempo de secado produce extractos con menor calidad desde el punto de vista de su bioactividad. La disminución en TPC entre 5 y 20h fue de aproximadamente un 15 % en base seca. Esto puede deberse a una degradación de compuestos fenólicos en las muestras deshidratadas de BSG y/o podría ser causado por un cambio físico en las muestras deshidratadas que disminuya la eficiencia de extracción de los mencionados compuestos bioactivos.

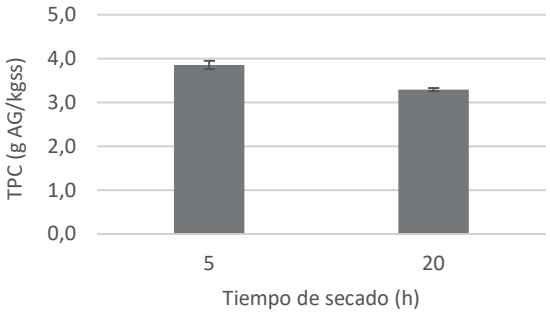

Fig. 1. Contenido de fenoles totales de extractos obtenidos a partir de BSG secado a 5 y 20 h.

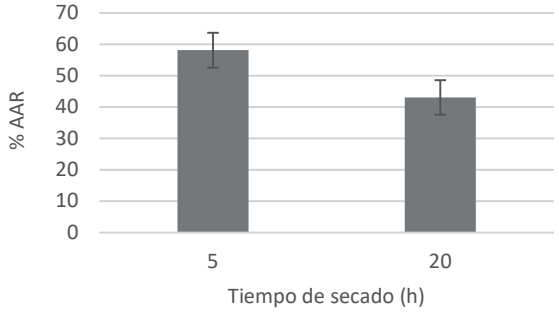

Fig. 2. Actividad antirradicalaria de extractos obtenidos a partir de BSG secado a 5 y 20 h.

Las Fig. 2 y 3 muestran los resultados obtenidos para la AAR y AAO, respectivamente. Al igual que para el caso del contenido de fenoles totales, ambos parámetros de calidad disminuyen al aumentar el tiempo de secado. En el caso de la AAO, esta disminución resultó de aproximadamente un 17 %, mientras que la AAR presentó una caída de alrededor del 26 %. Estas disminuciones se encuentran en concordancia con la menor concentración de compuestos fenólicos en los extractos, los cuales representan los compuestos bioactivos mayoritarios presentes en las muestras [2].

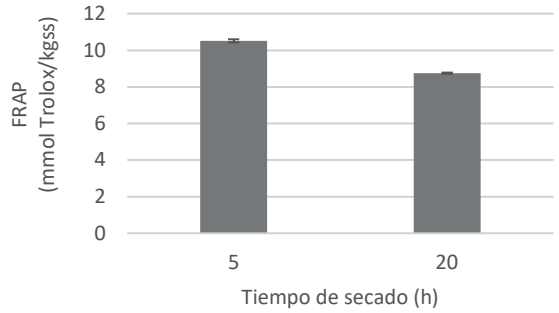

Fig. 3. Poder reductor de iones férricos de extractos obtenidos a partir de BSG secado a 5 y 20 h.

4 Conclusiones

Los resultados obtenidos al evaluar el efecto del tiempo de secado de BSG sobre el contenido de fenoles totales y la capacidad antioxidante y antirradicalaria de los extractos obtenidos mostraron que los tres parámetros de calidad estudiados sufrieron una importante disminución (15 – 26 %) al aumentar el tiempo de secado de 5 a 20 horas.

Estos resultados demuestran la importancia de no extender el tiempo de secado innecesariamente.

Resumen. La producción de polvos alimenticios se encuentra en crecimiento debido a la mejorada estabilidad que presentan y su fácil transporte y almacenamiento. Los compuestos antioxidantes presentes en las frutas y verduras pueden ser extraídos y vehiculizados en forma de polvos, lo cual además facilita su consumo. Esta estrategia permite también aprovechar compuestos bioactivos que se encuentran en partes de las plantas que no son habitualmente consumidas. Sin embargo, estos compuestos presentan cierta inestabilidad química fuera de su matriz natural. La microencapsulación es una posible solución para preservar la actividad antioxidante de estas sustancias hasta el momento de ser consumidas.
En el presente trabajo se planteó la microencapsulación de hojas de alcaparra, cáscara, albedo y jugo de naranja, obteniéndose un producto particulado rico en bioflavonoides -rutina, hesperidina y narirutina- y vitamina C. El proceso se llevó a cabo mediante secado por atomización utilizando maltodextrina como agente encapsulante. La temperatura de entrada del gas de secado se varió entre 130 y 150 ºC. Los polvos obtenidos fueron caracterizados determinando contenido de flavonoides individuales, vitamina C, fenoles totales, actividad antirradicalaria e higroscopicidad. Asimismo, la performance del proceso se evaluó calculando el rendimiento para cada ensayo. Los resultados obtenidos permitieron concluir que la temperatura de entrada del gas de secado afecta significativa únicamente la higroscopicidad del producto final, encontrándose el mínimo valor de este parámetro para 130 ºC.

Palabras clave: Microencapsulación, Antioxidantes naturales, Residuos agroindustriales.

1 Introducción

La naranja es un fruto rico en ácido ascórbico, narirutina y hesperidina, compuestos con reconocido efecto antioxidante. La hesperidina se encuentra en alta concentración en el albedo -la parte blanca de la cáscara-, mientras que el ácido ascórbico y la narirutina,

se encuentran concentrados en su jugo. Al utilizar la naranja como fuente de estas sustancias se aprovecha la fruta casi en su totalidad, disminuyendo así la generación de residuos. Sólo alrededor de un tercio de las frutas cítricas se utilizan para producir jugo fresco o bebidas a base de cítricos. Por lo tanto, estos alimentos no son debidamente aprovechados en la industria. Sus residuos (cáscaras) tienen valor bajo o nulo e incluso pueden constituir un problema ambiental debido a su acumulación cerca de las zonas industriales. Una posible forma de valorizar las cáscaras y semillas de cítricos, subproductos de la industria, es utilizarlas como fuentes de antioxidantes naturales [1].

Por otro lado, las hojas de alcaparra son una buena fuente de rutina confiriendo valor agregado a este residuo generado en las prácticas agrícolas. La rutina, también conocida como vitamina P, es un compuesto fenólico vegetal muy importante debido a su actividad antioxidante, antiinflamatoria y anticancerígena, y a su capacidad para reducir la fragilidad de los vasos sanguíneos [2].

Resulta interesante desarrollar fórmulas ricas en dichas sustancias, ya que los bioflavonoides (como rutina y hesperidina) son antioxidantes que presentan sinergismo con el ácido ascórbico [3], favoreciendo la asimilación de este último [4].

Otra característica de los antioxidantes es que son fácilmente degradables debido a su sensibilidad a factores ambientales como la luz, el calor, la humedad y el oxígeno [5], por lo que deben ser protegidos para preservar su bioactividad. La microencapsulación se presenta como una solución factible a este problema. En particular, el secado por atomización (spray drying) es un proceso que produce partículas de alta calidad y estabilidad, siendo relativamente flexible, de bajo costo y de operación continua y, por lo tanto, el método de encapsulación más utilizado en la industria alimentaria actualmente [6, 7, 8].

En el presente trabajo se propone coencapsular extractos brutos de albedo y cáscara de naranja, hojas de alcaparro y jugo de naranja con maltodextrina (MD) como agente encapsulante mediante secado por atomización. Se estudió el efecto del aumento de la temperatura del gas de secado sobre diferentes parámetros de calidad del proceso (rendimiento) y del producto (higroscopicidad del polvo, contenido de fenoles totales, flavonoides individuales -hesperidina, rutina y narirrutina- y vitamina C y actividad antirradicalaria).

2 Materiales y métodos

2.1 Materiales

El albedo de naranja fue obtenido a partir de naranjas variedad Valencia, teniendo especial cuidado en eliminar todo resto de flavedo y pulpa que pudiera haber quedado adherida al albedo. Se secó en estufa de circulación forzada a 60 ºC por aproximadamente 4 horas, hasta peso constante. Luego se pulverizó con mortero y se separó la fracción pasante por tamiz ASTM 50 (297 μm). El procedimiento de secado de las hojas de alcaparro fue similar. El jugo de naranja se obtuvo por prensado, para luego ser filtrado con filtro de tela. La MD DE 20 fue gentilmente proporcionada por Ingredion Argentina.

2.2 Métodos

Preparación de las suspensiones a atomizar. En función de determinaciones previas del contenido de flavonoides y ácido ascórbico en los materiales vegetales utilizados, se estableció la siguiente metodología de obtención de los extractos: 0,5:10 (p/v) de hojas secas de alcaparro a mezcla de etanol/agua (70:30, v/v) y 0,05:10 (p/v) de albedo seco a mezcla de etanol/agua (70:30, v/v). El sólido residual luego de la extracción fue separado por filtración con papel de filtro. El solvente orgánico presente en cada uno de los extractos fue evaporado de forma independiente en rotoevaporador. Los extractos fueron congelados hasta su utilización. Los volúmenes de extractos en la suspensión a atomizar fueron los siguientes: 10 mL de extracto concentrado de hojas de alcaparro, 15 mL de extracto concentrado de albedo y 30 mL de jugo de naranja filtrado. Una vez homogeneizados, se agregó un 70 % (p/p sólidos de jugo) de MD. Esta suspensión fue mantenida en continua agitación mientras era alimentada al secadero spray mediante bomba peristáltica.

Coencapsulación de los extractos. La encapsulación se llevó a cabo mediante secado por atomización en un secadero spray (Mini Spray Dryer Büchi B-290). Las condiciones operativas del mismo fueron: caudal de líquido atomizado: 7 mL/min, caudal de aire de atomización: 831 L/h (STP), caudal de gas de secado (nitrógeno): 33 m^3/h. La temperatura de entrada del gas de secado (Tin) se estableció en tres niveles: 130, 140 y 150 ºC.

Cálculo del rendimiento de proceso. Se estimó mediante la Ec. (1). Las masas se determinaron gravimétricamente pesando el producto final colectado en el secadero y considerando el contenido de sólidos de la suspensión atomizada.

$$\text{Rendimiento (\%)} = \left(\frac{\text{masa de sólido recuperado}}{\text{masa de sólido alimentado}}\right) 100\ \% \qquad (1)$$

Caracterización de los polvos obtenidos. Los extractos fueron caracterizados en cuanto a su bioactividad de acuerdo con la siguiente metodología:
Flavonoides individuales. Las soluciones de rutina, narirutina y hesperidina a ser analizadas se obtuvieron tomando 1 g de polvo, agregando 5 mL de agua (para solubilizar la maltodextrina), agitando durante 2 minutos para luego agregar 5 mL de DMSO (con el objetivo de solubilizar completamente los flavonoides) y agitando nuevamente durante 2 minutos. A continuación, se procedió a centrifugar las muestras a 7000 rpm durante 10 minutos. En algunos casos, fue necesario diluir las soluciones con una mezcla DMSO/agua (1:1). Finalmente, se filtró con membrana de PVDF de 0,45 μm de tamaño de poro. La cuantificación se llevó a cabo según Patil y col. [9] en un HPLC (Waters Alliance, e2695) provisto de una columna C18RS y un detector de arreglo de diodos (280 nm para hesperidina y narirrutina y 355 nm para rutina). La fase móvil consistió en un sistema binario de solventes: agua/ácido acético (96:4, v/v, solvente A) y acetonitrilo (solvente B). La elución se estableció en modo gradiente según la siguiente programación: 1) 85 % solvente A por 35 minutos, 2) 50 % solvente A por 5

minutos y 3) 85 % solvente A. El flujo volumétrico se mantuvo en 1 mL/min. La cuantificación se llevó a cabo mediante el método del estándar externo empleando rutina, narirutina y hesperidina comerciales como patrones analíticos. Los resultados se expresaron como mg flavonoide/g polvo.

Contenido total de compuestos fenólicos (TPC). La determinación del TPC se realizó según el método colorimétrico de Folin-Ciocalteu. Brevemente, una alícuota de 100 µL de extracto fue mezclada con 6 mL de agua y 0,5 mL de reactivo de Folin-Ciocalteu en matraz de 10 mL. Luego de 8 minutos, 1,5 mL de una solución al 7,5 % de Na_2CO_3 anhidro se agregó y se llevó a volumen con agua destilada. Se registró la absorbancia a 765 nm luego de 2 horas de incubación en oscuridad. Los resultados fueron expresados como mg de equivalentes de ácido gálico por kg de sólido seco (mg GAE/kg ss) haciendo uso de una curva de calibración construida previamente con ácido gálico como estándar de referencia.

Actividad antirradicalaria (AAR, método de decoloración de DPPH•): La medición de la AAR se determinó agregando una alícuota de los extractos conteniendo los antioxidantes a 3 mL de una solución de DPPH• con absorbancia de aproximadamente 1. Inmediatamente, se comenzó a medir la absorbancia a 517 nm en ciclos de 30 segundos durante 10 minutos, de manera de obtener el valor de absorbancia a tiempo infinito mediante extrapolación matemática. Este valor, junto con el de absorbancia a tiempo inicial, permite el cálculo del porcentaje de actividad antirradicalaria, según Ec. 1.

$$\% \, AAR = \left(1 - \frac{A_{10\,min}}{A_0}\right) 100\,\% \qquad (2)$$

A_0: absorbancia antes del agregado de la alícuota (aproximadamente 1,000).

$A_{10\,min}$: absorbancia transcurridos 10 min del agregado de la alícuota.

Determinación del contenido de vitamina C (VCC). La solución a ser analizada se obtuvo tomando 1 g de polvo, agregando 10 mL de una solución de ácido metafosfórico al 2 % [10], agitando durante 5 minutos para luego centrifugar la suspensión a 7000 rpm durante 10 minutos, para separar los compuestos insolubles en agua. Se procedió a realizar una dilución 1:1 con una solución acuosa de ácido sulfúrico pH 2,5 y luego se filtró con membrana de PVDF de 0,45 µm de tamaño de poro. Brevemente, la técnica de cuantificación se realizó en un HPLC (Waters Alliance, e2695) provisto de una columna C18RS y un detector de arreglo de diodos (254 nm). La fase móvil que se utilizó fue una solución acuosa de ácido sulfúrico pH 2,5. El compuesto de referencia que se utilizó para la construcción de las curvas de calibración fue ácido ascórbico puro (Saporiti), expresándose los resultados como mg AA/g polvo.

Higroscopicidad. Las muestras (1 g) fueron expuestas a una atmósfera de 75 % HR (sol. saturada de NaCl) a 25 ºC durante una semana. La higroscopicidad se calculó según la Ec. (2).

$$\text{Higroscopicidad (\%)} = \left(\frac{\text{masa de agua ganada}}{\text{masa de sólido seco}}\right) 100\,\% \qquad (2)$$

3 Resultados y discusión

En la Fig. 1 se muestra la dependencia del rendimiento del proceso con la temperatura de entrada del gas de secado. Se puede observar que se obtienen rendimientos muy buenos y similares para las tres temperaturas estudiadas.

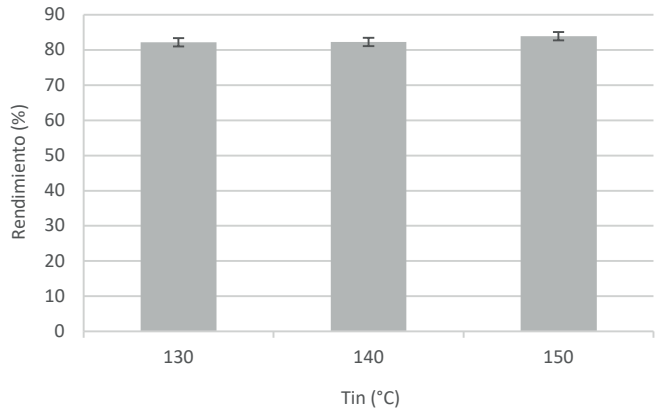

Fig. 1. Rendimiento del proceso de encapsulación en función de la temperatura de entrada del gas de secado.

La higroscopicidad (Fig. 2) muestra cierta dependencia con la temperatura de entrada del gas de secado. En este caso, este parámetro aumenta con dicha variable operativa. La higroscopicidad del polvo afecta negativamente sus propiedades de flujo y su estabilidad química; por lo tanto, se busca que ésta sea mínima, condición que se cumpliría para una temperatura de 130 ºC.

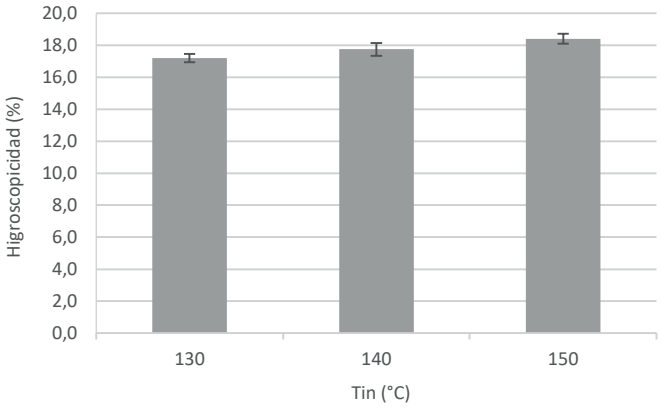

Fig. 2. Higroscopicidad de los polvos en función de la temperatura de entrada del gas de secado.

Respecto al contenido de compuestos bioactivos en los polvos obtenidos, los resultados del contenido total de compuestos fenólicos (TPC) se muestran en la Fig. 3.

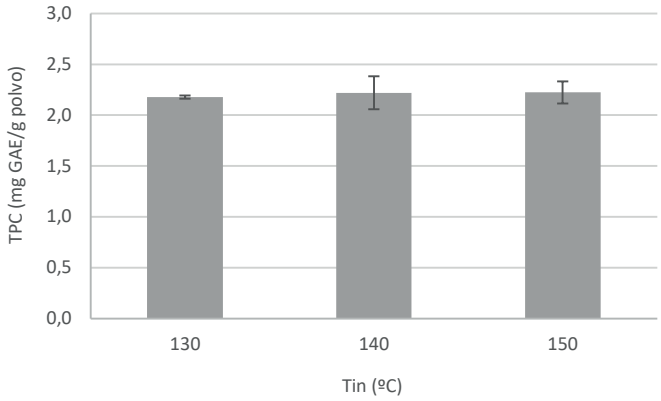

Fig. 3. Contenido total de compuestos fenólicos en función de la temperatura de entrada del gas de secado.

Se obtuvieron valores de aproximadamente 2,2 mg GAE/g polvo para las tres temperaturas de entrada del gas de secado, no encontrándose diferencias significativas entre los valores obtenidos.

En la Fig. 4 se muestran los resultados correspondientes a la actividad antirradicalaria de los polvos obtenidos.

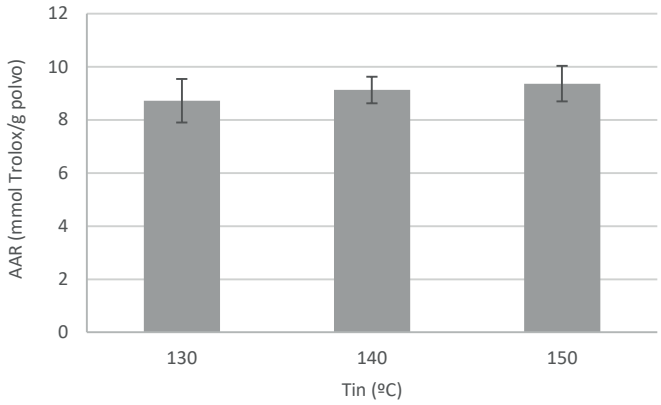

Fig. 4. Actividad antirradicalaria en función de la temperatura de entrada del gas de secado.

Al igual que para el TPC, se encontró que la AAR de los polvos obtenidos a las tres Tin estudiadas fue similar, concluyéndose que resultaría indistinto establecer la temperatura de entrada del gas de secado en cualquiera de los tres valores estudiados.

Finalmente, en la Fig. 5 y 6 se muestran los resultados para el contenido de los flavonoides individuales y de la vitamina C, respectivamente.

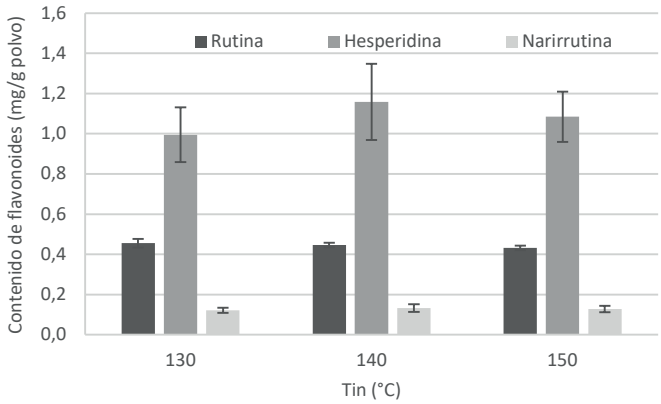

Fig. 5. Contenido de flavonoides individuales en función de la temperatura de entrada del gas de secado.

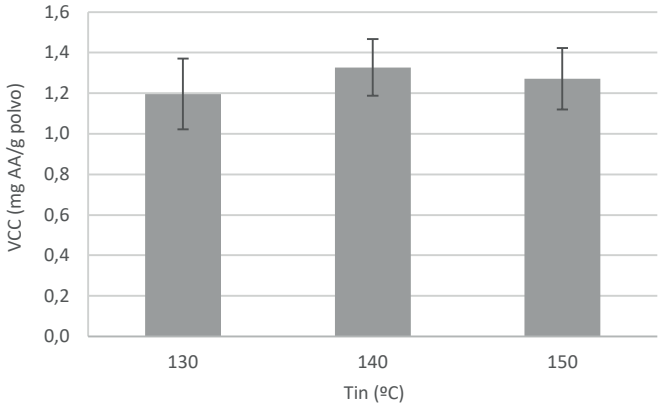

Fig. 6. Contenido de vitamina C en función de la temperatura de entrada del gas de secado.

Observando los valores obtenidos para el contenido de flavonoides individuales, la hesperidina resultó el predominante. Esto se debe a que el mismo está presente no sólo en el albedo de la naranja, sino también en su jugo. En el caso de la narirutina, ésta se encuentra presente principalmente en el jugo de este fruto, aunque en menor

concentración que la hesperidina. Evaluando el efecto de la temperatura de entrada del gas de secado sobre la concentración de estos compuestos en los polvos obtenidos, es posible concluir que no existe diferencia significativa entre los valores obtenidos. Este resultado está en concordancia con el obtenido para el TPC, si se considera que los compuestos fenólicos predominantes en el producto son los flavonoides individuales evaluados.

Respecto al contenido de vitamina C en los polvos, los valores encontrados fluctuaron entre 1,2 y 1,33 mg AA/g polvo, no encontrándose diferencias significativas para las distintas muestras analizadas.

La vitamina C resulta mucho más termolábil que los compuestos fenólicos de alto peso molecular, como la rutina, narirutina y hesperidina. Sin embargo, la primera no se ve afectada por el incremento de la temperatura del gas de secado. Anandharamakrishnan y col. [11] aseguran que las partículas permanecen a su temperatura de bulbo húmedo durante el proceso de evaporación del solvente, evitando que las mismas alcancen la temperatura del gas, protegiendo así los compuestos termolábiles. Por otro lado, el uso de nitrógeno (un gas inerte) en lugar de oxígeno, seguramente colabora en la estabilización de la vitamina.

4 Conclusiones

Se analizaron diferentes parámetros de calidad de proceso y del producto obtenido al manipular la temperatura de entrada del gas de secado durante el proceso de microencapsulación. Los resultados obtenidos permitieron inferir que el único parámetro que se vio afectado por la temperatura de entrada del gas de secado (en el rango estudiado) fue la higroscopicidad del polvo obtenido. Ésta resultó mínima para la menor temperatura evaluada. Como se mencionó anteriormente, es deseable que ésta tome valores lo más bajo posibles debido a que el aumento en el contenido de humedad del polvo durante su almacenamiento se relaciona con problemas en su flujo, dificultando su manipulación, además de acelerar las reacciones degradativas de los compuestos bioactivos contenidos en el producto.

Por este motivo, y dado que los restantes parámetros estudiados no presentaron dependencia con la temperatura de entrada del gas de secado, se recomienda 130 ºC como temperatura óptima de secado, dentro del rango estudiado.

Resumen. En este trabajo se estudiaron las cinéticas de degradación térmica del color, vitamina C y proteínas en leche para un rango de temperaturas de 70 a 100°C. El color fue cuantificado midiendo los parámetros colorimétricos CIELAB, con un colorímetro Kónica-Minolta CR400 (Japón), y determinado a partir de ellos el índice de Pardeamiento (*BI*) y cambio total de color (ΔE). La vitamina C fue determinada por HPLC, mientras que para la cuantificación de las proteínas séricas se utilizó la técnica de Bradford. Todos los parámetros estudiados siguieron una cinética de primer orden, a excepción del cambio de color, que siguió una cinética de orden cero. En todos los casos, la dependencia de la constante de velocidad (*K*) con la temperatura fue modelada mediante la Ecuación de Arrhenius, obteniéndose energías de activación de 148,09, 138,57, 13,04 y 60,03 kJ/mol para *BI,* ΔE*,* vitamina C y proteínas, respectivamente. Las energías de activación revelaron que *BI* es el parámetro más sensible a los cambios de temperatura, mientras que los valores de las constantes de velocidad (*K*) mostraron que la desnaturalización térmica de proteínas presentó la mayor velocidad de degradación en comparación con los demás parámetros estudiados.

Palabras clave: Estabilidad Térmica, Color, Vitamina C, Proteínas, Leche.

1 Introducción

La leche es un alimento de alto valor nutricional debido a su contenido de proteínas, grasas, vitaminas y minerales, necesarias para la nutrición humana [1]. Su compleja composición bioquímica junto con su pH y su alta actividad de agua hacen de ella un medio ideal para el crecimiento microbiano. Debido a esto, es necesario el tratamiento térmico de la leche cruda, siendo la pasteurización por calor uno de los procesos más utilizados para obtener un producto apto para el consumo humano y, por consiguiente, asegurar la inocuidad microbiológica y prolongar la vida útil de este alimento. En la

industria, tanto a nivel mundial como nacional, dicho proceso se lleva a cabo mayormente a través de sistemas continuos de calentamiento, empleando intercambiadores de calor tubulares o de placas [2]. Sin embargo, este procesamiento origina alteraciones en los componentes nutricionales de la leche, principalmente en aquellos componentes termosensibles como lo son las proteínas y las vitaminas hidrosolubles, y sensoriales, al producirse cambios en el color y sabor debido principalmente a reacciones de Maillard [3]. En este sentido, el objetivo del presente trabajo reside en desarrollar cinéticas de degradación térmica de dichos componentes de calidad en leche de vaca, considerando condiciones de tiempo y temperatura requeridas para la pasteurización de este tipo de producto. Dichas cinéticas serán de utilidad para predecir el efecto del procesamiento térmico en las características de la leche y, por consiguiente, para optimizar las condiciones de tratamiento y obtener, con ello, un producto de alta calidad.

2 Materiales y métodos

2.1 Muestras de leche

Para la realización de los ensayos experimentales se utilizó leche fresca entera provista por la Escuela Superior Integral de Lechería (ESIL) y por la Estancia YUCAT, ambas de la ciudad de Villa María, Provincia de Córdoba. Para la determinación de proteínas y ácido ascórbico, se requirió de leche descremada, proceso llevado a cabo por una desnatadora de escala laboratorio. Las muestras fueron almacenadas a 4°C.

2.2 Tratamiento térmico

Para el desarrollo de los estudios cinéticos, muestras de leche fueron colocadas en tubos de vidrio con tapa a rosca de 6 mL y calentadas por inmersión en un baño de agua termostatizado, manteniendo constante la temperatura requerida. Para el estudio de los diferentes parámetros nutricionales y sensoriales se utilizaron temperaturas y tiempos de calentamientos diferentes, lo cual se debe principalmente a las diferencias en las velocidades de formación o degradación de los componentes analizados: compuestos coloreados, vitamina C y proteínas séricas. Para el estudio de parámetros colorimétricos, se utilizó un rango de temperatura entre 80 y 100 °C y tiempos entre 0 y 120 min, para la degradación térmica de la vitamina C, temperaturas entre 70 y 100 °C y tiempos de entre 0 y 33 minutos, mientras que para la desnaturalización de proteínas séricas se realizaron experiencias entre los 70 y 100 °C y tiempos entre 0 y 3 minutos. Al finalizar el tratamiento térmico, las muestras fueron enfriadas rápidamente en un baño de agua-hielo, de manera de detener las reacciones de desnaturalización y degradación que tienen lugar durante el calentamiento.

2.3 Determinación de parámetros colorimétricos

Las muestras de leche tratadas térmicamente se homogeneizaron utilizando un vortex y se colocaron en un recipiente de cerámica de 3 cm de diámetro para realizar la medición de los parámetros colorimétricos. Dichos parámetros se basan en el espacio de color CIELAB compuesto por tres coordenadas colorimétricas, L *, a * y b *. El valor de L * representa luminosidad del color (L*=0 significa negro y L*=100 indica blanco), el valor a * indica su posición entre rojo y verde (valores negativos indican verde mientras valores positivos indican rojo) y el valor b * representa su posición entre amarillo y azul (valores negativos indican azul y valores positivos indican amarillo).

El instrumento utilizado fue un colorímetro Kónica-Minolta CR400 (Japón) y se calibró con una placa blanca estándar (sY = 93,2, sx = 0,3133 y sy = 0,3192). Con las coordenadas colorimétricas obtenidas se determinaron el índice de pardeamiento (BI) (Ecuación 1) y el cambio de color (ΔE) (Ecuación 3) y su variación en el tiempo.

$$BI = \frac{100\,(X-0{,}31\,)}{0{,}17} \tag{1}$$

donde X está definido como:

$$X = \frac{a^* + (1{,}75\,L^*)}{(5{,}645\,L^*) + a^* - (3{,}012\,b^*)} \tag{2}$$

$$\Delta E = \sqrt{(L^* - L_o^*)^2 + (a^* - a_o^*)^2 + (b^* - b_o^*)^2} \tag{3}$$

donde L_o, a_o y b_o son las coordenadas CIELAB de la leche en tiempo cero. Para desarrollar la cinética de cambio de color, el tratamiento térmico y el análisis de las muestras se llevaron a cabo por triplicado.

2.4 Contenido de vitamina C

La vitamina C se cuantificó por HPLC (High Performance Liquid Chromatography) teniendo en cuenta los trabajos de Chotyakul et al. [4] y Tiwari et al. [5] con adaptaciones. Se colocaron 4 mL de leche en un tubo de plástico y se realizó la extracción con 1 mL de ácido metafosfórico al 2,5 % (p/v). Los tubos se cubrieron con papel aluminio de manera de proteger las muestras de la luz, y evitar la oxidación de la vitamina. Luego, la mezcla se homogenizó en un vortex por 20 s y se centrifugó a alta velocidad y baja temperatura (10000 rpm y 4 °C) durante 10 min. Se colocó 1 mL del sobrenadante obtenido anteriormente en un eppendorf de 1 mL protegido de la luz, previamente filtrado utilizando un filtro de 45 µm. Por último, se inyectó 20 µL del sobrenadante filtrado en el equipo de HPLC.

El sistema cromatográfico utilizado consistió en un HPLC (Thermo Scientific ULTIMATE 3000, EE. UU.) con una columna C18. Se usó un detector DAD a una longitud de onda de 243 nm. La fase móvil consistió en una mezcla de 0,5% (p/v) de ácido metafosfórico con acetonitrilo (ACN) (pH:2) en relación fase acuosa – acetonitrilo 99:1. La misma fue bombeada a un caudal de 0,5 mL/min. Los resultados se calcularon utilizando la curva estándar de vitamina C y las áreas obtenidas en los

cromatogramas. Las determinaciones se realizaron por triplicado en las muestras obtenidas a los diferentes tiempos en un tratamiento térmico.

2.5 Determinación de proteínas

Para la determinación de proteínas en leche tratada térmicamente, las muestras se centrifugaron a 4°C, 10000 rpm y 30 minutos para producir la sedimentación de las proteínas desnaturalizadas, realizándose luego la determinación de las proteínas presentes en el sobrenadante con la técnica propuesta por Bradford [6] con ligeras modificaciones y utilizando albúmina de suero bovino (BSA) como estándar. Para ellos, se realizaron diluciones de 1/100 y 1/200 del sobrenadante obtenido en agua destilada. Posteriormente, se colocaron 10 µL de cada dilución en pocillos de una placa de 96 Wells y se añadieron 190 µL del reactivo color Bradford (BioRad) (dilución 1/5 en agua destilada) a cada uno de los pocillos, para leer finalmente las absorbancias a 570 nm en un espectrofotómetro de microplacas Multiskan Go (ThermoFisher Scientific). Las determinaciones se realizaron por duplicado en las muestras obtenidas a los diferentes tiempos en un tratamiento térmico.

2.6 Modelos cinéticos

Las cinéticas de cambio de color, índice de pardeamiento, degradación de vitamina C y desnaturalización de proteínas en leche tratada térmicamente fueron evaluadas teniendo en cuenta los modelos cinéticos de orden cero (Ecuación 4) y de primer orden (Ecuación 5).

$$C = C_o - K.t \tag{4}$$

$$\frac{C}{C_o} = e^{-K.t} \tag{5}$$

donde C es el parámetro a estimar, C_o es el valor del parámetro en el tiempo cero, t es el tiempo de procesamiento térmico y *K* es la constante de velocidad a la temperatura T. Luego de la medición de los parámetros a diferentes tiempos, se graficó C_o-C y C/C_o en función del tiempo para cinéticas orden cero y de primer orden, respectivamente y para cada temperatura. Posteriormente, se realizó el ajuste lineal o exponencial según el orden de reacción ensayado.

La dependencia de la constante de velocidad (*K*) con la temperatura fue modelada mediante la Ecuación de Arrhenius (Ecuación 6).

$$\ln(K) = ln(Kref) - \frac{Ea}{R}\left(\frac{1}{T}\right) \tag{6}$$

donde *Kref* es el factor preexponencial, *Ea* es la energía de activación, *R* es la constante universal de los gases y T es la temperatura absoluta. Los valores de *K,* para cada temperatura y para cada cinética, se obtuvieron de las ecuaciones (4) y (5), por lo que al graficar ln (*K*) vs. 1/T es posible encontrar los demás parámetros de la Ecuación de Arrhenius.

3 Resultados y discusión

3.1 Parámetros colorimétricos

El pardeamiento de la leche, producido durante el tratamiento térmico principalmente por reacciones no enzimáticas o reacciones de Maillard, puede ser considerado un indicador de la severidad del mismo. En la Tabla 1 se presentan los parámetros cinéticos correspondientes al índice de pardeamiento y el cambio de color. El primero siguió una cinética de primer orden (Figura 1) mientras que el segundo mostró una cinética de orden cero (Figura 2), en concordancia con lo encontrado por Pagliarini et al. [7]. Estos autores estudiaron el cambio de color en leche fresca descremada debido a tratamientos térmicos a temperaturas de entre 90 y 130 °C y un rango de tiempo de 0 a 60 minutos, reportando una energía de activación de 101,8 kJ/mol para el cambio de color. Por otro lado, Rhim et al. [8] evaluaron los parámetros colorimétricos Hunter *L*, *a* y *b* en un amplio rango de temperaturas (entre 100 y 150 °C) y tiempos (0 a 180 minutos), encontrando que el índice de pardeamiento aumentó con la temperatura siguiendo una cinética de orden cero y reportando una energía de activación de 123,5 kJ/mol. Como se puede observar, las energías de activación obtenidas en nuestro estudio para el cambio de color e índice de pardeamiento resultaron mayores a los reportados por Pagliarini et al. [7] y Rhim et al. [8], respectivamente. Lo anterior podría deberse a las diferencias de rangos de temperaturas evaluados en los diferentes trabajos; siendo mayor la Ea, que indica la sensibilidad a los cambios de temperatura, cuando las temperaturas son más bajas.

Como es de esperarse, los valores de *K* aumentaron con la temperatura para ambos parámetros, lo cual revela que a medida que se incrementa la temperatura aumenta la velocidad de aparición de componentes coloreados. Para ambos, la dependencia de la constante de velocidad (*K*) con la temperatura fue modelada mediante la Ecuación de Arrhenius, obteniendo coeficientes de correlación (R^2) de 0,99 y 0,97 para el índice de pardeamiento y cambio de color, respectivamente.

Tabla 1. Parámetros cinéticos de variación de color.

Índice de Pardeamiento					
T(°C)	*K (min^{-1})*	*R^2*	*K_{ref}*	*E_a (kJ/mol)*	*R^2*
80	0,0004	0,9260			
90	0,0014	0,9556	$3{,}13.10^{18}$	148,09	0,99
100	0,0060	0,9950			
Cambio de Color					
80	0,0042	0,9710			
90	0,0104	0,9637	$1{,}17.10^{18}$	138,57	0,97
100	0,0532	0,9898			

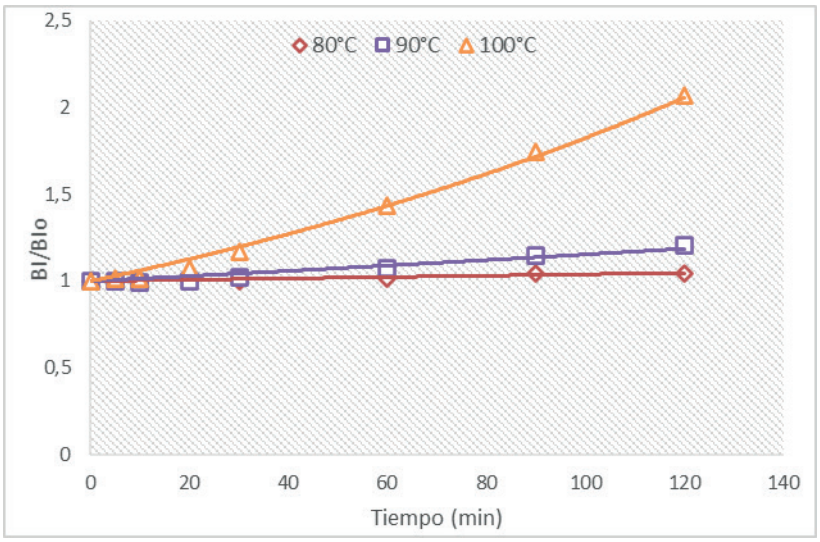

Fig. 1. Cinética de índice de pardeamiento en leche tratada térmicamente a diferentes temperaturas. Las líneas continuas corresponden al modelo ajustado de primer orden.

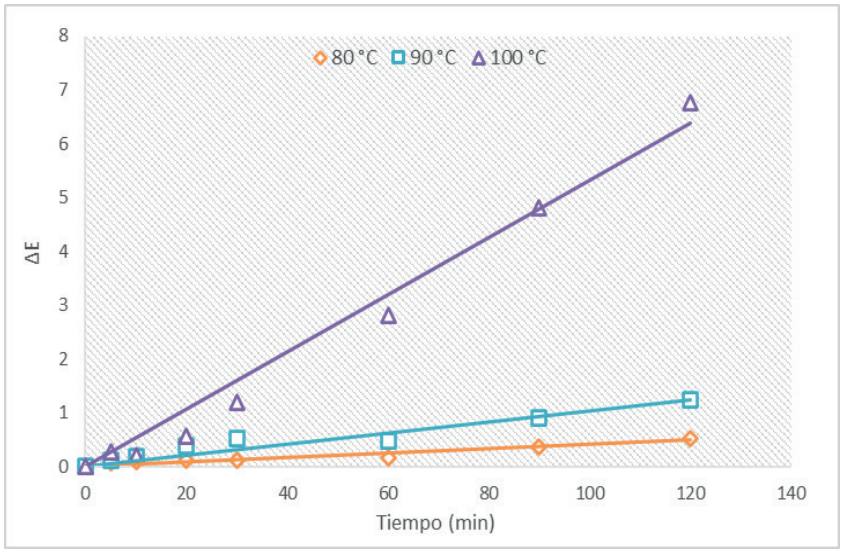

Fig. 2. Cinética de cambio de color en leche tratada térmicamente a diferentes temperaturas. Las líneas continuas corresponden al modelo ajustado de orden cero.

3.2 Degradación de vitamina C

En la Figura 3 se presenta la variación de vitamina C en leche, para diferentes tiempos y temperaturas de procesamiento. En la tabla 2 se presentan los parámetros cinéticos

obtenidos, encontrándose que la degradación térmica de esta vitamina siguió una cinética de primer orden, mientras que la dependencia de la constante de velocidad (*K*) con la temperatura fue modelada mediante la Ecuación de Arrhenius, consiguiendo un muy buen ajuste, con un R^2 de 0,94.

De todas las vitaminas hidrosolubles presentes en la leche, la vitamina C o ácido ascórbico es la más termosensible, reportándose pérdidas de hasta un 40% luego de tratamientos UHT [9]. Si bien son escasos los trabajos de investigación tendientes a evaluar el efecto del procesamiento térmico sobre la vitamina C en leche de vaca, muchos autores han estudiado la degradación térmica del ácido ascórbico en una gran variedad de alimentos durante los tratamientos térmicos y han encontrado que éste sigue una cinética de primer orden [10, 11, 12, 13]. Como se dijo anteriormente, en este estudio, se encontró que la degradación térmica de esta vitamina siguió una cinética de primer orden al igual que lo reportado por Bendicho et al. [9]. Estos autores evaluaron los efectos del tratamiento de campo eléctrico pulsado de alta intensidad (HIPEF) en vitaminas solubles (entre ellas el ácido ascórbico) y liposolubles en leche, comparándolo con los tratamientos térmicos convencionales, para los cuales trabajaron con tiempos de hasta 60 minutos a temperaturas entre 50 y 90 ° C. Como resultado, observaron que la retención de ácido ascórbico siguió un modelo cinético de primer orden tanto para HIPEF como para los procesos térmicos convencionales, mientras que la constante de velocidad (*K*) varió entre 9.10^{-3} y 8.10^{-2} min^{-1} para la cinética correspondiente a tratamientos térmicos convencionales. En cuanto a la energía de activación reportada por estos autores, es bastante superior (63,6655 kJ/mol) a la obtenida en el presente estudio, lo cual puede deberse no sólo al tratamiento térmico y las condiciones utilizadas, sino también al agregado de vitaminas, entre ellas ácido ascórbico, a la leche a tratar.

Tabla 2. Parámetros cinéticos de la degradación térmica de vitamina C

T(°C)	*K* (min^{-1})	R^2	K_{ref}	E_a (kJ/mol)	R^2
70	0,0231	0,9813	2,32	13,04	0,94
80	0,0287	0,9909

100	0,0342	0,9796			

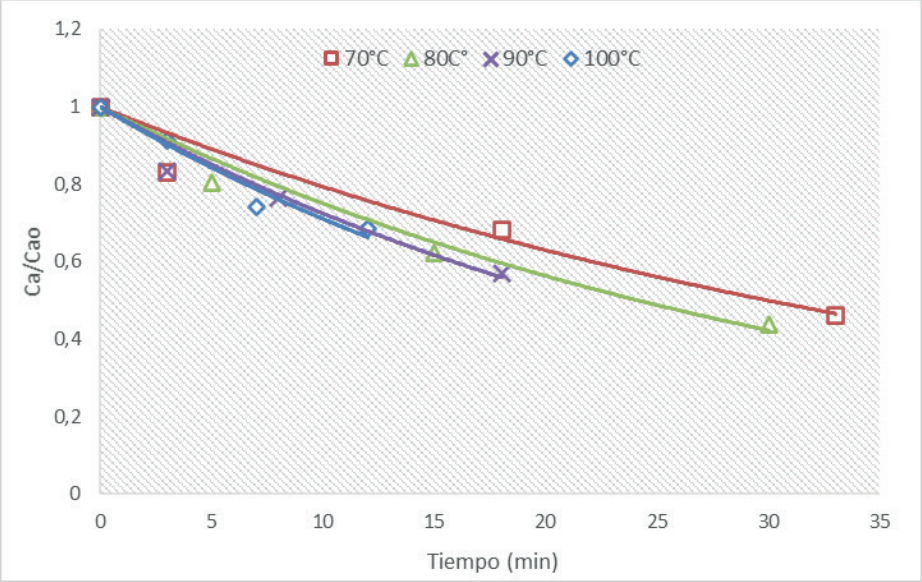

Fig. 3. Cinética de degradación térmica de vitamina C en leche tratada térmicamente a diferentes temperaturas. Las líneas continuas corresponden al modelo ajustado de primer orden.

3.3 Desnaturalización de proteínas

En la figura 4 se presentan las cinéticas de desnaturalización de proteínas de la leche debida a los tratamientos térmicos, a diferentes temperaturas. El tiempo necesario para alcanzar la temperatura de tratamiento fue inferior a 30 segundos, razón por la cual este período de tiempo se excluyó del análisis de los parámetros cinéticos. Los tratamientos térmicos de la leche tienen un gran efecto sobre la estructura y las propiedades de las proteínas del suero, siendo las principales proteínas séricas la β-LG y la α-LA, que representan el 50 y el 20% del total, respectivamente [14]. Un tratamiento térmico mayor a 60 °C da como resultado la desnaturalización de las proteínas del suero, proceso complejo que consiste en el despliegue de las moléculas de proteína, seguido inmediatamente por reacciones de agregación irreversibles [15]. Una gran cantidad de autores han realizado el estudio de las cinéticas de desnaturalización de estas proteínas, en leches con diferentes porcentajes de materia grasa, diferentes tratamientos térmicos con diferentes condiciones de tiempo-temperatura y métodos de determinación [14, 15, 16, 17, 18, 19, 20]. En dichos trabajos, encontraron que entre los factores que influyen en el grado de desnaturalización de las proteínas del suero, se encuentran las condiciones de calentamiento y sistemas de tratamiento térmico y el método de determinación de la desnaturalización de la proteína de suero [15]. Adicionalmente, han reportado que la cinética de desnaturalización de la α-LA es de primer orden, mientras que la de la β-LG puede seguir una cinética de orden 1, 2 o 1,5, dependiendo del autor. Sin embargo, la mayoría de los trabajos coinciden en que estas cinéticas son lineales en dos rangos

de temperaturas: entre 70 y 95 °C, en la cual se obtienen altas energías de activación y entre 95 °C y 140 °C, con bajas energías de activación.

En nuestro estudio se encontró que la desnaturalización de las proteínas séricas, entre 70 y 100 °C, siguió una cinética de primer orden (Figura 4), mientras que la dependencia de la constante de velocidad *(K)* con la temperatura fue modelada mediante la Ecuación de Arrhenius. Los parámetros cinéticos obtenidos se muestran en la tabla 3, reportándose un valor de energía de activación menor que el encontrado en la literatura para el rango de temperaturas estudiado, lo cual puede deberse fundamentalmente al sistema de calentamiento empleado y el método analítico utilizado para la determinación del grado de desnaturalización.

Tabla 3. Parámetros cinéticos de desnaturalización de proteínas séricas.

T(°C)	*K (min^{-1})*	*R^2*	*K_{ref}*	*E_a (kJ/mol)*	*R^2*

100	0,5006	0,9829			

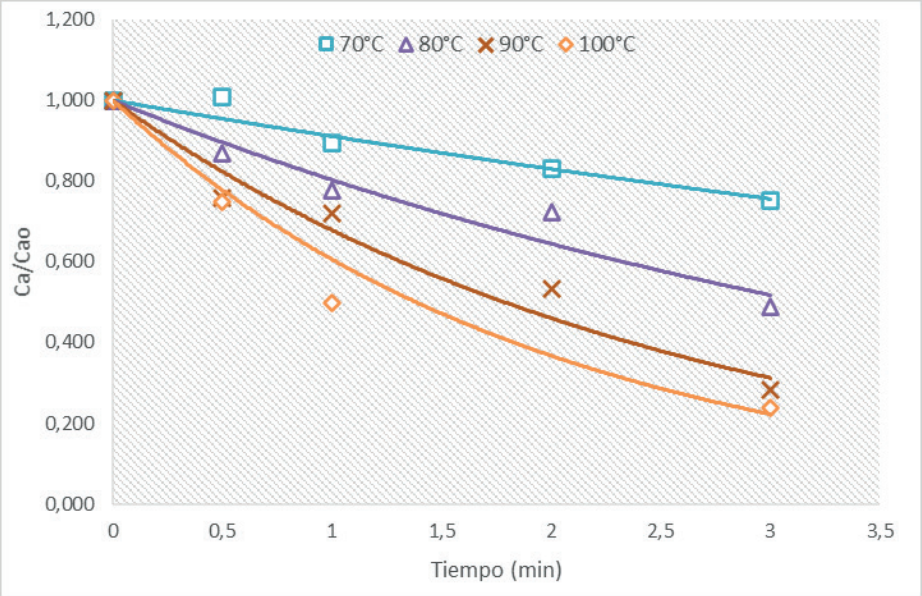

Fig. 4. Cinética de desnaturalización térmica de proteínas séricas en leche tratada térmicamente a diferentes temperaturas. Las líneas continuas corresponden al modelo ajustado de primer orden.

4 Conclusiones

Este trabajo tuvo como objetivo determinar la cinética de la degradación térmica de componentes nutricionales como la vitamina C y las proteínas séricas y de componentes sensoriales como el índice de pardeamiento y cambio de color. El modelo cinético de primer orden fue el más adecuado para las cinéticas analizadas, con excepción del cambio de color, el cual siguió una cinética de orden cero. Las variaciones de las constantes de velocidad con la temperatura fueron consistentes con la relación de Arrhenius. Al observar los resultados de los parámetros cinéticos, se puede concluir que las energías de activación revelaron que el índice de pardeamiento es el parámetro más sensible a los cambios de temperatura, mientras que los valores de las constantes de velocidad (K) mostraron que la desnaturalización térmica de proteínas séricas presentó la mayor velocidad de degradación en comparación con los demás parámetros estudiados. Los resultados obtenidos en este trabajo podrían ser útiles para optimizar el proceso de pasteurización de la leche, a fin de minimizar el pardeamiento y la pérdida de componentes nutricionales, a través de acoplar dichas cinéticas a modelos de transferencia de calor usando herramientas de simulación computacional

1 Introduction

Propolis is widely used in food and pharmaceutical industries because of their antioxidant and antimicrobial activity [1]. When the content of propolis wax is major than 40%, which is the maximum limit established by the Argentine legislation, raw propolis is considered as low quality and usually discarded [2]. However, propolis wax also has plenty of properties to be exploited in several fields of science and technology. Propolis wax exhibits similar composition and physicochemical properties to bee wax, is stable over time, solid at room temperature, insoluble in water, resistant to hydrolysis, and natural oxidization [3]. Due to its polyphenols content, about 2.4-5%, propolis wax also has antioxidant and antimicrobial activity [4].

Quercetin (3,3′,4′,5,7-pentahydroxyflavone) is a potent antioxidant flavonoid well known because of its health benefits as a neuroprotective, antioxidant, antiviral, anticancer agent, antihypertensive, vasodilator, anti-inflammatory, and anti-allergy [5]. Therefore, quercetin has been used as a nutritional supplement or added to food and beverages. However, the limitation of quercetin incorporation into foods is its degradation when it is exposed to high temperature, oxygen or light, and its poor solubility [6].

Lipid-based nanocarriers, such as nanostructured lipid carriers (NLCs) are solid lipid nanoparticles composed of a mixture of solid and liquid lipids, used as a nutritional supplement carrier in the food industry [7]. NLCs have the advantage to be loaded with hydrophilic or hydrophobic compounds with high loading capacity and a minimized expulsion during storage [8]. Thus, the incorporation into NLCs of poor water-soluble bioactive compounds such as oil-soluble vitamins, carotenoids or flavonoids, increases their stability and bioavailability in foods [9].

The uses of natural biomaterials were studied in the last years for lipid-based nanocarriers development. The aim of this work is to develop quercetin loaded NLCs from propolis wax residues, in order to improve the bioavailability and stability of quercetin into foods. Furthermore, it is worth mentioning that this add value to low quality propolis with high wax content.

2 Material and methods

Raw propolis samples were harvested from Río Negro province, Argentina. Propolis physicochemical characterization was carried out according to the Argentine regulation IRAM-INTA 15935-1: 2008 [2]. Propolis wax was extracted from propolis by Soxhlet extraction method using hexane as solvent. The traces of solvent remaining were removed with a nitrogen stream up to constant weight. The wax melting point and crystallization profile were determined by differential scanning calorimetry (DSC).

For NLCs preparation, the lipid phase was composed of propolis wax (PW) and as cosurfactant high oleic sunflower oil (SO) and soy lecithin (SL). Surfactant Tween 80 (T80) and ultra-pure water (W) were used for the aqueous phase composition. Quercetin (Q) was used for NLCs loaded. The proportions of the aqueous and lipid phase were previously optimized by a Simplex Lattice multicomponent mixtures experimental design. The optimized NLCs were synthetized in two successive steps. First, the lipid phase was prepared by melting 4.20% (w/w) PW, 1.80% (w/w) SO, 2.30% (w/w) SL and different Q proportions (from 8.5 to 200 mg) at 80 ± 5 °C. On the other hand, the aqueous phase was prepared with 6.20% (w/w) T80 and 85.5% (w/w) W at 80 ± 5 °C. The emulsion was performed by slowly dropped the aqueous phase on the lipid once, under constant stirring conditions at 500 rpm with a magnetic bar. Then, the pre-emulsion was obtained by homogenizing for 5 min at 10000 rpm and 80 ± 5 °C using a handheld homogenizer. The obtained pre-emulsion was ultrasonicated for 8 minutes with an ultrasonic homogenizer using a 12.7 mm diameter x 13.65 mm high titanium tip and 10.5 W dissipated ultrasonic power, keeping always the temperature above the wax melting point. Finally, the emulsion was rapidly immersed into an ice bath for 30 minutes to achieve NLCs formation.

The optimized NLCs were characterized by dynamic light scattering (DLS), transmission electron microscopy (TEM), and differential scanning calorimetry (DSC). NLCs entrapment efficiency (EE%) was calculated by determining the unencapsulated quercetin amount after a centrifugation step, using UV-Vis spectrometric [10]. The NLCs structure and stability were studied by multiple light scattering (MLS). Since emulsions were opaque, only the backscattering (BS) detector was used for data collection until 40 days approximately (≈1.000 hours).

The results were analyzed through a two-way ANOVA and LSD Fisher test and Bonferroni tests were used for comparison of means ($\alpha = 0.05$) with the statistical analysis software InfoStat (Version 2018, Grupo InfoStat, FCA, National University of Cordoba, Argentina).

3 Results and discussion

3.1 Raw propolis and propolis wax characterization

The physicochemical composition analysis of raw propolis is important in ordered to determine the quality of this material for industrial uses. The physicochemical requirements established by the Argentine Food Code (Código Alimentario Argentino – CAA) [11] and characterization results for raw propolis are shown in Table 1.

Table 1. Raw propolis characterization.

	* % (w/w)	Values accepted by CAA % (w/w)
Humidity	1.74 ± 0.04	Max 10.0
Wax	26.4 ± 2.82	Max 40.0
Resins	57.4 ± 2.51	Min 30.0
Ashes	2.05 ± 0.03	Max 5.0
Mechanical impurities	9.25 ± 0.39	Max 25.0

*Mean values ± confidence intervals are shown, n = 3.

The PW DSC thermograms presented transition temperatures from 34.9 to 63.7 °C and 60.0 to 38.8 °C, determined from the minima of the endothermic and exothermic transitions, respectively. The enthalpies were obtained by the integration of those using linear baselines. PW melting curve presents at least two composed chemicals, with a higher content on a melting peak at 61.3 °C and enthalpy of 121.5 J g^{-1}. Three crystallization peaks are presented with a maximum one at 59.0 °C and enthalpy of 117.2 J g^{-1}. The presence of several peaks is attributed to the complex composition and heterogeneity of the matrix. It was observed that changes between 40 to 60 °C were due to free acids, hydrocarbons, and fatty acid esters in waxes [12].

3.2 NLCs optimization synthesis

The ultrasound application time was selected based on the smallest particle size obtained. For this, the NLCs Z-average was studied after being exposed to 0, 2, 5, 8, and 10 minutes to the ultrasound probe action. As expected, an abrupt decrease in the NLCs particle size was observed. After 8 and 10 minutes, Z-average sizes were 131.0 ± 0.7 nm and 129.0 ± 2.7 nm, respectively. As there are no significant differences between both ultrasound application times, 8 min of treatment was selected in order to reduce synthesis time. Fisher's least significant difference (LSD) and Bonferroni tests were used for comparison of means ($P \leq 0.01$).

A simplex Lattice mixture experimental design was used to optimize aqueous and lipid phases proportion reagents [13]. Statistical experimental design methods are commonly used to achieve desired properties and establish the optimal proportions of ingredients in a mixture. The design study the interaction between factors and their effects over the response variable. The experimental domain was established selecting

a maximum and minimum value for each factor and setting the necessary restrictions. The levels for all variables were selected based on good results reported in the literature for wax NLCs synthesis [14]. In this work, restrictions were set for lipids proportion (PW and SO) from 6.0 to 10.0% (w/w) and surfactant phase (SL and T80) between 4.0 and 8.0% (w/w). The experimental design conditions for each variable are given in Table 2. A total of twenty-five experiments were carried out and NLCs particle size, determined by DLS, was used as a response. All of them were conducted randomly and the experimental data obtained were analyzed using ANOVA.

Table 2. Experimental design conditions

Level	Propolis wax	High-oleic sunflower oil	Tween 80	Soy lecithin	Water
Low (%)	3.0	1.8	2.9	0.8	83.4
High (%)	7.0	5.0	6.2	2.3	89.4

The fitted surface response obtained can be represented for the following equation:

$$Y\ (nm) = 80.64\ PW + \ 106.21\ SO - \ 77.38\ \ T80 - 92.86\ SL\ \ + 8.34\ W \quad (1)$$

According to eq. (1), the most significant effects were: propolis wax, high-oleic sunflower oil, and water percentages. Furthermore, increments in these parameters provide an increment of NLCs particle size, but an increase in surfactant and cosurfactant proportions cause a decrease in the analytical signal (as evidenced in eq. 1). The estimated model for mixtures is statistically significant, with a P-value < 0.01% and a coefficient of determination $R^2 = 0.952$, indicating a good fit. The NLCs obtained were in the size range between 40.7 ± 0.4 nm to 187.4 ± 1.7 nm. The optimum mixture parameters for smallest NLCs size were 4.20% (w/w) PW, 1.80% (w/w) SO, 6.20% (w/w) T80, 2.30% (w/w) SL and 85.5% (w/w) W.

3.3 NLCs characterization

The particle size of NLCs is considered as the mean hydrodynamic diameter (z-average), and the polydispersity index (PDI) represents the particle size population distribution. Free NLCs particle size was from 44.7 ± 1.3 nm and a PDI of 0.451 ± 0.013. For NLCs quercetin loaded (from 8.5 to 200 mg) size range was from 38.6 ± 0.1 to 77.2 ± 0.1 nm and PDI between 0.439 ± 0.003 and 0.623 ± 0.003. The TEM pictures of free NLCs and quercetin loaded dispersion synthetized under the optimal conditions are presented in Figure 1a). The images confirmed a particles size in the nano-range (~ 50nm), in concordance with the particle size measurements. Also, most NLCs particles appeared with a spherical shape. DSC analysis was used to characterize biological active agents loaded lipids nanocarriers. Also, the thermal analysis can provide detailed information on these loaded nanoparticles about their stability [15]. Figure 1b) shows the DSC thermograms of wax propolis and lyophilized free and 100 mg quercetin loaded NLCs formulation. The enthalpies were obtained by the integration of the

minima endothermic transitions using linear baselines. Developed NLCs presents a low ordered crystalline structure, due to the heterogeneous composition of propolis wax [16]. Free and loaded NLCs shows a broad shallow endothermic peak with a maximum at 61.1 °C and 60.7 °C, respectively. Enthalpy values were 41.7 J g^{-1} for free NLCs and 45.9 J g^{-1} for quercetin loaded NLCs.

For the optimized NLCs formulation loaded with quercetin between 8.5 and 200 mg, entrapment efficiency was from 82.6 to 99.1%, showing the best results when the amount of quercetin added was 150 mg. The use of a Turbiscan optical analyzer is a helpful tool to detect earlier than with naked eyes the instability phenomena. Fig. 2 shows the backscattering data values studied during 40 days of storage. The NLCs Q150 mg formulation resulted to have the lowest BS(%) variation and was considered to be the most stable one. Increments of BS(%) in the middle zone was associated with a particle size increase. Indeed, NLCs Q150 mg shows less than 5% of BS(%) increment during the first 5 days and then the signal was stable for at least the next 30 days.

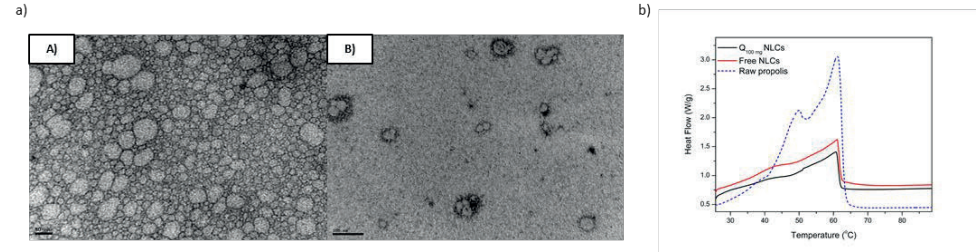

Fig. 1. a) TEM microphotograph of optimum A) free NLCs formulation and B) loaded with quercetin 100 mg and **b)** DSC thermograms of propolis wax, free and loaded NLCs.

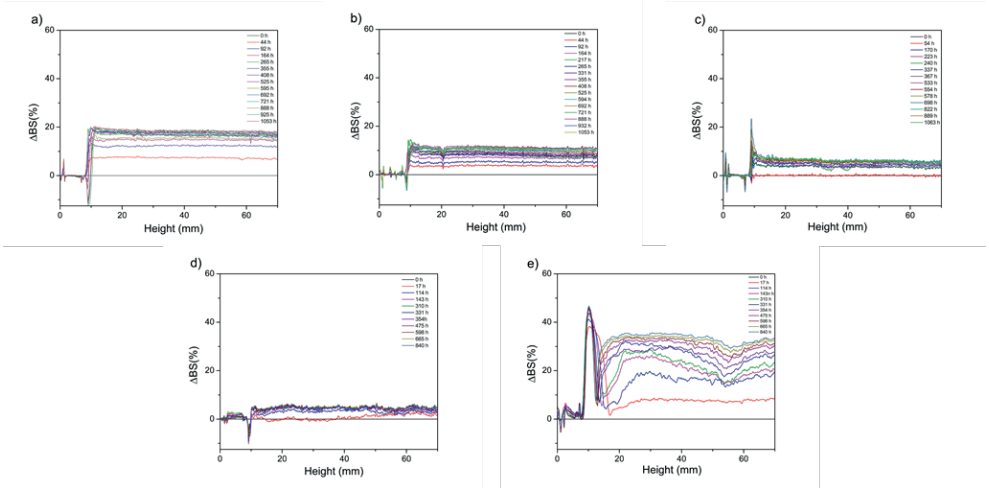

Fig. 2. Delta backscattering (ΔBS) profile as a function of cell height with storage time (samples were stored for 40 days) and photograph (2 h after preparation): **a)** Free NLCs, **b)** NLCs Q8.5mg, **c)** NLCs Q100mg, **d)** NLCs Q150mg and **e)** NLCs Q200mg.

4 Conclusion

The results confirmed that there is possible to obtain a stable NLCs quercetin loaded formulation using propolis wax residues. The reagent proportions in the aqueous and lipid phases were successfully optimized by a simplex lattice mixture experimental design. The optimum mixture parameters were 4.20% (w/w) PW, 1.80% (w/w) SO, 6.20% (w/w) T80, 2.30% (w/w) SL and 85.5% (w/w) W.

cpalla@plapiqui.edu.ar

Abstract. Mass fractal dimensions determined by microscopy and rheology were used to characterize the microstructure of oleogels emulsions prepared with recovered and commercial sunflower waxes as structuring agent. The emulsions were prepared using 2, 3.5, and 5% w/w wax in oleogel. Fractal dimension was related to macroscopic behaviors through analysis rheological and long-term kinetic stability of emulsions.

Keywords: Oleogel Emulsions, Sunflower Waxes, Fractal dimension, Rheology.

1 Introduction

Emulsions based on vegetable oil-wax oleogels have shown to be a promising alternative for replacing margarines and solid fats containing a high proportion of saturated and *trans* fatty acids (Hwang, Singh, Winkler-Moser, Bakota, & Liu, 2014; Merchán Sandoval, Carelli, Palla, & Baümler, 2020). Oleogels are systems in which liquid oil is structured into a three-dimensional network by adding one or more gelator molecules. In particular, the sunflower waxes have shown great efficiency to structure several edible oils using low concentrations (Hwang et al., 2014). They are obtained through the oil winterization process and subsequent purification stages. In this work, we are especially interested in elucidating the relationships between microstructure and macroscopic behavior of oleogel-based emulsions prepared using sunflower waxes recovered from filter cake from the winterization process with a simple hexane extraction procedure in comparison with those obtained using commercial sunflower waxes. Mass fractal dimensions determined by microscopy and rheology were used to quantify the microstructure of the studied systems since fractal dimension values are sensitive to the combined effects of crystal size, morphology, and the spatial distribution of mass within the fat crystal network (Tang & Marangoni, 2006). Furthermore, the rheological behavior of the emulsions and their long-term kinetic stability were analyzed.

2 Materials and Methods

2.1 Materials

High oleic sunflower oil (HOSO) was supplied by a local factory. Recovered sunflower waxes (RW) were obtained by processing filter cakes wastes from sunflower oil winterization, as it was described by Merchán et al. (Merchán Sandoval et al., 2020), and commercial sunflower waxes (CW) were provided by Koster Keunen Inc. LLC (Watertown, USA). All reagents were analytical grade unless otherwise stated. Soy lecithin powder, fat-free milk powder, and potassium sorbate were purchased from a local grocery store.

2.2 Preparation of oleogel emulsions

The oleogel emulsions were prepared through simultaneous oleogelation and emulsification from HOSO and waxes (CW or RW) -2, 3.5, and 5% w/w wax in oleogel- and an aqueous solution, following a procedure previously reported (Merchán Sandoval et al., 2020). The resulting emulsions were put into cylindrical containers and cooled at 5 °C for 24 h, allowing semisolid materials to be obtained. The emulsions were coded according to the type of wax and their concentration in the oleogel as CW2, CW3.5, CW5, RW2, RW3.5, and RW5.

2.3 Characterization of oleogel emulsions

Microstructural analysis from images. A small amount of oleogel emulsion sample was placed between a slide and a cover slide. After that, sample micrographs were obtained by a polarized light optical microscope (Carl Zeiss AG, Germany) with a 160x objective lens equipped with a digital camera.

The box-counting fractal dimension (Dbc) was determined following the methodology described by Palla et al. (Palla, de Vicente, Carrín, & Gálvez Ruiz, 2019), using FracLac plugin from ImageJ® software. Dbc was obtained as the average value from at least three processed images. The fractal dimension (D) was obtained as D=Dbc+1 (Palla et al., 2019).

Rheological analysis. Rheological measurements were conducted using a Paar Physica rheometer (Anton Paar GmbH, Austria) with a Peltier temperature control system. A parallel-plate geometry (50 mm) was used to analyze disk-shaped samples taken from the cylindrical containers. Oscillatory strain sweep tests from 0.01 to 100% at 10 rad/s were performed to determine the LVR. Frequency sweep tests were conducted from 1 to 100 rad/s at 20 °C (0.1% strain, 1.5 mm gap) to determine the storage (G') and loss (G'') moduli, and complex viscosity (η^*). Three replicates were performed.

Model Fitting. Experimental curves of viscoelastic properties (G' and η^*) obtained from frequency tests were fitted using a power law model (Palla, Giacomozzi, Genovese, & Carrín, 2017):

$$log\, G' = log\, G'_0 + m_{G'} \cdot log\, \omega \quad (1)$$
$$log\, \eta^* = log\, \eta^*_0 - m_{\eta^*} \cdot log\, \omega \quad (2)$$

Where, ω is the angular frequency and $log\, G'_0$, $m_{G'}$, $log\, \eta^*_0$, and m_{η^*} are constants to be determined experimentally.

Apparent yield stress (Y_s). The critical yield strain (γ_c) was obtained from strain tests as the onset value of the G' curves. This value was multiplied with the complex modulus value below γ_c to obtain Y_s (Cotabarren, Cruces, & Palla, 2019).

Fractal dimension based on the weak-link regime for colloidal dispersion. The macroscopic elastic constant of a network of particles is a function of both the spatial distribution of aggregating particles, characterized by the fractal dimension, and the mechanical properties of the particles which make up the network (Narine & Marangoni, 1999). This relationship can be described as:

$$G' = \gamma\, \Phi^m \quad (3)$$
$$m = 1/(3 - D) \quad (4)$$

Where m and γ are constants to be determined experimentally, Φ was assumed for oleogel systems equal to the gelator concentration, and D is the fractal dimension. G' value at 10 rad/s was used as a representative value. From the linearization of Eq. (3), the obtained slope m was used to find D.

Emulsion stability. 7 mL of each emulsion were dispensed into glass tubes to monitor their stability over time. The stability of oleogel emulsions was observed during 60 days at room temperature by a TurbiScan MA 2000 Analyzer (Formulaction, France), using only the backscattering (BS) detector for data collection due to the samples' opacity. A superimposition of sample fingerprints or "stability profile" was obtained, which characterized the stability or instability of the sample at different times. The parameters were represented by a curve showing the percentage of BS light (%BS) as a function of the height sample in mm (stability profiles). After obtaining the stability profiles of the emulsions, they were divided into three zones as follows: bottom, middle, and top of the tube, for analysis purposes.

Statistical Analysis. Values are mean ± standard deviation of the number of replicate measurements in one representative experiment of three independent experiments. Significant differences were analyzed using one-way ANOVA and Tuckey's test (α=0.05) for multiple comparisons. All analyses were done by IBM SPSS Statistics 25 software.

3 Results and Discussion

3.1 Microstructural analysis

Fractal geometry is a mathematical tool for describing complex shapes that cannot be expressed by the four topological dimensions in traditional Euclidean geometry (0-D for points, 1-D for straight lines, 2-D for planes, and 3-D for volumetric objects) (Schowengerdt, 2007). The D is an indicator of the spatial distribution of mass in a colloidal system, the higher the fractal dimension, the more uniformly filled space (smaller or fewer pores) (Blake, Co, & Marangoni, 2014).

In Fig. 1, the micrographs of two samples (RW2 and CW2) and their respective image analysis carried out by FracLac to obtain Dbc are shown as an example. As it can be seen, both oleogel emulsions exhibited needle-shaped crystals, but the crystals in CW2 were longer and more clustered than those of RW2. The same behavior was also found when the remaining samples (RW3 vs. CW3 and RW5 vs. CW5) were compared (data not shown). Table 1 reports the results of the 3D fractal dimension of all oleogel emulsions. RW emulsions showed D values higher than those obtained for CW emulsions, without significant differences among concentrations. On the contrary, CW emulsions showed an increase in D values with the increment of wax content. These results were in agreement with those previously reported for emulsion wax crystals sizes (Merchán Sandoval et al., 2020), corroborating the direct relationship between crystal size and mass distribution.

Table 1. Fractal dimension (D) and rheological parameters of the oleogel emulsions.

	D	$log\ G_0'$ (Pa)	$m_{G'}$ (Pa)	$log\ \eta_0^*$ (Pa.s)	m_{η^*} (Pa.s^2)	Y_s (Pa)
RW2	2.83±0.01^{D}	2.84±0.06^{A}	0.103±0.005^{AB}	2.85±0.06^{A}	0.89±0.00^{AB}	4.08±0.31^{A}
RW3.5	2.82±0.01^{D}	3.94±0.03^{C}	0.105±0.006^{AB}	3.96±0.03^{C}	0.89±0.01^{AB}	66.31±3.51^{B}
RW5	2.83±0.01^{D}	4.46±0.02^{D}	0.113±0.003^{B}	4.53±0.12^{D}	0.88±0.00^{A}	287.85±74.87^{C}
CW2	2.69±0.01^{A}	3.74±0.09^{B}	0.097±0.001^{A}	3.75±0.09^{B}	0.90±0.00^{B}	48.04±14.07^{B}
CW3.5	2.72±0.01^{B}	4.34±0.07^{D}	0.105±0.007^{AB}	4.36±0.07^{D}	0.90±0.00^{AB}	217.90±8.79^{C}
CW5	2.78±0.01^{C}	4.94±0.03^{E}	0.115±0.008^{B}	4.96±0.04^{E}	0.88±0.01^{A}	1498.87±274.42^{D}

Data are expressed as mean values ± standard deviation of three replicates. In each column, values with different letters are significantly different ($p < 0.05$).

3.2 Rheological analysis

From frequency sweep tests, elastic modulus (G') and complex viscosity (η^*) curves of all oleogel emulsions were obtained (Fig. 2a, b, c and d). For all samples, it was observed that G' showed a small dependence on frequency (ω), which indicated a strong gel-like behavior (Tavernier, Doan, Van der Meeren, Heyman, & Dewettinck, 2018). CW emulsions were found to have higher G' values than RW emulsions at the same amount of wax. Furthermore, G' showed a dependence of wax concentration for both

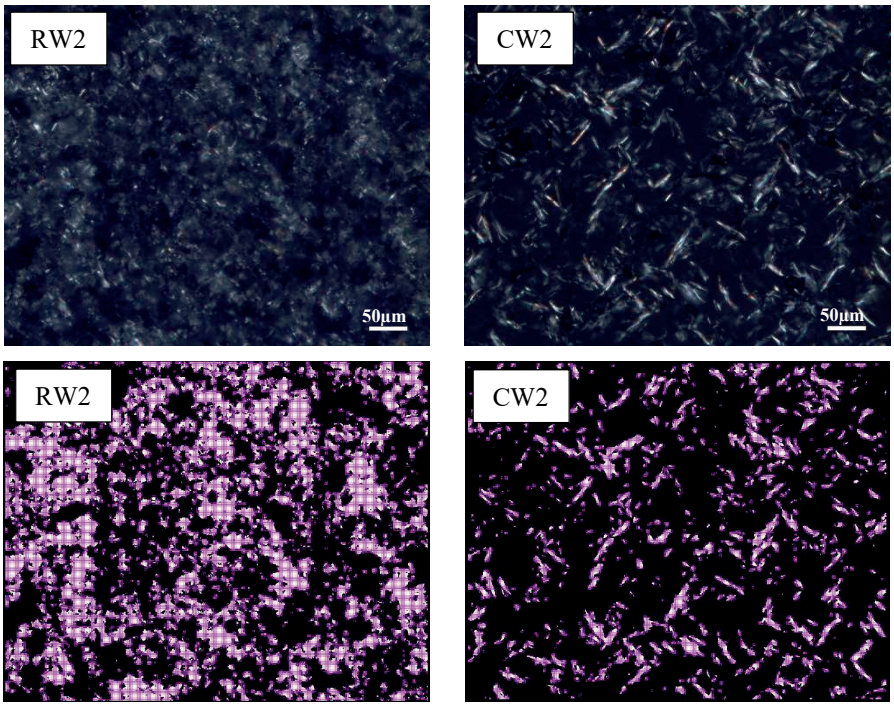

Fig. 1. Micrographs of oleogel emulsions formulated with 2% of recovered sunflower waxes (RW2) and commercial sunflower waxes (CW2). Original images (top) and processed image by FracLac using box-counting analysis (bottom)

oleogel emulsions, since higher wax contents displayed higher G' values. This behavior indicated that more elastic emulsions were obtained due to the presence of a greater amount of wax crystals.

Regarding to η^* behavior, it was observed that η^* values decreased as the frequency increased, showing a process of disaggregation of the wax clusters into smaller pieces (Patel, 2015). Similar to G', the η^* values of the CW emulsions were higher than those of the RW emulsions comparing the same wax content, and it was also observed that the η^* value increased as the amount of wax increased in both oleogel emulsions.

The G' and η^*curves of all oleogel emulsions were properly fitted by Eq. (1) and Eq. (2), respectively, since all the fits presented a high R^2 value (> 0.993). The values of the parameters for both models are given in Table 1. The parameter $log\ G'_0$, which is associated with G' magnitude, increased with the wax content for both CW and RW oleogel emulsions. Furthermore, CW emulsions presented higher $log\ G'_0$ values than RW emulsions for the same wax concentration. The parameter $m_{G'}$ was slightly higher as the wax content increased for both the RW and CW emulsions, but there was no difference between RW and CW for the same amount of wax. Related to $log\ \eta^*_0$, their values showed a similar behavior than those observed for $log\ G'_0$. However, the parameter m_{η^*} did not present a clear trend, which indicated that the frequency-dependence of η^* of all samples was similar.

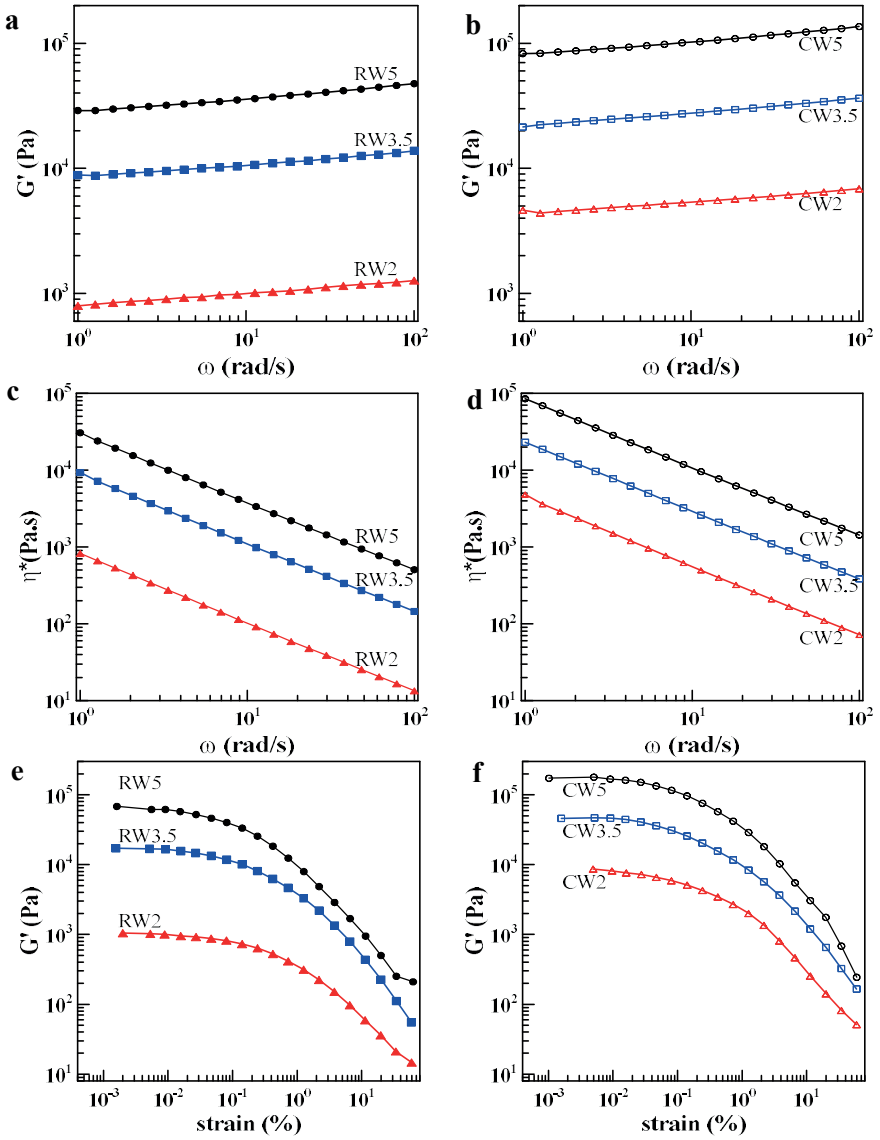

Fig. 2. Rheological behavior of oleogel emulsions formulated with recovered sunflower waxes (RW) (a, c and e) and commercial sunflower waxes (CW) (b, d and f) at 2%, 3.5%, and 5% w/w wax in oleogel. Elastic moduli (G') (a and b) and complex viscosity (η^*) (c and d) from frequency sweep tests and G' (e and f) from oscillatory strain sweep tests.

Oscillatory strain tests are used to evaluate the linear viscoelastic region of materials, and can also be employed to determine the apparent yield stress (Y_s) which can be related to spreadability and material stability (Cotabarren, Cruces, & Palla, 2019; Sun & Gunasekaran, 2009). The G' curves versus strain (%) of oleogel emulsions are displayed

in Fig. 2e and f. Similar to G' and η^* frequency curves, the G' strain curves of CW emulsions presented higher values than RW emulsions and also greater values as the wax content increases.

The Y_s is the point at which deformation of solid becomes liquid-like when stress increases (Truong, Prakash, & Bhandari, 2019) and is associated with the quality and consumer acceptance of spreadable foods (Daubert, Tkachuk, & Truong, 1998). As can be seen in Table 1, Y_s increased as the wax amount increased for both CW and RW oleogel emulsions. For the same wax content, the CW emulsions showed higher Y_s values. The Y_s value of CW5 was comparable to that reported for margarine at 19°C (1200 Pa ± 100 Pa) by Daubert et al. (Daubert et al., 1998) and are placed in the range of easy spreadability products.

The fractal dimension from the weak-link regime approach was determined from the regression slope (Fig. 3) as a unique value for each type of emulsion, being 2.76±0.01 and 2.68±0.02 for RW and CW emulsions, respectively. These results agreed with the trend found on D values from image analysis. The fact that RW emulsions with higher D values presented lower values of G', η^* and Y_s suggests that additional factors affected these properties, such as the presence of "impurities" (Merchán Sandoval et al., 2020) that could have weakened the structural network or the existence of a more disordered molecular arrangement with weaker crystal-crystal interactions.

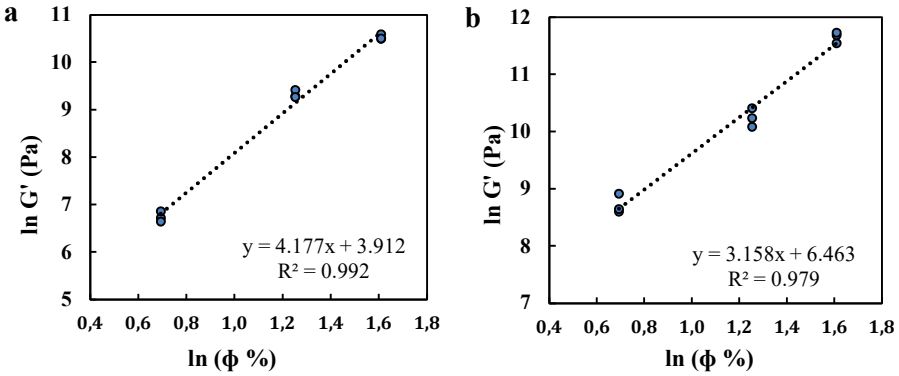

Fig. 3. ln G'as a function of gelator concentration (ln (ϕ %)) for oleogel emulsions formulated with recovered sunflower waxes (RW) (a) and commercial sunflower waxes (CW) (b). The dotted lines in both graphs represent the best fit line through the points, calculated by linear regression. The slope (m) was used to calculate D from Eq. 4.

3.3 Emulsion stability

The stability profiles were divided into three zones: bottom, middle, and top of the tube, for analysis purposes. Migration phenomena are related to the variation of BS in the bottom and the top zones, while particle size variations are related to BS changes in the middle region (McClements, 1999).

The destabilization kinetics of the top of the tubes are shown in Fig. 4a and Fig. 4b for RW and CW, respectively. The increment in the wax content for RW emulsions

caused more stable emulsions, with the destabilization rate being higher for RW2, compared to RW3.5 and RW5. For CW emulsions, it is possible to note that CW5 and CW2 showed curves with similar slopes, while CW3.5 emulsion was more stable showing a more constant profile on time.

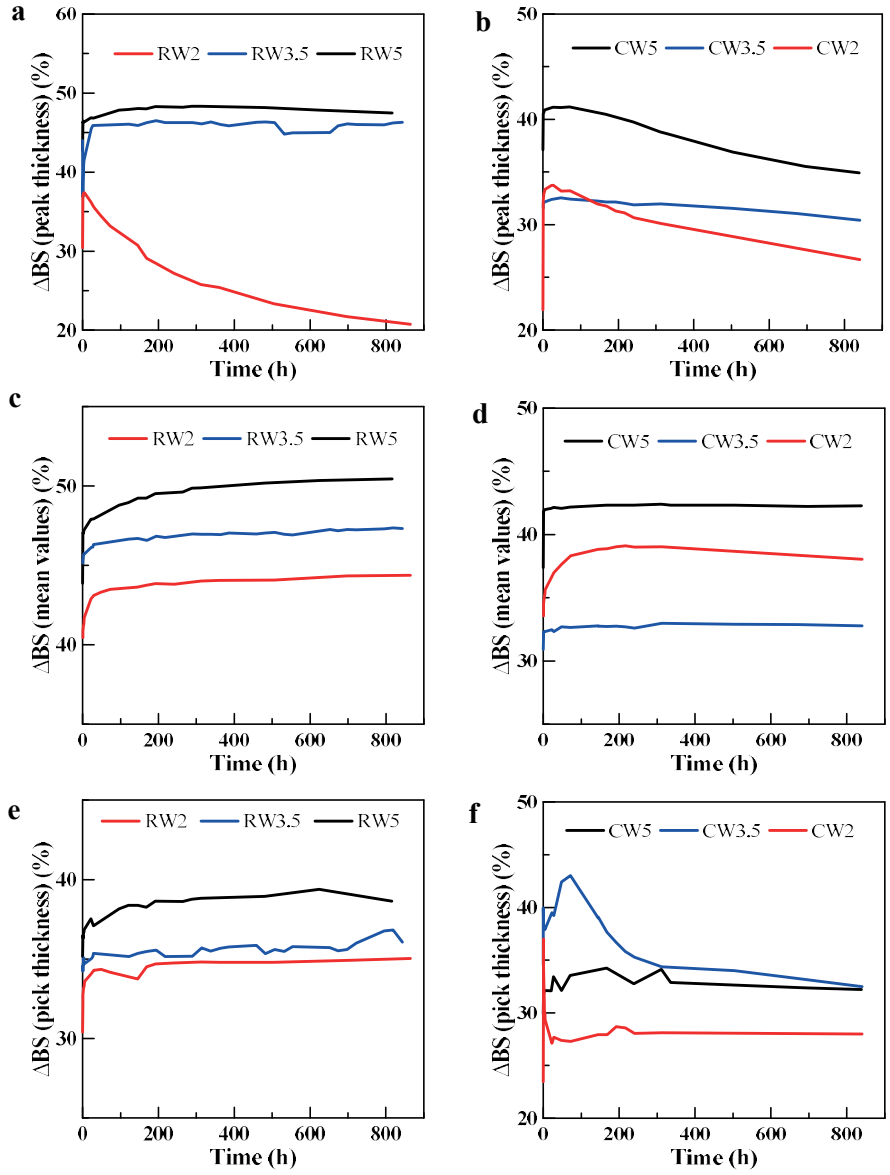

Fig. 4. Destabilization kinetics of oleogel emulsions formulated with recovered sunflower waxes (RW) (a, c and e) and commercial sunflower waxes (CW) (b, d and f) at 2%, 3.5%, and 5% w/w wax in oleogel. Top (a and b), middle (c and d), and bottom zone (e and f) of the tube.

The coalescence destabilization kinetics measured in the middle region for RW oleogel emulsions is shown in 4c. The slope of the curves is similar, indicating that the destabilization speed was not affected by the wax content. The same behavior was observed for CW emulsions (4d).

The destabilization kinetics of the bottom of the tubes are shown in Fig. 4e and Fig. 4f for RW and CW, respectively. For RW emulsions, the destabilization speed seems to be the same, despite the increase in wax content in the emulsion. CW emulsions exhibited similar behaviors, except for the CW3.5 emulsion with a destabilization rate decreasing after 250 hours (10 days) of measurements.

In general, the kinetic stability of both types of oleogel emulsions was not affected by the presence of a greater amount of microstructural elements and therefore, a relationship between D and kinetic stability was not found in the present study.

4 Conclusions

The fractal dimension of CW oleogel emulsions correlated well with the rheological behavior of emulsions. However, RW emulsions showed that besides D, other microstructural characteristics such as molecular arrangement and interactions should be evaluated to achieve a better understanding between micro- and macroscopic behavior. The kinetic stability of both types of oleogel emulsions was not affected by the presence of a greater amount of microstructural elements and therefore, a relationship between D and kinetic stability was not found in the present study.

Resumen El trabajo presenta un modelo matemático para simulación de un equipo Desolventizador-Tostador (DT), usado en la eliminación de solvente del producto sólido harina en la industria de producción de aceite y harina a partir de semillas de oleaginosas. El modelo considera el equipo dividido en tres zonas, en las que se plantean los balances microscópicos de masa y energía con parámetros geométricos, que son integrados en las bandejas que conforman cada una de las zonas. Estas son: Zona de Precalentado (ZPC), Zona de Desolventizado con Frente de Receso y Calentamiento (ZDFRC), y Zona de Desolventizado y Tostado (ZDT). Balances macroscópicos con datos de literatura son resueltos preliminarmente para inicializar las variables del sistema algebraico-diferencial riguroso de la simulación. El modelo fue implementado y resuelto en la plataforma R. Se presentan resultados de perfiles de concentraciones de solvente en las fases sólida y vapor, así como temperaturas en las diferentes zonas del equipo. El modelo predice coherentemente estos perfiles constituyendo una herramienta computacional útil para diseño y simulación operativa de un equipo DT industrial.

Palabras clave: desolventizador-tostador, modelado matemático, desolventización

1. Introducción

En la producción industrial de aceite y harina a partir de semillas de oleaginosas, luego del proceso de extracción del aceite mediante solvente, habitualmente hexano, la torta residual queda con un importante contenido de solvente. La eliminación del mismo se lleva a cabo en un equipo conocido como desolventizador-tostador (DT: Desolventizer-Toaster por su nombre en inglés). Esta etapa es una de las más críticas del proceso, no solo porque determina la calidad final de este

producto para su comercialización, sino porque representa uno de los principales ítems del costo operativo debido al alto consumo de vapor que implica. En esta etapa también se produce el tostado de la harina, que le confiere las características finales para su uso como alimento balanceado para animales.

El DT posee una serie de bandejas en las cuales la harina sólida saturada con hexano es calefaccionada indirectamente con vapor, y además puesta en contacto directo con el mismo a través de una corriente ascendente. El vapor permite calentar y vaporizar el solvente en el interior de las partículas sólidas y arrastrarlo para su eliminación del equipo. Operativamente la harina ingresa por tope y el vapor por fondo como vapor vivo y lateralmente a las bandejas huecas como vapor indirecto. La mezcla de vapor-hexano sale por tope y el sólido libre de solvente y con un proceso adicional de tostado por fondo. El sólido circula en forma descendente por el movimiento giratorio de las bandejas y el accionar de paletas que mueven la torta sólida y la pasan a la bandeja inmediata inferior [1].

Debido al elevado consumo energético de los equipos DTs, resulta de interés optimizar su operación para acotar los costos operativos de la planta. Esto ha originado el interés de la comunidad científica por abordar el problema. Sin embrago, si bien existen varios trabajos donde se describe el proceso de desolventización y los diferentes equipos existentes [1, 2], son relativamente pocos los que abordan el desarrollo de modelos matemáticos de simulación de equipos DTs de escala industrial.

Cardarelli y col. [3, 4], presentan un modelo del proceso controlado por difusión que ocurre en la sección de desorción del solvente absorbido en el sólido. En Pramparo y col. [5] se presenta un modelo de tipo semi-empírico, con parámetros estimados en base a datos de planta, en particular la relación entre el contenido de hexano en el vapor y la concentración de hexano en el sólido. Sobre la base del modelo matemático de un absorbedor presentado por Burningham y Otto [6], Paraíso y col. [7] desarrollaron un modelo de un desolventizador consistente en una columna con etapas donde se resuelven balances de masa y energía macroscópicos. Posteriormente Cauneto y col. [8] introdujeron varias actualizaciones a este modelo, permitiendo la incorporación de vapor directo en cualquiera de las etapas, considerando la condensación de agua en el sólido que desciende, empleando regresiones más precisas para el cálculo de propiedades termodinámicas, y obteniendo así un modelo más riguroso.

Sin embargo, estos modelos tienen algunas limitaciones. En el caso del de Cardarelli y col. [3, 4], no tiene en cuenta los balances de energía y solo se aplica a una parte de un equipo, aunque incorpora algunos parámetros geométricos de las unidades industriales, así como de las partículas de sólido y las isotermas de sorción. Por su parte los otros modelos de Paraíso y col. [7] y de Cauneto y col. [8] no tienen en cuenta las características geométricas del equipo industrial, ni las propiedades del sólido y los fenómenos de transporte. Por último, el modelo de Pramparo y col. [5] requiere de información de planta para ser utilizado.

Recientemente, Coletto y col. [9] presentaron un trabajo donde se adopta un enfoque más detallado de modelado, postulando la división del equipo industrial en cuatro zonas (precalentamiento, pre-desolventizado con frente de receso,

pre-solventizado con calentameinto y desolventizado-tostado), cada una con sus características particulares y con un modelo específico. El trabajo se basa en el de Cardarelli y col. [4] para la zona de desolventizado-tostado y presenta un nuevo modelo para la zona de precalentamiento, permitiendo tener predicciones coherentes del perfil de contenido de hexano en el sólido a medida que éste pasa por las zonas modeladas del equipo.

En este trabajo se presenta un modelo mejorado del de Coletto y col. [9], incorporando mayor detalle en diferentes secciones, con el objetivo de obtener una herramienta matemática que permita simular y optimizar el equipo para asistir en el diseño y operación del mismo.

2. Métodos

Al igual que el modelo propuesto anteriormente [9], el DT ha sido subdividido en zonas acorde a los fenómenos que ocurren a lo largo del equipo. Sin embargo, como se muestra en la Fig. 1, el mismo ha sido dividido en tres zonas en vez de cuatro: Zona de Precalentado (ZPC), Zona de Desolventizado con Frente de Receso y Calentamiento (ZDFRC), y Zona de Desolventizado y Tostado (ZDT). En este nuevo modelo dos zonas del modelo anterior han sido unificadas en la ZDFRC debido a que ha sido posible aplicar el mismo modelo a ambas.

El sólido ingresa por la ZPC la cual abarca las tres primeras bandejas o "pisos" del equipo para el caso aquí considerado. La ZDFRC está contenida en un pequeño segmento de la cuarta bandeja, es decir, es el ingreso a la primer bandeja en contra-corriente descrita por Kemper[1], donde tienen lugar diversos fenómenos en simultáneo, como condensación del agua contenida en el vapor ascendente, evaporación del hexano contenido en el sólido, y consecuente disminución en la temperatura de rocío del vapor.

En el sólido la evaporación de hexano ha sido descrita mediante el modelo de Frente de Receso, el cual postula que a medida que disminuye el contenido de solvente por debajo de la saturación líquida de poros, comienza a crecer una capa "seca de solvente", generándose una resistencia conductiva a la transferencia de calor [10, 11]. Así, el sólido está separado en dos partes: una seca y una húmeda, y el solvente está en equilibrio en la interfase. La evaporación ocurre en el frente móvil que avanza hacia el interior de la partícula utilizando toda la energía proveniente del medio externo para la evaporación. Consecuentemente, los perfiles de temperatura y humedad pueden ser despreciados en la región húmeda, y la temperatura del sólido húmedo en hexano puede ser considerada prácticamente constante e igual a la de ebullición. Al llegar a la concentración de hexano de equilibrio (sin líquido en los poros de las partículas), el sólido empieza a aumentar su temperatura hasta llegar a igualar aproximadamente a la del vapor ascendente donde es considerado el fin de la ZDFRC. Durante este proceso, el contenido de hexano va disminuyendo por desplazamiento de su isoterma de sorción.

Finalmente, la parte restante de la cuarta bandeja, y las bandejas sucesivas son consideradas dentro de la ZDT. En dicha zona, a medida que disminuye el

contenido de hexano en el vapor dentro de los poros del sólido, se desplaza el equilibrio de sorción y absorción en el sólido y el aceite, respectivamente. Para este caso ha sido aplicado un sub-modelo doble-escala similar al de Cardarelli, realizando además el balance de energía para ambas escalas.

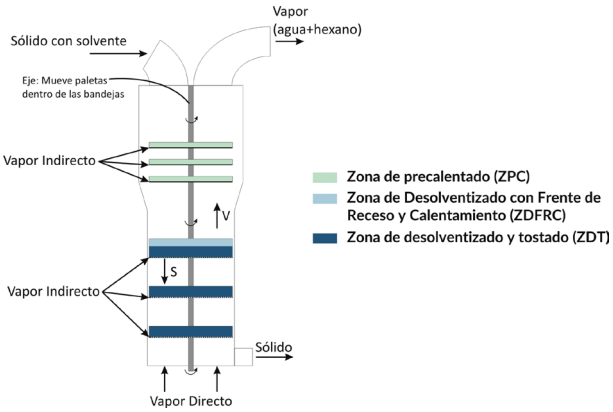

Figura 1. División en zonas para el modelado matemático.

2.1. Zona de Precalentado (ZPC)

En la ZPC la única fuente de energía es el calor indirecto proveniente desde el fondo de cada bandeja, mientras que el vapor ascendente proveniente desde la cuarta bandeja circula por el espacio lateral circundando a las mismas. En esta zona, el sólido llega a la temperatura de ebullición del hexano, pudiendo empezar a evaporarse e integrándose a la corriente de vapor ascendente. En el modelo de la ZPC cada bandeja es discretizada en n_z celdas, suponiendo una distribución uniforme del sólido y sus propiedades, y que cada celda recibirá la misma cantidad de calor volumétrico (calor indirecto dividido volumen de sólido en la bandeja). Dado que no hay vapor ascendente en los espacios interpartícula proveniente del resto del equipo, el único vapor que eventualmente puede haber es de hexano evaporándose. Así, a los efectos de los balances de materia y energía, la harina es contemplada como una mezcla uniforme, y son tomados valores medios de mezcla para el cálculo de sus propiedades termofísicas.

De este modo, los balances microscópicos de materia y energía son integrados al volumen de las celdas,teniendo en cuenta no solo el calentamiento sino también la posibilidad de inicio de la evaporación en los respectivos términos surgentes. De modo similar, también son resueltos los balances de materia y energía en el vapor circundante. La Figura 2 describe el procedimiento aplicado en la resolución del modelo de esta zona.

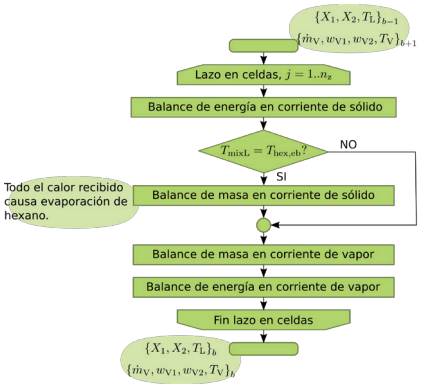

Figura 2. Algoritmo de resolución del modelo de ZPC.

2.2. Zona de Desolventizado con Frente de Receso y Calentamiento (ZDFRC)

Acorde a información de literatura sobre el intercambio de calor y materia en la primer bandeja de contracorriente y curvas de equilibrio de fases del sistema agua-hexano [1] [13], el paso del vapor ascendente es aquí subdividido en dos estadíos; uno de vapor sobrecalentado (V-SCAL) y otro de vapor saturado (V-SAT), siguiendo así el comportamiento de equilibrio vapor/líquido/líquido (EVLL) característico de esta mezcla.

El contenido de hexano de equilibrio a la temperatura de salida en el sólido es estimado suponiendo que la temperatura del sólido a la salida de esta zona es aproximadamente igual a la del vapor ascendente que ingresa a la misma (condición de borde inferior). Además, la cantidad de hexano total que es removido en esta zona es fácilmente calculado conociendo la temperatura y contenido de hexano del sólido al ingreso de la ZDFRC (condición de borde superior), la cual será el hexano total que recibirá la corriente de vapor ascendente en la ZDFRC. La zona es discretizada en celdas en la coordenada axial, y los balances de materia y energía microscópicos son integrados en el volumen de las celdas, suponiendo que en cada celda es removida la misma cantidad de hexano, y despreciando eventual transferencia de agua desde el sólido hacia el vapor. El término surgente para el balance de materia queda conformado únicamente por el intercambio de hexano entre corrientes. En el V-SCAL es tenido únicamente en cuenta el intercambio de calor convectivo en el balance de energía, y a partir del punto en que la composición y temperatura del vapor son los de rocío, es sumada la condensación de agua a todos los balances. La Figura 3 resume el algoritmo de cálculo empleado para la resolución del modelo de esta zona.

2.3. Zona de Desolventizado y Tostado (ZDT)

La harina es considerada como un lecho móvil descendente de partículas que se encuentra con vapor ascendente, y donde ambas corrientes cambian su

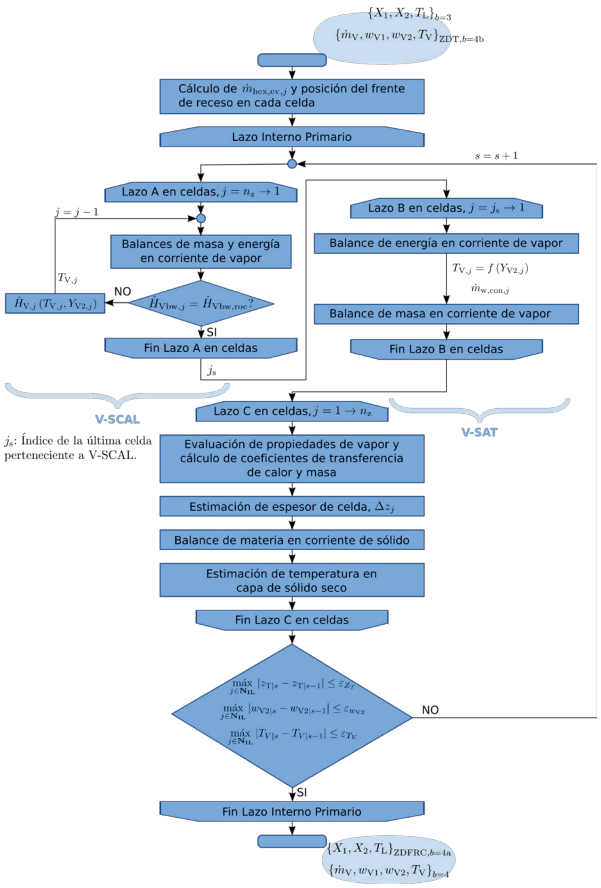

Figura 3. Algoritmo de resolución del modelo de ZFFRC.

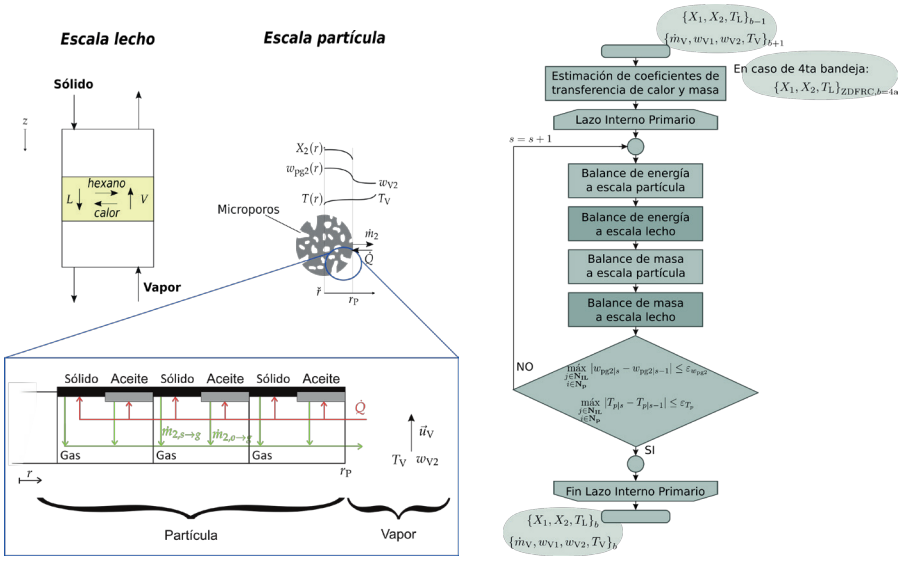
composición y temperatura a medida que se desplazan dentro del equipo. En la "escala partícula" los balances de materia y energía determinan el transporte de calor y materia dentro de las partículas individuales, mientras que a "escala lecho" los balances de materia y energía son resueltos para obtener la interacción entre el sólido y el vapor.

La escala partícula tiene en cuenta las fases sólido (s), aceite (o), y gas (g), y supone despreciables los gradientes de temperatura y hexano en las direcciones polar y aximutal. Consecuentemente, el hexano de la fase gas se encuentra distribuido únicamente en la dirección radial dentro de los microporos de manera desuniforme, mientras que la temperatura es idéntica para todas las fases, presentando solamente un perfil de distribución radial. El solvente de la fase gas, a su vez, se encuentra en equilibrio localmente en cada punto de la partícula con el hexano adsorbido en la fase sólida y absorbido en la fase aceite. En cuanto al intercambio de materia y energía, el calor es transferido desde la corriente de

vapor ascendente por convección a la superficie de la partícula, y conducido al centro, mientras el camino opuesto es seguido por el hexano, el cual es transportado difusivamente hacia la superficie y convectivamente transportado por la corriente de vapor ascendente (Figura 4(a)).



Por otro lado, a escala lecho son despreciados los gradientes radiales y angulares de hexano y temperatura, considerando únicamente la dirección axial. Además, dado que las propiedades del sólido varían únicamente en la dirección axial, se supone que una única partícula representa a todas las presentes a una dada altura del lecho. Así, las propiedades del sólido descendente, tales como temperatura y contenido de hexano, son evaluadas calculando una media volumétrica de los valores obtenidos de la resolución de los balances de materia y energía a escala partícula.

Otras suposiciones realizadas en el modelo de la ZDT son: el proceso es realizado a presión atmosférica con caída de presión despreciable en el equipo; la cantidad de hexano agregado a la corriente ascendente es muy baja, con lo cual es despreciada la variación de densidad del vapor; el contenido de solvente de una única partícula depende del tiempo de residencia o, en otras palabras, de su posición en el lecho. Por lo tanto, el modelo puede ser resuelto como transitorio a escala partícula y de estado estacionario a escala lecho, relacionando ambas escalas con la velocidad del sólido [3, 4]; tanto las fracciones volumétricas de vapor y sólido a escala lecho como las fracciones volumétricas ocupadas por las tres fases a escala partícula son constantes en todo el equipo. En la Figura 4(b) es representado el algoritmo general empleado en la resolución de los distintos balances en la ZDT.

2.4. Algoritmo general de cálculo

En términos generales, dado que el modelo para cada zona requiere condiciones de contorno, las cuales son a su vez las de la zona o bandeja precedente, el simulador es inicializado mediante un balance macroscópico con estimaciones de literatura alrededor de cada zona. Luego los valores de temperaturas y composiciones del sólido y el vapor son interpolados en función de la altura en el equipo para cada bandeja y cada zona (como el caso de la ZDFRC) y los balances en cada bandeja son resueltos de manera modular desde arriba hacia abajo. En el caso de la cuarta bandeja, es resuelto el modelo de la ZDFRC primero, y luego el correspondiente a la ZDT. Esta secuencia se va repitiendo de manera iterativa hasta llegar a convergencia en los valores de temperaturas y composición tanto de la corriente de vapor ascendente como en la de sólido descendente como se muestra en la Figura 5.

En la Tabla 1 son mostrados los valores típicos de entradas al equipo, tanto en composición como caudales, utilizados en el presente trabajo. En cuanto al las características físicas, fue supuesto un equipo de seis bandejas (tres de precalentamiento y 3 de contra-corriente) de 4 m de diámetro cada una. El espesor ocupado por el sólido las bandejas fue de 30 cm para las primeras tres, de 1 m para la cuarta bandeja (contando desde arriba), y de 60 cm para las dos últimas.

(b) Algoritmo de resolución del modelo de ZDT.

Figura 4. Diagramas del modelo de la ZDT.

En cuanto a las propiedades físicas del sólido e isotermas de sorción fueron utilizados los valores reportados por Cardarelli [3, 4] y Faner [11].

Tabla 1. Valores típicos, utilizados en la simulación.

	Sólido (tope)	Vapor directo (fondo)	Vapor Indirecto
Caudal másico [kg/h]	70.000	8.500	2.500
Temperatura [°C]	58	142	180
		Fracciones en masa	
Agua	0,0900	1,0000	1,0000
Hexano	0,2900	0,0000	0,0000
Aceite	0,0085	-	-
Sólido seco	0,6115	-	-

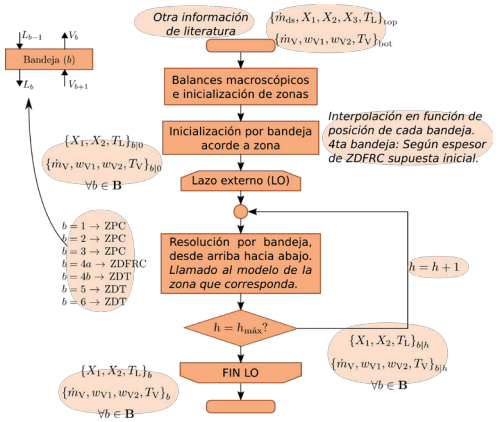

Figura 5. Algoritmo general de cálculo para modelado del desolventizador.

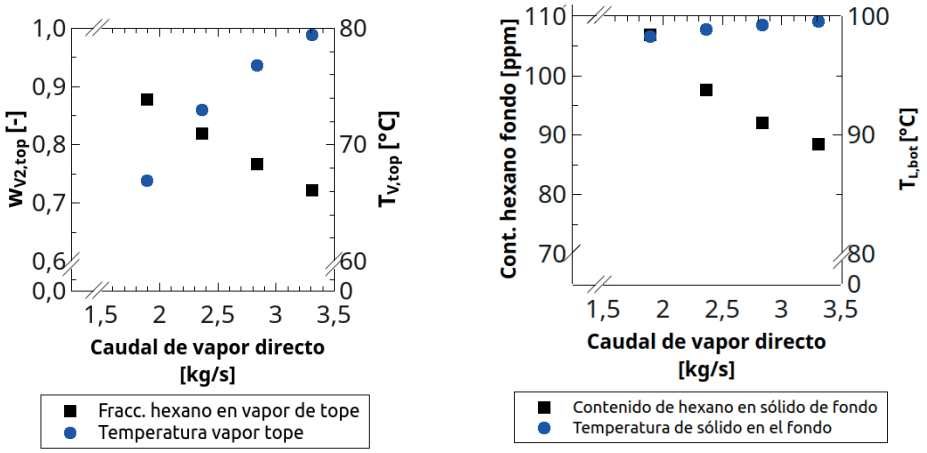
3. Resultados y Discusión

3.1. Simulación global



En las Figuras 6(a) y 6(b) son mostrados las temperaturas y contenido de hexano para la salida de la corriente de vapor y de sólido, para variaciones del caudal másico de vapor directo en un rango de ±40 % de un valor típico (2,36 kg/s). Los puntos para 1,42 kg/s (-40 %) no son mostrados dado que en este caso la temperatura del vapor queda por debajo de la temperatura de condensación del hexano y el simulador fue programado para cortar el cálculo en ese caso.

Como podría esperarse, puede notarse que a medida que aumenta la cantidad de vapor directo que ingresa al equipo, las temperaturas de salida tanto del sólido como del vapor aumentan, mientras que el contenido de hexano en ambas disminuye. Sin embargo, se esperaría que la temperatura del sólido a la salida fuera entre 5 y 10°C más. Esta diferencia puede explicarse principalmente teniendo en cuenta las simplificaciones realizadas en el actual modelo de la ZDFRC, donde los efectos de transferencia de calor y materia sobre el sólido son tenidos en cuenta de manera parcial, tomando principalmente lo que ocurre en la corriente de vapor, situación que será resuelta en un nuevo modelo.

Por otro lado, los valores de temperatura de salida del vapor son coincidentes con valores típicos reportados en literatura para el DT descrito [1] [5].

3.2. Zona de Precalentado (ZPC)

En la Figura 7 son mostrados los perfiles de temperatura y contenido de hexano en las tres bandejas de precalentado consideradas. Puede notarse que la evaporación de hexano comienza a fines de la segunda bandeja y avanza en la tercera. Además puede notarse que el comportamiento predicho por el modelo es coherente con lo esperable. Esto es, mientras el sólido se calienta, su concentración de hexano permanece constante, para luego empezar a disminuir cuando su

(a) Salida de la corriente de vapor (tope). (b) Salida de la corriente de sólido (fondo).

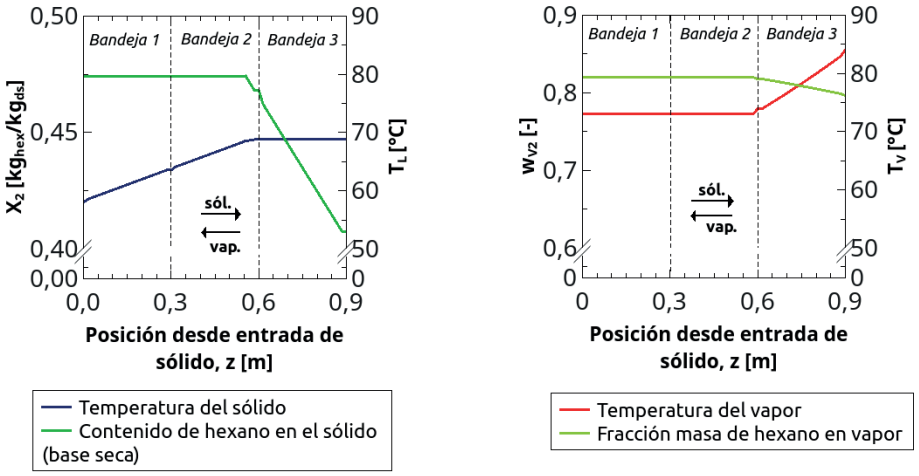


Figura 6. Efectos de la variación del caudal de vapor directo

temperatura alcanza los 68°C (Figura 7(a)). En cuanto al vapor (Figura 7(b)), puede notarse que la fracción en masa de hexano en el vapor en la Bandeja 3 aumenta mientras su temperatura disminuye como producto de la incorporación de hexano vapor a 68°C. Luego, en las Bandejas 1 y 2 mientras continua ascendiendo, estos valores permanecen constantes mientras se produce el aumento de temperatura del sólido. Por otro lado, al final de la ZPC (o última bandeja de predesolventización) el contenido de hexano se ha reducido en un 15 %, en línea con los valores esperables de literatura (10-25 %) [1].

3.3. Zona de Desolventizado con Frente de Receso y Calentamiento (ZDFRC)

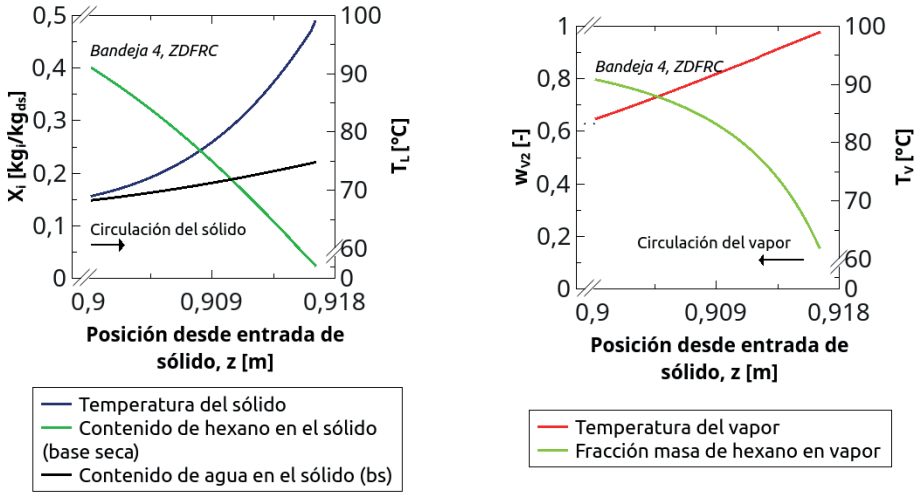
El espesor total de la ZDFRC predicho por el modelo ha resultado de aproximadamente 1,6 cm. Debido la falta de información experimental al respecto, y a que este valor además sería sumamente difícil de medir en un equipo industrial, no puede conocerse si el valor real será mayor o menor al calculado. Sin embargo, teniendo en cuenta que debido a la condensación de vapor de agua sobre la superficie expuesta de las partículas, la evaporación del hexano se producirá de manera violenta y abrupta [4, 12], sería esperable que el espesor de la ZDFRC sea sumamente pequeño con respecto a la altura total del material que ocupa la primer bandeja de contra-corriente.

Por otro lado, en la Figura 8(a) puede notarse que en esta zona se produce una reducción de aproximadamente un 94 % del hexano con respecto al ingreso a la misma (lo cual representa una reducción de un 95 % con respecto a la entrada al equipo). Además, teniendo en cuenta que el contenido de aceite en el sólido utilizado en la simulación es de 0,0139 $kg_{aceite}/kg_{s.seco}$, el contenido de humedad

(a) Corriente de sólido.

(b) Corriente de vapor.

Figura 7. Perfiles de contenido de hexano y temperatura en las bandejas de la ZPC.



se incrementa de 9 % a 17,5 % en peso. Todo ello se encuentra en concordancia con los valores esperables según literatura especializada.

En cuanto a la temperatura de salida del sólido y de ingreso del vapor a la ZDFRC (Figuras 8(a) y 8(b)), los valores típicos rondan entre 100 y 110°C. Sin embargo, los valores aquí predichos se encuentran por debajo de los 100°C, lo cual es atribuido a los valores estimados por le modelo de la ZDT. En dicho modelo, se supone que parte del calor indirecto pasa al vapor (al atravesar los orificios de la bandeja), y parte pasa al sólido transmitido por conducción en un lecho mixto sólido-vapor, y luego es contemplado dentro del término surgente en el balance de energía a escala partícula. Sin embargo, la parte de calor que va al sólido es estimando mediante el cálculo de un calor conductivo axial por diferencia de temperatura, y calculando la fracción que va al vapor como la diferencia entre el calor indirecto total y dicho valor. Debido a que la diferencia de temperatura entre capas de sólido es prácticamente despreciable, el calor conductivo axial estimado mediante este método puede resultar subestimado.

Como consecuencia de lo anterior, también puede notarse en la Figura 8(b) que no hay estadío V-SCAL para el vapor, ingresando directamente en V-SAT.

3.4. Zona de Desolventizado y Tostado (ZDT)

Como puede notarse en la Figura 9(a), la desolventización en las bandejas pertenecientes a la ZDT avanza mucho más lento debido al control difusivo dentro de las particulas de sólido, a medida que el vapor se va cargando de hexano. El sólido ingresa a la ZDT de la cuarta bandeja con alrededor de 20.000 ppm de hexano, y sale de la ZDT de la última bandeja con alrededor de 100

(a) Corriente de sólido.

(b) Corriente de vapor.

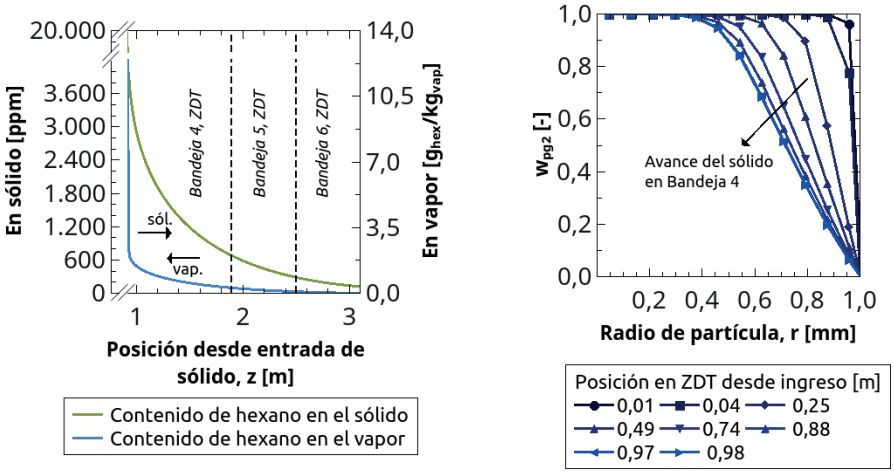


Figura 8. Perfiles de contenido de hexano y temperatura en las bandejas de la ZDFRC.

ppm, valor que se encuentra dentro de los rangos reportados en la literatura. En cuanto al perfil de temperaturas (no mostrado), se mantiene aproximadamente constante a lo largo de las bandejas en donde se encuentra la ZDT. Por las razones antes expuestas, el modelo actual no puede predecir mayores variaciones en la temperatura del sólido.

Por otra parte, en la Figura 9(b) es mostrado el perfil de fracción en masa de hexano dentro de la fase gas de cada partícula, para distintas posiciones del sólido en la cuarta bandeja. Puede notarse que, a medida que el sólido desciende, el contenido de hexano en la fase gas va disminuyendo, resultando en los típicos perfiles de transferencia de materia controlada por difusión (simimilares a los obtenidos por Mattea [12]). Además, estos valores se encuentran en relación directa con el contenido total de hexano en la partícula mediante su relación de equilibrio de adsorción en el sólido y absorción en el aceite.

4. Conclusiones

Se propone una versión rigurosa de un modelo matematico de un DT industrial que posee mayor nivel de detalle que otras publicadas previamente. La división en zonas, donde cada una tiene su propio modelo (que actúa de submodelo del cálculo global), permite describir matemáticamente a cada zona con las ecuaciones que gobiernan los fenómenos que allí ocurren teniendo en cuenta fenómenos de equilibrio termodinámico en la corriente de vapor, adsorción y absorción de hexano en las fases sólida y aceite, y descripción completa del fenómeno difusivo en la última etapa del proceso. Además, si bien no se cuenta

(b) Perfil de fracción en masa de hexano dentro de la fase gas de la partícula para distintas posiciones de la parte ZDT de la cuarta bandeja.

Figura 9. Perfiles de contenido de hexano en la ZDT (bandejas y partícula).

con una completa y detallada información de planta del desolventizador, el modelo integrado arroja resultados dentro de los valores esperables reportados en la literatura.

Por otro lado, se está trabajando en la actualidad en el mejorado del modelo de la ZDFRC con el objetivo de describir mejor el intercambio de energía y, de este modo, mejorar la predicción de la estimación de la temperatura del sólido.

Con todo ello, un modelo riguroso completo permitirá en un futuro, además de simular el funcionamiento del equipo, obtener las condiciones óptimas de entrada al mismo que permitan minimizar el consumo de energía.

Abstract. A major challenge in the physical distribution of Cold Chain products is ensuring product quality while minimizing process costs. In this context, this study seeks to propose a routing model with restrictions by the Clarke and Wright method that considers the behavior of the temperature variation of refrigerated loads during their physical distribution and to compare it with the results obtained through the Nearest Neighbor method. The objective of the study is to propose a simulation tool that is capable of planning routes for the physical distribution of refrigerated products, making the entire logistics process more efficient, reducing the unwanted gain of internal temperature of the vehicle and the product, considering the time windows available, number of vehicles and available capacity. Five scenarios in total were compared and, as a result, the Clarke and Wright method with temperature restriction proved to be more effective for routing within the imposed temperature limits and aiming at savings in the number of vehicles and distance traveled.

Keywords: Cold Chain; Routing; Transport; Cooling.

1 Introduction

The increase in the world population and the usual rush of large cities lead to the consumption of more chilled and frozen foods. Among its advantages are ease and agility in preparation, preservation of sensory, physical and organoleptic properties, increased validity and high quality of products (CARVALHO, 2013). This type of supply chain, known as the cold chain, is defined by Heap (2006) as a chain in which a controlled temperature environment is required to guarantee the integrity of the product handled, from production to the final consumer.

Carvalho (2013) explains that temperature determines the rate of microbial activity in cold chain products, the main cause of the deterioration of this type of food, which can lead to loss of product quality. Another important factor concerns its physical distribution. The distance traveled directly impacts the temperature to which the product

is subjected, as well as its unloading conditions. It is also important to note that the vehicle's cooling is not designed to cool the load, but to preserve it within the proper limits.

Thus, the objective of this article is to propose a model aimed at routing vehicles with restrictions, considering the thermal performance of the transported cargo, distance traveled, window of available time and necessary fleet.

2 Literature review

Dias (2012) defines logistics as the part of the supply chain that plans, programs and controls efficiency, the flow of storage of goods, services and information between the point of origin and consumption. It also defines the supply chain as the union of suppliers with manufacturers, distributors, wholesalers and customers. Therefore, logistics is essential for connecting the supply chain.

The activities of transportation, inventory maintenance and order processing, according to Ballou (2006), represent the largest portions in terms of logistics costs and are essential for the coordination and fulfillment of the logistics task, being a constant concern. Wanke (2011) complements by defining distribution as the development of a system that covers all activities, from the production line to delivery.

2.1 Physical distribution of Cold Supply Chain products

Annually about 300 million tons of products in the cold chain are lost due to a deficient refrigeration process along the supply chain, most of which occurs in the transport process, due to temperature fluctuation (CARVALHO, 2013). Heap (2006) points out that the lack of control of microbiological reactions can lead to cumulative and irreversible losses in product quality.

Pereira et al. (2010) presents as parameters inherent to the process that cause thermal variation: opening of doors, gain of thermal gradient of the external environment, non-uniformity of temperature inside the vehicle and number of stops, in addition to the distance between production and consumption. In the case of long distances, even when transport provides satisfactory temperatures, the travel time can be long for short expiration dates. On the other hand, for shorter deliveries, the refrigerated or frozen product may be subject to many door openings, with heat exchange with the outside air, in addition to the heat acquired by the movement of the operators responsible for removing and delivering the products (PEREIRA et al., 2010).

Another critical point highlighted by Pereira et al. (2010) is that the goods must be shipped with the temperature within the prescribed range, since the vehicle's refrigeration unit is not designed to cool it, but rather to preserve it within the appropriate standards. Therefore, the vehicle must be pre-cooled before loading.

2.2 Routing with restrictions

According to Gama (2011), the physical distribution system has as an element the routing of delivery vehicles, with the objective of obtaining routes that minimize

distribution costs of a fleet of vehicles from one or more central depots, supplying the entire demand. Novaes (2016) indicates that one of the biggest problems in the physical distribution of products is related to the time limits or capacity of the vehicle.

The traveling salesman problem is one of the most classic problems and consists of finding a route of minimum length, starting from a given starting place, visiting a set of points in the best possible order, and returning to the place of origin, using it for that, only the existing paths that connect these points (SANTOS, 2006). Because they are difficult to solve problems, it is common to use heuristic methods (such as the Clarke and Wright method and the Nearest Neighbor method), achieving good results in less time.

Clarke and Wright method. According to Santos and Leal (2007), one of the most used heuristics to solve the VRP problem is the Clarke and Wright algorithm. This method has the flexibility to solve a large number of restrictions relatively quickly in computational terms, generating solutions close to optimality (BALLOU, 2006).

As detailed by Novaes (2016), the method is based on the concept of gain and starts with the worst situation, where each vehicle leaves the distribution center (DC) and serves only one customer before returning. Considering that a customer *j* is served after a customer *i*, the vehicle would travel a distance L of:

$$L = 2 \times d_{D,i} + 2 \times d_{D,j} \qquad (1)$$

From the initial situation, it is sought to find improvements by uniting the two clients *i* and *j* in the same route, making the distance traveled by the vehicle:

$$L' = d_{D,i} + d_{D,j} + d_{i,j} \qquad (2)$$

Joining the two customers *i* and *j* in a single route, savings will be generated equal to the difference between L and L ', equal to:

$$g_{i,j} = d_{D,i} + d_{D,j} - d_{i,j} \qquad (3)$$

The Clarke and Wright method consists of analyzing all possible combinations between the nodes, two by two, ordering the gains $g_{i,j}$ in decreasing order and joining the nodes until the economy is the maximum possible.

Nearest Neighbor method. This method consists of, starting from a point, looking for the point closest to it. Goldbarg and Luna (2000) explain the heuristic how, starting from the vertex of origin, the vertex not yet visited is added to each step, whose distance from the last visited vertex is minimal. The procedure ends when all vertices have been visited. At the end, a connection is made between the last visited vertex and the original vertex.

As Santos (2006) explains, this method is usually used to find an initial solution to the problem, which solution is then gradually improved by other techniques and models. It has simple and fast application and can be used for highly complex problems.

3 Materials and Methods

3.1 Input data

In order to compare the two mentioned methods, the data used were the same used by Müller et al. (2019), presented in Table 1. In the example applied, a complete graph of 8 nodes is considered, where node 1 is the Distribution Center (DC) and the others are product distribution points.

Table 1. O/D Matrix (minutes).

O/D	1	2	3	4	5	6	7	8
1	0	14,14	8,39	20	14,14	21,27	15	25,03
2	14,14	0	16,82	31,62	28,28	32,83	20	15,28
3	8,39	16,82	0	14,86	16,05	27,59	22,53	30,73
4	20	31,62	14,86	0	14,14	29,19	31,62	44,79
5	14,14	28,28	16,05	14,14	0	15,06	20	37,67
6	21,27	32,83	27,59	29,19	15,06	0	15,06	36,03
7	15	20	22,53	31,62	20	15,06	0	20,97
8	25,03	15,28	30,73	44,79	37,67	36,03	20,97	0

To use the data in the program, the O/D matrix was converted from minutes to kilometers, considering the average speed of the truck during distribution 40 km/h.

The demands considered for each node were 310, 165, 155, 500, 300, 210 and 360 kg, respectively, the capacity of each vehicle is 2.000 kg, the maximum working day is 24 hours, the point of temperature abuse is -10°C and the stopping time at each node depends on the amount of product to be discharged, as shown in Equation 4, according to Müller et al. (2019).

$$downtime = 297{,}61 * demand - 0{,}1348 \qquad (4)$$

These data were imputed in the scenarios considered in the next section, in order to discover a good routing method for the case study.

3.2 Temperature calculations

The calculations of temperature variations that occurred during the physical distribution process of Cold Chain products that were applied in this study were based on the studies by Müller et al. (2019). Therefore Equation 5 was adapted from these authors.

$$\theta(\tau) = \theta_{source} + (\theta_0 - \theta_{source}).\exp\left(-\beta.\frac{\tau}{m}\right) \qquad (5)$$

Where $\theta(\tau)$ (K) represents the product temperature in time τ (minutes), θ_0 (K) is the initial product temperature, m (%) is the product mass ratio contained in the truck, β is the coefficient of temperature variation, shown in Equation 6, and θ_{source} (K) is the temperature that the system exerts on the product, assuming the value of 4°C when the vehicle is moving between one point and another, and 20°C when the product is being

downloaded from a given customer. For the calculation of β values, the equation was used:

$$\beta = \frac{\ln\left(\frac{\theta_j}{\theta_{j-1}}\right)}{\frac{dt_{j-1,j}}{m}} \qquad (6)$$

Since θ_j (K) is the air temperature at point *j*, θ_{j-1} (K) is the initial product temperature at point *j*-1, m (%) the total mass ratio contained in the vehicle, dt (minutes) the time interval between points *j*-1 and *j*.

Therefore, for each visited point the value of β was calibrated and $\theta(\tau)$ was calculated twice, once for the period of displacement and once for unloading. For the starting point, DC, the θ_j considered was -40°C, also according to the proposal by Müller et al. (2019).

The implementations of the methods of Clarke and Wright and the Closest Neighbor were made in C ++ in order to determine the minimum fleet necessary for physical distribution, supplying all the demand, without exceeding the capacity of each vehicle and the established time windows, covering the shortest possible distance and respecting the temperature limits.

4 Results and discussions

Initially, it is proposed to analyze the initial scenario, generated by the model without considering temperature control, only considering the routing heuristic. The graphs resulting from each route, considering the thermal performance over time, are also presented, as well as all the information of the generated routes.

The main results generated by the simulation include the number of vehicles needed for the fleet, the route to be taken by each vehicle with their respective distances, the average and maximum temperatures reached during the distribution and the time spent on each journey.

4.1 Initial scenario

The initial scenario considered was that of the highest possible cost, where each vehicle supplies only one node, leaving and returning to the DC. The total cost considered is given by the distance to be covered by all routes, that is, it is the sum of the distances covered by each route. Thus, the initial total cost is 157,29 km, with seven routes to be covered and seven vehicles required for distribution. The routes are represented in Figure 1 and described in Tables 2 and 3.

As expected, temperatures did not even come close to reaching the point of abuse, since the distributor serves only one customer per trip, and there is no time for excessive temperature rise. The increase in temperature as a function of time for each route is shown in Figure 2.

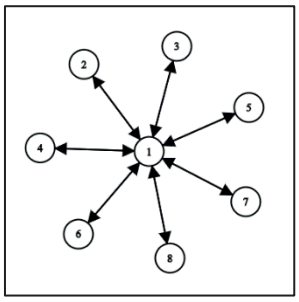

Fig. 1. Representation of the routes generated by the initial scenario.

Table 2. Routes generated by the initial scenario

Route	Path	Demand (kg)	Journey (h)	Distance (km)	Average temperature (°C)	Maximum temperature (°C)
1	1 - 2 - 1	310	1,24	18,85	-28,22	-23,43
2	1 - 3 - 1	165	0,69	11,19	-28,22	-23,43
3	1 - 4 - 1	155	1,05	26,67	-28,22	-23,43
4	1 - 5 - 1	500	1,71	18,85	-28,22	-23,43
5	1 - 6 - 1	300	1,45	28,36	-28,22	-23,43
6	1 - 7 - 1	210	1,02	20,00	-28,22	-23,43
7	1 - 8 - 1	360	1,72	33,37	-28,22	-23,43

Table 3. Results generated for the initial scenario.

Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
7	-23,43	-28,22	No	157,29

It is important to note that, although the method is quite attractive in terms of temperature values, it has a high cost for the distributor, which would need to have a vehicle for each customer, not being an economically viable option.

Although it is not feasible, the initial scenario will be used for comparison with the other scenarios, since, from there, it seeks to improve the number of vehicles used in the distribution of products, in order to keep temperatures below the point of abuse and reduce the total distance to be covered. It is important to note that each generated route corresponds to a different vehicle, as a vehicle cannot travel two routes simultaneously. Therefore, in this study it was considered that the number of vehicles needed for the fleet will be the number of routes generated by the program.

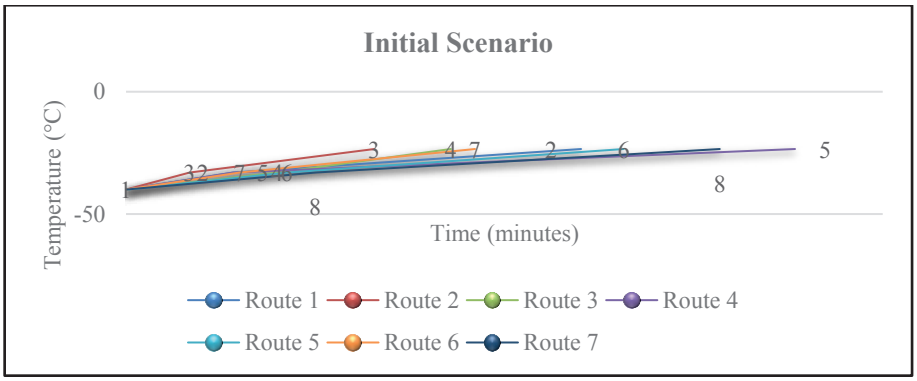

Fig. 2. Temperature variation of routes generated by the initial scenario.

4.2 Scenario 1: routing with C&W without temperature restriction

In this scenario, the results of the first application of Clarke and Wright will be presented, without the use of any temperature restriction of the products along the route. The routes found, as well as their specificities, are described in Tables 4 and 5 and in Figure 3.

Table 4. Routes generated by the scenario 1.

Route	Path	Demand (kg)	Journey (h)	Distance (km)	Average temperature (°C)	Maximum temperature (°C)
1	1 - 2 - 8 - 1	670	2,56	36,30	-22,93	-17,06
2	1 - 3 - 4 - 5 - 6 - 7 - 1	1330	4,66	55,01	-14,07	-3,60

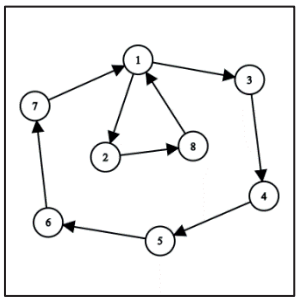

Fig. 3. Representation of the routes generated by the scenario 1.

Table 5. Results generated for the scenario 1.

Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
2	-3,91	-18,54	Yes	91,31

The minimum total distance found was 91,31 km, a value that will be used for comparison with the other scenarios, as well as their temperatures. In the generated route, the temperature exceeds -10°C during the unloading of cargo at point 5 of Route 2. Figure 4 illustrates the behavior of the temperature along the route, where this abuse is better evident.

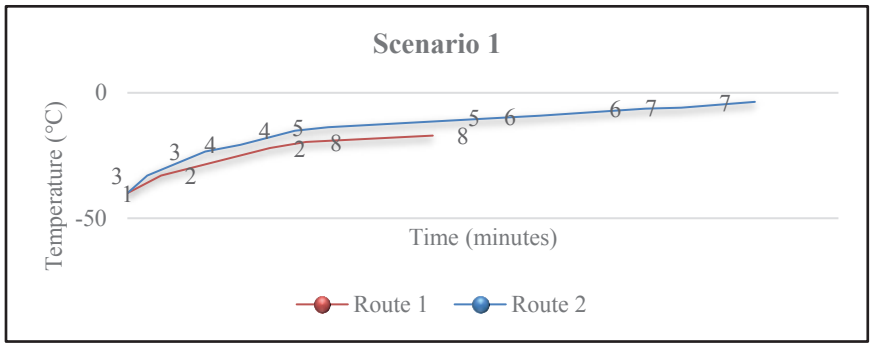

Fig. 4. Temperature variation of routes generated by the scenario 1.

4.3 Scenario 2: routing with C&W with temperature restriction

This scenario has the same heuristic as scenario 1, however blocking routes that reach the point of temperature abuse. Because of this restriction, there was an improvement in temperature values, as expected, increasing the distance covered, as shown in Tables 6 and 7 number of routes, and the number of routes as shown in Figure 5.

Table 6. Routes generated by the scenario 2.

Route	Path	Demand (kg)	Journey (h)	Distance (km)	Average temperature (°C)	Maximum temperature (°C)
1	1 - 2 - 8 - 1	670	2,56	36,30	-22,93	-17,06
2	1 - 3 - 4 - 1	320	1,51	28,83	-23,05	-15,06
3	1 - 6 - 7 - 1	510	2,12	34,22	-23,05	-15,06
4	1 - 5 - 1	500	1,71	18,85	-28,22	-23,43

Table 7. Results generated for the scenario 2.

Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
4	-15,06	-24,31	No	118,21

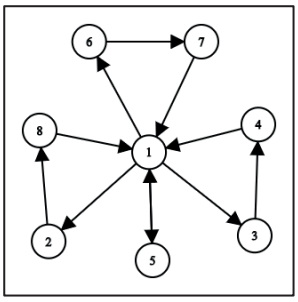

Fig. 5. Representation of the routes generated by the scenario 2.

The temperature variations along the described routes are illustrated in Figure 6.

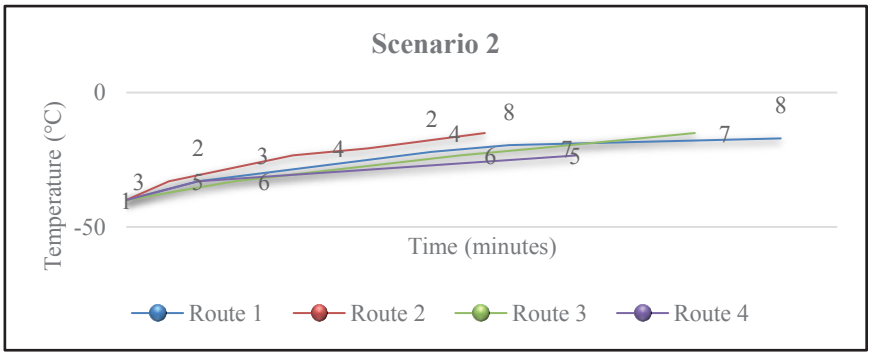

Fig. 6. Temperature variation of routes generated by the scenario 2.

It is observed that this scenario provides lower values of temperature compared to scenario 1, with a difference of 11,15°C in the maximum temperature and 5,77°C in the average temperature, being necessary to consider the advantage of the increase in distance covered (26,9 km) and the required fleet (with two more vehicles) in relation to this decrease.

4.4 Scenario 3: routing with Nearest Neighbor without temperature restriction

The method used in this scenario is simpler than the previous one, based only on the search for a route with the shortest total distance to be covered. As this scenario relaxed the temperature restriction, it was possible to generate only one route, including all the 7 nodes (distribution points), and, considering the total vehicle capacity of 2.000 kg (as declared in Section 3.1), it was possible to attend all the demand. Figure 7 illustrates the generated route, with a total distance of 78,60 km, lower in 14% when compared to the Scenario 1 (Clark and Wright without temperature restriction). Its major disadvantage is in the temperature values, as can be seen in Tables 8 and 9, which exceeded the point of temperature abuse. If compared with Scenario 1, the temperature results

were worst, increasing the maximum obtained temperature in 4,06°C. The increase in temperature during the route is shown in Figure 8, where it can be seen that, from point 5 onwards, the point of abuse is reached and exceeded by up to 10,15°C.

Table 8. Routes generated by the scenario 3.

Route	Path	Demand (kg)	Journey (h)	Distance (km)	Average temperature (°C)	Maximum temperature (°C)
1	1 - 3 - 4 - 5 - 6 - 7 - 8 - 2 - 1	2000	7,24	78,60	-10,50	0,15

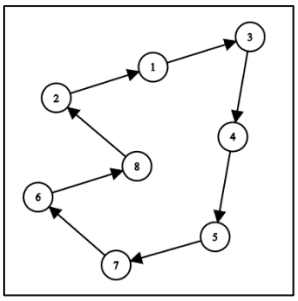

Fig. 7. Representation of the routes generated by the scenario 3.

Table 9. Results generated for the scenario 3.

Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
2	0,15	-10,5	Yes	78,6

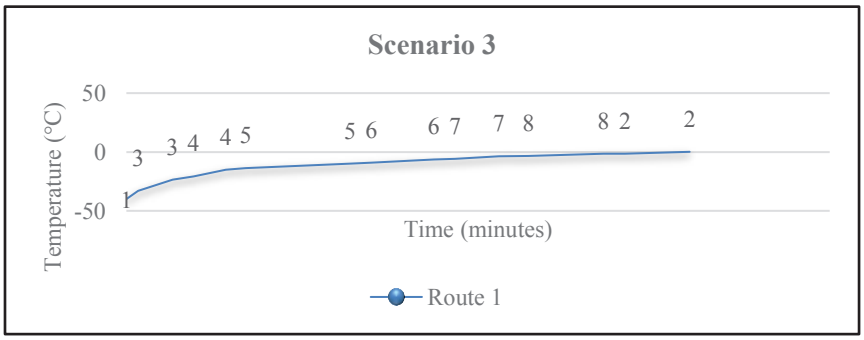

Fig. 8. Temperature variation of routes generated by the scenario 3.

This method, therefore, is not particularly good for a situation like the one in this case study, where temperature variation is a fundamental factor for product quality.

4.5 Scenario 4: routing with Nearest Neighbor with temperature restriction

In order to try a better solution than scenario 3, scenario 4 was generated, which considers the restriction of the abuse point on the route. As a consequence, there were four routes more than scenario 3, as shown in Figure 9, and, in addition, the distance also increased from 78,60 km to 127,23 km, as can be seen in Tables 10 and 11. The maximum and average temperatures were -15,06°C and -26,13°C for scenario 4, while in scenario 3 they were 0,15°C and -10,5°C.

Table 10. Routes generated by the scenario 4.

Route	Path	Demand (kg)	Journey (h)	Distance (km)	Average temperature (°C)	Maximum temperature (°C)
1	1 - 3 - 1	165	0,69	11,19	-28,22	-23,43
2	1 - 4 - 1	155	1,05	26,67	-28,22	-23,43
3	1 - 5 - 1	500	1,71	18,85	-28,22	-23,43
4	1 - 2 - 8 - 1	670	2,56	36,30	-22,93	-17,06
5	1 - 6 - 7 - 1	510	2,12	34,22	-23,05	-15,06

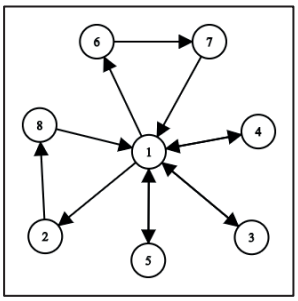

Fig. 9. Representation of the routes generated by the scenario 4.

Table 11. Results generated for the scenario 4.

Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
5	-15,06	-26,13	No	127,23

Representing what has already been described in the tables, Figure 10 shows the temperature variations over time for each route. With the insertion of the temperature restriction, this scenario generated better results, even with the increase of the distance (of 61,87%) in relation to scenario 3, since, in this case, the temperature reached is a fundamental factor for the choice of the route.

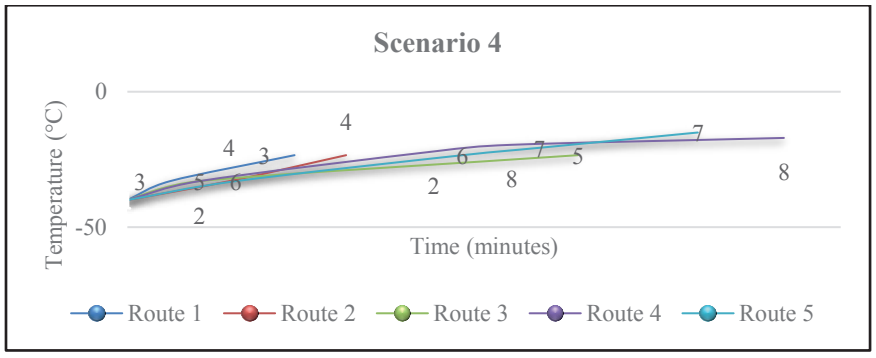

Fig. 10. Temperature variation of routes generated by the scenario 4.

4.6 Scenarios comparison

Since the objective of the study is to suggest a method for routing the distribution of products in the Cold Chain and a very important factor for the product to maintain its quality is the temperature at which it is maintained during the transport operation, the comparison between the scenarios were due to factors such as the maximum and average temperature reached in each scenario, in addition to the fact of having or not having abuse of temperature at some point, as shown in Table 12.

Table 12. Scenario results.

Scenario	Vehicles	Maximum temperature (°C)	Average temperature (°C)	Temperature abuse	Total distance (km)
Initial	7	-23,43	-28,22	No	157,29
1	2	-3,91	-18,54	Yes	91,31
2	4	-15,06	-24,31	No	118,21
3	2	0,15	-10,5	Yes	78,6
4	5	-15,06	-26,13	No	127,23

From Table 12, only scenarios that did not contain temperature abuse were selected. Therefore, the initial scenario, scenario 2 and scenario 4, highlighted in the table, were selected. From these, other comparative analyzes were carried out ignoring the remaining scenarios, as they are outside the study's field of interest.

Analyzing the maximum and average temperatures reached in the three selected scenarios, it is noticed that the initial scenario has the lowest values for temperatures (-23,43°C and -28,22°C, respectively). However, when observing the number of vehicles needed for the fleet and the total distance to be covered, the method does not become advantageous, since the distributor would need to have a vehicle for each delivery point, not being a sustainable possibility for the company. Therefore, the initial scenario was eliminated due to lack of viability.

With this, the ideal for choosing the best method between scenarios 2 and 4 is to consider together the values of the required fleet, maximum and average temperatures and total distance covered. For this specific case, there is no need to compare the maximum temperature as it is identical (-15,06°C) in both scenarios. Therefore, three criteria were considered: total number of vehicles needed, average temperature in °C and total distance traveled in kilometers, as shown in Figure 11.

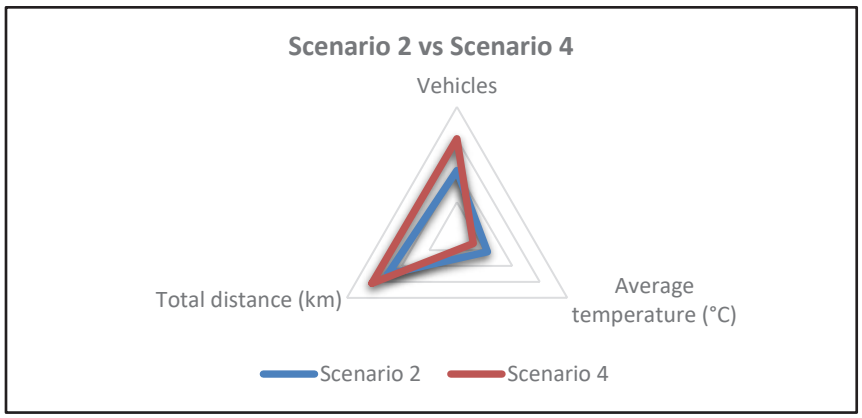

Fig. 11. Radar chart for comparison between scenarios 2 and 4.

It can be seen in Figure 11 where each scenario is better or worse. Scenario 2 requires one vehicle less than Scenario 4, in addition to traveling a shorter distance during the distribution of products, in 9,02 km, being more advantageous in these two criteria. Scenario 4 is more advantageous in the average temperature, with a difference of 1,82°C. Such advantages and disadvantages are summarized in Table 13.

Table 13. Differences between scenarios 2 and 4**.**

Scenario	Vehicles	Average temperature (°C)	Total distance (km)
2	4	-24,31	118,21
4	5	-26,13	127,23
Δ	1	1,82	9,02

Despite the difference of 1,82°C in the average temperature, it is important to realize that both temperatures are far from reaching abuse, not making this an advantageous criterion. The number of vehicles is an important indicator of advantage for scenario 2, greatly reducing costs for the distribution company during the distribution of Cold Chain products. The total distance traveled also represents such an advantage, even though it is not an expressive value. Because of this, the scenario with the best results for the case study was scenario 2, that is, the one generated through the Clarke and Wright method added by the temperature restriction.

5 Conclusions

The increase in the world population and the fast pace of life today mean that customers from different places demand large quantities of fresh or frozen food products. An important factor for the conservation of these foods is the storage temperature, both at the origin and destination, and in the displacement between them. Although there are refrigeration options for vehicles, it is very important to carry out a routing study so that the route taken by the distributor is effective. Factors such as the distance between delivery points, the amount of product to be unloaded at each point, as well as the time required for such activity, in addition to the time windows available for the service, must be taken into account.

In this study, two heuristic methods (Clarke and Wright and, Closest Neighbor) were considered, creating four possible scenarios for scripting, based on the example proposed by Müller et al. (2019), where the maximum and average temperatures reached on each generated route and the minimum total distance traveled were compared, since for the distribution company it is very important that the quality of the product is combined with a viable negotiation cost.

In the initial scenario, the proposal is to have a vehicle for each delivery point, which easily proves to be an unfeasible strategy for a given company, due to the high cost of capital and high idleness of the vehicle and the employee. For the following scenarios, the strategy of proposing the same routing method was used, but adding temperature restrictions imposed or not. For scenarios 1 and 3, this restriction is relaxed, unlike scenarios 2 and 4. When it comes to cases without restriction, these brought very attractive values for the total distance covered, however the temperatures reached exceed the point of abuse, which can decrease the quality of the products, and it is not interesting for the company that supplies the product or even for the customer that receives it. Thus, the scenarios analyzed in order to propose the best routing method were 2 (Clarke and Wright method) and 4 (Nearest Neighbor method).

Considering the two selected scenarios, four variables were considered as important for decision making: the required fleet, the maximum temperature reached, the average temperature during distribution and the total distance covered on each route. As the variables were not initially hierarchical, they were analyzed one by one in order to compare the advantages and disadvantages for each of the two scenarios. As a result, scenario 2 was similar to scenario 4 at the maximum temperature reached (-15,06°C) and was more attractive in terms of the required fleet (4 vehicles) and the total distance covered (118,21 km). Analyzing the only item in which scenario 4 was better, it is clear that there is not much difference between them and that, even scenario 2, has a very attractive value for it, not getting close to reaching temperature abuse. Therefore, scenario 2 was considered the best method for routing the case study in question, that is, the Clarke and Wright method generated better results, which was to be expected since this considers the maximum savings in the elaboration of the routes, achieving good results for the covered distance, managing to restrict the result to the restrictions imposed.

It is important to note that, with the increase in the number of delivery points and demand, the complexity of the problem also increases. In the considered example, the

total load demanded did not exceed the capacity of the truck and the number of delivery points did not require the fulfillment of the entire workday of the distributor. In order to meet greater demands without the need to increase the fleet and less idle vehicle, without interfering with the quality of the cargo, a good practice is to negotiate the time windows available for delivery, allowing the same delivery person to make more than one trip, even if it is necessary to return to the DC for refueling.

En los últimos años, la vitivinicultura nacional recuperó el lugar de relevancia que históricamente tuvo dentro de las agroindustrias. En la región del Comahue (Patagonia noroccidental) este renacer de la vitivinicultura se tradujo en una significativa reactivación de la actividad en las áreas productivas históricas (Alto Valle de Río Negro) y en el desarrollo de nuevas áreas (Departamento de Añelo, provincia del Neuquén). Actualmente la producción regional está mayoritariamente orien- tada a la elaboración de vinos tintos jóvenes y secos (80%) de variedades neutras de vid como Mal- bec y Merlot [1], contando la región con condiciones agroecológicas óptimas para expresar todo su potencial enológico [2]. No obstante, una economía globalizada, manejada por el consumo y mer- cados exigentes por productos cada vez más selectos, impone a los vitivinicultores regionales nuevos desafíos que requieren de innovación tecnológica. Mientras la vinificación es un proceso complejo desde el punto de vista ecológico en el que las levaduras, responsables de conducir la fermentación primaria o alcohólica (FA), desempeñan un rol protagónico, las tendencias innovadoras de la eno- logía actual están mayoritariamente orientadas a la exploración de las propiedades del vino relacio- nadas con este recurso microbianos y a su manejo adecuado mediante el uso de cultivos iniciadores de la FA [3].

Los cultivos iniciadores son cultivos puros de cepas de levaduras especialmente selecciona- das por sus propiedades para uso en enología que se comercializan bajo la forma de levadura seca activa (LSA) y que previa rehidratación se adicionan al mosto fresco en altas densidades celulares con el fin de normalizar la biota asociada al proceso fermentativo y rendir vinos de calidad contro- lada. Existe evidencia que variaciones geográficas observadas en la composición de las poblaciones microbianas asociadas a terruños vitivinícolas se correlacionan con las características organolépticas distintivas de los vinos elaborados en ellos, permitiendo proponer el concepto de "terroir micro- biano" [4, 5 y 6], comunidades constituidas por especies y cepas de

microorganismos típicas de la zona geográfica de producción del vino [7]. En este contexto, la conducción de las vinificaciones mediante el uso de cultivos iniciadores (*starters*) autóctonos de cada terruño es actualmente una tendencia en expansión en la vitivinicultura mundial con el fin de agregar valor a los vinos mediante el control y la diferenciación de su calidad [8].

Con el objetivo de desarrollar cultivos iniciadores de la FA autóctonos de la Patagonia, ac- tualmente inexistentes en el mercado, en trabajos previos se caracterizaron la diversidad específica e intraespecífica de la biota levaduriforme asociada a uvas, mostos de fermentación y superficie de bodegas de la región del Comahue seleccionándose diversas cepas autóctonas con propiedades ade- cuadas para uso enológico [9]. Una de estas cepas, *Saccharomyces cerevisiae* F8 (*Sc* F8 propagada en pie de cuba fue evaluada en vinificaciones regionales a escala piloto con excelentes resultados [10] proponiéndose su producción a nivel industrial en la forma de LSA para su comercialización como cultivo iniciador.

1. Objetivo del trabajo

Evaluar a escala industrial (Bodega) la capacidad de esta cepa autóctona *S. cerevisiae* F8 de conducir exitosamente vinificaciones en tinto regionales otorgando carácter diferencial en la calidad del vino previa propagación de su biomasa en un sustrato no convencional.

2. Metodología y resultados

Las células de *Sc* F8 se propagaron a escala piloto utilizando un sustrato no convencional abundante en la región como es el bagazo de manzanas (medio EBM) [11] en sistema de cultivo por lotes a 30°C [12]. Previa evaluación de su calidad sanitaria y microbiológica por métodos convencionales y moleculares [12], la biomasa húmeda se inoculó en 15.000L de mosto Malbec sulfitado (Bodega Favretto, Villa Regina, Vendimia 2019). Los controles fueron vinificaciones conducidas por cultivos comerciales ampliamente utilizados en vinificaciones en tinto regionales, *S. cerevisiae* F15 de Laf- fort (*Sc* F15, LSA) o por la bodega elaboradora, *S. cerevisiae* Bacofer de Tudela (*Sc* BA, levadura líquida). La cinética de las fermentaciones alcohólicas (FA) se siguió por evolución de los grados Baumé (°Bmé) y de la temperatura, y la capacidad de implantación de las cepas por recuento de viables en GPY agar y análisis molecular para identificación de especies (ITS PCR/RFLP) [13] y discriminación de cepas (ADNmit/RFLP con *Hinf*I) [14] El análisis fisicoquímico de los vinos se realizó conforme a los métodos propuestos por el Instituto Nacional de Vitivinicultura (INV) y el sensorial mediante una prueba de preferencia realizada por 17 enólogos regionales de vasta expe- riencia profesional. En esta prueba los diferentes vinos elaborados se identificaron con diferentes letras (A, B y C) debiendo el consumidor asignarle a cada vino un valor 1, 2 o 3 según su preferencia. Uno, el preferido en primer lugar, dos en segundo lugar y tres en tercer lugar. En esta degustación a ciegas, el promedio obtenido para cada vino es más cercano a uno cuanto mayor es su preferencia

por el consumidor.

Todas las vinificaciones conducidas mostraron cinéticas correspondientes a FA normales (Fi- gura 1) y los ensayos moleculares de discriminación a nivel de individuos evidenciaron que las tres cepas de *S. cerevisiae* son capaces de implantarse, entendiendo por implantación la capacidad de dominar numéricamente a la biota indígena, y conducir la exitosamente la FA (datos no mostrados). No obstante, los cultivos autóctonos presentaron un inicio de fermentación y un secado mosto más rápido que los comerciales (Figura 1) completando el proceso 48 h antes que éstos. Esta mayor actividad fermentativa no se tradujo en una mayor temperatura del proceso, que nunca superó los 22°C (Figura 1), evidenciando una mayor iciencia energética de la cepa autóctona acreditada por la menor disipación de energía en forma de calor respecto de sus contrapartes comerciales. Ambos comportamientos del cultivo autóctono son de gran importancia industrial por sus efectos positivos sobre los costos de producción (reducción de tiempo y energía).

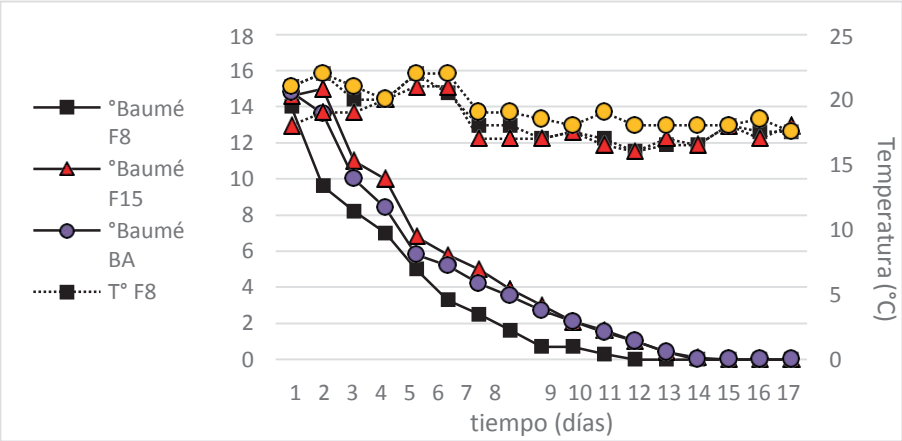

Figura 1: Cinética de las fermentaciones alcohólicas de las vinificaciones en tinto Patagónicas conducidas por los cultivos iniciadores autóctono (*Sc* F8) y comerciales (*Sc* F15 y *Sc* BA).

Los vinos presentaron características fisicoquímicas de vinos normales, aunque *Sc* BA fue incapaz de secar el mosto (ART>2 g L^{-1}) debido a su mayor dificultad de fermentar la fructosa respecto de la glucosa (Tabla 1). El cultivo iniciador autóctono y *Sc* F15 presentaron buena capacidad para fer- mentar ambos monosacáridos y menores concentraciones de ácido málico y mayores de ácido láctico en sus vinos en relación a las observadas en el elaborado con *Sc* BA indicando una mayor permisi- vidad de estos cultivos para el desarrollo de la maloláctica que la *Sc* BA. La FML, descarboxilación enzimática del ácido L-(-) málico en ácido L-(-) láctico realizada por las bacterias del ácido láctico

es una fermentación secundaria opcional deseable en la elaboración de los vinos tintos porque in- crementa su estabilidad microbiológica y su complejidad aromática [15].

Finalmente, el análisis sensorial realizado por los consumidores mediante pruebas de prefe- rencia (Tabla 2) indican que el vino elaborado con el cultivo autóctono *Sc* F8 obtuvo el mejor promedio, pero, por el tamaño muestral analizado, la diferencia no fue significativa respecto de la preferencia por el elaborado con el *Sc* F15, pudiendo concluirse que los consumidores mostraron una mayor preferencia por los vinos elaborados con los cultivos iniciadores *Sc* F8 y *Sc* F15 que por el elaborado con BA.

Tabla 1: Calidad fisicoquímica de vinos Malbec obtenidos en la Vendimia 2019 mediante fermentaciones alcohólicas conducidas por cultivos iniciadores autóctono puro (*Sc* F8) comerciales (*Sc* BA y *Sc* F15)

Parámetro	**VINOS**		
	***Sc* F8**	***Sc* BA**	***Sc***

Medias con superíndices diferentes, son significativamente diferentes, modelo lineal gene- ralizado y prueba de DGC con $p<0,05$ y n=17. [16]

3. Conclusión

La capacidad demostrada por la biomasa de la levadura *Sc* F8 propagada en medio EBM de iniciar rápidamente la fermentación, implantándose satisfactoriamente, conduciendo el pro- ceso hasta el completo secado del mosto y rindiendo vinos con características sensoriales dife renciales y de preferencia por los consumidores permite concluir que el proceso de propagación propuesto conserva en la cepa las propiedades tecnológicas por las que fuera seleccionadas reafirmando a escala industrial la aptitud de esta levadura para uso enológico como cultivo iniciador autóctono de la Patagónica.

Resumen. En los últimos años se ha estudiado el potencial del ozono como estrategia postcosecha en diversos productos frutihortícolas. En estudios previos, los autores desarrollaron tratamientos de ozono en fase acuosa capaces de reducir la incidencia fúngica y la pérdida de peso durante el almacenamiento refrigerado de frutillas cv. Albion. El objetivo de este trabajo fue evaluar el efecto de dichos tratamientos en el contenido de compuestos bioactivos y la capacidad antioxidante de frutillas cv Albion durante el almacenamiento a 5 ± 1 ºC, para lo cual se realizó la puesta a punto de una metodología de extracción asistida por ultrasonido. Los frutos fueron sumergidos en la columna de tratamiento previamente cargada con 1,25 L de agua destilada, y sometidos durante 5 y 15 minutos a un burbujeo de ozono (18 mg $O_3.L^{-1}$ en la corriente de alimentación a la columna) a 20 ± 1 ºC, y posteriormente almacenados en bandejas de polipropileno a 5 ± 1 ºC. El contenido de compuestos bioactivos y la capacidad antioxidante de los frutos ozonizados y sin tratar (control) fueron evaluados a los 0, 4 y 8 días de almacenamiento. Las condiciones óptimas de extracción resultaron: $V_{solvente}$ = 80 mL; Amplitud = 60 %; Tiempo = 15 min. La acumulación de antocianinas totales (AT) dependió de la dosis de ozono aplicada, resultando en una disminución significativa para el tratamiento de 15 min. Por el contrario, el contenido de fenoles totales (FT) y la capacidad antioxidante no se vio afectada por ninguna de las dosis evaluadas.

Keywords: Ozono, Frutilla, Antioxidantes

1 Introducción

En los últimos años diversos estudios han evaluado la efectividad de los tratamientos con ozono en fase gaseosa o acuosa en la extensión de la vida postcosecha de diversos frutos y vegetales [1]. El mecanismo de acción del ozono radica en su elevado poder oxidativo, que ocasionaría daños en componentes celulares vitales que conllevan a la inhibición del desarrollo microbiano, como así también a un efecto indirecto asociado a la inducción de mecanismos de defensa de la matriz vegetal. Esta respuesta resulta dosis-dependiente y está asociada a la inducción de sistemas antioxidantes, la acumulación de compuestos fenólicos con actividad antimicrobiana, el refuerzo de paredes celulares, entre otros [2-4]. La identificación y cuantificación de los compuestos fenólicos en frutillas ha sido ampliamente reportado, incluso para diferentes cultivares y en distintos estadios de madurez [5,6]; como así también los potenciales beneficios que la ingesta de los mismos tendría para la salud humana [7,8]. La evidencia existente respecto al efecto de los tratamientos con ozono sobre el contenido de antocianinas, compuestos fenólicos y capacidad antioxidante no es concluyente y revela la necesidad de realizar estudios sistemáticos que permitan arribar en forma más precisa a las condiciones óptimas de tratamiento. En estudios previos se ha demostrado que el tratamiento con ozono en fase acuosa de frutillas cv. Albion permitió reducir la incidencia fúngica y la pérdida de peso durante el almacenamiento refrigerado, sin afectar las propiedades mecánicas de dichos frutos [9].

Con el fin de maximizar los rendimientos en cuanto a la extracción de antocianinas y compuestos fenólicos totales en frutillas, se han evaluado distintas mezclas extractoras, como así también diferentes metodologías de extracción y de separación de dichos compuestos [10-12]. Un aspecto a tener en cuenta a la hora de evaluar el efecto de distintos tratamientos poscosecha en los atributos antioxidantes de las frutas es obtener un extracto concentrado de estos compuestos sobre el cual se puedan realizar la mayor cantidad posible de determinaciones. En base a estudios previos del grupo donde se evaluó la efectividad de distintas mezclas extractoras para la extracción de compuestos bioactivos de frutillas [13], se encontró que la extracción por maceración utilizando una mezcla extractora de etanol-ácido clorhídrico 0,1N (85:15 v/v) permitió obtener un buen rendimiento en la cuantificación de estos compuestos, pero el tiempo de extracción resultó muy prolongado (24 horas). La extracción asistida por ultrasonido se ha propuesto, entre otras técnicas convencionales y no convencionales, para maximizar la obtención de compuestos de interés de frutas y matrices vegetales en general y/o incrementar la velocidad de extracción [10,14].

Los objetivos de este trabajo fueron 1-optimizar una técnica de extracción asistida por ultrasonido para la evaluación de las propiedades antioxidantes de frutillas, y 2-evaluar el efecto de la aplicación de ozono en fase acuosa en el contenido de compuestos bioactivos y la capacidad antioxidante de frutillas cv. Albion durante el almacenamiento a 5 ± 1 ºC.

2 Materiales y métodos

2.1 Materia prima

Se utilizaron frutillas cv. Albion con grado de madurez comercial (100% color rojo), provenientes de un productor local de la zona de Pilar, provincia de Buenos Aires. Los frutos fueron clasificados según su tamaño y se descartaron aquellos que presentaron anormalidades fisiológicas, daño mecánico, deterioro microbiológico o bien, que no tuviesen la madurez indicada.

2.2 Tratamientos con ozono

Se utilizó un generador de ozono por descarga corona modelo UTK-O-4 (Unitek S.A., Argentina), y oxígeno como gas de alimentación a una temperatura de 20 ± 1 ºC. El ozono proveniente del generador se inyectó por la parte inferior de la columna de tratamiento, previamente cargada con 1,25 L de agua destilada y 10 frutillas (~200 g). En base a estudios previos [9] se determinó la concentración de ozono disuelto en función del tiempo de tratamiento, que luego de 5 min de estabilización resultó en una concentración residual de 3,5 ± 0,5 $mg.L^{-1}$.

Los frutos fueron expuestos a 5 y 15 min de tratamiento con ozono. El tratamiento de 5 min fue elegido por su desempeño en la inhibición de la micobiota nativa y en otros parámetros de calidad evaluados [9], mientras que el de 15 min se seleccionó en el objeto de evaluar el efecto de una exposición al ozono más prolongada. Luego de los tratamientos con ozono, los frutos fueron secados con papel absorbente, empacados en bandejas de polipropileno permeables al aire (10 frutillas/bandeja) y almacenadas a 5 ± 1 ºC. Se consideraron frutos control a las frutillas sin tratar y almacenadas en las condiciones antes descriptas.

2.3 Extracción de compuestos bioactivos

Se evaluó la extracción asistida por ultrasonido utilizando un diseño factorial de 3^3 (factores: volumen de solvente, amplitud de onda de ultrasonido y tiempo de sonicación) aumentado en 8 puntos centrales; cada condición se realizó por duplicado. Las condiciones evaluadas en la extracción asistida por ultrasonido fueron volumen de solvente (mL): 50, 75 y 100; tiempo de sonicación (min): 5, 10 y 15; amplitud (%): 20, 40 y 60. Se utilizó un diseño de superficies de respuesta para obtener las condiciones de operación óptimas que lograran maximizar el rendimiento en antocianinas, compuestos fenólicos y capacidad antioxidante (medida con la técnica ABTS). La mezcla extractora consistió en una mezcla de alcohol etílico y ácido clorhídrico (0,1 N) en una proporción 85:15 (v/v), seleccionada a partir de estudios previos del grupo de investigación [13].

Se pesaron 10 g de pulpa de fruta y se la maceró con la mezcla extractora durante unos minutos. Posteriormente se colocó en un vaso doble camisa de 150 mL de capacidad (7 cm de diámetro exterior y 10 cm de alto) para someterlo a sonicación. El vaso fue conectado a un baño termostático modelo Rotovisco RV12 (HAAKE, Alemania). Se ajustó la temperatura del mismo a 12 ± 2 ºC de manera que la temperatura

del extracto alcanzara los 30 ± 1 ºC durante los primeros 3 min de sonicación, y permaneciera constante hasta cumplir los distintos tiempos de extracción evaluados. Se utilizó un equipo de ultrasonido Vibracell VCX-600 (Sonic Materials Inc., Estados Unidos) de alta intensidad y baja frecuencia (20 kHz, 600 Watts, 119 µm de amplitud de onda). Finalmente, los extractos fueron filtrados a vacío con papel Whatman (#1), se fraccionaron en 4 frascos de vidrio ámbar de 10 mL de capacidad, y se almacenaron a -80 ºC en un ultrafreezer MDF-U55V (Panasonic, Japón) hasta el momento de realizar las determinaciones. Para la evaluación de los tratamientos con ozono se utilizaron 10 extractos para cada tiempo de exposición al ozono y cada tiempo de almacenamiento.

2.4 Determinación del contenido de antocianinas, compuestos fenólicos y capacidad antioxidante

Antocianinas monoméricas totales (AT)

El contenido de AT fue determinado mediante la técnica de pH diferencial descripta por [15]. Los extractos fueron diluidos en frascos ámbar en una proporción 1:10 (v/v) en solución buffer de cloruro de potasio (0,025 M, pH 1,0) y en solución buffer de acetato de sodio (0,4 M, pH 4,5), agitados en un vórtex y, luego de 15 minutos de reposo a temperatura ambiente, se determinó la absorbancia a dos longitudes de onda, 510 y 700 nm, mediante un espectrofotómetro UV-VIS modelo V-630 (Jasco, Japón). El contenido de antocianinas fue expresado como miligramos de pelargonidina 3-glucósido (antocianina mayoritaria en frutillas) por cada 100 gramos de fruta (base seca). Las absorbancias de cada extracto se midieron por triplicado.

Compuestos fenólicos totales (FT)

El contenido de FT se determinó por el método colorimétrico de Folin-Ciocalteu utilizando la técnica modificada por [16]. En frascos de vidrio ámbar (5 mL) se colocaron 0,2 mL de extracto diluido (1/2,5) con 2,6 mL de agua bidestilada y 0,2 mL del reactivo Folin-Ciocalteu. Los frascos fueron agitados en vórtex y luego permanecieron 6 minutos en reposo al resguardo de la luz y a temperatura ambiente. Luego, se agregaron 2 mL de solución de carbonato de sodio 7 % (p/v), se agitó nuevamente en vórtex y se dejó reposar durante 90 minutos en las condiciones antes descriptas. Finalmente, se determinó la absorbancia de las muestras a 760 nm. Cada extracto se midió por duplicado. Los resultados se expresaron en mg equivalentes de ácido gálico presentes en 100 g de fruta (base seca) (mg EAG/100 g b.s.). La curva de calibración con ácido gálico se construyó a partir de 8 concentraciones diferentes en el rango 1 - 8 mg $AG.L^{-1}$.

Capacidad antioxidante (CA)

Para la evaluación del efecto de los tratamientos de ozono sobre la capacidad antioxidante se utilizaron dos metodologías: TEAC (capacidad antioxidante como equivalentes de Trolox) y ORAC (capacidad de absorción de radicales de oxígeno).

La determinación de CA mediante el método TEAC se realizó de acuerdo a la metodología descripta por [17] con ligeras modificaciones. En frascos de vidrio ámbar se colocaron 80 µL del extracto diluido (1/5) (v/v) con 7,92 mL de la solución de radical $ABTS^{\cdot+}$. Se agitó en vórtex y se incubó durante 2 h a 30 ºC en un baño termostático modelo Masson (Vicking, Argentina). Finalmente, se registró el decrecimiento en la intensidad de absorción del catión $ABTS^{\cdot+}$ debido a la interacción con compuestos donantes de hidrógeno o de electrones, midiendo la absorbancia a 734 nm. El blanco consistió en 80 µL de buffer fosfato pH 7,4 y 7,92 mL de la solución de radical $ABTS^{\cdot+}$. Los resultados se expresaron como mmol Trolox presentes en 100 g de fruta (base seca) (mmol Trolox/100 g b.s.). La CA se obtuvo mediante la comparación con curvas de calibración realizadas con Trolox, obtenidas a partir de 12 concentraciones diferentes en el rango 6-17 µM Trolox.

La determinación de CA mediante el método ORAC se realizó de acuerdo a la técnica descripta para la determinación de antioxidantes hidrofílicos [18] adaptada por [19]. Se utilizaron dos diluciones diferentes de los extractos, 1:160 (v/v) y 1:240 (v/v). La evolución de la fluorescencia durante el tiempo fue medida con un luminómetro Victor Multilabel 1420 (Perkin Elmer, Estados Unidos) sobre microplacas de poliestireno negras de 96 pocillos, de fondo plano y superficie sin tratamiento (Corming, Estados Unidos). En cada pocillo se colocaron 115 µL de fluoresceína ($8{,}16.10^{-5}$ mM) y 25 µL del extracto diluido. La mezcla se incubó bajo agitación a 37 ºC durante 10 minutos. Posteriormente, se adicionaron 60 µL de solución AAPH (153 mM), se agitó la placa durante 1 minuto y se comenzó inmediatamente con la medición manteniendo la temperatura fija en 37 ºC. Las lecturas en cada pocillo fueron registradas cada 40 s hasta cumplir un tiempo total de 66 minutos, utilizando filtros de emisión y excitación de 520 y 485 nm, respectivamente. El blanco consistió en utilizar 25 µL de buffer fosfato de potasio (75 mM, pH 7,4) en lugar del extracto. Los resultados fueron expresados como mmol equivalentes de Trolox presentes en 100 g de fruta (base seca) (mmol Trolox/100 g b.s.). La curva de calibración se construyó a partir de 6 concentraciones diferentes en el rango de 3,125 - 50 µM. Los diferentes extractos y patrones se midieron por duplicado.

2.5 Análisis estadístico

Los resultados fueron expresados como la media ± desviación estándar y fueron analizados mediante el programa Infostat v.2008 (Universidad Nacional de Córdoba, Argentina). Los datos fueron analizados mediante un ANOVA de dos factores (tratamiento y tiempo de almacenamiento). En caso de encontrarse diferencias significativas se aplicó un test de Tukey. Con el fin de determinar el grado de correlación entre el contenido de AT y FT con la capacidad antioxidante evaluada por TEAC y ORAC, se calcularon los coeficientes de correlación de Pearson. El nivel de confianza para todos los análisis se fijó en un 95 %. Para el análisis de superficies de respuesta y la optimización de las condiciones de extracción se utilizó el programa Statgraphics Centurion XVI (Statgraphics Technology Inc., Estados Unidos).

3 Resultados

3.1 Optimización de la extracción asistida por ultrasonido

En la Tabla 1 se presenta el diseño experimental utilizado para la optimización de las condiciones de extracción asistida por ultrasonido, estudiándose el efecto de tres variables independientes (volumen de solvente, tiempo y amplitud de sonicación) sobre tres variables respuesta (AT, FT, TEAC). Los resultados del modelo indicaron que el efecto principal del tiempo de sonicación en las tres variables respuesta evaluadas no resultó significativo. Sin embargo, para la capacidad antioxidante el término cuadrático de dicho factor si lo fue. Las interacciones Vsolvente -Tiempo, Amplitud - Tiempo y el término cuadrático del factor amplitud tampoco tuvieron un efecto significativo, por lo cual no fueron incluidos en el modelado y posterior optimización.

El modelo de regresión fue ajustado con las siguientes ecuaciones:

$$Y_{AT} = 28{,}681 + 1{,}054X_1 + 0{,}635X_2 + 0{,}023X_3 - 1{,}135X_1^2 - 1{,}384X_1X_2 + 0{,}256X_3^2 \quad (1)$$

$$Y_{FT} = 238{,}50 + 17{,}93X_1 + 13{,}50X_2 + 4{,}78X_3 + 3{,}60X_1^2 - 5{,}16X_1X_2 + 7{,}36X_3^2 \quad (2)$$

$$Y_{TEAC} = 4{,}045 + 0{,}043X_1 + 0{,}141X_2 + 0{,}077X_3 - 0{,}324X_1^2 - 0{,}044X_1X_2 - 0{,}188X_3^2 \quad (3)$$

Donde: X_1 representa el volumen de solvente, X_2 la amplitud y X_3 el tiempo de sonicación.

En la Figura 1 se presentan las superficies de respuesta obtenidas al representar las funciones del modelo. Para la representación gráfica de las variables de respuesta, el tiempo de sonicación se fijó en el valor optimizado, que resultó de 15 minutos. La optimización de las variables respuesta fue realizada mediante la maximización de la función "Deseabilidad", representada en la Figura 2.

Las condiciones de extracción optimizadas que maximizaron el rendimiento en AT, FT y TEAC resultaron: X_1 = 80 mL, X_2 = 60 %, X_3 = 15 min. La concentración de compuestos bioactivos y capacidad antioxidante predichos para las condiciones optimizadas fueron: AT: 29,51 mg Pg3/100g, FT: 266,27 mg AG/100g y TEAC: 4,07 mmol Trolox/100g; mientras que los valores observados resultaron: AT: 29,60 ± 0,70 mg Pg3/100g, FT: 265,61 ± 3,15 mg AG/100g y TEAC: 3,98 ± 0,10 mmol Trolox/100g. Puede observarse entonces que los resultados obtenidos utilizando las condiciones de extracción optimizadas son muy similares a los predichos por el modelo.

Tabla 1. Datos experimentales de las variables de respuesta obtenidos para las combinaciones de volumen de solvente (X_1), amplitud de sonicación (X_2) y tiempo de extracción (X_3).

	Variables independientes			Variables de respuesta

3.2 Efecto de los tratamientos de ozono en el contenido de antocianinas y compuestos fenólicos totales.

En la Tabla 2 se presentan los contenidos de antocianinas (AT) y compuestos fenólicos totales (FT) de frutillas control y ozonizadas durante el almacenamiento. El análisis estadístico indicó que la interacción entre los factores "tratamiento" y "tiempo de almacenamiento" resultó significativa ($F_{4,81}$ = 6,1, p<0,0002 y $F_{4,81}$ = 3,5, p<0,012, respectivamente. Los frutos control mostraron un incremento del contenido de AT durante el almacenamiento, que resultó significativo al día 8. En cuanto a los frutos ozonizados, las muestras tratadas durante 5 minutos no presentaron diferencias significativas en el contenido de AT durante el almacenamiento, al compararlas con el control. Por el contrario, los frutos tratados con ozono durante 15 minutos presentaron un contenido de AT significativamente menor que el control al día 8 de almacenamiento.

Los frutos control mostraron un incremento significativo en el contenido de FT al día 8 de almacenamiento, en concordancia con lo observado en el contenido de AT. El contenido de FT de los frutos ozonizados durante 5 minutos también aumentó significativamente al día 8, aunque sin presentar diferencias significativas respecto al control. Por otra parte, las muestras tratadas durante 15 minutos y almacenadas 8 días, mostraron un leve incremento no significativo en el contenido de FT a pesar de la disminución en el contenido de AT observado para ese mismo período de almacenamiento.

Tabla 2. Valores promedio y desviación estándar del contenido de antocianinas (AT), de fenoles totales (FT) y de capacidad antioxidante evaluada por ORAC y ABTS de frutillas control y ozonizadas durante el almacenamiento a 5 ± 1 ºC. Promedios seguidos de distinta letra minúscula difieren significativamente (p<0,05). (n = 10)

Parámetro	Tiempo de tratamiento (min)	Tiempo de almacenamiento (día)		
		0	4	8
AT (mg Pg3/100g b.s.)	0	224,7 ± 68,5 ^{a}	309,1 ± 49,9 ^{ab}	350,7 ± 88,7 ^{b}
	5	285,6 ± 43,9 ^{ab}	240,2 ± 72,9 ^{a}	271,4 ± 66,2 ^{ab}
	15	274,2 ± 75,6 ^{ab}	302,9 ± 75,0 ^{ab}	230,6 ± 46,8 ^{a}
FT (mg AG/100g b.s.)	0	1655,5 ± 234,2 ^{a}	1725,3 ± 174,0 ^{a}	2417,8 ± 297,9 ^{cd}
	5	1902,0 ± 187,0 ^{ab}	1649,3 ± 205,6 ^{a}	2589,6 ± 374,2 ^{d}
	15	1917,2 ± 399,6 ^{ab}	1689,5 ± 211,6 ^{a}	2201,9 ± 185,7 ^{bc}

Los resultados de la evaluación de la capacidad antioxidante determinada por las técnicas TEAC y ORAC se presentan en la Tabla 3. El análisis estadístico indicó que la interacción entre los factores "tratamiento" y "tiempo de almacenamiento" no fue significativa ($F_{4,81}$ = 1,76, p>0,1 y $F_{4,81}$ = 1,25, p>0,1, respectivamente). Al analizar el efecto principal de cada factor, en ambos casos se observó un efecto significativo del tiempo de almacenamiento sobre los valores TEAC y ORAC (p<0,05 y p<0,0001, respectivamente), mientras que el efecto principal del tratamiento con ozono no resultó significativo (p>0,05).

Se observó una disminución significativa en los valores TEAC al día 4, principalmente en los frutos ozonizados. En general, los valores TEAC tendieron a incrementarse hacia el final del almacenamiento (día 8), alcanzando valores que no difirieron significativamente con los correspondientes al día 0. Por el contrario, los resultados obtenidos mediante la técnica ORAC presentaron una tendencia diferente; tanto las muestras control como tratadas presentaron un incremento significativo de los valores ORAC a lo largo de todo el período de almacenamiento estudiado.

El análisis de correlación entre las variables medidas (Tabla 4), indicó que la correlación entre el contenido de AT y FT de las muestras no fue significativa (p>0,5), lo cual podría explicarse por la diferente tendencia observada entre la acumulación de AT y FT de los frutos ozonizados durante 15 minutos a lo largo del almacenamiento. Por otro lado, se observó una correlación significativa entre FT y los valores TEAC (r = 0,59), FT y los valores ORAC (r = 0,45), y AT y los valores ORAC (r = 0,39). Si bien los compuestos fenólicos, incluyendo las antocianinas, son compuestos abundantes en las frutillas y con conocida actividad antioxidante, la correlación observada entre AT y FT con la capacidad antioxidante fue débil, con coeficientes de correlación menores a 0,6.

Tabla 3. Valores promedio y desviación estándar del contenido de antocianinas de capacidad antioxidante evaluada por ORAC y ABTS de frutillas control y ozonizadas durante el almacenamiento a 5 ± 1 ºC. En una misma fila, los promedios seguidos de distinta letra mayúscula difieren significativamente ($p<0,05$). (n = 10)

Parámetro	Tiempo de tratamiento (min)	Tiempo de almacenamiento (día)		
		0	4	8
TEAC (mmol Trolox/100 g b.s.)	0	32,8 ± 3,1 ^{A}	31,8 ± 5,7 ^{B}	33,8 ± 5,1 ^{AB}
	5	36,1 ± 4,0 ^{A}	31,2 ± 5,6 ^{B}	36,6 ± 6,8 ^{AB}
	15	36,9 ± 4,9 ^{A}	32,1 ± 5,1 ^{B}	31,5 ± 4,0 ^{AB}
ORAC (mmolTrolox/100 g b.s.)	0	27,2 ± 5,9 ^{A}	42,5 ± 5,9 ^{B}	48,0 ± 4,2 ^{C}
	5	31,5 ± 7,5 ^{A}	36,1 ± 6,7 ^{B}	45,3 ± 4,5 ^{C}
	15	31,8 ± 1,9 ^{A}	43,5 ± 5,7 ^{B}	47,2 ± 10,9 ^{C}

Tabla 4. Resultados del análisis de correlación de Pearson para el contenido de antocianinas, compuestos fenólicos y capacidad antioxidante de frutos tratados y control durante el almacenamiento a 5 ± 1 ºC.

	AT	FT	TEAC	ORAC
AT	1,00	0,6739	0,6988	0,0040
FT	0,04	1,00	<0,0001	0,0006
TEAC	0,04	0,59	1,00	0,1902
ORAC	0,38	0,45	0,18	1,00

Resultados similares fueron reportados por [20,21]; mientras que por el contrario, otros autores [22] encontraron una correlación fuerte y positiva entre el contenido de AT y FT con los valores ORAC de frutillas almacenadas en refrigeración. Entre los factores que pueden afectar estas determinaciones, se encuentran las interacciones (aditivas o sinérgicas) entre distintos compuestos fenólicos de la fruta, como también con otros fitoquímicos; y la contribución a los valores ORAC de otros componentes como la vitamina C que no han sido evaluados en este trabajo. En particular, se ha reportado que esta vitamina representa entre el 9 y 15 % del valor ORAC [22].

Por otra parte, existen reportes acerca del incremento de las propiedades antioxidantes de diversas frutas como consecuencia de la exposición de los mismos al ozono [4,23,24]. Este incremento estaría asociado a respuestas de defensa desencadenadas por la exposición de los frutos a condiciones de estrés abiótico. Sin embargo, en las dosis ensayadas en este trabajo no se detectó un aumento en el potencial antioxidante de las frutillas.

4 Conclusiones

La acumulación de antocianinas en frutillas cv. Albion tratadas con ozono dependió de la dosis aplicada, resultando en una disminución significativa para el mayor tiempo de exposición al ozono, 15 min. Por el contrario, el contenido de compuestos fenólicos totales y la capacidad antioxidante no se vio afectada por ninguna de las dosis de ozono evaluadas. Por lo tanto, el tratamiento con ozono en fase acuosa durante 5 minutos podría ser una estrategia para extender la vida poscosecha de frutillas cv Albion sin afectar negativamente sus propiedades antioxidantes. Estudios complementarios en otros cultivares de frutillas contribuirían a una mejor caracterización del efecto del tratamiento y su potencial aplicación poscosecha.

5 Agradecimientos

Los autores agradecen el apoyo financiero de la Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) y Agencia Nacional de Promoción Científica y Tecnológica (ANPCyT).

Desarrollo de yogur descremado deslactosado reducido en sacarosa mediante hidrólisis enzimática

Perez Cenci, M.[1]; Dominguez, R. C.[1]; Fernandez, A. R.[1] y Fuertes, G.[1]

[1] Facultad de Ingeniería, UNMDP, Mar del Plata, Argentina
mperezcenci@fi.mdp.edu.ar

Resumen. Como Trabajo Final de la carrera Ingeniería en Alimentos, se buscó desarrollar un yogur descremado deslactosado, reducido en sacarosa a partir de la utilización de la enzima β-galactosidasa. Su formulación reducida en lactosa fue obtenida a partir de las experiencias prácticas llevadas a cabo en las instalaciones de la Facultad de Ingeniería, de la Universidad Nacional de Mar del Plata. Las materias primas requeridas fueron provistas por la Cooperativa de Trabajo Nuevo Amanecer Ltda. con quien se llevó a cabo el proyecto, mediante un convenio específico. Además de las prácticas de laboratorio, se realizaron cuatro instancias de análisis sensorial, con la colaboración de 10 panelistas entrenados. A partir de ellas se pudieron determinar diversos parámetros tales como: el tiempo de deslactosado mínimo requerido, el dulzor aportado por la hidrólisis enzimática, los endulzantes y espesantes a utilizar para obtener los atributos deseados y el rendimiento del proceso. Fue posible obtener dos formulaciones de similar aceptación sensorial entre sí.

Palabras clave: Yogur Deslactosado, Hidrólisis Enzimática, Yogur Reducido en Sacarosa.

1 Introducción

El presente trabajo se realizó en el marco de la materia Trabajo Final de Ingeniería en Alimentos (Facultad de Ingeniería, UNMDP) para obtener el título de grado de Ingeniera en Alimentos.

Desde el comienzo, la idea se centró en desarrollar un producto que satisficiera las necesidades de una porción de la población que eligiera un estilo de vida más saludable, buscando mantener la salud a partir de los alimentos elegidos para consumo cotidiano. Además, siempre se consideró interesante el hecho de facilitar el acceso a dichos alimentos. Es por ello que la idea de realizar un alimento saludable y accesible para toda la comunidad estuvo siempre presente.

Luego, se presentó la posibilidad de trabajar en convenio con una industria tradicional de la ciudad, como es la Cooperativa de Trabajo Nuevo Amanecer Ltda. cuyos orígenes se remontan al año 1939. La propuesta planteada por la empresa fue mejorar la formulación de un producto ya existente como es el yogur descremado saborizado. La mejora consistía en reducir la cantidad de sacarosa agregada mediante un tratamiento

enzimático de la materia prima, ya que se entendía que los consumidores que buscaban un producto descremado, también deseaban que fuera reducido en azúcares.

Para referirse al yogur según la normativa vigente es necesario recurrir al CAA [1] el cual establece que se entiende por yogur al producto adicionado o no de otras sustancias alimenticias, obtenidos por coagulación y disminución del pH de la leche (adicionada o no de otros productos lácteos) por fermentación láctica realizada con cultivos protosimbióticos de *Lactobacillus delbrueckii subsp. bulgaricus y Streptococcus salivarius subsp. thermophilus* a los que en forma complementaria pueden acompañar otras bacterias acidolácticas que, por su actividad, contribuyen a la determinación de las características del producto terminado. Estos microorganismos deben ser viables, activos y abundantes en el yogur durante su período de validez. La regulación también establece ciertos parámetros sensoriales, físico-químicos y microbiológicos a los que el yogur debe responder.

Los beneficios del consumo de yogur residen principalmente en el gran número de microorganismos vivos que el mismo contiene. Dichos microorganismos vivos hacen del yogur un alimento probiótico. Se define con este término a los organismos vivos que administrados en cantidades adecuadas proporcionan un beneficio saludable en el huésped [2]. Es así como los microorganismos generan beneficios mejorando el balance microbiano intestinal, lo que hace del yogur un alimento funcional, considerado un alimento que pueda proporcionar un beneficio a la salud, superior al de los nutrientes tradicionales que contiene, según la Academia Nacional de Ciencia de los Estados Unidos.

Se propone, entonces, como objetivo desarrollar un yogur descremado deslactosado firme sabor vainilla, con un menor contenido de sacarosa que el yogur descremado actual de la Cooperativa de Trabajo Nuevo Amanecer Ltda. a partir de la hidrólisis de la lactosa.

Para ello se parte de la hipótesis de que al hidrolizar el disacárido lactosa (proceso denominado deslactosado) que está presente en la leche (materia prima) utilizando la enzima β-galactosidasa se obtienen como productos glucosa y galactosa, los cuales son monosacáridos con un poder edulcorante mayor que el del disacárido mencionado.

2 Materiales y métodos

La materia prima base de todas las experiencias fue leche de vaca pasteurizada, homogeneizada y estandarizada con un contenido de materia grasa de 0,5 % p/p.

2.1 Experiencia 1: determinación del tiempo de deslactosado

El objetivo de la primera experiencia fue determinar el tiempo mínimo de hidrólisis de lactosa para alcanzar el máximo dulzor posible.

Para ello se adicionó la enzima Ha-Lactase 5200 de CHR HANSEN a una muestra de leche. La elección de la dosis de enzima (2000 NLU/L) y la temperatura de operación (40 °C) se realizó en base a los datos provistos por la ficha técnica [3]. En estas condiciones se ha observado una hidrólisis de entre 80 y 90 % en un tiempo de entre 2 y 4 h.

Por este motivo, se ensayó el deslactosado hasta 5 h, tomando muestras a diferentes tiempos.

Se decidió evaluar el dulzor alcanzado en cada tiempo de deslactosado a través de una evaluación sensorial con 10 jueces entrenados. No se realizó de manera analítica la determinación de lactosa, glucosa y galactosa ya que no se contaba con el instrumental necesario en el tiempo disponible.

La evaluación se basó en un test descriptivo, en el cual se evaluó la intensidad de sabor dulce utilizando una escala continua [4].

La experiencia se realizó como se detalla a continuación:

1. Se colocaron 5 L de leche en un recipiente y se llevó a T = 40 °C utilizando una olla y mechero con difusor.
2. Se agregaron 206 g de leche en polvo descremada y se agitó.
3. Se reservó una muestra de 500 mL de leche y se virtió en 2 recipientes de 250 mL (muestra t0).
4. A los 4,5 L restantes se les agregó 2 g (2000 NLU/L) de la enzima Ha-Lactase 5200 de CHR HANSEN y se agitó.
5. Se dividió el volumen total en 18 recipientes de 250 mL y se los colocó en baños termostáticos a 40 °C.
6. Se retiraron del baño termostático 3 muestras para cada uno de los tiempos de deslactosado (ver Tabla 1).

Tabla 1. Tiempos de deslactosado.

Muestra	Tiempo [h]
t1	0,5
t2	1
t3	2
t4	3
t5	4
t6	5

7. A medida que se retiraron las muestras del baño termostático a 40 °C, se las colocó en otro baño a 90 °C. Una vez que la temperatura en el interior del recipiente alcanzó 85 °C, se dejó durante 5 min para inactivar la enzima y se dejó templar a temperatura ambiente.
8. Se refrigeraron las muestras en heladera a 4 °C hasta su utilización en la evaluación sensorial.
9. Se realizó el análisis sensorial de las muestras t1, t2, t3, t4 y t5 para intensidad de sabor dulce, utilizando como anclajes las muestras t0 como muy baja y la muestra t6 como muy alta (ver Fig. 1).

4

Fig. 1. Escala de evaluación sensorial evaluando de 0 (muy baja) a 10, representando el anclaje "muy alto" el valor de 8.

Los resultados obtenidos se analizaron con ANOVA y posteriormente se utilizó el test de comparaciones múltiples de Tukey, en caso de hallarse diferencia significativa en las muestras. El nivel de significancia (α) utilizado fue de 0,05.

2.2 Experiencia 2: determinación del dulzor alcanzado con la hidrólisis

Los objetivos planteados para esta experiencia fueron:

- Analizar la intensidad de sabor dulce del yogur elaborado con leche deslactosada y con diferentes cantidades agregadas de sacarosa, a fin de determinar qué cantidad de sacarosa se puede reducir en la formulación original del yogur.
- Analizar la aceptabilidad sensorial de las diferentes muestras de yogur.
- Realizar un perfil de acidez del yogur durante la fermentación.

Para llevar a cabo esta experiencia se prepararon muestras de yogur con diferentes porcentajes de sacarosa respecto de la formulación original, las cuales fueron evaluadas por 10 jueces entrenados. La evaluación se basó en un test descriptivo, para el cual se utilizó una escala continua de intensidad de sabor dulce y un test de aceptabilidad sensorial, en el que se utilizó escala hedónica de 9 puntos [5].

La experiencia se realizó como se detalla a continuación:

1. Se colocaron 5 L de leche en un recipiente y se llevó a T = 40 °C utilizando una olla y mechero con difusor.
2. Se agregaron 206 g de leche en polvo descremada y se agitó.
3. Se reservaron 800 mL en un Erlenmeyer y se refrigeró a 4 °C (muestra A).
4. A los 4 L restantes en la olla se les agregó 1,6 g de enzima Ha-Lactase 5200 de CHR HANSEN y se agitó.
5. Se tomaron 4 Erlenmeyers, se vertieron 800 mL de la mezcla en cada uno de ellos y se colocaron en un baño termostático a 40 °C durante 2,5 h.
6. Se colocaron en todos los Erlenmeyers 4,7 g de estabilizante comercial E1[1], incluyendo la muestra A reservada en el paso 3.
7. Se agregaron distintas cantidades de sacarosa en cada uno de los Erlenmeyers como se indica en la Tabla 2:

[1] En todos los casos se omiten los nombres comerciales de los espesantes utilizados por acuerdo de confidencialidad con la Cooperativa de Trabajo Nuevo Amanecer Ltda.

Tabla 2. Contenido de sacarosa de las diferentes muestras.

Muestra	Contenido de sacarosa [g]	% de agregado de sacarosa con respecto a la formulación original
A	75,3	100
B	60,2	80
C	37,7	50
D	22,6	30
E	0	0

8. Se colocaron los recipientes en un baño termostático a 95 °C y una vez alcanzados los 85 °C dentro de los recipientes se esperaron 5 min.
9. Se retiraron las muestras del baño termostático y se las enfrió hasta 42 °C bajo un chorro de agua de red, con agitación continua.
10. Se disolvieron 50 U del fermento CHR HANSEN en 1 L de leche 0,5 % p/p de contenido graso, con agitación en un matraz.
11. Se agregaron 3 mL del fermento disuelto a cada muestra y se incubaron a 40-42 °C.
12. Se tomaron 10 mL de cada muestra con ayuda de una pipeta a diferentes tiempos (1 h, 1,5 h, 2 h, 2,5 h, 2,75 h, 3 h, 3,25 h) y se realizó una titulación con solución Dornic (0,09 N NaOH) utilizando fenolftaleína como indicador. Se registró el volumen gastado.
13. Al registrar un volumen gastado mayor a 6 mL (60 °D), se retiraron las muestras del baño termostático y se le agregaron 0,1 mL de esencia de vainilla.
14. Se colocaron 40 mL de cada muestra en 10 vasos plásticos (cada uno de 100 mL de capacidad) y se almacenaron a 4 °C hasta su utilización en la evaluación sensorial.
15. Se realizó una evaluación en la que se analizó la intensidad de sabor dulce de las muestras y la aceptabilidad sensorial de diferentes atributos de cada una de ellas (aroma, apariencia, color y brillo, textura en boca, sabor, sabor dulce y aceptabilidad global). Para el caso del análisis de la intensidad de sabor dulce se utilizaron como anclaje la muestra A como “alta” y la muestra E como “baja”.

La escala utilizada para la intensidad de sabor dulce es la presentada en la experiencia anterior (ver Fig. 1). A continuación, se muestra la escala hedónica de 9 puntos utilizada en la evaluación de los diferentes atributos de cada muestra (ver Fig. 2):

Fig. 2. Escala hedónica de 9 puntos utilizada para la evaluación sensorial de los atributos de las muestras.

2.3 Experiencia 3: elección del endulzante

En esta experiencia se evaluaron dos tipos de endulzantes para reemplazar una parte o la totalidad de la sacarosa, teniendo en cuenta que se debía cubrir el dulzor que aportaba el 80 % de sacarosa de la formulación original. Los endulzantes seleccionados fueron estevia y sucralosa, el primero por tratarse de un endulzante natural que no aporta cantidades significantes de calorías y el segundo por ser una halogenación del azúcar de mesa, que presenta un sabor similar al mismo, con un poder edulcorante 600 veces mayor, pero sin aporte calórico [6]. Para realizar la elección, se llevó a cabo una evaluación sensorial con 9 jueces entrenados. La evaluación se basó en una prueba hedónica para la cual se utilizó una escala de 9 puntos [7].

La experiencia se realizó como se detalla a continuación:

1. Se colocaron 4 L de leche en un recipiente y se llevó a T = 40 °C utilizando una olla y mechero con difusor.
2. Se agregaron 164,8 g de leche en polvo descremada y se agitó.
3. Se agregaron 1,6 g de enzima Ha-Lactase 5200 de CHR HANSEN y se agitó.
4. El recipiente con la mezcla se colocó en un baño termostático a 40 °C durante 2,5 h.
5. Se adicionaron 23,53 g de estabilizante comercial E1 a la mezcla, previamente disuelto en leche con 0,5 % p/p de contenido graso a 85 °C.
6. Se tomaron 5 Erlenmeyers y se colocaron 800 mL de la mezcla en cada uno.
7. Se agregaron distintas cantidades de endulzantes comerciales (solución líquida de esteviósidos 117 % p/v y sucralosa en polvo) en cada una de las muestras como se indica a continuación en la Tabla 3:

Tabla 3. Agregado de endulzantes (sacarosa, estevia y sucralosa) para las diferentes muestras.

Muestra	Agregado de sacarosa [g]	Agregado de estevia [g]	Agregado de sucralosa [g]
A	60,2	-	-
B	30,1	3,5	-
C	30,1	-	0,037
D	-	3,5	0,037
E	-	-	0,074

8. Las muestras se colocaron a 95 °C en un baño termostático y una vez alcanzados los 85 °C dentro de los recipientes se esperaron 5 min.
9. Las muestras se enfriaron hasta 42 °C bajo un chorro de agua de red, con agitación continua.
10. Se disolvieron 50 U del fermento CHR HANSEN en 1 L de leche 0,5 % p/p de contenido graso con agitación en un matraz.
11. Se agregaron 3 mL del fermento disuelto a cada muestra y se incubaron a 40-42 °C. El sobrante del fermento disuelto se congeló para utilizar en experiencias posteriores.

12. Utilizando una pipeta, se tomaron alícuotas de 10 mL de las muestras A y D (testigos) a diferentes tiempos (0 h, 0,5 h, 1 h, 1,5 h, 2 h, 2,5 h, 2,75 h, 3 h, 3,25 h) y se realizó medición de pH y titulación con solución Dornic (0,09 N NaOH) utilizando fenolftaleína como indicador. Se registró el volumen gastado.
13. Al registrar un volumen gastado mayor a 6 mL (60 °D), se retiraron las muestras del baño termostático y se le agregaron 0,1 mL de esencia de vainilla.
14. Se colocaron 40 mL de cada muestra en 9 vasos plásticos (cada uno de 100 mL de capacidad) y se almacenaron a 4 °C hasta su utilización en la evaluación sensorial.
15. Se realizó una evaluación sensorial en la que se analizó aceptabilidad de apariencia, textura en boca y sabor y aceptabilidad global, utilizando la escala presentada en la Fig. 2.

2.4 Experiencia 4: selección del espesante

En las experiencias anteriores se utilizó el espesante comercial E1, el cual fue provisto por la Cooperativa de Trabajo Nuevo Amanecer Ltda. Si bien se experimentó a nivel laboratorio en condiciones similares a las que se trabaja en la industria, no se logró la consistencia esperada para el yogur firme. Por ello se decidió realizar una cuarta experiencia para alcanzar la textura deseada, trabajando con otros espesantes o una combinación de ellos. La mezcla de endulzantes utilizada para esta experiencia en particular fue la de sacarosa con sucralosa, correspondiente a la muestra C de la experiencia 3, considerando que fue la que obtuvo mayor promedio en su puntaje de aceptabilidad.

La experiencia se realizó como se detalla a continuación:

1. Se colocaron 1,8 L de leche con en un recipiente y se llevó a T = 40 °C utilizando una olla y mechero con difusor.
2. Se agregaron 74,16 g de leche en polvo descremada y se agitó.
3. Se agregaron 0,72 g de enzima Ha-Lactase 5200 de CHR HANSEN y se agitó.
4. El recipiente con la mezcla se colocó en un baño termostático a 40 °C durante 2,5 h.
5. Se calentó la mezcla hasta 90 °C aproximadamente utilizando la misma olla y mechero con difusor. Se agregaron 67,73 g de sacarosa y 0,087 g de sucralosa en polvo. Se mezcló para homogeneizar con un batidor.
6. Se tomaron 6 Erlenmeyers y se colocaron 300 mL de la muestra en cada uno de ellos.
7. Se agregaron distintas cantidades de espesantes previamente disueltos (E1, E2 y E3) en cada uno de las muestras como se indica a continuación en la Tabla 4.

Tabla 4. Agregado de espesantes para las distintas muestras.

Muestra	E1 [g]	E2 [g]	E3 [g]	% en la formulación
A	-	1,96	-	0,6
B	-	2,62	-	0,8
C	-	3,28	-	1
D	-	-	0,98	0,3
E	1,63	-	0,33	0,5 de E1 y 0,1 de E3

8

F	1,63	-	0,65	0,5 de E1 y 0,2 de E3

8. Se colocaron las muestras en un baño termostático a 100 °C y una vez alcanzados los 95 °C dentro de los recipientes se esperaron 5 min.
9. Las muestras se enfriaron hasta 42 °C bajo un chorro de agua de red, con agitación continua.
10. Se colocó en cada muestra 1,2 mL del fermento descongelado conservado en la experiencia anterior y se incubaron a 40-42 °C.
11. Utilizando una pipeta, se tomaron alícuotas de 10 mL de las muestras a las 3 h y se realizó una titulación con solución Dornic (0,09 N NaOH) utilizando fenolftaleína como indicador. Se registró el volumen gastado.
12. Se retiraron las muestras del baño termostático y se le agregaron 0,03 mL de esencia de vainilla.
13. Se almacenaron las muestras a temperatura de refrigeración hasta realizar la evaluación sensorial.
14. La apariencia y la textura en boca fueron analizadas sensorialmente por 5 jueces entrenados en yogur, de manera grupal, comparando las muestras con el yogur firme descremado sabor vainilla de la Cooperativa de Trabajo Nuevo Amanecer Ltda.

2.5 Experiencia 5: determinación experimental del rendimiento

Para determinar el rendimiento experimental del yogur elaborado, se llevó a cabo el seguimiento de las muestras B y F en simultáneo a la realización de la Experiencia 4. Se registraron los pesos en distintas etapas del proceso y al final del mismo, es decir, finalizada la fermentación.

3 Resultados y discusión

3.1 Experiencia 1: determinación del tiempo de deslactosado

El test de ANOVA permitió determinar que al menos una muestra tenía diferencia significativa con respecto al resto, ya que F resultó mayor a F crítico, siendo estos valores 8,7 y 2,7 respectivamente. El test de Tukey permitió, mediante una comparación múltiple, identificar cuáles son las muestras entre las que existe diferencia significativa. Estos resultados se observan en el gráfico siguiente (ver Fig. 3).

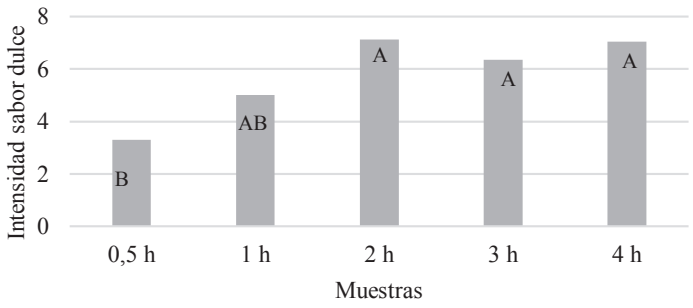

Fig. 3. Resultados de la intensidad de sabor dulce de leche descremada en función del tiempo de deslactosado con la enzima β-galactosidasa. Letras diferentes indican diferencias significativas en el sabor dulce debido al tiempo de deslactosado (Test de Tukey, α=0,05).

A partir de estos análisis fue posible determinar el tiempo mínimo de hidrólisis para alcanzar el máximo dulzor, siendo este de 2 h. Considerando que se trata de un proceso enzimático, el cual es susceptible a cambios en el medio, y que se pueden presentar variaciones tanto en la composición de la materia prima como en las condiciones del proceso, al tiempo de deslactosado determinado se le adicionó un 25 % más. De esta manera se estableció que esta etapa del proceso durara 2,5 h.

3.2 Experiencia 2: determinación del dulzor alcanzado con la hidrólisis

Perfil de acidez. Se presentan los presentan los valores de acidez obtenidos en las titulaciones realizadas (ver Fig. 4).

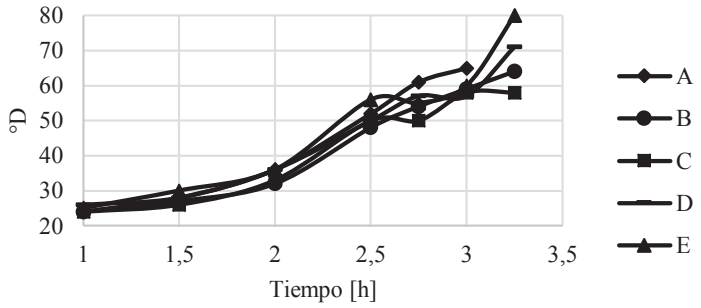

Fig. 4. Resultados obtenidos de la acidez del yogur durante la fermentación en función del tiempo.

En el gráfico de la Fig. 4 puede observarse que todas las muestras acidifican el medio de manera similar a lo largo del tiempo. Al ser el ácido láctico un producto del metabolismo de las BAL inoculadas, su concentración es proporcional a la población microbiana que se desarrolla en la etapa de fermentación. Esto puede relacionarse debido

a que la forma de las curvas obtenidas coincide con la curva típica de crecimiento microbiano, en la que se distinguen tres fases: latencia, exponencial y estacionaria [8].

Evaluación sensorial. El análisis de los datos recopilados en la evaluación sensorial se realizó de igual manera que en la experiencia 1 (utilizando el mismo nivel de significancia α=0,05) y los resultados se observan en el gráfico de la Fig. 5.

El test de ANOVA permitió determinar que al menos una muestra tenía diferencia significativa con respecto al resto, ya que F resultó mayor a F crítico, siendo estos valores 52,8 y 2,9 respectivamente. El test de Tukey permitió, mediante una comparación múltiple, identificar cuáles son las muestras entre las que existieron diferencias significativas.

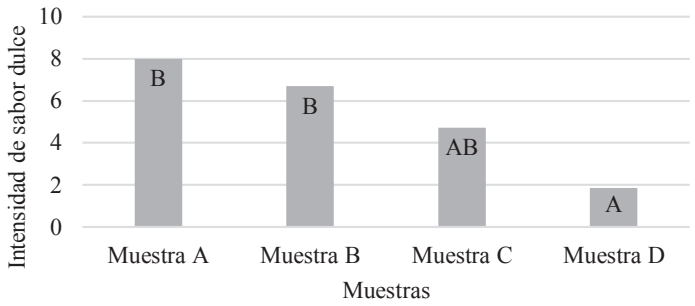

Fig. 5. Resultados de la intensidad de sabor dulce de yogur en función de la cantidad agregada de sacarosa. Letras diferentes indican diferencias significativas en el sabor dulce debido al agregado de sacarosa en distintas proporciones (Test de Tukey, α=0,05).

Como puede observarse, si bien la muestra A se utilizó como anclaje en 8 puntos, se decidió analizarla de igual manera que el resto. Esto es así ya que contenía la misma cantidad de sacarosa que el producto vigente de la Cooperativa de Trabajo Nuevo Amanecer Ltda. y, de esta manera, permitió realizar una comparación entre esta muestra y el resto, estableciendo o no diferencias significativas.

En el gráfico se observa que las muestras pueden ordenarse, según su intensidad de sabor dulce percibida por los panelistas, de manera coincidente con la cantidad de sacarosa agregada.

En cuanto al análisis estadístico, se puede observar que entre la muestra A y la muestra B no existieron diferencias significativas en la intensidad de sabor dulce percibida por los panelistas. De esta manera fue posible reducir la sacarosa agregada al yogur en un 20 %.

3.3 Experiencia 3: elección del endulzante

El análisis de los datos recopilados en la evaluación sensorial se realizó de igual manera que en la experiencia 1 (utilizando el mismo nivel de significancia α=0,05). El test de

ANOVA arrojó como resultado que no había diferencias significativas entre las muestras en ninguno de los atributos, por lo que no fue necesario realizar el test de Tukey. Considerando que una variación del endulzante afectaba principalmente el sabor y la aceptabilidad global, se muestran en la Fig. 6 y en la Fig. 7 los promedios de los puntajes obtenidos para cada muestra en estos atributos.

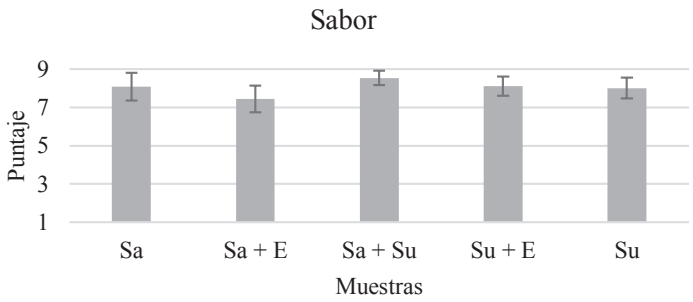

Fig. 6. Puntajes promedio obtenidos en la evaluación sensorial para la aceptabilidad del sabor (Sa: sacarosa, E: estevia, Su: sucralosa).

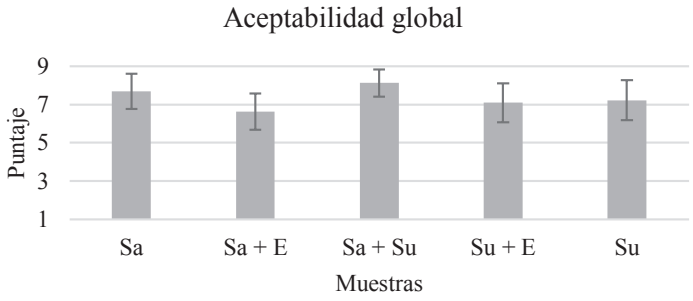

Fig. 7. Puntajes promedio obtenidos en la evaluación sensorial para la aceptabilidad global (Sa: sacarosa, E: estevia, Su: sucralosa).

Si bien no se observaron diferencias significativas en la aceptabilidad de los atributos ni en la aceptabilidad global de las muestras, cabe destacar que la de mayor puntaje fue la de sacarosa con sucralosa tanto en aceptabilidad del sabor como en aceptabilidad global.

Por otro lado, también puede notarse que todas las muestras obtuvieron puntajes mayores a 6, siendo el menor puntaje obtenido de aproximadamente 6,5, representando en la escala un punto medio entre “Me gusta poco” y “Me gusta”. Esto demostró que todas las muestras fueron aceptadas y, por lo tanto, la elección del endulzante o mezcla de endulzantes a utilizar en la formulación final dependía del concepto de producto que se deseaba o de su costo de producción.

3.4 Experiencia 4: selección del espesante

A partir de la evaluación y la comparación con el yogur firme descremado sabor vainilla utilizado como referencia, se determinó que la muestra B presentó mejor apariencia y textura en boca. La firmeza del coágulo fue similar a la del yogur de la Cooperativa de Trabajo Nuevo Amanecer Ltda., además, presentó un corte limpio acorde con la consistencia de un yogur firme.

3.5 Experiencia 5: determinación experimental del rendimiento

El cálculo del rendimiento total del proceso, el cual se obtiene a partir de la siguiente ecuación:

$$Rendimiento\ (\%) = \frac{masa\ final \cdot 100}{masa\ inicial} \quad (1)$$

Se tuvieron en cuenta los pesos iniciales y finales de las muestras B y F. A partir de dichos datos, se obtuvo el rendimiento para ambas muestras y, finalmente, el rendimiento promedio del proceso (ver Tabla 5).

Tabla 5. Masa inicial y final de las muestras B y F y Rendimiento del proceso.

	Muestra B	**Muestra F**
Masa inicial (g)	336,9	336,6
Masa final (g)	319,9	318,6
Rendimiento (%)	94,9	94,7
Rendimiento promedio (%)	95 %	

Como se puede observar, el rendimiento promedio resultó del 95 %. Este valor es similar al hallado en bibliografía, la cual indica que el rendimiento teórico del proceso es del 94 % [9]. Cabe destacar, que dicho valor está asociado a la elaboración a escala laboratorio del producto. Es así, que el mismo se ve afectado por el equipamiento, lo que sugiere que a escala industrial dicho valor podría verse modificado.

3.6 Formulaciones

Se presentan dos posibles formulaciones que fueron obtenidas para la fabricación de yogur descremado deslactosado firme sabor vainilla. La única diferencia que presentan entre sí está dada por la variación de uno de los endulzantes, ya que recibieron la misma aceptabilidad sensorial. Por un lado, la formulación A contiene como endulzantes sacarosa y sucralosa. Por otro lado, la formulación B presenta estevia y sucralosa. Ambas formulaciones se muestran a modo comparativo en la Tabla 6 donde, además, se detallan los componentes para las mismas. Vale aclarar que los porcentajes son en peso.

Tabla 6. Formulaciones del yogur descremado deslactosado.

Componentes	Formulación A (%)	Formulación B (%)
Leche descremada 0,5 % p/p	91,787	94,950
Leche en polvo descremada	3,676	3,803
Sacarosa	3,343	-
Estabilizante comercial E2	0,777	0,804
Inóculo	0,368	0,380
Enzima	0,036	0,037
Esencia de vainilla	0,009	0,010
Sucralosa	0,004	0,004
Estevia	-	0,012
Total	100,000	100,000

4 Conclusiones

Se logró obtener un yogur descremado firme sabor vainilla reducido en sacarosa. Dicho alimento puede ser considerado funcional debido a que contiene probióticos que ofrecen múltiples beneficios al consumidor.

A partir de la Experiencia 1 se determinó el tiempo óptimo de hidrólisis de la leche, para asegurar el máximo dulzor posible, en el menor tiempo involucrado. De esta manera, se llegó a un tiempo óptimo de deslactosado de 2,5 h. Por otro lado, en la Experiencia 2 se determinó que es posible reducir el contenido de sacarosa en el yogur en un 20 %, al utilizar la leche deslactosada según la Experiencia 1. Además, en cuanto al endulzante a utilizar, luego de probar diversas combinaciones en la Experiencia 3, se llegó a que la combinación sucralosa + sacarosa es la más aceptada. Sin embargo, no se observaron diferencias significativas entre las muestras, por lo que se concluye que todas las combinaciones evaluadas son factibles de utilizar en la formulación. Por último, en la Experiencia 4 se determinó el espesante a incluir en la formulación. De esta forma, se seleccionó el espesante E2 en una concentración de 0,8 %, debido a que otorga la apariencia y textura en boca deseadas.

En paralelo, se concluyó que el rendimiento del proceso fue del 95 %.

Abstract. In this study, the effects of naringin (NAR), neohesperidin (NEO) and quercetin (QUER), at 0.2 mM, were evidenced on the ultrastructure of *Aspergillus flavus*, *A. parasiticus* and *Fusarium verticillioides* by transmission electron microscopy images. Flavonoids were applied at 0.2 mM, alone or in combination affecting the structure of the cell wall, membranes and cytoplasm. In general, the cell wall lost rigidity and the cells appeared highly deformed with ruptured plasma membrane, regardless of the fungal species assayed.

The effect of flavonoids, in the same concentrations, on mycotoxins accumulation in maize at 0.98 aw, permitted the reduction of aflatoxins in a range from 82 to 99 % and a reduction up to 100% of fumonisins. The studied citrus flavonoids, which can be obtained from the citrus processing wastes, may provide an environmentally friendly alternative for decreasing aflatoxins and fumonisins accumulation in stored maize, replacing synthetic compounds.

Keywords: Mycotoxins · Maize · Flavonoids

1 Introduction

Mycotoxins are fungal toxic secondary metabolites encountered in food and feed. Aflatoxins (AFs) can be found in maize, among a variety of agricultural commodities and food products. AFs are produced by certain strains of *Aspergillus*, commonly *A. flavus*, *A. parasiticus* and *A. nomius* [1]. Aflatoxin B1 (AFB1), B2 (AFB2), G1 (AFG1) and

G2 (AFG2) are the most important, due to their occurrence in maize and to their mutagenic, carcinogenic, and hepatotoxic effects. Also, AFB1 has been classified as Group 1 (carcinogenic to humans) by the International Agency for Research on Cancer [1]. Main international markets set regulations for AFs in cereals and other foods, ranging between 1 and 12 μg/kg for AFB1, 4 and 15 μg/kg for AFB2, and 1 to 35 μg/kg for total AFs [2, 3].

Fumonisins (FBs) are mycotoxins with high occurrence in maize and its by-products [4]. FBs are mainly produced by *Fusarium verticillioides*, *F. proliferatum* and *F. fujikuroi*, among others [5]. Their production is stimulated by certain environmental conditions, being 25 °C and 0.98 a_w in the maximum accumulation range for *F. verticillioides* in maize [6]. Fumonisins B1, B2 and B3 (FB1, FB2 and FB3, respectively) are the analogues most frequently found in foods and those that exhibit the highest toxicity [5, 7] being associated with esophageal cancer and neural tube defects in humans [7]. FB1 is classified as a possible carcinogen within group 2B [8]. The maximum limits regarding FBs that were established by the EU according to the Commission Regulation N ° 1126/2007 [9] are 1000 μg/kg for corn and by-products used for human consumption, 800 μg/kg for breakfast cereals and 200 μg/kg for baby food, among others. The maximum values proposed by the Codex Alimentarius Comission and adopted by Argentina are 4000 μg/kg for corn grains and 2000 μg/kg for its by-products [10, 11].

It has been found that the highest co-occurrence of mycotoxins is given by AFs + FBs in cereals and derived products [12]. The study of mycotoxins in maize from different areas of Argentina between 1999 and 2010, showed that the co-occurrence of AFs + FBs was the most frequently detected combination, both at harvest and during maize storage [13].

Fungicides used to control post-harvest fungal diseases may promote fungal resistance, can leave persistent residues raising consumer concerns and cannot be used in organic or agroecological production systems, thus leading to a growing demand in favor of safe and effective natural preservatives [14].

Flavonoids are bioactive compounds from plants, with wide-ranging functions in plant metabolism. They can be classified into various sub-classes on the basis of the different oxidation level, unsaturation and substitution pattern. The flavonoids that occur in *Citrus* spp. belong to four groups: flavanones, flavones, flavonols and anthocyanins [15].

Approximately 50 % of the weight of the initial citrus fruit raw material remains as waste of the citrus processing industry, reaching more than 40 million tons worldwide [16]. Among all the possible applications, some flavonoids could be extracted at low cost from these agroindustrial by products and could represent an effective treatment against fungal contamination and also against mycotoxin accumulation in food products.

As an example, Naringin (NAR), neohesperidin (NEO), and hesperidin completely inhibited AFs accumulation by *A. flavus* when binary mixtures of these flavanones, extracted from citrus residues, were added to MEA, being the optimal mixture NAR 0.04 mM and NEO 0.2 mM [17].

The application of 0.8 mM of QUER to Czapek yeast extract agar reduced more than 50% ochratoxin A accumulation by *A. carbonarius* [18]. Moreover, QUER at a concentration of 0.37 mM in corn flour proved to dimminish *A. flavus* growth and aflatoxin production by suppressing MAPK signaling pathway involved in the AFs biosynthesis [19].

There are, to our knowledge, few studies available on the effect of flavonoids NAR, NEO and QUER, applied individually or in combination, on the ultrastructure of *A. flavus*, *A. parasiticus* and *F. verticillioides*. Recently, it has been shown that an optimal mixture composed of 0.39 mM NAR, 0.24 mM , and 0.40 mM QUER reduced from 85 % to 100 % the accumulation of AFs by *A. parasiticus* in maize adjusted to 0.95 and 0.98 a_w, with a deteriorative effect on the fungal ultrastructure [20]. Therefore, the aim of this study was to evaluate and compare the effect of two flavanones, NAR and NEO, and a flavonol, QUER, which can be extracted from the residuals of citrus industrialization, on the ultrastructure of *A. flavus*, *A. parasiticus* and *F. verticillioides* by transmission electron microscopy (TEM) and in the reduction of AFs and FBs accumulation in maize adjusted to 0.98 a_w, to be used as replacement of synthetic antifungal compounds.

2 Materials and Methods

2.1 Reagents and Chemicals

Sintorgan (Buenos Aires, Argentina) provided acetic acid (HAc), acetone, acetonitrile (ACN), glycerol, ethanol (EtOH), hexane and methanol (MeOH), HPLC grade, were purchased from; trifluoroacetic acid (TFA) from Tedia Company Inc. (OH, USA). Waters Milli-Q system was used to prepare HPLC quality water (Waters Associated, MA, USA). AFs and FBs standards were from Sigma (MO, USA). Malt extract broth (MEB), sodium hydroxide (NaOH), orthophosphoric acid, o-phthaldialdehyde, 2-mercaptoethanol, and tetraborate were purchased from Merck (Darmstadt, Germany). Culture medium MEA, and Tween 80 were purchased from Biokar (Beauvais, France).

2.2 Flavonoids

Immature grapefruit (*Citrus* × *paradisi*, Ruby Red cv.) and bitter orange fruit (*Citrus* × *aurantium*), which were discarded during juice processing, were processed to obtain the flavanones NAR and NEO, respectively [21]. The extraction was performed according to Salas [22], obtaining NAR 95 % pure and NEO 99 % pure. The flavonol QUER was purchased from Sigma (product no. 337951, purity of 95 %, Darmstadt, Germany).

2.3 Strains Selection

A. flavus, *A. parasiticus* and *F. verticillioides* species, belonging to the MICA culture collection of this research group, were selected according to their toxigenic capacity.

All of them were morphologically identified according taxon-specific diagnostic characters [23], and further subjected to PCR analysis in order to validate the morphological identification [20, 24] confirming the putative species. The strains were cultured in MEA slant tubes during 7 days. Then, tubes were filled with 10 ml of Tween 80 (0.02%) and the conidia were separated from the rest of the medium shaking 1 min in a vortex. The a_w of the suspension was adjusted with glycerol to a_w 0.98 as needed and its concentration was set to 5 10^6 conidia/ml. The volume of the inoculum used was 500 µl.

2.4 Transmission Electron Microscopy

For ultrastructure study flavonoids were added to MEB at 50 °C, previously adjusted to 0.98 a_w with glycerol. The treatments assayed were NAR, NEO or QUER individually applied at 0.2 mM, and the mixture composed of 0.2 mM NAR, 0.2 mM NEO and 0.2 mM QUER in combination. Tubes containing 10 ml of media were inoculated with 500 µL of conidia suspension and incubated at 25 °C for 5 d. Samples were prepared, fixed, and cut following traditional techniques [25]. Samples were observed in a Zeiss 109 transmission electron microscope (Carl Zeiss, Oberkochen, Germany) at 80 kV.

2.5 Mycotoxin assay

Substrate corresponding to 25 g of maize grains adjusted to 0.98 a_w, according to the maize sorption isotherms [26], was sterilized at 121 °C during 15 min using an autoclave (VZ, Buenos Aires, Argentina). Flavonoids were dissolved in 5 ml of EtOH and added to 100 ml water:glycerol 90:10 (w/w) (0.98 a_w), and stirred 5 min in an ultrasonic bath (Branson, MO, USA) at 50 °C until complete dissolution.

For each treatment, a total of 15 ml of the working solutions were added to maize. The appropriate flavonoid concentration were obtained in mmol/kg of maize (mM). Once the maize substrates were prepared and thoroughly shaken, they were inoculated and incubated during 14 days, in the case of *A. flavus* and *A. parasiticus*, or during 28 days in the case of *F. verticillioides*, both at 25 °C in sealed polyethylene bags. In order to maintain maize a_w level constant, open flasks containing water:glycerol solution where placed inside the bags.

Positive controls (maize inoculated following the same procedure but without adding flavonoids to the glycerol solution) and blank matrix (substrate without fungal inoculation) were also evaluated, by triplicate.

2.6 Quantification of Mycotoxins

Aflatoxins. The AFs quantification was performed according to Method 994.08 [27] using an Agilent 1100 series HPLC-FLD equipment (Agilent Technologies, CA, USA). For AFs extraction 25 g of maize were extracted with 100 ml ACN:H_2O (84:16 v/v). It was blended for 3 min at high speed (Osterizer, FL, USA) and filtered through Whatman paper no. 4 (Maidstone, UK). Then, 5 ml of the supernatant were passed through a solid-phase clean-up column MycoSep® 224 AflaZon (Romers, Getzersdorf, Austria). Subsequently, 1 ml was destined to AFs analysis. This extract was evaporated

under vacuum in a water bath at 60 °C until dryness, and then was reconstituted in 200 µl hexane. Derivatization was performed with 50 µl TFA, shaken for 30 s and after 5 min neutralized with 950 µl ACN:water (1:9, v/v). After that, 400 µl of the water phase was withdrawn. Silanized glass material was used throughout the procedure. For HPLC separation, a PhenoSphere-Next C18 reverse phase column (Phenomenex, CA, USA), 5 µm, 250 x 4.5 mm, was used. The mobile phase was water:ACN:MeOH (70:15:15, v/v/v), the flow rate was 1 ml/min, injection volume was 100 µl, and temperature fixed at 40° C. Fluorescence excitation and emission wavelengths were set at 360 nm and 440 nm, respectively. LOD and LOQ for AFs were 0.2 µg/kg and 0.4 µg/kg for AFB1, AFG1 and AFG2, respectively, and 0.3 µg/kg and 0.5 µg/kg for AFB2, respectively.

Fumonisins. Determination of FBs was performed according to the Official Method 995.15 [28]. Samples were blended for 3 min at high speed with 50 ml of MeOH:water 75:25 (v/v). The extract was filtered with Whatman paper no. 4, adjusted to pH 6 with 1 M NaOH, and centrifuged for 10 min at 2000 g (GELEC model G142, G-650 rotor, Buenos Aires, Argentina). Then, 10 ml of the extract were passed through quaternary amine solid phase extraction columns (CUQAX15Z, 500 mg; UCT, Bristol, PA, USA), previously conditioned with 5 ml of MeOH and 5 ml of MeOH:water 75:25 (v/v), consecutively added. Later they were washed with 5 ml MeOH:water 75:25 (v/v) and 5 ml of MeOH. FBs were then eluted with HAc:MeOH 1:99 (v/v) at a speed of 1 ml/min and the solvents were evaporated to dryness at 60 °C under a stream of nitrogen. The residue was resuspended in 500 µl of ACN:water 50:50 (v/v) and analyzed using Agilent 1100 series HPLC-FLD. FBs were derivatised online with a solution of o-phthaldialdehyde 2-mercaptoethanol (OPA-2-MCE). The injection program was set to mix 17 µl OPA-2-MCE, 20 µl sample and then 17 µl OPA-2-MCE prior to injection. Fluorescence excitation and emission wavelengths were set at 335 and 440 nm, respectively. An analytical LiChrospher RP-18 HPLC column of 250 × 4.0 mm × 5 µm (Merck, Darmstadt, Germany) was used. The isocratic mobile phase consisted of 1000 ml of 1 M sodium phosphate, 3348 ml of MeOH and 24 ml of orthophosphoric acid, adjusted to pH 3.3, with a flow rate of 1 ml/min and a column temperature of 30 °C. The limits of detection (LOD) were 2.3, 1.9 and 1.8 µg/kg for FB1, FB2 and FB3, respectively. The limits of quantification (LOQ) were 7.8, 6.2 and 5.8 µg/kg for FB1, FB2 and FB3 [29].

3 Results and Discussion

3.1 Alterations in Fungal Ultrastructure

The ultrastructure changes in *A. flavus*, *A. parasiticus* and *F. verticillioides* exposed to the different flavonoids were observed by TEM. Representative micrographs of the effects produced by the treatments in the different species are shown in Fig. 1.

The characteristic ultrastructure of untreated *A. flavus*, *A. parasiticus* and *F. verticillioides* is observed in Fig. 1A-C, respectively [20]. Cells of regular, turgid shapes can be noted, with normal cytoplasmic content and some distinguishable organelles.

Cell membranes appear intact. The cytoplasm is clearly surrounded by the cell wall and the fibrillar layer, both with high electronic density.

Treatment with 0.2 mM NAR produced severe damage to the structure of *A. flavus* cells (Fig. 1D). Disruption of the cell membrane and endomembrane system, and lysis of the cytoplasmic content, irregularities and rupture of cell walls and loss of content to the medium (black triangle), formation of numerous vesicles and detachment and agglomeration of the outer fibrillar layer were visualized. Similarly, treatment with 0.2 mM NAR induced a reduction in the thickness of the fibrillar layer and the cell wall in some areas of the *A. parasiticus* cells (Fig. 1E). The formation of multiple lipid bodies was striking, visualized both inside the cell and in the external zone (micrograph not shown). Disruption of the plasmalemma and other membranes occurred, with the formation of small vesicles and probably loss of permeability, and significant degradation of the cytoplasm. The same treatment altered the morphology of *F. verticillioides* cells, resulting in irregular shapes, undulating cell walls with invaginations or protrusions and, in some cases, walls appeared with lower electron density and some incipient disruption episodes (Fig. 1F). Disorganization of the cytoplasmic content and damage to the membrane of the nucleus and mitochondria were also observed in some cells.

A. flavus treated with 0.2 mM NEO (Fig. 1G) resulted in detachment and agglomeration of the fibrillar layer. The plasma membrane was damaged and detached from the irregular cell wall, without being able to contain the cytoplasm. Nuclei, mitochondria, and other organelles were observed with evident degradation. The treatment of *A. parasiticus* with 0.2 mM NEO (Fig. 1H) caused deformation of cell walls, detachment and rupture of the cell membrane, retraction of the cytoplasm (empty triangle) and formation of vesicles; lysis of the membranous organelles and the presence of large lipid bodies. The structure of the fibrillar layer was more similar to the control than in the case of the 0.2 mM NAR treatment. The application of 0.2 mM NEO to *F. verticillioides* produced some loss of rigidity of the cell wall, which appeared undulated, and deterioration in membranes with the consequent incipient disorganization of the cytoplasm, which exhibited numerous vesicles and good electron density (Fig. 1I).

The effects of 0.2 mM QUER, in the case of *A. flavus*, can be seen in Fig. 1J. Some cells were seen to be highly deformed, with irregular and folded cell wall, with deterioration of the cytoplasm. The plasma membrane appeared separated from the cell wall (empty triangle) and discontinuous. The cytoplasm was disorganized, with deteriorated material and the formation of small vesicles. The walls and the fibrillar layer were electronically very dense. The same treatment against *A. parasiticus*, induced agglutination and detachment of the fibrillar layer, formation of electronically dense grains in the inner part of the wall, disruption of the nuclear membrane and other organelles, and contraction and degradation of the cytoplasm (Fig. 1K). On the other hand, *F. verticillioides* treated with QUER 0.2 mM can be seen in Fig. 1L. Collapsed cells, an irregular cell wall, in some cases thicker compared to the control, and absence of cytoplasmic content in several cells were distinguished.

The treatment with the mixture of flavonoids (composed of 0.2 mM NAR, 0.2 mM NEO and 0.2 mM QUER) altered *A. flavus* cells (Fig. 1M). Although the external fibrillar layer was not absent, there were changes in its structure and detachment from the wall. The cell walls presented variable thickness, being broken in some cells (black

triangle). However, most of them did not appear folded. The cytoplasmic content was observed disorganized by the lysis of the membranes and the formation of vesicles, without distinguishing characteristic organelles. Cells without cytoplasmic content were also distinguished. On the other hand, when flavonoids were used in combination against *A. parasiticus* (Fig. 1N), cell contraction or deformation, along with membrane rupture and degradation were observed. The walls were folded and electronically very dense, indicating a specific effect of the mixture on its architecture. The fibrillar layer appeared adhered to the wall. Dispersed cytoplasmic content was noted inside, with formation of few vesicles. In the case of *F. verticillioides*, the treatment mainly altered the cell walls, as can be seen in the micrographs in Fig. 1O. In this case the combined use of NAR 0.2, NEO 0.2 and QUER 0.2 mM caused severe deformation, with cells folded several times on themselves, with invaginations and protuberances in the cell wall. The cells were agglutinated. Although the cytoplasm was disorganized, there is no indication that the cells have lost content. Some nuclei without membranes were present, also vacuoles and lipid bodies were differentiated.

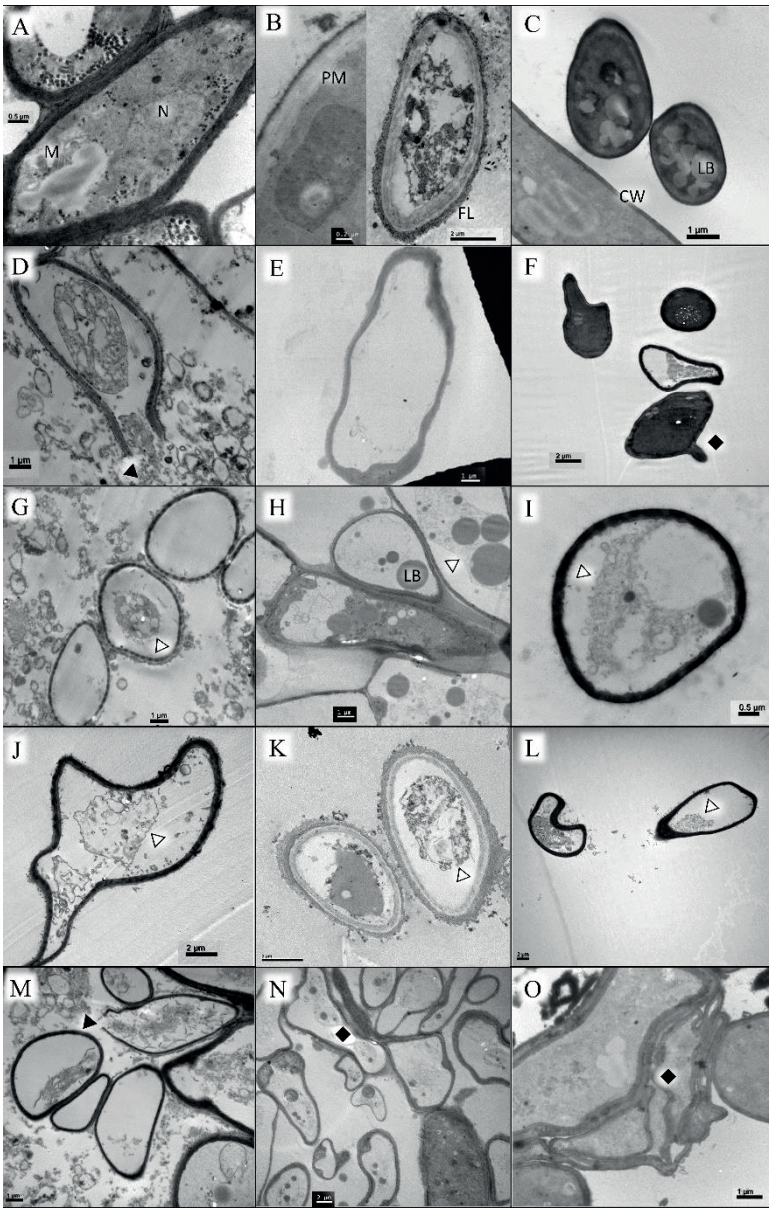

Fig. 1. Micrographies corresponding to *A. flavus* (first column), *A. parasiticus* (second column), and *F. verticillioides* (third column). Control (A-C), treatment with NAR 0.2 mM (D-F), NEO 0.2 mM (G-I), QUER 0.2 mM (J-L), and treated with mixture of NAR 0.2 mM, NEO 0.2 mM and QUER 0.2 mM (M-O). N: nuecleus, M: mitochondria, PM: plasmalemma, FL:fibrillary layer, CW: cell Wall, LB: lipid bodies. (▲): Cell wall disruption. (▷): Detachment and deterioration of plasmalemma. (◆): Unusual cell shrinkage.

The degeneration of various fungal organelles, the disorganization and breakage of lipid bilayer membranes and the changes in cell walls observed by TEM indicated that flavonoids targeted multiple sites of these three species cellular ultrastructure. These alterations can be compared to the morphological damages produced in *A. parasiticus* when applying Akacid®plus, which is a synthetic fungicide, eventually leading to cell death [30]. Also these alterations are similar to those caused by the synthetic antifungals fludioxonil + metalaxyl-M typically applied in maize against *F. verticillioides* [31]. The application of 1.5 mg/L of these compounds generated the loss of the characteristic structure of the hyphae, which appeared contracted with defects on the cell wall, evidenced by scanning electron microscopy. Although treatment with fludioxonil + metalaxyl-M interfered in *F. verticillioides* mycelial morphology and sporulation, it also significantly raised FB1 accumulation levels. The morphological effects of natural compounds, such as *Zingiber officinale* essential oil, on microconidia of *F. verticillioides* presented reduction of turgor, loss of membrane integrity and inhibition of ergosterol production and reduction of FB1 and FB2 accumulation *in vitro* [32].

Hydroxyl (-OH) groups and double bonds, present in the studied flavonoids, could be responsible of the antimicrobial activity, as these groups could promote the delocalization of electrons that reduce the gradient across the cytoplasmic membrane of microbial cells [33] possibly due to the interactions with the hydrophilic region of phospholipids in the cell membrane and the eventual penetration to the hydrophobic nucleus, producing alterations in the fluidity of the membranes, evidencing an increase in ion flux and relative conductivity [34]. In the case of *Candida albicans* treated with 0.03 mM QUER, Mg^{2+} accumulation increased due to the disruption of mitochondrial membranes, leading to an disarrange of antioxidant systems, subsequently resulting in DNA fragmentation [35]. In this work the application of flavonoids induced alterations in the cell wall in addition to those in the plasma membrane and the endomembrane systems. Fungal cell walls are composed of chitin microfibrils inter chained by hydrogen bonding, glucan chains (principally β-glucan) and modified glycoproteins with N-linked and O-linked oligosaccharides [36]. These components provide the cell wall with mechanical strength. As seen in TEM, flavonoids QUER, NAR and NEO affected the macromolecular crosslinking of the walls, which became pliant, affecting cell osmotic stability and favoring the malformation of the cells.

Despite the fact that different media were used to assess ultrastructure damage and mycotoxin accumulation so that a direct relationship between both effects is not possible, the individual flavonoids evidently altered the structure and promoted the formation of vesicles due to the disorganization and disruption of the membranes. Fewer organelles remained, and scarce cytoplasmic content was evidenced when the flavonoid mixture was applied (Fig. 1M-O).

3.2 Effect on Mycotoxin Accumulation

After incubation time, AFs and FBs accumulation in maize were analyzed. The accumulation of AFs by *A. flavus* control reached 1578 ± 1214 µg/kg for AFB1 and 74 ± 68 µg/kg for AFB2. In the case of *A. parasiticus* AFs accumulation levels were 53557 ± 47880 µg/kg, 145960 ± 130086 µg/kg, 2965 ± 2592 µg/kg, and 9132 ± 8575 µg/kg

for AFB1, AFG1, AFB2 and AFG2, respectively. Regarding FBs accumulation by *F. verticillioides* concentration of FB1, FB2 and FB3 reached 2807 ± 1356 µg/kg 229 ± 330 µg/kg 1687 ± 191 µg/kg, respectively. All strains were considered highly mycotoxigenic, surpassing the maximum levels set by the European Commission regulations. The percentage decrease in concentration of these mycotoxins in maize, produced by the addition of the studied flavonoids, are shown in Table 1.

Table 1. Relative pergentage reduction of the different mycotoxins studied in maize at 0.98 a_w. (*) Accumulation was increased.

Treatment	AFs reduction (%)						FBs reduction (%)		
	A. flavus		*A. parasiticus*				*F. verticillioides*		
	AFB1	AFB2	AFB1	AFG1	AFB2	AFG2	FB1	FB2	FB3
mixture	95 ± 5	99 ± 1	90 ± 2	92 ± 1	94 ± 1	97 ± 0	58 ± 8	36 ± 26	97 ± 3
NAR	87	94	95	94	98	98	29	*	84
NEO	90	98	95	96	96	98	90	100	100
QUER	82	95	94	95	97	98	69	88	82

AFs reduction surpassed the 80% in the case of *A. flavus* and *A. parasiticus*, regardless of the flavonoids used, alone or in combination.

Based on the data corresponding to the *A. flavus* transcriptome, it has been shown that certain genes necessary for the development of its conidia and mycelia are down regulated when QUER is applied to the culture medium [37]. Likewise, some of the transcription factors related to sexual development and to specific conidiation proteins were also decreased. Furthermore, the redox state in *A. flavus* mycelia has been shown to be closely related to AFs production. QUER proved to be effective in reducing the level of reactive oxygen species (ROS) in *A. flavus*, therefore, a mechanism of QUER effect on mycotoxins could be the depletion of intracellular ROS levels [38].

The functional importance of vesicles and vacuoles in the biosynthesis and export of fungal secondary metabolites in *A. parasiticus* has been demonstrated in the case of aflatoxins, as its production is completed in vesicles and vacuoles. These membranous organelles, endosomes or aflatoxisomes, participate in compartmentalization and export of AFs to the growth medium, potentially by exocytosis [39]. The metabolic pathways of these secondary metabolites, as well as the proteins involved in the response to stress factors would be present in the cell fraction corresponding to endosomes, transport vesicles and vacuoles [40]. Then, the low production of AFs due to treatment with flavonoids would be explained, at least partially, by a very severe alteration of these structures of the fungal cells [20].

Regarding *F. verticillioides*, evidence about the mechanisms of action of flavonoids on FBs concentration is scarce. Although some authors may link the decrease in FBs production with growth alterations, in some cases, as can be seen in this work, hyphae malformation and distortion does not lead to the reduction in FBs accumulation [41]. The application of NAR increased 75% FB2 accumulation in maize, in spite of the ultrastructure alterations evidenced in Fig. 1F.

4 Conclusions

Flavonoids produced severe alterations on *A. flavus*, *A. parasiticus*, and *F. verticillioides* ultrastructure and reduced the mycotoxin accumulation by these species. In general, the application of flavonoids NAR, NEO or QUER resulted in cell wall alterations, degradation of cytoplasm and depletion of plasmalemma and other membranes, with a reduction effect in mycotoxins accumulation, possibly due to the effect in the cell wall ductility with loss of osmotic stability and to the disarrangement of antioxidant systems.

AFs produced by *A. flavus* and *A. parasiticus* highly toxigenic strains were efficiently reduced by all applied treatments. FBs by *F. verticillioides* were best inhibited from 90 % to 100% with NEO 0.2 mM. Conversely, NAR 0.2 mM increased FB2 accumulation.

The flavonoid mixture composed of NAR, NEO and QUER reduced the mycotoxins produced by these three species. It would be interesting to find an optimal mixture that achieve total mycotoxin inhibition. These flavonoids may represent environmentally friendly additives against mycotoxins, as they can be extracted from the wastes of the citrus industrialization, being an alternative strategy to replace chemical additives for stored maize.

Resumen. El objetivo del presente estudio fue investigar el efecto de los diferentes procedimientos de salado sobre las características reológicas y la microestructura de filetes de merluza. Los tres procedimientos salado seco (SS), húmedo (SH) y mixto (SM) presentaron un aumento en el módulo elástico y de pérdida con el incremento del tiempo de salado. En todos los casos, G' excedió los valores G´´, indicando un comportamiento sólido predominante. Los valores de G' para SH con 48 h de salado fueron similares a los alcanzados con 8 h de SS y SM. En términos de prueba de barrido de temperatura, para la merluza fresca, el primer pico en G´ se asoció con la desnaturalización de la miosina, mientras que la actina fue más resistente al aumento del contenido de sal en el músculo. En muestras saladas, la miosina y la actina convergieron a un mismo pico de temperatura de desnaturalización (Td). Los métodos SS y SM presentaron una Td levemente mayor, mientras que las muestras SH mostraron una Td más cercana a la merluza fresca. Las micrografías SEM revelaron que las diferencias encontradas entre métodos se deben a los cambios conformacionales sobre las proteínas miofibrilares y sobre los componentes estructurales como el colágeno del tejido conectivo, directamente relacionadas con el contenido de agua y sal. Los efectos del salado seco fueron más relevantes en comparación con la inmersión en salmuera ya que SS mostró los valores más altos de z_{NaCl} y el SH presentó los menores.

Palabras clave: Salado, *Merluccius hubbsi*, Propiedades reológicas, Microestructura, Proteínas miofibrilares.

1 Introducción

Merluccius hubbsi es la especie dominante en Argentina en términos de biomasa y habita desde Cabo Frío, en Brasil (22° S), hasta el sur de Argentina (55° S), en profundidades entre 50 y 500 m [1]. Es la base de la industria pesquera del país y la especie más importante en el consumo interno. El 90 % de la producción es exportada fundamentalmente como filete congelado y descabezada y eviscerada (H&G). Los alimentos de origen marino son actualmente aceptados como un alimento esencial para el ser humano

debido a sus proteínas de alto valor biológico, ácidos grasos poliinsaturados, principalmente omega-3 y otros nutrientes, como minerales, oligoelementos y vitaminas [2]. Las proteínas del músculo de los peces se pueden dividir en tres grupos: proteínas miofibrilares (actina, miosina, tropomiosina y actomiosina), que constituyen el 70-80 % del contenido total; proteínas sarcoplasmáticas (mioalbúmina, globulina y enzimas), fracción que constituye el 25-30 % del total de proteínas; y, proteínas del tejido conectivo (colágeno), que representan entre 3-10 % [3].

Diferentes métodos de salado han sido utilizados para conservar los alimentos desde el Antiguo Egipto [4]. Para el salado de pescado, existen tres procedimientos: salado húmedo, salado seco y una combinación de ambos. En el salado húmedo, los filetes se sumergen en una solución de sal y agua, mientras que en el salado seco el pescado se apila en capas alternas de pescado y sal. El pescado absorbe sal, mientras que el líquido que difunde desde el músculo se permite que drene. El procedimiento de salado mixto es similar al procedimiento de salado seco, pero en recipientes cerrados. La calidad y los cambios estructurales de las proteínas en los productos salados están influenciadas por el método utilizado. Las proteínas sufren desnaturalización, siendo la cadena pesada de miosina más susceptible a la desnaturalización por salado fuerte [5].

La textura es un parámetro esencial en los alimentos que influye directamente sobre la aceptación de los consumidores. Las propiedades texturales de un alimento son el grupo de características que dependen de sus elementos estructurales y se relacionan con la deformación, desintegración y flujo por la aplicación de una fuerza. Una propiedad importante del alimento que se asocia con la textura es su comportamiento reológico. Estas propiedades están íntimamente relacionadas con las propiedades fisicoquímicas y funcionales de los constituyentes de un sistema alimenticio, así como, las variables de operación que se aplican en las diferentes etapas del proceso [6].

El efecto del salado sobre las propiedades reológicas y estructura del tejido muscular de mamíferos es bien conocido [7]. Sin embargo, se encuentra disponible muy poca información relacionada con este efecto en proteínas de pescado. No existen estudios sobre los cambios reológicos provocados por el salado en *Merluccius hubbsi*. Así, la merluza salada podría ser una alternativa para incrementar el valor agregado de los productos pesqueros y diversificar la oferta de productos del mar.

En este contexto, el objetivo del presente trabajo fue estudiar el efecto del salado sobre las características reológicas de filetes de merluza salados por diferentes métodos y comprender sus cambios estructurales mediante imágenes de microscopía electrónica.

2 Materiales y Métodos

2.1 Materia prima

Se trabajó con filetes de merluza (*Merluccius hubbsi*) frescos, sin piel, provistos por una pescadería local (Mar del Plata, Buenos Aires, Argentina). Los filetes se obtuvieron de forma manual y éstos se cortaron en trozos de 100x50x10 mm. Se mantuvieron a 4 ± 1 °C hasta el momento del procesamiento.

2.2 Procedimientos de salado

Los filetes de merluza fueron salados a 4 ± 1 °C siguiendo tres procedimientos. Inmersión en salmuera saturada (**SH**): solución con sal entrefina comercial (CELUSAL, Buenos Aires, Argentina) y agua corriente (26 % p/p NaCl, relación pescado:salmuera 1:10). Salado seco (**SS**): capas alternas de pescado y sal se colocaron uniformemente en un recipiente con drenaje, empezando y terminando con una capa de sal. Salado mixto (**SM**): se colocaron de la misma forma capas de pescado y sal en un recipiente sin drenaje. Muestras con 0, 2, 8, 24 y 48 h de salado fueron destinadas para las distintas determinaciones experimentales. Muestras extraídas a 0,5 y 4 h de salado fueron diseñadas adicionalmente para microscopía electrónica con el objetivo de evidenciar más claramente los efectos de salting-in y salting-out que ocurren en el músculo a fuerzas iónicas por debajo y por encima de 1 molar (M), respectivamente [8].

2.3 Determinaciones fisicoquímicas

Las muestras del salado húmedo una vez extraídas se dejaron escurrir y se secaron con papel absorbente, mientras que los trozos con salados seco y mixto fueron sumergidos previamente en salmuera saturada por 30 segundos para retirar el exceso de sal de la superficie. A continuación, se sometieron a un homogeneizado con procesadora (MOULINEX, Buenos Aires, Argentina) para las determinaciones fisicoquímicas. El contenido de agua (x_w) se realizó por secado en estufa a 105 ± 2 °C hasta peso constante [9]. Contenido de cenizas a partir de la calcinación del residuo seco en mufla a 500 ± 5 °C hasta cenizas blancas (8 h) [9]. Determinación de NaCl (x_{NaCl}) mediante la técnica de Mohr [10] partiendo de las cenizas. Las determinaciones de contenido de agua, cenizas y NaCl fueron realizadas por triplicado. Asimismo, se calculó la concentración de NaCl en fase líquida (z_{NaCl}) con la **Ecuación (1)** [11]:

$$z_{NaCl} = \frac{X_{NaCl}}{X_w + X_{NaCl}} \qquad \text{Ec. (1)}$$

2.4 Ensayos oscilatorios

Se realizó un barrido de frecuencias para evaluar las propiedades reológicas del músculo de merluza fresca y salada, con un reómetro Anton Paar (Physica MCR 301, Ostfildern, Alemania). Para ello, se determinó primeramente el rango viscoelástico lineal (RVL) con un barrido de amplitud con control de la deformación de cizalla (BA CDC). Se fijó la frecuencia angular en 1 s^{-1}, barriendo la amplitud de deformación entre 0,001-10 %. Dentro del RVL, se realizó el barrido de frecuencias para determinar los espectros mecánicos (G', G" y η*). Se utilizó una platina de 25 mm de diámetro, un rango de frecuencia angular de 0,5-50 s^{-1} y la temperatura de trabajo fue de 20 °C. Para evitar deslizamientos de la muestra y errores en las mediciones asociados a cambios en el volumen (contracción de las fibras musculares), en todos los casos se aplicó un esfuerzo normal de 0,5 N [12]. Las muestras fueron cortadas paralelo a la dirección de

las fibras musculares utilizando un sacabocado cilíndrico de igual diámetro que la platina. Adicionalmente, se realizaron ensayos de termo-reología (1 $\mathbf{s}^{-1}$; 0,05 % de deformación) en el rango de temperatura de 20-90 °C, velocidad de calentamiento 3 °C/min.

2.5 Microscopía SEM

Los cambios en la microestructura del tejido de merluza durante el salado fueron evaluados a través de micrografías de cortes del filete longitudinales. Para ello, cubos (10 mm) de merluza fresca y salada fueron sumergidos en N_2 líquido y liofilizados (3 días, 1 Pa) (Boyikang Laboratory Instruments Co., Ltd, Beijing, China). Los cubos se colocaron en portaobjetos SEM y se metalizaron con oro (100 Å de espesor). Las muestras se observaron en un microscopio electrónico de barrido (JSM 6460 LV, JOEL, Japón) equipado con un sistema de procesamiento de datos a un voltaje de 15 kV.

2.6 Análisis estadístico

Se utilizó el análisis de varianza de dos factores (ANOVA) para establecer la presencia o ausencia de diferencias significativas en los valores de x_w, x_{NaCl} y z_{NaCl} de los filetes de merluza, según los factores "método de salado" y "tiempo" con un nivel de significación de $p < 0,05$ (Infostat v 2009, Universidad Nacional de Córdoba, Argentina).

3 Resultados y Discusiones

3.1 Parámetros fisicoquímicos

El contenido de humedad, cloruro de sodio y cloruro de sodio en fase líquida del pescado para filetes de merluza fresca y salada, se presentan en la **Tabla 1**.

Para los tres procedimientos de salado estudiados, z_{NaCl} en merluza mostró un aumento con el tiempo de salado. Los análisis de varianza mostraron diferencia significativa en la interacción entre el tiempo y el método de salado ($p < 0,05$). Luego de 2 h, las muestras SS presentaron valores de z_{NaCl} significativamente diferentes con respecto a las muestras SM y SH. Las muestras SS y SM no mostraron diferencias significativas en los valores finales de z_{NaCl}. Para 48 h, el SS mostró los valores más altos de z_{NaCl} y el SH presentó los menores. Para tiempos de salado cortos (< 8 h), el comportamiento de SM fue similar al de muestras SH, pero para tiempos de salado más prolongados, los valores de z_{NaCl} de muestras SM se acercaron a los valores de SS. Las diferencias observadas en los valores de z_{NaCl} entre los diferentes métodos podrían atribuirse a diferencias en las fuerzas impulsoras presentes en cada sistema. Barat et al. [11], [13] observaron efectos similares con diferentes concentraciones de salmuera durante el salado de bacalao (*Gadus morhua*).

Tabla 1. Humedad promedio (x_w), cloruro de sodio (x_{NaCl}), cloruro de sodio en fase líquida (z_{NaCl}) y desviación estándar para 0, 2, 8, 24 y 48 h de SH, SM y SS de filetes de merluza.

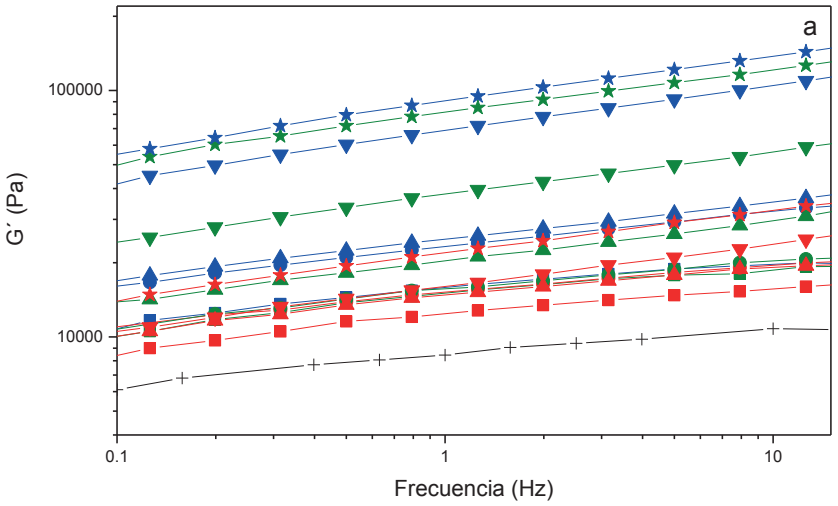
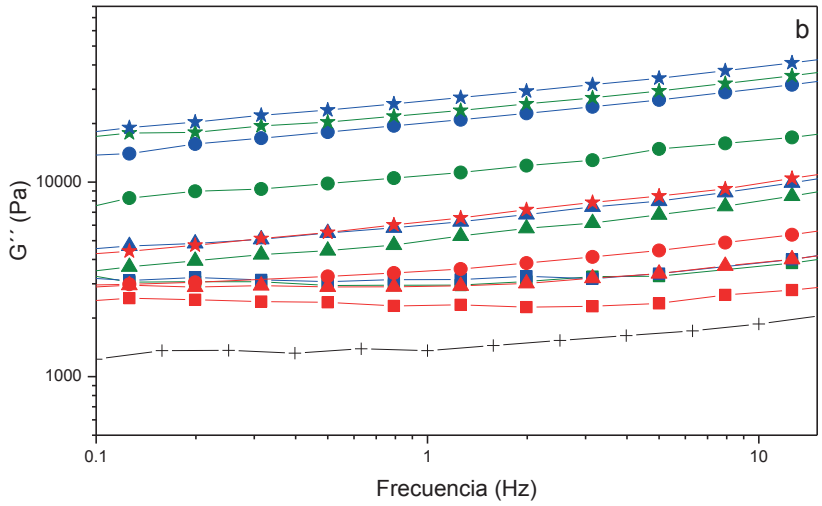
Letras diferentes en una misma columna indican diferencias significativas ($p < 0,05$).



3.2 Ensayos oscilatorios



El módulo de almacenamiento o elástico (G'), el módulo de pérdida (G'') y la viscosidad compleja (η*) en función de la frecuencia angular para 0, 2, 8, 24 y 48 h de SH, SM y SS, se muestran en la **Figura 1**.

G' y G" presentaron una ligera dependencia con la frecuencia angular (**Fig. 1a y 1b**). La dependencia del módulo de almacenamiento fue directamente proporcional a la frecuencia. Un leve incremento en el módulo se correspondió con un aumento de la frecuencia. Con respecto a la dependencia del módulo de pérdida, a bajas frecuencias se observó un "*plateau*" en las muestras que presentaban menor contenido de sal. Para muestras con mayor tiempo de salado (> 8 h) el "*plateau*" seguramente se evidenció a frecuencias más bajas que las evaluadas en este ensayo, ya que G´´ mostró una pendiente con la frecuencia desde el comienzo. En todos los casos, G' excedió los valores G´´, indicando un comportamiento sólido predominante.

Analizando el efecto del tiempo sobre los métodos de salado, los tres procedimientos (SH, SM y SS) presentaron un aumento en el módulo elástico y de pérdida con el incremento del tiempo de salado asociados a la ganancia de sal y deshidratación. Un mayor contenido de sal provoca mayor agregación de proteínas y contracción de las fibras musculares [14]. Por otro lado, un mayor contenido de humedad ejerce mayor efecto plastificante, es decir, mayor aporte de flexibilidad por reducción de fuerzas intermoleculares y mayor movilidad de moléculas. Este último comportamiento se vio reflejado para el tejido de merluza fresca y para tiempos cortos de salado donde las muestras presentaban mayor contenido de agua (**Tabla 1**). Thorarinsdottir [15] reportó

resultados similares sobre los módulos durante el salado de bacalao por vía seca y húmeda.

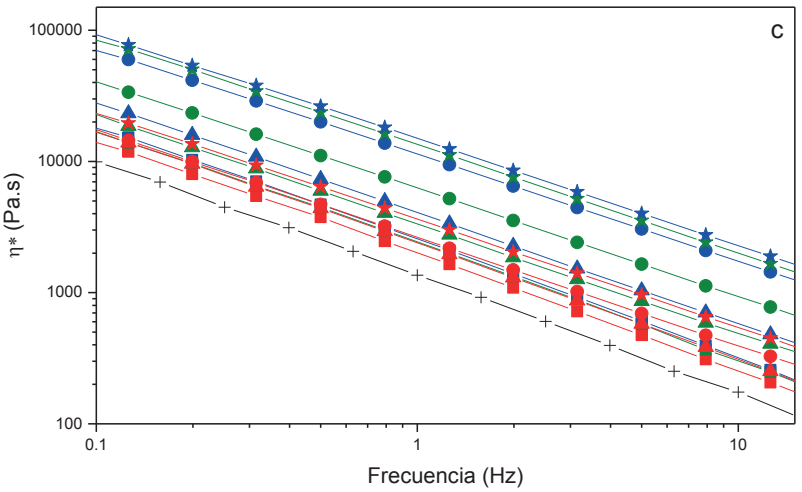


Fig. 1. Barrido de frecuencias para músculo de merluza fresco (+) y salado por 2 h (■), 8 h (▲), 24 h (●) y 48 h (★). a) Módulo de almacenamiento (G'), b) módulo de pérdida (G'') y c) viscosidad compleja (η*). SH (■), SM (■) y SS (■).

Analizando el efecto del método de salado, los valores de G' para SH con 48 h de salado fueron similares a los alcanzados con 8 h de SS y SM (**Fig. 1a**). Por otro lado, los métodos de salado seco y mixto, presentaron comportamientos similares, con valores levemente mayores en los espectros mecánicos para el SS durante las primeras 24 h; luego, estas diferencias se fueron reduciendo presentando una estructura similar a las 48 h de salado, acorde con los valores de z_{NaCl} determinados. Las diferencias encontradas entre métodos se deben a los cambios conformacionales sobre las proteínas miofibrilares y sobre los componentes estructurales como el colágeno del tejido conectivo [14]. Valores altos de G' (salado seco y mixto) se relacionaron con una mayor degradación y agregación de las miofibrillas y pérdida de colágeno; además de la mayor deshidratación que sufren las muestras procesadas por estos métodos.

Analizando el espectro de G´´ (**Fig. 1b**), se desprende prácticamente la misma tendencia que la encontrada para G´, incluso con diferencias aún más marcadas. Si se comparan los valores de G´´ para merluza fresca con los alcanzados al final del proceso de salado con los distintos métodos, se observa que el módulo de pérdida incrementó más de tres veces su magnitud con el método SH, mientras que para los métodos SS y SM el módulo superó cerca de 15 veces su magnitud original.

Independientemente del procedimiento aplicado, la viscosidad compleja (**Fig. 1c**) aumentó con el tiempo de salado. La presencia de NaCl en el músculo de merluza inicia la formación de una estructura tipo gel aumentando la viscosidad y favoreciendo la despolimerización de la miosina lo cual da lugar a un incremento en la hidrofobicidad de la superficie. Por ello, las muestras con mayor contenido de sal (48 h) presentaron valores de viscosidad significativamente más elevados. Por otro lado, la viscosidad

compleja disminuyó al aumentar la frecuencia angular presentando un comportamiento del tipo pseudoplástico.

Los resultados correspondientes a los espectros termo-mecánicos del músculo de merluza fresco y luego de 48 h de salado por distintos métodos (SH, SM y SS) se muestran en la **Figura 2**.

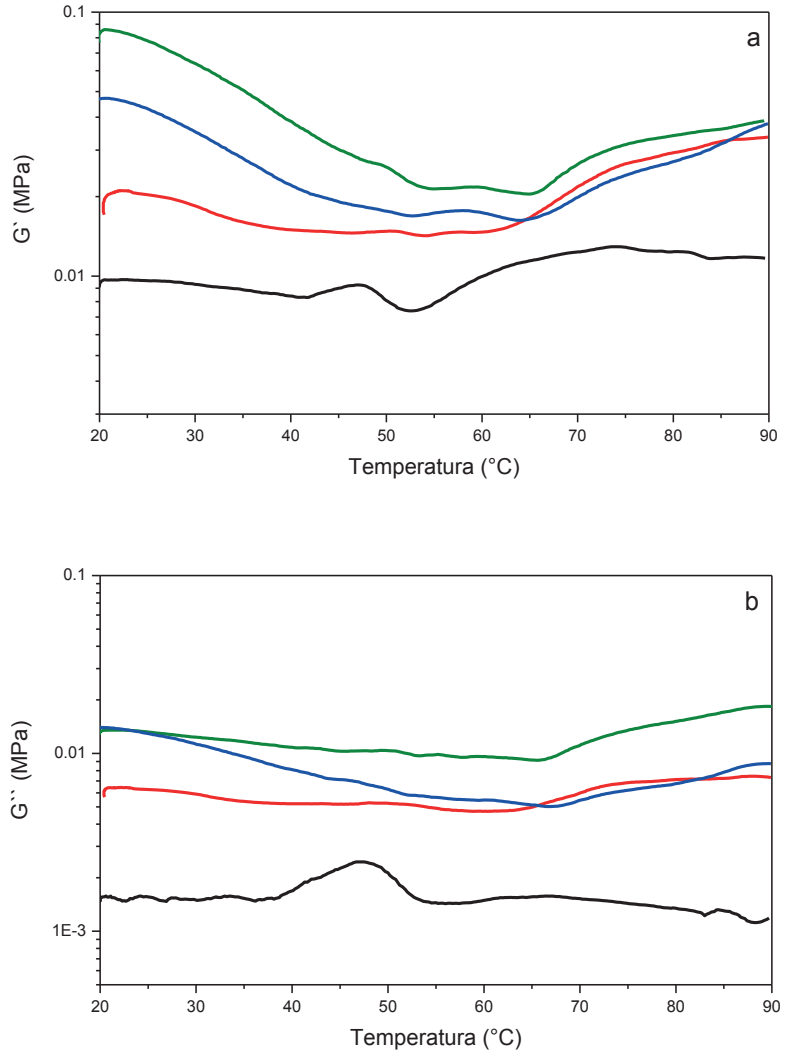

Fig. 2. Espectros mecánicos en función de la temperatura para músculo de merluza fresco y luego de 48 h de salado por distintos métodos. a) Módulo de almacenamiento (G') y b) módulo de pérdida (G''). Fresca (—) SH (—), SM (—) y SS (—).

Las curvas mostraron un comportamiento típico de gelación térmica de sistemas cárnicos, donde la mayor parte de los cambios están asociados a la desnaturalización de la miosina [16]. El módulo elástico de la merluza fresca disminuyó ligeramente desde los 20 °C hasta los 39 ± 4 °C (G´ = 0,0081 ± 0,0002 MPa). Pequeños descensos del valor de G´ entre 25 y 40 °C fueron asociados a disociación de la tropomiosina del esqueleto de F-actina y disociación de F-actina de su estructura de hélice [17]. El primer pico de G´ se obtuvo para 46,7 ± 0,4 °C (G´ = 0,010 ± 0,002 MPa), luego se observó un leve descenso de G' hasta los 53,6 ± 1,3°C (G´ = 0,0079 ± 0,0007 MPa). Varios estudios han reportado que las proteínas miofibrilares, especialmente miosina y actina, son responsables de la gelificación. La cadena pesada de miosina es la principal subunidad involucrada en dicho proceso; mientras que en lo que respecta a las cadenas ligeras, parece ser que su rol es dependiente de la fuerza iónica [18]. El desplegamiento de la miosina, causa un incremento en la fluidez de la estructura preformada del gel y puede interrumpir algunos entrecruzamientos que existen durante el estado inicial, resultando en el descenso del valor de G´ [18]. Howell et al. [19] reportaron una temperatura de desnaturalización para la miosina de 42 °C y 45,7 °C para bacalao (*Gadus morhua*) y trucha (*Salmo gairheri*), respectivamente. El segundo máximo se obtuvo para 74,1 ± 0,8 °C (G´ = 0,0131 ± 0,0003 MPa) y puede ser atribuido a la formación de una red permanente con los filamentos de miosina desnaturalizada; luego de esta temperatura el módulo se mantuvo prácticamente invariable hasta el final del calentamiento, donde la miosina y la actina se encontraban completamente desnaturalizadas. Se cree que la actina es más resistente al aumento del contenido de sal en el músculo [18].

Como se observa en la **Figura 2**, las muestras saladas (48 h) presentaron inicialmente un valor de G´ significativamente mayor en comparación con la merluza fresca. A medida que avanzó el calentamiento, se observó un descenso inicial de G´ más pronunciado en muestras saladas en comparación con la merluza fresca, siendo esta caída más abrupta para SS y SM y en menor medida para SH. El módulo de almacenamiento en muestras SH y SS descendió entre 20 y 46 °C; luego, se mantuvo hasta los 67 °C aproximadamente, superada dicha temperatura G´ creció hasta el final del calentamiento. En el caso de SM, G´ descendió desde el comienzo del calentamiento hasta aproximadamente 52 °C. Para los tres métodos, las muestras saladas presentaron un pico previo al ascenso final del módulo, pero desplazado a temperaturas mayores. A medida que la cantidad de agua libre disminuye, es necesaria una mayor temperatura para poder desarrollar la estructura tipo gel. Las diferencias encontradas entre métodos de salado estarían directamente relacionadas con el contenido de agua y sal. Los métodos SS y SM presentaron una mayor pérdida de agua y una temperatura de desnaturalización (Td) levemente mayor, mientras que las muestras procesadas con SH mostraron mayor contenido de humedad y una Td más cercana a la merluza fresca.

En general, se observó que la ganancia de sal disminuye la estabilidad térmica de las proteínas miofibrilares, siendo necesaria una mayor temperatura para poder desarrollar la estructura de gel. La miosina y la actina prácticamente convergieron a un mismo pico de Td ya que la temperatura del primer pico se vio incrementada. Estos resultados concuerdan con lo reportado por Zhou y Labuza [20], quienes encontraron menores valores de temperaturas de desnaturalización en tejidos con mayor actividad de agua y, por ende, con una mayor movilidad de las proteínas.

3.3 Microscopía SEM

La microfotografías de filetes de merluza frescos (0 h) y salados durante 0,5, 4, 8 y 48 h por distintos métodos (SH, SM y SS) se muestran en la **Figura 3**.

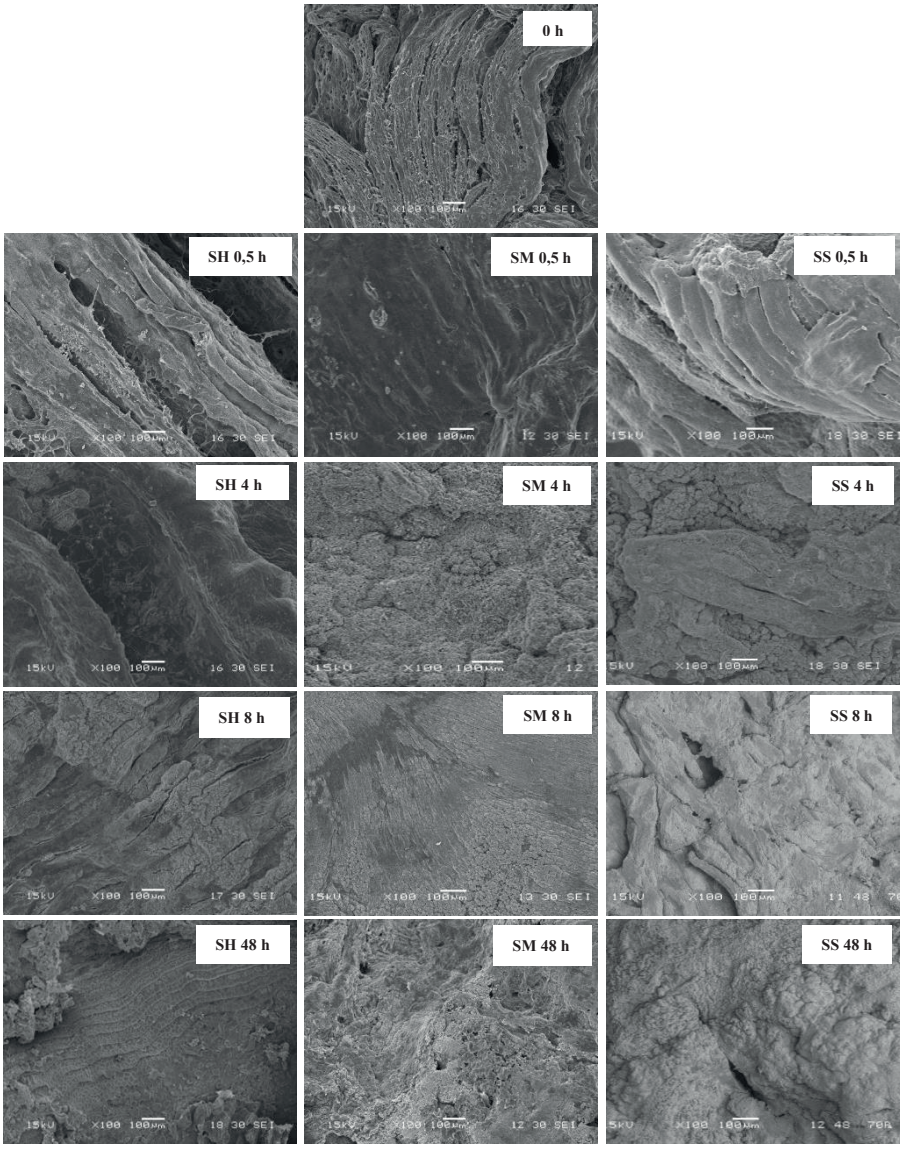

Fig. 3. Imágenes de microscopia electrónica de barrido para tejido de merluza fresca y salada por diferentes métodos (SH, SM y SS). Tiempos de salado: 0, 0,5, 4, 8 y 48 h.

El tejido muscular está constituido por fibras musculares, las cuales están rodeadas por tejido conjuntivo que las mantienen unidas. El tejido conjuntivo que rodea a las células musculares forma una capa delgada que constituye el endomisio; a su vez, un haz de fibras musculares con endomisio son rodeadas por una capa de mayor grosor de tejido conjuntivo que constituye el perimisio; varios haces de fibras musculares forman un músculo que es rodeado por una capa aún más gruesa que forma el epimisio. La unidad estructural y funcional del músculo estriado se llama sarcómero. El sarcómero contiene la matriz de filamentos de actina y miosina. Los filamentos gruesos de miosina están intercalados con los filamentos delgados de actina [3]. Es sabido que con el microscopio electrónico se puede observar mejor la estructura del sarcómero, con filamentos finos de actina, tropomiosina y troponina, y filamentos gruesos dispuestos de manera regular formados por miosina [3].

En relación a lo anterior, la microfotografía del tejido fresco de merluza mostró un paquete organizado de miofibrillas con presencia de tejido conectivo y pocos espacios intercelulares (0 h). Sin embargo, durante el salado, la microestructura del músculo se alteró significativamente (**Figura 3**).

Analizando el efecto del tiempo sobre los métodos de salado, para 0,5 h, las muestras SH mostraron una ligera contracción de las miofibrillas y aumento de los espacios intercelulares. Además, en las microfotografías, se observaron pequeños depósitos de sal en las fibras y desprendimiento del tejido conectivo (SH 0,5 h). Para las muestras SM y SS, se observó que sólo 0,5 h de salado fueron suficientes para que las fibras del tejido de merluza queden prácticamente cubiertas en su totalidad por una fina capa de sal. Efecto que se evidenció a las 4 h para SH. A medida que avanzó el tiempo de salado, se observó un aumento gradual en el espesor de la capa de sal que recubre las fibras, más notorio en las micrografías con salado SS. Para 48 h, en las micrografías SS y SM, se observó la formación de una costra gruesa irregular (ya evidente a las 8 h en el SS), lo que sugeriría mayor daño o desnaturalización proteica por estos métodos de salado (SS 48 h; SM 48 h) [21]. En contraste, para 48 h de salado húmedo, se evidenció un patrón hexagonal que formaron los cristales de sal de menor tamaño. Una vez saladas las fibras, por efecto de la desecación de la capa superficial, el tejido se contracta y se fractura y empiezan a desarrollarse los polígonos (SH 48 h). La salmuera sube por capilaridad por estas fisuras y se cristaliza al llegar a la superficie constituyendo los brotes de pequeños cristales de sal. Finalmente, el músculo queda cubierto de placas hexagonales y pequeños surcos de sal. Esta textura tan característica del salado húmedo, se evidencia naturalmente de forma macroscópica en algunos salares del mundo [22].

Durante los salados seco y mixto, los cristales de sal que cubren los filetes de pescado crean una mayor diferencia de concentración entre el exterior y el interior de los filetes, lo que provoca una mayor tasa de penetración de sal y deshidratación. El método de inmersión por salmuera, en cambio, controla más fácilmente la absorción de sal y reduce la agregación y desnaturalización de las proteínas [14]. En general, el salado fuerte de los filetes conduce a cambios irreversibles en las proteínas miofibrilares, especialmente en la molécula de miosina. Se cree que la agregación más fuerte de proteínas se produce en los filetes salados en seco [15].

La información sobre el análisis microestructural en el músculo de alimentos en relación con el salado es limitada. Sigurgisladottir et al. [23] comparó el efecto del salado

seco y húmedo en filetes de salmón. Encontraron que el contenido de sal fue similar para ambos métodos, sin embargo, el salado seco tendió a disminuir en mayor medida el área de la sección transversal de la fibra, debido a mayores gradientes de concentración y extracción de agua del músculo en comparación con los inmersos en salmuera. El análisis microestructural del músculo de cerdo salado en salmuera de NaCl al 3 %, 7 %, 10 % y 20 % mostró que bajas concentraciones de NaCl dieron como resultado la hinchazón de las fibras musculares y absorción de agua (efecto salting-in). Lo contrario se observó a concentraciones más altas (20 %), es decir, las proteínas se agregaron dando lugar a disminuciones en el volumen de las fibras y deshidratación del músculo (efecto salting-out) [24], [25].

4 Conclusiones

El estudio mostró que las variaciones en el contenido de agua y sal en el músculo de pescado, tienen un efecto significativo sobre los cambios conformacionales de las proteínas miofibrilares y sobre los componentes estructurales del músculo como el colágeno del tejido conectivo, dependientes, a su vez, del método de salado aplicado. Los principales cambios ocurrieron durante el salado seco, donde el contenido de sal (z_{NaCl}) en el músculo fue mayor en comparación con los métodos húmedo y mixto. En el SS se observaron los mayores incrementos de las propiedades reológicas (G´, G´´ y η*), temperatura de desnaturalización y mayor degradación de la estructura proteica. Los filetes inmersos en salmuera, en cambio, soportaron la menor desnaturalización a través del proceso de salado. Esta observación estuvo de acuerdo con las microfotografías SEM de los filetes. Inmersión en salmuera sería, por lo tanto, el método de salado recomendado en la producción de merluza salada, dando como resultado un producto con un menor daño superficial por salado. El estudio de las propiedades reológicas y el análisis de la microestructura, desempeñó un papel importante en la comprensión del comportamiento muscular durante el procesamiento.

Abstract. Las frutas representan un sustrato alternativo con gran potencial para el desarrollo de alimentos funcionales probióticos; sin embargo sus características intrínsecas como la acidez, representan un desafío para la supervivencia de las cepas. En el presente trabajo se propone la co-encapsulación de dos cepas probióticas (*Lactobacillus casei* ATCC 393 y *L. rhamnosus* ATCC 53103) en microgeles de pectina mediante gelación ionotrópica con inulina de distintos orígenes como estrategia para mejorar la viabilidad en condiciones de almacenamiento en refrigeración. Los resultados muestran que el diámetro promedio de las partículas encapsuladas no se vio afectado por los factores analizados, en tanto que la eficiencia de encapsulación fue > 90%. Los recuentos de ambas cepas al cabo de 6 semanas de ensayo fueron mayores a 7 unidades logarítmicas lo cual asegura una concentración de células viables acorde a las normativas vigentes para ser considerado un alimento funcional probiótico.

Keywords: *Lactobacillus,* Microencapsulación, Pectina, Inulina.

1 Introducción

La inclusión de cultivos probióticos en distintos alimentos se ha realizado tradicionalmente en productos de base láctea, sin embargo la creciente presencia de intolerancias, alergias y distintos regímenes alimentarios, promueven el uso de matrices alternativas no lácteas. En este contexto, las frutas y sus derivados representan sustratos interesantes para la elaboración de un alimento probiótico, ya que además de sus características nutritivas, son aceptadas por todos los grupos etarios y percibidas como alimentos saludables por sí mismos. Sin embargo el principal desafío en el desarrollo de alimentos funcionales a base de frutas es garantizar la supervivencia de las cepas

durante el almacenamiento debido principalmente a su naturaleza ácida. Entre las estrategias propuestas para proteger a los probióticos hasta su llegada al sitio de acción, manteniendo y/o aumentando su viabilidad y actividad están: la fortificación con prebióticos, dando lugar a un alimento simbiótico, y la microencapsulación, utilizando matrices que actúen como una barrera física biocompatible protegiendo a las células bacterianas del ambiente externo [1,2].

La inulina es un carbohidrato de reserva de las plantas, posee propiedades prebióticas y es considerada GRAS. A nivel industrial se la obtiene mayormente de la achicoria; sin embargo un cultivo de creciente interés para su obtención es el topinambur (*Helianthus tuberosus* L.) debido a su interesante y poco explorado potencial agronómico en Argentina y otras partes del mundo [3]. La pectina, de amplio uso en la industria de alimentos, representa un ingrediente de alto valor funcional que ha ganado atención como agente encapsulante de probióticos debido a su bajo costo, no toxicidad y biocompatibilidad, además de ser resistente a las enzimas gastrointestinales y es fácilmente digerida por las pectinasas generadas por la microbiota colónica [4].

El objetivo del presente trabajo consistió en evaluar la microencapsulación en microgeles de pectina con el agregado de inulina de distintos orígenes como estrategia para mejorar la viabilidad de dos cepas probióticas en condiciones de almacenamiento en refrigeración.

2 Materiales y Métodos

2.1 Materiales

Como prebióticos de interés, se utilizaron inulina comercial (IC) de grado alimentario (Sigma-Aldrich Chemical Co.) e inulina obtenida de *Helianthus tuberosus* (ITub), donada por la Dra. Irene Rubel (Universidad Nacional del Centro de la Provincia de Buenos Aires). La metodología de extracción y caracterización química de ITub se informan en Rubel [5] y Rubel [3].

En la formulación de los microgeles se utilizó pectina de bajo metoxilo Genu Pectin LM104 AS (CPKelco, Limeira, Brasil), con un grado de esterificación del 27% y el 20% de los grupos carboxilos reemplazados por grupos amida (datos del fabricante). Como fase dispersante se utilizó aceite de girasol Molinos Rio de la Plata S.A. (Buenos Aires, Argentina) y como agente entrecruzante se utilizó cloruro de calcio (Anerda S.A., San Fernando, Buenos Aires, Argentina).

2.2 Microorganismos y condiciones de cultivo

Se utilizaron dos cepas de reconocida capacidad probiótica, *Lactobacillus casei* ATCC 393 y *Lactobacillus rhamnosus* ATCC 53103 (ATCC, Rockville, MD). Para los ensayos, un vial de cada cepa fue re-suspendido en caldo Man, Rogosa y Sharpe (MRS, Biokar Diagnostics, Beauvais, France), y cultivado durante 24 h a 37 ± 1ºC. Cada cultivo fue centrifugado a 5000 x g durante 10 min y el pellet lavado dos veces con solución buffer fosfato (PBS). Para la preparación de los inóculos cada cepa fue re-suspendida en soluciones de PBS+prebiótico (IC e ITub) hasta alcanzar una carga

microbiana de ~ 10 log UFC/mL. Las concentraciones bacterianas finales se determinaron por recuento en placa en agar MRS (48h a 37ºC). Se utilizaron soluciones de inulina al 1% (p/v) previamente esterilizadas por microfiltración con membranas de 0,22 µm de tamaño de poro (Gamafil S.A., Argentina).

2.3 Preparación de las micropartículas

Para la encapsulación de cada combinación probiótico-prebiótico se utilizó el método de gelación ionotrópica mediante la formación de una emulsión agua/aceite utilizando pectina de bajo metoxilo al 2% (p/p) y una solución de $CaCl_2$ al 1% de acuerdo a lo establecido por Holkem [6] con algunas modificaciones. Brevemente, se preparó una solución de pectina en agua destilada estéril bajo agitación magnética (300 rpm, 2 h) a 50ºC, se dejó enfriar hasta alcanzar una temperatura de 30ºC momento en el cual se incorporó la solución de probióticos y se agitó durante otros 30 min. Para la preparación de la emulsión agua/aceite se mezclaron 20 mL de dicha mezcla con 20 mL de aceite de girasol comercial que contenía Tween 80 (Merck KGaA, Alemania) al 1% (v/v), y se utilizó un sistema de agitación mecánico de paletas planas a 1000 rpm por 4 min. Las micropartículas se obtuvieron mediante goteo de una emulsión de $CaCl_2$ de similares características sobre la emulsión agua/aceite original, que contenía los probióticos al mismo tiempo que se mezcló con el sistema de agitación mecánica para lograr la formación de las microesferas de gel. Luego de un paso previo de maduración bajo agitación suave (< 300rpm) durante 1 h aproximadamente las microesferas fueron lavadas con solución al 0,1% de Tween 80.

Se calculó el diámetro promedio en base área (D_{32}) siguiendo la siguiente fórmula

$$D_{32} = \sum_{i=0}^{n} d_i^3 \Big/ \sum_{i=0}^{n} d_i^2$$

Donde d_i es el diámetro de cada partícula y n es el total de partículas. Para esto se analizaron micrografías digitales tomadas con un microscopio Primo Star-Zeiss de las emulsiones resultantes y se analizaron con el software Image J 1.50i [National Institute of Health (NIH), Bethesda, MD, USA].

Eficiencia de encapsulación (EE)

La EE se determinó mediante como se indica en Reid [7]:

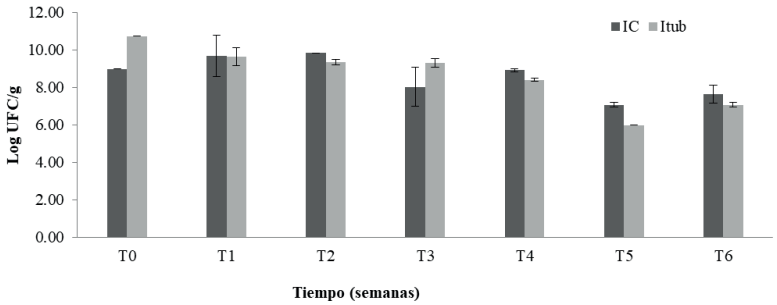
$$EE = (Log\ 10\ N / Log\ 10\ N_0) \times 100$$

Donde N es el número de células viables encapsuladas y liberadas de las micropartículas y N_0 el número de células libres (suspensiones iniciales) agregadas inmediatamente antes de la encapsulación.

Para su determinación, 0,1 g de micropartículas se suspendieron en citrato de sodio 0,1 % (p/v, pH 6,2) y luego de 20 min bajo agitación suave para lograr la disolución se realizaron diluciones decimales y se procedió al recuento celular en agar MRS a 37ºC durante 48h.

Supervivencia de las células probióticas microencapsuladas bajo condiciones de almacenamiento.

Las cepas co-encapsuladas con los prebióticos fueron almacenadas a temperatura de refrigeración (4ºC) por 6 semanas. Para determinar la supervivencia de las mismas se tomaron muestras semanalmente y se realizaron recuentos en placa en agar MRS a 37ºC por 48 h, siguiendo la metodología detallada en el apartado anterior.



3 Resultados y Discusión

Las reglamentaciones nacionales e internacionales establecen que para que un alimento sea considerado probiótico al momento de su consumo debe presentar una carga de células probióticas viables entre 10^6 y 10^9 UFC/g o mL, por lo tanto mantener su viabilidad es imprescindible. Es por esto que en el presente trabajo se planteó el uso combinado de técnicas de microencapsulación con el agregado de prebióticos como estrategia para la asegurar la viabilidad en condiciones de almacenamiento.

La EE en las condiciones ensayadas fue del 94 ± 9 % para ambas cepas, siendo el diámetro promedio (en base área) de las partículas resultantes de entre 60 y 80 µm para IC y de 90 µm en el caso de ITub, sin encontrarse un efecto significativo entre los factores analizados (la cepa probiótica y el tipo de inulina). En cuanto a la supervivencia al cabo de las 6 semanas a 4ºC, *L. casei* presentó recuentos de 7,65 ± 0,49 log UFC/g (IC) y 7,09 ± 0,12 log UFC/g (ITub) mientras que *L. rhamnosus* presentó recuentos de 9,74 ± 0,06 log UFC/g (IC) y 8,65 ± 0,49 log UFC/g (ITub). En las Figuras 1 A y B se puede observar la progresión de ambas cepas a lo largo del tiempo. Como se puede observar tanto IC como Itub presentan un gran potencial simbiótico, manteniéndose niveles de células viables por encima de las recomendadas por las legislaciones. En el caso de ITub se presenta como alternativa no convencional para un aprovechamiento integral de recursos poco explorados como es el caso de los tubérculos de topinambur (*H. tuberosus* L.).

La inmovilización en microgeles de pectina con el agregado de prebiótico brindó un buen soporte de protección bajo condiciones de almacenamiento a temperaturas de refrigeración, siendo el efecto del tipo de prebiótico cepa dependiente. Los resultados muestran un promisorio futuro hacía la administración de los mismos suplementos funcionales en productos a base de frutas asegurando una carga microbiana adecuada en el sitio de acción en el huésped.

Abstract. Rice starch was physically modified by thermo-mechanical action avoiding the use of chemical agents and minimizing the process waste. The aim was to evaluate the aptitude of Rittinger and Holmes equations to simulate the relationship between milling energy and particle size. First, the particle size distribution was fitted by the Rosin-Rammler-Bennett (RRB) equation determining the effect of milling energy on model parameters n and D_{65}. Particle size distribution was measured by laser diffraction and the specific milling energy provided by the planetary ball mill (PM100, Retsch, Germany) was determined as a function of milling conditions (10-40 min, 400 rpm). Due to the asymmetric profile of particle distribution at all levels of milling energy (0.26 - 4.08 kJ/g), the fit by the RRB model resulted very satisfactory ($R^2 > 0.98$). As milling energy changed from 0.26 to 1.99 kJ/g, the homogeneity index increased (n: 0.86-1.86) and the values of D_{65} decreased from 85 to 15 μm. Between 1.99 and 4.08 kJ/g, the model parameters showed an asymptotic tendency. Polynomial relationships between these model parameters and milling energy were found ($R^2 > 0.91$). The prediction of energy-size relationship by Holmes equation was more satisfactory ($R^2 = 0.98$) than that of the Rittinger model ($R^2 = 0.75$). This revealed the significant effect of heat dissipation on the milling process. The results pointed out the relevance of the mechanic activation in high impact milling and corroborated the ability of Holmes equation to simulate the ultra-fine pulverization, which takes place in the planetary ball mill.

Keywords: Ball Milling, Specific Milling Energy, Particle Size.

1 Introduction

Starch is obtained from different sources such as cereal grains or tubers and it has important applications in the food and non-food industries [1]. In particular, rice starch is a popular ingredient in infant food products where is used to create soft gel structures. It is also valued due to its excellent shelf-life stability and its ability to act as a fat replacer [2].

Native starch is frequently modified by chemical, physical or biotechnological procedures in order to improve its functional properties [1]. Among these methods, physical treatments such as extrusion [3], ball milling [4], jet-milling [5], and hydrothermal [6] or high pressure treatments [7] are becoming popular because they are considered good and environmentally friendly techniques.

Recently, the high-impact dry milling has promoted the interest of researchers as a tool for the physical modification of starches [8, 9, 10, 11]. This type of milling can cause significant changes in the morphology and crystalline structure of starch granules, which affects their physicochemical and functional properties, and thus expands their industrial applications [12, 13].

Traditional milling models are based on relationships between particle size and specific milling energy [14]. The size reduction is a process with a high level of energy consumption and low efficiency. Since the particle surface increases as the particle size is reduced, the measure of the process efficiency is based on the energy required to create a new surface [15]. There are three basic postulates for the prediction of energy requirements for the particle comminution: the laws of Rittinger [16], Kick [17], and Bond [18]. Later, Holmes [19] proposed a generalised milling equation. Particularly, Rittinger equation has been successfully applied to model ultra-fine grinding [14].

Milling energy is dependent on milling conditions, which are frequently expressed in terms of grinding time and rotation speed, and these variables are strongly dependent on the mill device [20, 21]. The application of milling models is important to control the process and to design milling protocols to produce a specific starch modification.

Several methods for particle size measurement have been reported based on sieving methods, microscope counting techniques, sedimentation, and particle flow scanning, such as laser diffraction [22]. Particle size distribution can be described by mathematical expressions in terms of relative frequencies or cumulative frequencies [14]. The Gaussian model is useful to represent the symmetric particle distribution obtained through chemical condensation or precipitation processes. However, to evaluate the particle distributions obtained by crushing and grinding operations, the Rosin–Rammler–Bennet (RRB) model is frequently used, which describes the particle distribution of food powders that do not present a symmetric distribution [14, 22, 23].

Simulation studies of the grinding process in food area are still very scarce which are based on the relationships between milling energy and particle size reduction. For this reason, the objective of the present work was to evaluate the aptitude of the Rit- tinger and Holmes equations to simulate the energy-size relationship during rice starch pulverization. For this purpose, the specific milling energy was recorded as a function of milling time, and the particle size analysis was first performed.

2 Materials and Methods

2.1 Material

Native rice starch of food grade (Remy B7, Beneo GmbH, Germany) was supplied by Saporiti S.A. (Buenos Aires, Argentina). The amylose content of the rice starch (18.4 g/100 g of total starch) was obtained according to an iodine binding-based method [24].

Chemical composition (dry basis) of rice starch was provided by the manufacturer as follows: 88.7 % carbohydrates (by difference), 13.7 % moisture, 1.0 % protein, 0.0 % lipid, 0.2 % ash.

2.2 Rice Starch Modification by Ball Milling

Starch was grinding in a planetary ball mill model PM 100 manufactured by Retsch (Retsch GmbH, Germany) with zirconium jar (500 mL) and balls (diameter: 5 mm) at different levels of milling energy within 0.26 - 4.08 kJ/g and constant rotational speed of 400 rpm. A previous calibration was performed by using an empty jar (energy at "ralenti") to obtain milling energy [25]. Specific milling energy was expressed in kJ/g of starch. Starch sample (115 g) and five times weight balls were used according to the milling protocol proposed by Gonzalez et al. (2018) [26] which involved pauses of 40 min each 10 min of grinding and a change in the rotational direction of the jar every 30 s. By this method, sample temperature was controlled and it never exceeded 55 °C. Native rice starch was adopted as the control sample.

2.3 Determination of Particle Size Distribution

Particle size distribution was determined by static light scattering (SLS) in a Mastersizer 2000 device (Malvern Instruments Ltd., Worcestershire, UK), which is equipped with a dispersion unit Hydro 2000MU. The pump was operated at 1800 rpm. Bi-distilled water was used as the dispersing agent, whose diffraction index and absorptivity were 1.53 and 0.001, respectively. The instrument provides the volume size distribution. Characteristic parameters: D_{50} (median) and D_{80} (corresponding to the diameters of 50 % and 80 % of cumulative volume, respectively), specific surface area (SSA), mean volumetric diameter ($D_{4.3}$), and dispersion index (Span) were obtained from the device software (Malvern Application v5.60, Malvern Instruments Ltd., Worcestershire, UK). The average of five replicates was reported.

2.4 Particle Size Distribution Model

Particle size distributions of starch samples obtained with different milling energy levels were adjusted by the Rosin-Rammler-Bennett (RRB) model (Equation 1), which is commonly used for the characterisation of food powders when they do not follow a normal distribution [22].

$$F(x) = 1 - \exp\left[-\left(\frac{x}{D_{63}}\right)^{n}\right] \quad (1)$$

Where, F(x) is the accumulated distribution, x the particle size, D_{63} the particle diameter correspondent to 63.2 % of the accumulated distribution, and n a constant associated with the homogeneity of the sample. Low n values are associated with high size dispersion, while high values of this parameter involve greater uniformity. Yan and Barbosa-Cánovas (1997) [27] evaluated different distribution models for various food

matrices and concluded that such models present enough flexibility to describe the distribution of powders, and they pointed out that RRB equation is one of the most appropriate equations for its characterisation.

2.5 Energy-Particle Size Milling Models

Rittinger Model. Rittinger (1867) [16] proposed that the energy required for the reduction of the particle size is directly proportional to the increase of the created surface. If the energy required for particle fragmentation is expressed based on the particle diameters, the resulting equation is as follows:

$$E = C_r \left(\frac{1}{x_2} - \frac{1}{x_1}\right) \quad (2)$$

Where, E is the specific milling energy by mass unit (kJ/g), C_r the Rittinger milling coefficient, x_1 the initial particle size, and x_2 the particle size after milling. Diameter D_{63} in equation (1) was adopted as a measure of x.

Generalised Milling Model. Holmes (1957)[19] proposed equation (3), known as generalised milling model, which states that the energy required to produce a small change in the size of unit mass can be expressed as a power function of the size of the material.

$$\frac{dE}{dx} = -C\frac{1}{x^{n_1}} \quad (3)$$

The integrated form of the equation yields:

$$E = \left(\frac{c}{1-n_1}\right)\left(D_{xi}^{1-n_1} - D_{xf}^{1-n_1}\right) \quad (4)$$

Where n_1 and C are the parameters of the model, D_{xi} and D_{xf} are the diameter of the native rice starch and the diameter of the modified starch at a specific milling energy, respectively. Diameter D_{63} in equation (1) was adopted as a measure of D.

2.6 Statistical Analysis

Analysis of variance (ANOVA) and regression analyses were performed using the statistical program Statgraphics Centurion version XVI (Statistical graphics Corporation, USA), comparing the means by the least significant difference test of Fisher (LSD), with a confidence level of 95 %.

3 Results and Discussion

3.1 Particle Size Distribution

The effect of milling energy on particle size distribution can be seen in Fig. 1 for samples of native rice starch and modified starches in the planetary ball mill. The Figure shows the asymmetry of the curves. As the energy level increased, the curves moved towards the smaller size region and displayed a lower dispersion. Native starch (control) presented a bimodal distribution, with maximums at 28.2 μm and 148.3 μm, and the latter is more important as to volumetric fraction than the former. In contrast, starches modified by high impact milling showed monomodal distributions.

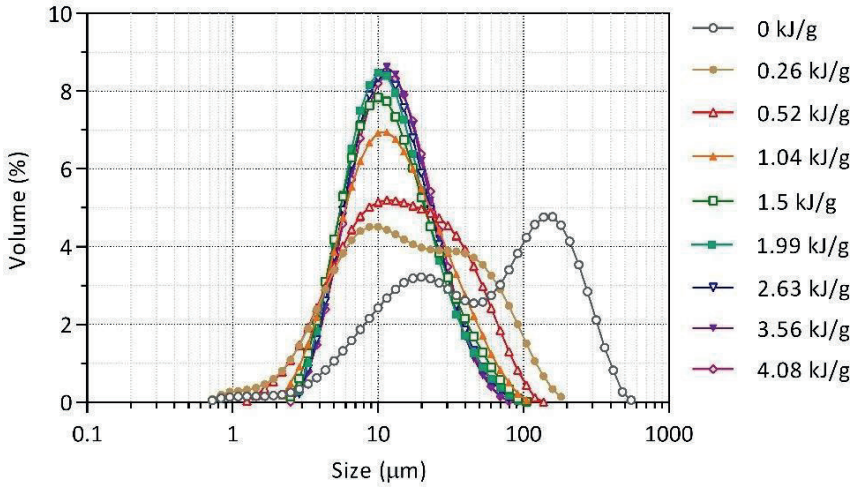

Fig. 1. Volume size distribution by static light scattering (SLS) of native rice starch (control, 0 kJ/g) and starches modified by ball milling at different energy levels.

It should be noted that starches milled at 0.26 kJ/g and 0.52 kJ/g presented a monomodal distribution (modes at 10.7 μm and 12.3 μm, respectively), but with a "shoulder" to the right of the maximum, showing larger particle remnants. In contrast, starches subjected to milling energies higher than 1.04 kJ/g presented a monomodal distribution (modes between 10.7 μm and 12.3 μm) with a defined "peak". Table 1 shows, as a function of milling energy, some characteristic parameters of the size distribution such as the values of D_{50} and D_{80} as well as the dispersion index (Span).

Between 0 and 1.99 kJ/g the values of D_{50} decrease from 60.9 to 12.2 μm but in the range 1.99 -4.08 kJ/g an slight increase in the values of median up to 13.2 μm was observed due to particle agglomeration. A similar effect of milling energy on $D_{4,3}$ and for D_{80} can be appreciated in the Table. Other authors [10, 28, 29] have reported two effects during ball milling: particle size reduction (grinding) and mechanical activation

of starch (agglomeration). They are dynamic equilibrium processes which were also detected by Tian et al., (2011) [29] in planetary ball milling of maize starch working at 500 rpm during 3 h. Powder activation by high impact grinding takes place when particles become smaller than the size of tough–brittle transition [4, 28]. As regards the dispersion index, it decreased as milling progressed, indicating an increase in starch homogeneity.

Table 1. Characteristic parameters of the particle size distribution of rice starches as a function of milling energy.

Energy (kJ/g) [Time] (min)	D_{50} Median [$D_{4,3}$] (μm)	D80 (μm)	SSA (m2/g)	Span (dimension-less)
0 [0]	60.9 ± 10.8^{a} [97.4 ± 10.0^{a}]	174.1 ± 16.5a	0.285 ± 0.031^{g}	3.9 ± 0.3^{a}
0.26 [5.4]	16.9 ± 0.6^{b} [29.3 ± 1.1^{b}]	48.5 ± 2.2b	0.622 ± 0.009^{a}	4.0 ± 0.0^{a}
0.52 [10.6]	15.5 ± 0.4^{b} [$22.9 \pm 0.8^{b,c}$]	36.5 ± 1.5c	0.579 ± 0.009^{b}	3.1 ± 0.1^{b}
1.04 [21.8]	13.4 ± 0.2^{b} [18.5 ± 0.6^{c}]	27.2 ± 1.1c,d	$0.559 \pm 0.004^{c,d,e}$	2.5 ± 0.1^{c}
1.5 [31.7]	12.4 ± 0.1^{b} [16.9 ± 0.5^{c}]	23.8 ± 0.9d	$0.570 \pm 0.003^{b,c}$	2.3 ± 0.1^{c}
1.99 [42.0]	12.2 ± 0.1^{b} [15.9 ± 0.3^{c}]	21.9 ± 0.6d	$0.567 \pm 0.004^{b,c,d}$	2.0 ± 0.1^{d}
2.63 [57.4]	12.8 ± 0.2^{b} [16.3 ± 0.5^{c}]	22.8 ± 0.9d	$0.547 \pm 0.006^{d,e,f}$	2.0 ± 0.1^{d}
3.56 [75.3]	12.9 ± 0.3^{b} [16.0 ± 0.4^{c}]	22.4 ± 0.8d	$0.541 \pm 0.006^{e,f}$	1.8 ± 0.0^{d}
4.08 [86.9]	13.2 ± 0.3^{b} [16.3 ± 0.6^{c}]	23.1 ± 1.0d	0.533 ± 0.007^{f}	1.9 ± 0.1^{d}

D_{50} and D_{80} represent the particle diameters that cumulative volume of particles are 50% and 80%, respectively. SSA: Specific Surface Area. Size dispersion index [Span = $(D_{90}-D_{10})/D_{50}$]. The reported values represent the average of five determinations ± the standard deviation. Values followed by the same online letter within a column do not differ significantly ($p < 0.05$).

3.2 Rosin-Rammler-Bennett Model

The particle size distributions of native and modified rice starches (Fig. 1) were adjusted by equation (1), and the values of the model parameters were determined by regression analysis: D_{63} (particle diameter corresponding to 63.2% of the accumulated distribution) and n; the latter is related to the homogeneity of sizes in the sample. Table 2 shows the values of the parameters of equation (1) for each level of milling energy.

Table 2. Parameters n and D_{63} of the Rosin-Rammler-Bennet equation, as a function of milling energy.

Energy (kJ/g)	n	D_{63} (μm)	R^2
0	0.86	85.07	0.994
0.26	1.02	23.97	0.992
0.52	1.22	20.06	0.993
1.04	1.51	16.31	0.991
1.5	1.65	14.76	0.989
1.99	1.80	14.10	0.990
2.63	1.81	14.66	0.991
3.56	1.88	14.61	0.992
4.08	1.86	14.99	0.993

As the energy increased, D_{63} values decreased from 85.07 to 14.1 μm, while n increased as the homogeneous character of the sample was accentuated. The degree of milling was similar to the one reported in the literature for other starches processed by ball milling [10, 30]. However, smaller particle sizes (2.9 -6.7 μm) can be obtained by jet-milling treatment where higher levels of rotational speed (1800-3900 rpm) are applied.

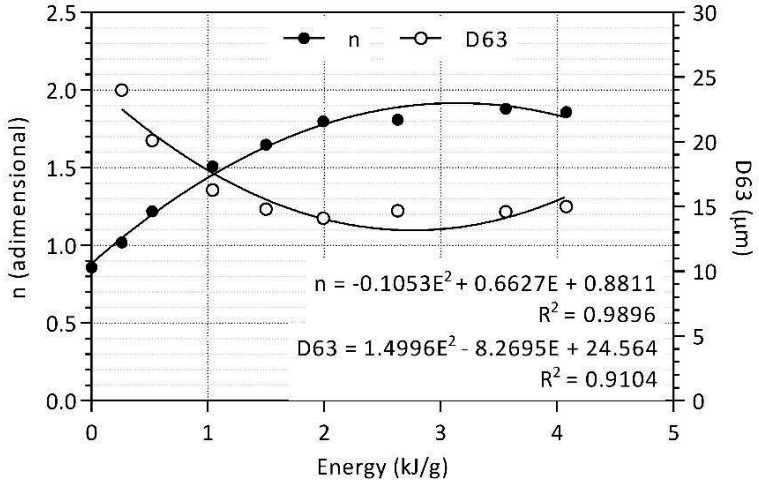

Fig. 2. Relationships between the parameters of the RRB equation and the specific milling energy.

Figure 2 shows the relationships of D_{65} and n with milling energy. Both parameters were successfully adjusted using second degree polynomials as a function of energy. It

can be seen that for energies higher than 1.99 kJ/g, both n and D_{63} tended to asymptotic values.

3.3 Holmes and Rittinger Milling Models

Table 3 shows the results of the regression analysis for the Holmes model (equation 3) using different characteristic sizes: D_{50}, D_{63} and D_{80}. Satisfactory adjustments ($R^2 > 0.92$) were obtained for the three cumulative diameters evaluated. The best adjustment was obtained for D_{63} ($R^2 = 0.98$) and, in this case, parameters C and n_1 adopted values of 34.08 kJ/[mg*$\mu m^{(1-n1)}$] and 4.2, respectively. For the three accumulated diameters evaluated, the values of n_1 were higher than 2, which, considering Rittinger model, confirms the obtaining of fine particles by planetary ball milling.

Table 3. Parameters and adjustment of the generalised equation (Equation 4) for accumulated diameters D_{50}, D_{63} and D_{80}.

Parameters:	D_{50}	D_{63}	D_{80}
C kJ/[mg*$\mu m^{(1-n1)}$]	940.9	29.8	1.4
n_1 (dimensionless)	5.6	4.2	3.0
R^2	0.9635	0.9833	0.9253

It should be clarified that the values of constants C and n_1 shown in Table 3 were obtained by taking only the energy values between 0 kJ/g and 1.99 kJ/g for regression since at higher energies no significant changes were noticed in the particle size decrease and the model did not provide an effective adjustment of the asymptotic part of the curve.

Figure 3 shows the relationship between energy and size. The exponential growth of the energy requirement is evident for particle sizes smaller than 20 μm as well as the loss of energy efficiency as milling progresses. The more the particle size is reduced, there are fewer weak areas available for rupture and, consequently, the fracture strength to be exceeded increases. When there are no more weak zones left, new cracks must be created to reduce the particle size, which requires additional energy. In this way, the energy requirement increases as the particle size decreases [4, 31].

The experimental values and those predicted by the generalised model (Equation 4) and the Rittinger model (Equation 2) are shown in Fig. 3. There are two aspects that can be highlighted: the evolution of the particle size reduction process (D_{63}) as a function of milling energy (0 – 1.99 kJ/g), and the good concordance between the experimental values and those predicted by Holmes model ($R^2 = 0.9846$).

In contrast, when using the Rittinger equation, the value of the C_R parameter was 0.024 kJ/[mg*μm^{-1}] and a less satisfactory result was obtained ($R^2 = 0.7499$). As Rittinger maintains that the energy consumed is proportional to the newly created surface, the lack of adjustment indicates that a significant part of the energy provided by the mill is dissipated as heat and it is not used for the reduction of the particle size [4, 14, 20, 22].

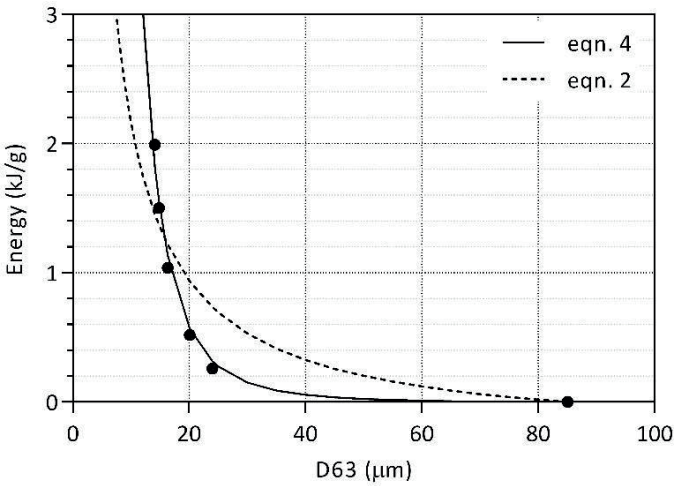

Fig. 3. Relationship between milling energy and particle diameter D63. (•): experimental data, (—): predicted values by the generalised Holmes equation, (- -): predicted values by the Rittinger model.

Furthermore, the Holmes n index should be considered, which connects the energy applied for the size reduction with the efficiency for the creation of new surface. Where n is 2, the Holmes equation is in agreement with the Rittinger model, and maximum efficiency is achieved. Therefore, the higher n value (4.2) obtained also points out that, in this case, the process takes place with less efficiency and there is a loss of energy. In this regard, Roa et al. (2014) [21], who obtained a value of n1 higher than two (2.71) by means of the generalised milling equation to simulate amaranth milling, have remarked the importance of the heat dissipation phenomenon when using a high impact mill.

4 Conclusions

The planetary ball milling was an efficient method to physically modify rice starch that avoids the use of chemical substances and the generation of waste during and after treatment. The milling energy had a significant effect on the particle size distribution that was determined by laser diffraction. The modified starches were found to have a smaller particle size and a greater homogeneity in size distribution, compared to native starch. A size reduction was observed between 0 and 1.99 kJ/g, while a slight size increase was observed for higher energies (1.99 – 4.08 kJ/g).
The size distribution curves were asymmetric and they could be satisfactorily modelled by means of the Rosin-Rammler-Bennett equation, whose parameters provided information about the size (D_{63}) and the sample homogeneity. D_{63} value was adopted as the

sample size when applying the Rittinger and Holmes models to simulate the energy-size relationship during milling.
While the Holmes equation provided a good adjustment of the experimental data, the Rittinger model was not satisfactory. From the analysis carried out based on the milling models, it could be inferred that not all the energy provided by the mill is used for size reduction. A significant part is dissipated as heat. This corroborates the importance of the heat dissipation phenomenon in high impact milling. The model presented is expected to be effective for controlling the degree of modification of rice starch, which is subject to the thermo-mechanical action typical of this type of milling. This allows the design of processes to obtain starches with specific structural and functional properties.

Abstract. Olive oil extraction performed with the two-phase extraction system generates a waste named "alperujo" or two-phase olive mill waste (TPOMW), which has a high percentage of water (65%), slightly acidic pH, high concentration of salts, organic matter and phenolic compounds. Because of these components, the alperujo is a significant source of environmental pollution, hindering the disposal of this waste. Nevertheless, biophenols have high nutraceutical and antioxidant power and could be used in the food, pharmaceutical and cosmetic industries. This work aimed to evaluate the ability of an aqueous extract from alperujo (AE) and the liquid fraction of alperujo (Alperujo water, AW), with different levels of phenols to sustain the growth and carotene production of *Rhodotorula mucilaginosa*. Extraction with ethyl acetate reduces the concentration of phenols from AE and AW, without affecting protein or glucose levels. The yeast was able to grow and produce carotenoids in all mediums, although growth was better when phenols were partially removed. Carotenoid production was significantly higher in the most concentrated dephenolized alperujo mediums (AE 30%, AW). Our study represents a new approach to the valorization of alperujo, with a dual benefit, the recovery of valuable compounds, i. e. biophenols and the bioproduction of new ones, i.e. carotenoids.

Keywords: Alperujo, Carotenoids, Waste Valorization, Microbial Growth,

1 Introduction

Olive oil extraction can be performed by the continuous two- or three-phase processes, in which the oil is obtained using centrifugal decanters. In the two-phase process, no water is added and a semi-solid waste composed of olive pomace and vegetation water is generated, called "alperujo" or two-phase olive mill waste (TPOMW) [1]. The alperujo is characterized by a pH of 4–6, low activity water [2] and almost 90% of its dry weight is organic matter comprising: lignin, cellulose, hemicellulose, lipids, carbohydrates and biophenols [3]. Olives contain a wide variety of phenolic compounds, such as: phenolic alcohols, (Hydroxytyrosol), secoiridoids (oleuropein and verbascosids) and flavonoids [4,5] with interesting biological activities [6]. However, they are considered responsible for alperujo phytotoxicity [7], since they affect seed germination, soil microbial ecosystem, and surfaces water [3, 7-8]. Therefore, removal of biophenols

from alperujo would have a dual impact on alperujo valorization, the recovery of a high-added-value product and a reduction in the toxicity of alperujo making it more suitable for subsequent bioprocesses. The objective of the present work is to studied the changes in the growth and production of carotenoids by the yeast *Rhodotorula mucilaginosa* when growing in mediums derived from alperujo before and after dephenolization.

2 Results and Discussion

2.1 Substrate characterization: dephenolized and non-dephenolized medium.

To reduce the polyphenol content present in alperujo we performed a liquid-liquid partition with ethyl acetate as in [5], a treatment that was shown to allow the recovery of these valuable compounds from alperujo. Since polyphenols have antibacterial activity, their removal could leave the AE and AW more suitable for bioprocess. As shown in Figure 1a, dephenolization with ethyl acetate effectively reduced polyphenol content in ~45 % in both AEs and about 30 % in AW. A reduction in pH was also observed in all mediums probably due to some hydrolysis of the ethyl acetate and the release of acetic acid that is water-soluble. Glucose and protein content were not affected by polyphenol extraction (Fig 1 c-d).

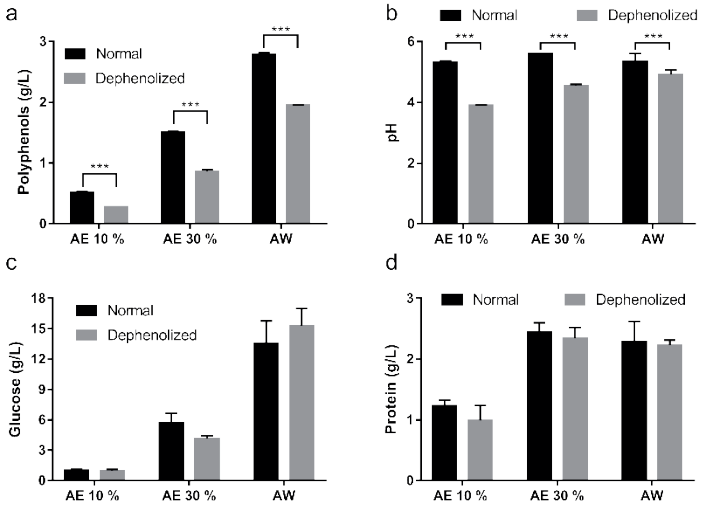

Fig. 1. Some physicochemical characteristics of the mediums used for *Rh. mucilaginosa* growth.

2.2 *Rh. mucilaginosa* growth and carotenoid production in the different mediums

We next studied the growth of *Rh. mucilaginosa* in the different mediums (Fig. 2). In AE 10 %, yeast reaches the stationary phase at 2 days, and no lag period is detected, probably due to the sampling period used. Both curves (Normal and dephenolized) are almost superimposed, thus dephenolization does not affect *Rh. mucilaginosa* growth, indicating that this phenol concentration is not inhibitory for the yeast. However, in AE 30 % and AW, a significantly higher number of cells are produced when the yeast grew in dephenolized mediums, being this effect more evident in AE 30%. In both dephenolized mediums, the stationary phase is reached at 1 day, and an acceleration of cell division is observed. Interestingly, when dry weight is measured, different behavior is observed. Changes are only detected in AW, where dephenolization increases the mass of yeast obtained. Although it is clear that dephenolization favors *Rh. mucilaginosa* development, the phenol content and yeast growth, (measured as the number of cells or dry weight) are not linearly related. Indeed, the same number of cells are obtained in all dephenolized mediums despite the differences in phenol content. Interestingly, dry weight increase in 30 % AE and in dephenolized AW respect with 10 % AE. This could be explained considering that in these mediums cells are accumulating reserve substances like triglycerides and/or carotenoids. *Rhodotorula* yeasts are known for its ability to produced these compunds [9]. In dephenolized AW, for instance, that has slightly higher phenol content than AE 30 %, we obtained threefold the number of yeast. Thus, other factors may influence yeast development in these complex mediums.

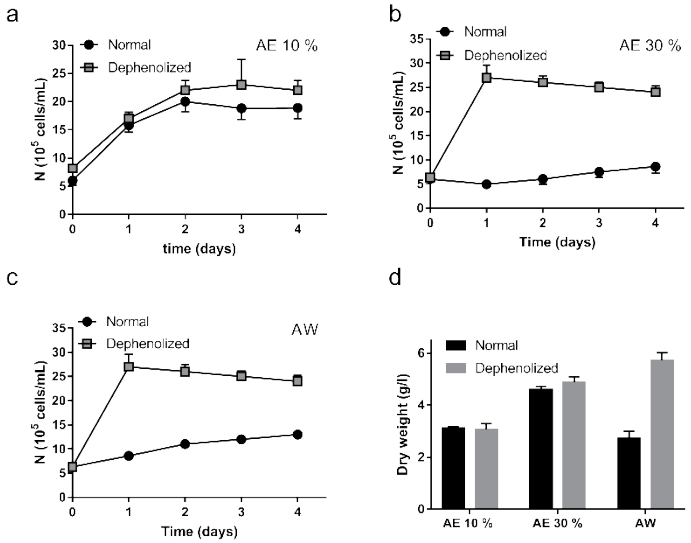

Fig. 2. Kinetics of *Rh. mucilaginosa* growth in different mediums.

Total carotenoid production was also affected by dephenolization. As shown in Fig. 3, the total carotenoid volumetric production increases when *Rh. mucilaginosa* starts

the stationary phase. This is expected since carotenoids are secondary metabolites. In AW and AE 30 % dephenolization result in a higher carotenoid production. This effect is more evident in AW, where dephenolization not only increases carotenoid amounts but also the pattern of production. In normal AW a plateau is reached at 3 days where for dephenolized AW, carotenoid production continues even at 4 days.

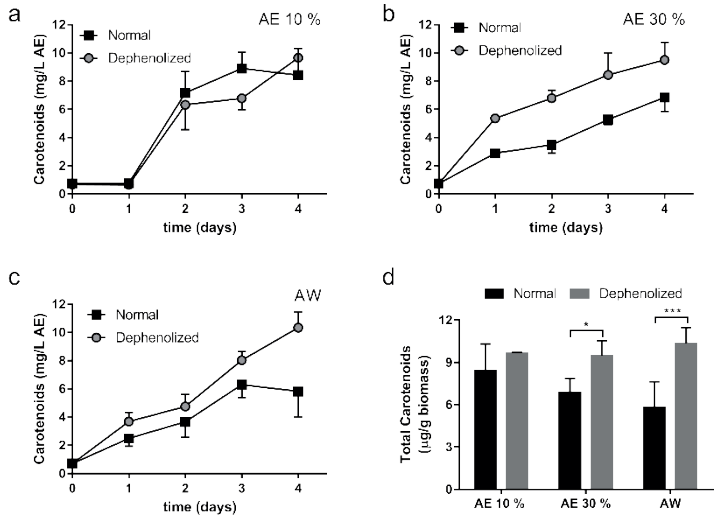

Fig. 3. Carotenoid production in different mediums.

3 Materials and Methods

3.1 Microorganism:

Rh. mucilaginosa was kindly provided by the Instituto de Botánica "Carlos Spegazzini" and it was maintained in agar slants at 4 °C until required.

3.2 Two-phase olive mill waste (TPOMW) samples and culture medium preparation:

Arbequina fresh TPOMW samples were provided by an oil processing plant located in Coronel Dorrego, province of Buenos Aires (Argentina). The samples were stored at -20 ºC until further use. Alperujo Water (AW) was obtained by centrifuging fresh alperujo at 1372g for 20 min. The liquid phase was separated, filtered and sterilized by autoclaving at 120 ºC for 15 min. Aqueous extracts (AE) were prepared from freeze-dried and defatted alperujo in concentrations of 10 and 30 % (w/V) as in [10]. To prepare dephenolized mediums, a volume of culture medium (AW, AE:10% and 30%) was mixed with ethyl acetate in a 3:1 ratio and polyphenols were extracted at 25 °C, with

magnetic stirring for 2h. Two successive extractions were performed. Upon completion, the content was transferred into a 250 mL separation funnel and the aqueous phase (i.e. the dephenolized medium) was collected in a 250 mL beaker. The remaining ethyl acetate was evaporated under a nitrogen stream at room temperature.

3.3 Analytical procedures:

Total phenolic content was determined spectrophotometrically at 725 nm according to the Folin-Ciocalteu method using caffeic acid as standard (Gutfinger 1981). Glucose was measured with an enzymatic-Glicemia kit, kindly provided by Wiener Lab (Rosario, Argentina). The pH was measured with an Altronix TPX-I electrode. Protein was determined by the Lowry method (Lowry et al. 1951) previous precipitation with trichloroacetic acid. Dry cell weight was determined at 85 °C using a Kern DLB 160-3A thermobalance (Kern, Germany). The number of yeasts was counted in a Neubauer chamber using an inverted microscope Zeiss Primo Star (Carl Zeiss, Germany).

3.4 Production, extraction, and quantification of carotenoids:

Cultures were performed in 250 mL Erlenmeyer flasks containing 50 mL of the desired concentration of AE and incubated for 4 days at 30 ºC under orbital shaking (150 rpm). Samples were taken on days 0, 1, 2, 3, and 4. To measure glucose, total phenolics, pH and biomass, 2 mL of culture were removed under sterile conditions. The medium was centrifugated at 1372 g for 15 min, the biomass separated and the supernatant was filtrated and stored at -20 ºC until required. The carotenoids were extracted using a custom-manufactured laboratory ball mill (Electronics Laboratory and Turning - Metallurgy UAT, Conicet Bahía Blanca). Briefly, freeze-dried biomass samples (~ 20 mg) were weighed in 1.5 mL Eppendorf tubes and 3 stainless-steel balls of 5 mm diameter were added. Three consecutive grinding cycles were performed, at 25 Hz and 60 seconds long each. Finally, 500 µL of acetone was added and a final grinding cycle was carried out. Then, the tubes were left to stand for 30 minutes in dark and centrifuged at 15.000 g for five minutes at 4 ºC. Quantification was performed by measuring absorbance at 450 nm in a Shimadzu UV-160A spectrophotometer. A calibration curve was prepared with β-carotene in acetone and the result was expressed as β-carotene equivalents. Each culture condition was run in triplicate.

Resumen. El caseinomacropéptido (CMP) es un péptido abundante en el suero de queso. El acetato de calcio ($CaAc_2$) es una de las sales más prescriptas en EE.UU para el tratamiento de la hiperfosfatemia. El objetivo de este trabajo fue explorar la interacción entre el CMP y las sales de calcio ($CaCl_2$ y $CaAc_2$) a través de la dinámica de gelificación inducida por calentamiento a pH 3,5. Interpretar cómo interacciona el CMP con los iones calcio permitirá desarrollar formulaciones que permitan mejorar la funcionalidad de los suplementos dietarios de sales de calcio. Se evaluó la textura, el color y las características reológicas de los geles formados, tanto a temperatura ambiente como por calentamiento, y se analizaron los correspondientes espectros FTIR. La transparencia de los geles en presencia de 100 mM de $CaCl_2$ o $CaAc_2$ se debería a la formación de unidades estructurales de menor tamaño que interaccionan con el calcio. A pH 3,5, se favorece termodinámicamente la formación de calcio iónico cuando se utiliza $CaAc_2$. Asimismo, los cambios observados en los espectros FTIR del CMP en presencia de $CaAc_2$ y más marcadamente con $CaCl_2$, confirmarían una estructura molecular más ordenada. La relación de saturación sal/CMP encontrada fue 0,83 mmoles/g, sin embargo, los geles admiten concentraciones mayores de $CaCl_2$ o $CaAc_2$. Por consiguiente, la formación de geles de CMP y sales de calcio a pH 3,5 podría ser una excelente alternativa para vehiculizar calcio iónico, si se utiliza $CaAc_2$ para el tratamiento de la hiperfosfatemia.

Palabras clave: caseinomacropéptido, acetato de calcio, gelificación

1 Introducción

El caseinomacropéptido (CMP) es un péptido abundante en el suero de quesería. Constituye la porción hidrofílica C-terminal de la κ-caseína y contiene todas las modificaciones postraduccionales (glicosilación y fosforilación) presentes en ella [1]. Naturalmente es mezcla heterogénea de dos fracciones principales: glicosilada (gCMP), y

no glicosilada (aCMP) [2]. Se identificaron catorce formas glicosiladas para el CMP [3] en las cuales el carbohidrato más abundante es el ácido N–acetilneuroamínico (ácido siálico) [4], que tiene un valor de pKa de 2,2. Debido a su alta heterogeneidad, el CMP no tiene un único punto isoeléctrico (pI). Kreuß et al. [2] determinaron que el pI del aCMP es cercano a 4,15, relacionado con la abundancia de residuos ácidos en su cadena peptídica. En contraste, el pI del gCMP es 3,15, debido a la carga negativa de los residuos glicosilados y en especial del ácido siálico que reducen su carga neta [2].
A pH 3,5, el CMP se autoensambla con el tiempo por la reducción de la repulsión electrostática y finalmente gelifica a temperatura ambiente [5]. Es por ello que resulta una proteína ideal para la nanoencapsulación, sólo o en combinación con otras proteínas. Recientemente, Bourbon et al. [6] realizaron nanohidrogeles de CMP y lactoferrina, una proteína láctea catiónica transportadora de hierro. La nanoencapsulación o el desarrollo de sistemas de entrega a nanoescala de compuestos bioactivos presenta interés por sus funcionalidades, alta eficiencia y capacidad de carga, la mejora de la biodisponibilidad y estabilidad, además de un perfil de liberación sostenida y el enmascaramiento de sabores indeseables [7]. Interpretar cómo interacciona el CMP con los iones calcio permitirá desarrollar formulaciones que permitan mejorar la funcionalidad de los suplementos dietarios de sales de calcio.
El acetato de calcio ($CaAc_2$) es una de las sales más prescriptas en EE.UU para el tratamiento de la hiperfosfatemia en pacientes sometidos a diálisis por su función como quelante de fosfatos [8, 9]. El CMP podría facilitar la ingesta de la gran cantidad de $CaAc_2$ prescripta para un paciente con hiperfosfatemia, aumentando tanto la bioaccesibilidad como la palatabilidad.
El objetivo de este trabajo fue explorar la interacción entre el CMP y las sales de calcio ($CaCl_2$ y $CaAc_2$) a través de la dinámica de gelificación inducida por calentamiento a pH 3,5. Se evaluó la textura, el color y las características reológicas de los geles formados, tanto a temperatura ambiente como por calentamiento, y para interpretar cómo afecta este pH (3,5) a las interacciones entre el CMP y el calcio, se analizaron los correspondientes espectros FTIR.

2 Materiales y métodos

2.1 Materiales

Se utilizó caseinomacropéptido BioPURE-GMP® de Davisco Foods International (USA). Su pureza, según el proveedor, fue (en base seca): 90,0 ± 3,0% (p/p) de CMP (N x 7,07). Su contenido mineral fue (100 g de muestra): 950 mg de Na; 125 mg de K y 682 mg de Ca determinados mediante espectrometría de absorción atómica Analyst 200 Perkin Elmer (USA). Se utilizó $CaCl_2$ anhidro (Merck, Alemania) y $CaAc_2$ monohidratado (Merck, Alemania) de calidad analítica. El agua utilizada para preparar las soluciones fue ultrapura (Thermo Scientific Barnstead, modelo Easypure RF) y su conductividad fue 1,8 ± 0,1 μS/cm. El pH de todos los sistemas se ajustó a 3,5 con HCl 1 N para evitar dilución.

2.2 Métodos

2.2.1. *Preparación de las soluciones.* Se utilizó una concentración de CMP del 12% (p/p) como en trabajos previos [10, 11] con el objeto de acelerar los tiempos de gelificación. Las soluciones de CMP se prepararon como en Loria et al. [12] hasta alcanzar la concentración de sal deseada (entre 0 y 250 mM) de $CaCl_2$ o $CaAc_2$. El CMP es muy soluble en agua y no se formó ningún precipitado después de añadir las soluciones salinas.

2.2.2. *Transición sol-gel*. El tiempo de transición solución-gel se determinó por un test de inclinación modificado o "tilting test" [13]. Las soluciones de CMP al 12% y a pH 3,5 se calentaron en tubos de ensayo cerrados a temperatura constante entre 30 y 70ºC y se observaron en el tiempo. Se determinó el tiempo de gelificación (t_{til}) como aquel necesario para que el menisco de la solución contenida en los tubos no fluya al inclinarlo. Los valores reportados fueron la media de triplicados.

2.2.3. *Dinámica de gelificación y propiedades viscoelásticas de los geles.* La dinámica de gelificación se registró en un reómetro de esfuerzo de corte controlado Paar Physica (MCR 301, Graz, Austria) con una geometría de cono y plato PP25 con un gap de 1 mm. Inmediatamente luego de ajustar el pH, se vertieron 490 µl de solución en el plato del reómetro. Se eligió la temperatura de 70ºC con el objeto de acelerar los ensayos según Martinez et al. [14]. El ensayo duró 40 minutos, tiempo suficiente para permitir que G' alcance el equilibrio. Luego se enfrió el sistema a 25ºC en 10 min.
Las propiedades viscoelásticas del gel formado se midieron en función de la frecuencia de oscilación entre 0,05 y 10 Hz a 25 ºC con la misma deformación, 0,01% [11]. Se informó el módulo complejo, que describe la relación entre la deformación y el esfuerzo a través de la siguiente ecuación:

$$G^* = G' + i\,G'' \quad (1)$$

donde, G' es el módulo de almacenamiento o elástico; G" es el módulo de pérdida o viscoso.

2.2.4. *Color y Textura de los geles.* Los geles de CMP y diferentes concentraciones de $CaCl_2$ o $CaAc_2$ (10 ml) se formaron a temperatura ambiente en recipientes herméticos y cilíndricos de plástico de 2,5 cm de diámetro y 4 cm de altura. Los geles se almacenaron 24 hs bajo refrigeración antes de realizar los ensayos de color y textura. Como los geles de CMP no se autosoportaron, estos ensayos se realizaron en el mismo recipiente en el cual fueron preparados.
La medición del color en unidades CIELAB (L*, a*, b*) de las muestras se realizó con un colorímetro portátil MiniScan® EZ (Hunter Lab, Reston, VA, USA). El escaneo de cada muestra se realizó 3 veces, obteniendo los parámetros del color L*, a* y b*. Las determinaciones se realizaron por cuadriplicado. La diferencia de color después y antes de la gelificación se calculó con la siguiente ecuación:

$$\Delta E = [\Delta L^2 + \Delta a^{*2} + \Delta b^{*2}]^{1/2} \quad (2)$$

donde ΔL es la diferencia de luminosidad; Δa* es la diferencia de intensidad de color verde/rojo y Δb* es la diferencia de intensidad de color azul/amarillo después y antes de gelificar.
El análisis de perfil de textura (TPA) se realizó a 25ºC en un analizador de textura Texture Analyzer (modelo TA-XT2i; Stable Microsystems, Godalming, Reino Unido) usando una sonda cilíndrica de ebonita (P/05 1,27 cm de diámetro). Las muestras se comprimieron al 20% de la altura inicial con una velocidad de compresión de 0,5 mm s^{-1}. Los ensayos se realizaron por cuadriplicado.

2.2.5. *Espectroscopía FTIR*. Las muestras en solución fueron almacenadas en freezer a una temperatura de -80ºC durante 24 hs y posteriormente liofilizadas (Labconco® freezone 12). Los espectros fueron registrados a temperatura ambiente en un espectrofotómetro infrarrojo Shimadzu® (modelo IR Prestige-21, Japón) en un rango de longitud de onda de 4000 nm^{-1} a 500 nm^{-1}. Se utilizó 1 mg de muestra liofilizada mezclada con 100 mg de KBr, pulverizada en un mortero de ágata y luego presionada a 20 Bar para obtener una pastilla. Cada muestra se sometió a 40 scans con 2,0 cm^{-1} de resolución. El registro de datos se realizó con el software LabSolution IR®, y el análisis de los espectros y los picos con el software OriginPro® 8 SR0, V8.0724, USA.

2.2.6. *Análisis estadístico.* Se utilizó el software GraphPad Prims v7.0 (GraphPad Software, San Diego, CA, USA) para el análisis estadístico. Los datos fueron analizados a través de un análisis de varianza (ANOVA). Las diferencias fueron determinadas por la prueba de Tukey para $P < 0,05$.

3 Resultados y discusión

3.1. Transición sol-gel

Martinez et al. [14] demostraron que el CMP se autoensambla a temperatura ambiente a valores de pH inferiores a 4,5. Estas estructuras autoensambladas conducen, con el tiempo, a la formación de geles opacos dependiendo de los tiempos de gelificación de la concentración. A concentraciones tan bajas como 3% (p/p), a pH 3,0 o 3,5 los tiempos necesarios para la gelificación son tan largos como 6-15 días, pero para concentraciones superiores a 7-8% (p/p), el tiempo se acorta (<50 h) [5]. Otro factor que afecta drásticamente a la velocidad de gelificación es la temperatura. Calentar desde 25ºC hasta 60ºC produce un aumento en las velocidades de autoensamblaje y gelificación. Por encima de 60 ºC ambas velocidades permanecen constantes [10, 14]. Con el propósito de investigar la temperatura óptima para la gelificación de las soluciones de CMP en presencia de $CaCl_2$, se determinó el tiempo de transición sol-gel a través del ensayo de "tilting test". Se evaluó el tiempo de gelificación (t_{til}) y la velocidad de gelificación ($V_{til} = 1/t_{til}$) de las muestras de CMP 12% (p/p) con concentraciones variables de $CaCl_2$ (0 - 250 mM) a diferentes temperaturas (30-70ºC). La Fig. 1A muestra la gráfica de Arrhenius, donde se representa el lnVtil en función de la inversa de la temperatura absoluta (1/T). Las curvas mostraron un comportamiento lineal entre 30 y 60ºC, y un quiebre a partir de esa temperatura. Hasta los 60 ºC, V_{til} dependió sólo de la

temperatura independientemente de la cantidad de $CaCl_2$ presente en la muestra. Por encima de los 60ºC, V_{til} fue constante y tampoco se hallaron diferencias por la presencia de $CaCl_2$.

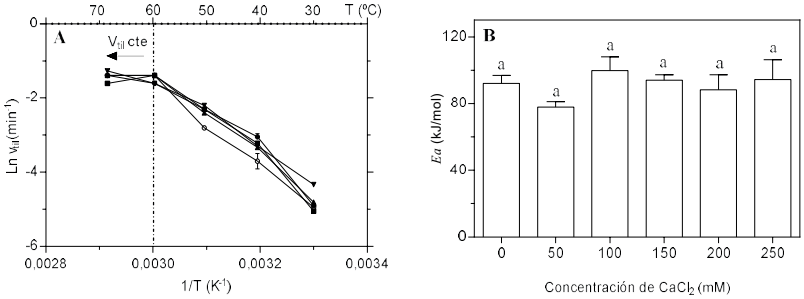

Fig. 1 A) Gráficos de Arrhenius para las velocidades de gelificación (V_{til}) de soluciones de CMP al 12% (p/p) y diferentes concentraciones de $CaCl_2$: (○) 0 mM; (▼) 50 mM; (■) 100 mM; (▲) 150 mM; (●) 200 mM a pH 3,5. **B)** Energía de activación (E_a) en función de la concentración de $CaCl_2$. Las barras de error representan el desvío estándar (n=3). Letras diferentes indican diferencias significativas ($p<0,05$).

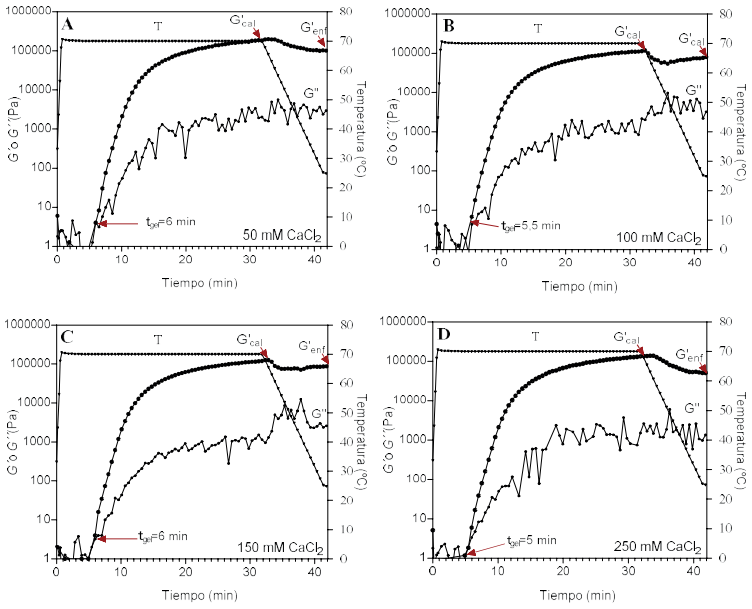

Fig. 2 Evolución de G' (●) y G'' (■) durante la gelificación de soluciones de CMP 12% (p/p) y $CaCl_2$ (50 - 250 mM) a pH 3,5 y 70ºC.

Se determinaron las energías de activación (E_a) involucradas en la gelificación de los sistemas CMP/$CaCl_2$ mediante la ecuación de Arrhenius. Las pendientes de las rectas obtenidas multiplicadas por la constante universal R corresponden a la E_a, que se muestra en la Fig.1 B en función de la concentración de $CaCl_2$. El valor de E_a promedio determinado en el rango 30-60ºC fue de 91 ± 8 kJ/mol y no fue afectado por la presencia de $CaCl_2$. Estos valores fueron relativamente bajos en comparación con la gelificación de aislado de proteína de suero (WPI) inducida por acidificación (pH 4,0) con glucano-δ-lactona (155 kJ/mol) o por $CaCl_2$ (210 kJ/mol) [15]. Con el propósito de reducir los tiempos de gelificación, se gelificó a las soluciones a la temperatura de 70ºC, donde V_{til} fue independiente de la temperatura.

3.2. Dinámica de gelificación

La Fig. 2 muestra la dinámica de gelificación inducida por calor de las soluciones (CMP 12% p/p y $CaCl_2$ entre 50 y 250 mM) a pH 3,5. El cruce de los módulos elástico (G') y viscoso (G'') indicó el tiempo (t_{gel}) y temperatura de gelificación (70ºC) [16]. Se puede observar en la Fig. 2 un solo punto de gel (t_{gel}) a 5,4 ± 0,5 min que no fue afectado por la concentración de $CaCl_2$. Los valores de t_{gel} hallados por esta metodología estuvieron en el orden de los encontrados por la técnica del tilting test, aunque en este último caso fueron mayores porque el ensayo del "tilting" requiere de una estructura que soporte el gel [17].

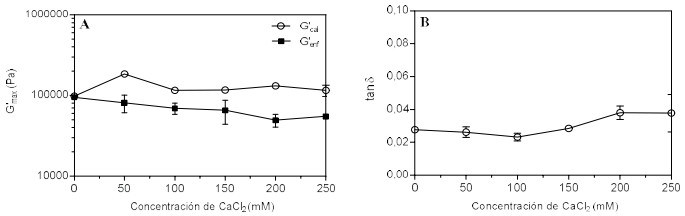

Fig. 3 A) Evolución de G'_{cal} (○) y G'_{enf} (■) durante el calentamiento y enfriamiento de geles de CMP 12% (p/p) con $CaCl_2$ (0 - 250 mM) a pH 3,5. **B)** Evolución de tan δ de los geles a pH 3,5 y 25ºC.

En el reograma del CMP en ausencia de $CaCl_2$ (datos no mostrados) se evidenciaron dos puntos de gel (t_{gel1}=1 min y t_{gel2}=6,5 min) como fue descripto en [14] a pH 3,5. Este comportamiento se atribuye a la existencia de dos estructuras que gelificaron a diferentes tiempos. Según el modelo de gelificación [14], el CMP gelifica en dos etapas en ausencia de sales y a pH 3,5. La primera es la formación de dímeros a través de uniones hidrofóbicas y la segunda, es la formación de una estructura de gel a través de interacciones electroestáticas. A pH 3,5, la fracción no glicosilada del CMP (aCMP) está protonada (pI = 4,15) [2], por lo cual los dímeros de aCMP-aCMP tienen carga positiva. En cambio, los dímeros de la fracción glicosilada gCMP-gCMP tienen carga negativa (pI = 3,15) [2]. Una situación intermedia se da para los dímeros aCMP-gCMP. Por lo tanto, a pH 3,5 coexisten dímeros cargados positivamente que contienen aCMP y

dímeros cargados negativamente que contienen gCMP que interactúan electrostáticamente. La existencia de dos puntos de gel en los reogramas del CMP a pH 3,5 se explicaría por los posibles estados isoeléctricos de los dímeros [14]. Por consiguiente, la presencia de $CaCl_2$ (aún a baja concentración) afectó principalmente a las estructuras que gelificaban primero y determinaban el t_{gel1}.

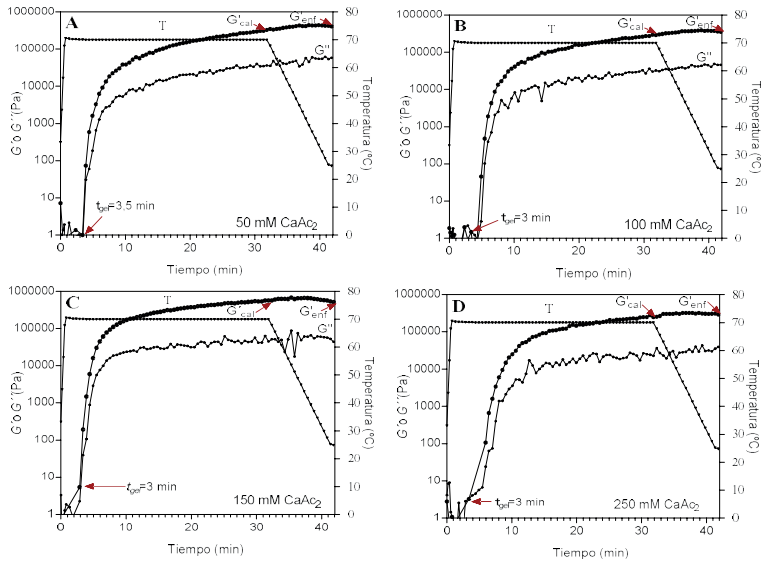

Fig. 4. Evolución de G' y G'' durante la gelificación de CMP (12 % p/p) con $CaAc_2$ (50-250 mM) a pH 3,5 y 70ºC.

Los reogramas obtenidos en el estudio de la gelificación del CMP en presencia de $CaAc_2$ (50; 100; 150 y 250 mM) a pH 3,5 se muestran en la Fig. 4. En todos los casos se encontró un único punto de gel en aprox. 3 min. Se puede observar que a diferencia de los geles en presencia de $CaCl_2$, G' se desarrolló muy rápidamente luego del punto de gel. Aún a bajas concentraciones de $CaAc_2$, G'_{enf} superó a G'_{cal}. Por otro lado, las diferencias entre G'_{enf} y G'_{cal} no fueron significativas. Pero es de destacar que todos los sistemas con CMP/$CaAc_2$ presentaron un desarrollo de G' con valores 3 veces superiores a los de CMP a fuerza iónica nula.

Si bien G'_{cal} no varió significativamente con la concentración de $CaCl_2$, G'_{enf} presentó una tendencia decreciente (desde 95.000 Pa en ausencia de sal, hasta 55.000 Pa en presencia de 200 y 250 mM de $CaCl_2$). Luego del t_{gel}, los valores de G' siempre fueron superiores a los de G''. El valor de G' máximo alcanzado durante el período de calentamiento fue denominado G'_{cal} y el G' obtenido al final del enfriamiento G'_{enf}. En la Fig. 3A se realiza un análisis detallado mostrando que G'_{cal} y G'_{enf} discrepan en su valor en presencia de $CaCl_2$, aún a bajas concentraciones (50 mM), evidenciando que en el enfriamiento disminuyeron ligeramente las interacciones de las estructuras gelificadas.

La tangente del ángulo de fase δ (tan δ) es un indicador de la organización estructural de un material. Los valores de tan δ (G" /G') obtenidos al finalizar el período de enfriamiento (25 ºC) fueron similares en todos los sistemas y claramente muy bajos (0,03 – 0,04), sugiriendo un arreglo de red elástica (Fig. 3B). Por ejemplo, la tan δ de la gelatina es 0,03 [18]. Se puede visualizar que los valores de tan δ fueron similares independientemente de la concentración de $CaCl_2$ adicionada al CMP.
La dinámica de gelificación del CMP en presencia de $CaAc_2$ a pH 3,5 y 70 ºC (Fig. 4), mostró que las sales influyeron en todos los parámetros reológicos: el tiempo de gelificación, en los módulos G' y G" y en la tan δ. Los tiempos de gelificación en presencia de $CaCl_2$ fueron independientes de la concentración y más largos (aprox. 6 min), mientras que, en presencia de $CaAc_2$ se redujeron a la mitad. Los geles con $CaCl_2$ mostraron una disminución de G´ durante la etapa de enfriamiento, en cambio los geles con $CaAc_2$ mostraron un ligero incremento. La tan δ de estos últimos fue 0,12 ± 0,01 independientemente de la concentración de $CaAc_2$ y superior a aquella obtenida para el CMP en ausencia de sal (0,03). Un valor de tan δ más alto indica que el material responde a la tensión externa en un modo más viscoso y menos elástico. Evidentemente, la presencia de $CaAc_2$ alteró la estructura del gel de CMP. El anión acetato consolida las fuerzas atractivas en los geles de CMP, mientras que el anión cloruro las disminuye durante el enfriamiento.

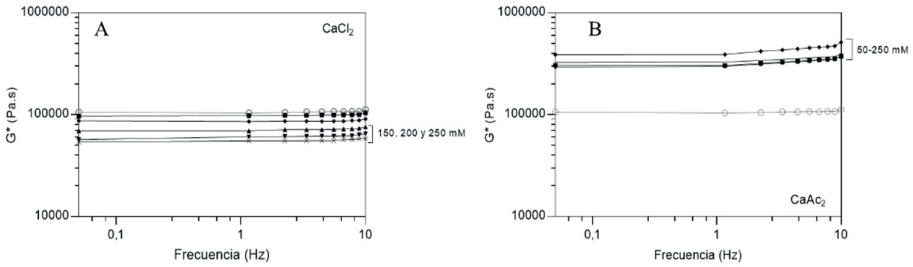

Fig. 5. G* en función de la frecuencia de oscilación para geles de CMP a pH 3,5 con A) $CaCl_2$ y B) $CaAc_2$ con (○) 0 mM; (●) 50 mM; (◆) 100 mM; (■) 150 mM; (▲) 200 mM y (▼) 250 mM (n=2 o 3).

3.3. Propiedades de los geles de CMP en presencia de $CaCl_2$ o $CaAc_2$.

3.3.1. Pequeñas deformaciones.

En el rango de frecuencia analizado (0 a 10 Hz), no se observó dependencia con la frecuencia para ambos módulos (G' y G") en los espectros mecánicos del CMP en presencia de $CaCl_2$ o $CaAc_2$. G' fue siempre superior a G". Los valores de G' fueron aproximadamente 110.000 Pa para los geles con 0, 50 y 100 mM de $CaCl_2$, 76.000 Pa para 150 mM y 56.000 Pa para 200 y 250 mM $CaCl_2$. Se encontró una tendencia similar en G" cuyo valor también disminuyó, desde 4.000 Pa a 3.000 Pa, para 200 y 250 mM

de $CaCl_2$ (datos no mostrados). En los geles de CMP/$CaCl_2$, el módulo complejo (G*) fue independiente de la frecuencia de oscilación para todos los sistemas (Fig. 5A). G* disminuyó desde $7{,}0.10^4$ hasta $5{,}5.10^4$ Pa en presencia de $CaCl_2$ (150-250 mM).
Los barridos de frecuencia de los geles de CMP en presencia de $CaAc_2$ también mostraron el típico comportamiento de gel fuerte, donde G' fue siempre superior a G" y no se observaron entrecruzamientos en la frecuencia estudiada. La Fig. 5B muestra que G* fue independiente de la frecuencia de oscilación para los geles de CMP/$CaAc_2$. Los valores de G* fueron superiores en presencia de $CaAc_2$ por el mayor aporte viscoso de G". Por otro lado, los valores de tan δ fueron cercanos a 0,15, relacionados con el incremento del carácter viscoso del gel (aumento de G") (datos nos mostrados).

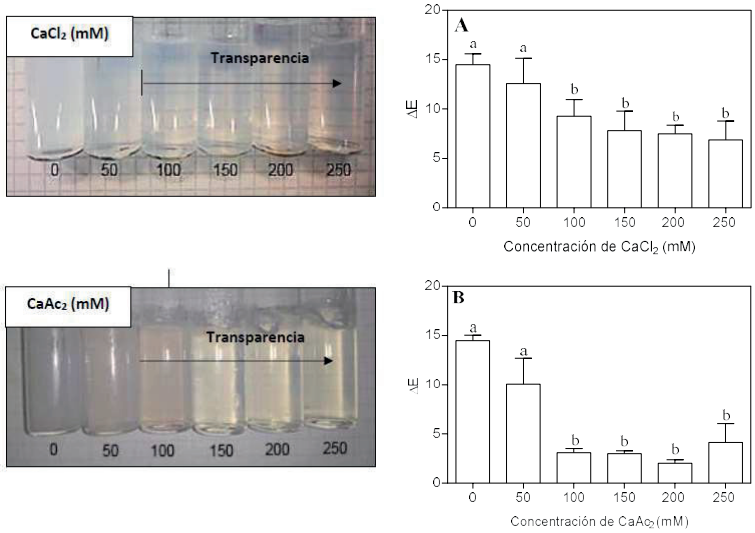

Fig. 6. Izq.) Imágenes de los geles de CMP con $CaCl_2$ o $CaAc_2$ a pH 3,5, formados a 70 ºC y enfriados a 25 ºC. Der.) Diferencia de color (ΔE) de los geles de CMP 12% (p/p) antes y después de gelificar a pH 3,5, formados a 25ºC, con: **A)** $CaCl_2$, **B)** $CaAc_2$.

3.3.2. Parámetros del color

Los geles de CMP formados en ausencia de sales fueron opacos a pH 3,5 como fue informado en Farías y Pilosof [11]. En presencia de $CaCl_2$ o $CaAc_2$ los geles se tornaron transparentes a partir de concentraciones superiores a 100 mM (Fig. 6). La temperatura de formación de los geles no afectó a su coloración como se informó previamente en Farias [19] para geles de CMP a pH 2 a 3,5 en condiciones de fuerza iónica nula. Ninguno de los geles obtenidos fueron desmoldables. En todo momento los recipientes se mantuvieron sellados herméticamente para evitar la evaporación del agua. La **Fig. 6** muestran el cambio de los parámetros de color (L*, a* y b*) de las muestras de CMP a pH 3,5 antes y después de la gelificación a temperatura ambiente y la apariencia de los

geles. La medición del color corroboró la observación visual. Los resultados mostraron que los geles de CMP con $CaCl_2$ o $CaAc_2$ presentaron resultados similares a partir de la concentración de 100 mM o superior. Dado que la concentración de los geles fue de 12% (p/p), la relación de sal de calcio por gramo de CMP fue 0,8 mmoles calcio/g. Evidentemente, el agregado de las sales de calcio provocó cambios en el tamaño de los agregados que conforman la estructura del gel, haciéndolos más transparentes.

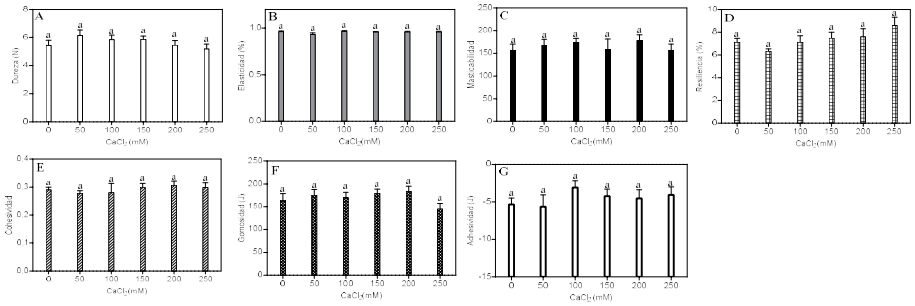

Figura 7. Parámetros de textura **A)** Dureza, **B)** Elasticidad, **C)** Masticabilidad, **D)** Resiliencia, **E)** Cohesividad, **F)** Gomosidad y **G)** Adhesividad de geles de CMP 12% (p/p) a diferentes concentraciones de $CaCl_2$ formados a 25 ºC y a pH 3,5.

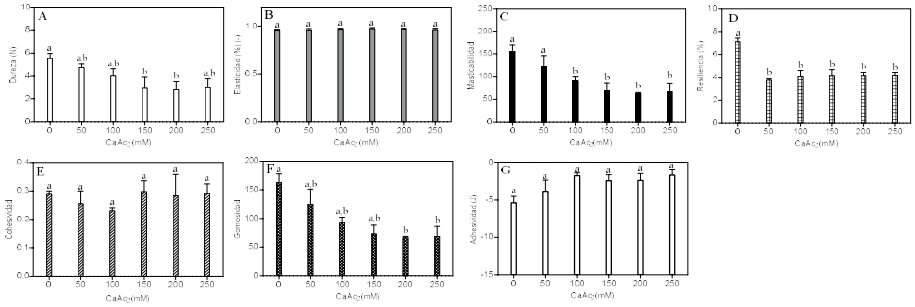

Fig. 8. Parámetros de textura **A)** Dureza, **B)** Elasticidad, **C)** Masticabilidad, **D)** Resiliencia, **E)** Cohesividad, **F)** Gomosidad y **G)** Adhesividad de geles de CMP 12% (p/p) a diferentes concentraciones de $CaAc_2$ formados a 25 ºC y a pH 3,5.

3.3.3 Parámetros de textura

Las propiedades texturales de los geles de CMP no dependieron de la temperatura en la que se formaron [11, 19]. Los parámetros texturales obtenidos del ensayo TPA (Texture Profile Analysis) fueron dureza, elasticidad, masticabilidad, resiliencia, cohesión, gomosidad y adhesividad (Fig. 7 y 8). La Fig. 7A muestra que no se encontraron diferencias significativas ($p < 0,05$) en la dureza de los geles de CMP en presencia de $CaCl_2$ (≈ 6 N). Por otro lado, la dureza de los geles de CMP disminuyó hasta aproximadamente 4 N en presencia de $CaAc_2$ (Fig. 7B). La elasticidad denota cómo el gel se recupera luego de ser deformado. Los resultados mostraron que los geles de CMP fueron muy elásticos con un valor muy cercano a 1%, independientemente del tipo o concentración de sal incorporada al CMP (Fig. 7B y 8B). La masticabilidad, que es el producto entre la dureza, la cohesividad y la elasticidad, fue similar para los geles de CMP en presencia de $CaCl_2$ (Fig. 7C). Sin embargo, los geles con $CaAc_2$ presentaron valores más bajos a concentraciones superiores a 100 mM (Fig. 8C). La resiliencia fue relativamente baja en todos los geles, con valores de 7 – 9% para los geles de CMP con $CaCl_2$ (Fig. 7D) y valores aún más bajos, (4 – 6%) con $CaAc_2$ (Fig. 8D). La cohesividad es la propiedad que mide la recuperación del gel luego de la segunda deformación. Los geles de CMP no presentaron diferencias significativas con la incorporación de $CaCl_2$ o $CaAc_2$ y tuvieron un valor de ≈ 0,3 (Fig. 7 y 8E). La gomosidad, que es el producto entre la dureza y la cohesividad, se define como la energía requerida para romper un alimento semisólido antes de tragarlo [20]. La gomosidad de los geles de CMP fue cercana a 150 a fi nula o en presencia de $CaCl_2$ (Fig. 7 F). Sin embargo, este parámetro disminuyó a valores cercanos a 100 en presencia de $CaAc_2$ (Fig. 8F). Finalmente, en cuanto a la adhesividad, se observó que todos los geles tuvieron un valor despreciable (Fig. 7 y 8G).

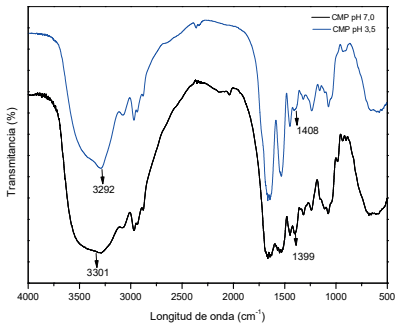

Fig. 9 Espectro FTIR del CMP a pH 7 y 3,5 (4000 - 500 cm^{-1}).

3.1 Espectroscopía infrarroja por transformada de Fourier (FTIR)

En la Fig. 9 se muestra el espectro completo FTIR del CMP a pH 3,5. La banda ancha de alta intensidad de absorción (Amida 2º A) se desplazó desde 3301 a 3292 cm^{-1} al disminuir el pH desde 7,0 a 3,5. La zona de vibración (1700 - 1600 cm^{-1}) correspondiente a la Amida I (tensión del enlace C=O, tensión del enlace C-N y flexión del enlace N-H) mostró un profundo valle y además de otros picos (1643, 1664 y 1674 cm^{-1}) con

respecto a los hallados en el espectro del CMP a pH 7,0 (1649 y 1655 cm^{-1}). El autoensamblaje y gelificación del CMP a pH 3,5 evidentemente establecería un cierto orden estructural del cual carece el péptido a pH 7,0 de conformación "random coil". La señal de la Amida I es el mejor indicador de la estructura secundaria de una proteína [21]. La región de Amida II (flexión de los enlaces N-H y C-N) también es indicativa de cambios en la estructura secundaria de las proteínas, sin embargo, también es muy sensible a la hidratación [22]. La señal correspondiente a los grupos COO^-, que en el CMP a pH 7,0 se observó a 1399 cm^{-1} se desplazó a 1408 cm^{-1} a pH 3,5. Un desplazamiento de esta señal fue encontrada por Ustunol et al. [23] para el ácido glutámico en las asignaciones de las vibraciones de los COO^- a pH 2 (1410 cm^{-1}) en comparación a los pH entre 6 y 9 (1401 cm^{-1}).

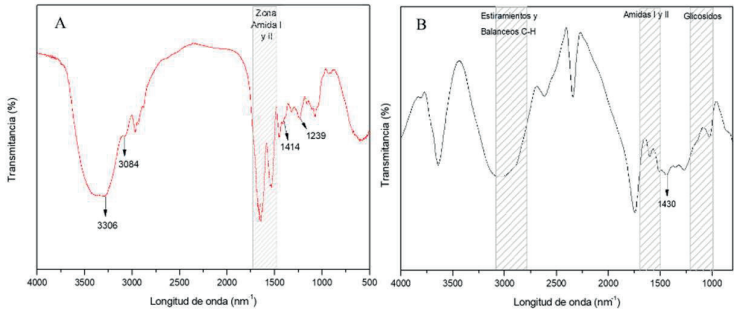

Fig. 10. Espectro FTIR del CMP con A) $CaCl_2$ y B) $CaAc_2$ (relación 1,2 mmoles de $CaCl_2$/g CMP) a pH 3,5.

El espectro FTIR del CMP y $CaCl_2$ en la relación 1,2 mmoles de $CaCl_2$/g CMP se muestra en la Figura 10A. La banda de absorción de Amida 2º A, que en el CMP a pH 3,5 se ubicó a 3292 cm^{-1}, se desplazó a 3306 cm^{-1} en presencia de $CaCl_2$ con una señal más intensa y la banda de Amida 2º B desde 3077 cm^{-1} a 3084 cm^{-1}. En la zona de absorción de la Amida I (1700 - 1600 cm^{-1}) y Amida II (1600 - 1500 cm^{-1}) se observaron nuevos picos a 1628 - 1636 cm^{-1} y 1539 - 1548 cm^{-1}, respectivamente. Interesantemente, estos nuevos picos (1628 y 1636 cm^{-1}), se asignan a una estructura secundaria β-plegada [22]. Además, en presencia de $CaCl_2$, la absorbancia de la Amida I decreció, mientras que la de la Amida II se incrementó. Estos cambios estarían asociados al decrecimiento de la estructura "random coil" y el incremento de una estructura más organizada (β-plegada), como fue explicado por Villarreal-Ramirez et al. [24] para fosfopéptidos obtenidos de la dentina. El pico correspondiente a la señal de la Amida III (1236 cm^{-1}) a pH 3,5 se desplazó ligeramente a 1239 cm^{-1} en presencia de $CaCl_2$. El pico a 1408 cm^{-1}, que representa el estiramiento simétrico de los COO^- a pH 3,5, se desplazó a 1414 cm^{-1} en el espectro CMP/$CaCl_2$, sugiriendo que estos grupos interaccionan con calcio iónico a pH 3,5. Además, aparecen dos bandas a 1548 y 1539 cm^{-1}. Byler y Farrell [25] demostraron que el corrimiento de las bandas a 1410 y 1565 cm^{-1} son indicadoras de una interacción de las proteínas con el calcio iónico.

La Figura 10B muestra el espectro de CMP con $CaAc_2$ a pH 3,5. Se encontraron una gran cantidad de señales solapadas entre 3250 y 3000 cm^{-1} que corresponderían

principalmente a estiramientos y balanceos de las uniones C-H. Tambien se observó un solapamiento de muy alta intensidad en la zona de amida I (1700 - 1600 cm^{-1}) y amida II (1600 - 1500 cm^{-1}). Por otro lado, no se observó señal a 1408 cm^{-1} (estiramientos simétricos de los COO^-) y también cambió la zona del espectro en la zona de la huella digital (1300-400 cm^{-1}). Problablemente, los solapamientos observados se deban a las interferencias de los grupos funcionales con el anión acetato. A pH 3,5, las fracciones del CMP tienen cargas opuestas, por lo tanto puede interactuar electrostáticamente tanto el $CaAc^+$, el Ca^{2+} como el Ac^-. Cabe recordar aquí que la gelificación se realizó ajustando el pH a 3,5 con HCl de alta normalidad, por lo tanto el desplazamiento del Ac^- para formar HAc permite la liberación de Ca^{2+}. El espectro del CMP en presencia de $CaAc_2$ es diferente a los observados anteriormente confirmando una naturaleza más compleja en las interacciones.

4. Conclusiones

El efecto de las sales de calcio en la gelificación del CMP a pH 3,5 es muy complejo debido a que interaccionan tanto el catión como el anión con los diferentes estados eléctricos de las diversas fracciones del péptido. Evidentemente, el anión acetato consolida las fuerzas atractivas en los geles de CMP, mientras que el anión cloruro las disminuye durante el enfriamiento. A pH 3,5, se favorece termodinámicamente la formación de calcio iónico cuando se utiliza $CaAc_2$, como lo muestran los espectros FTIR y la coloración de los geles. Asimismo, los cambios observados en los espectros FTIR del CMP en presencia de $CaAc_2$ y más marcadamente con $CaCl_2$, confirmarían una estructura molecular más ordenada. La relación de saturación sal/CMP encontrada de 0,83 mmoles/g fue independiente del tipo de sal utilizada y ligeramente menor que a pH 7 (1,2 mmoles/g). La formación de geles de CMP y sales de calcio a pH 3,5 podría ser una excelente alternativa para vehiculizar calcio iónico, si se utiliza $CaAc_2$ para el tratamiento de la hiperfosfatemia porque los geles al 12% (p/p) admiten concentraciones de $CaCl_2$ o $CaAc_2$ hasta 250 mM.

Abstract. El grano agotado de cebada malteada (bagazo) obtenido de la elaboración de cerveza, es uno de los subproductos más abundantes de la industria cervecera y es rico en compuestos bioactivos, fibras, proteínas y aceite. Si bien en la actualidad el bagazo se utiliza principalmente para alimentación animal, su rico contenido nutricional lo convierte en una alternativa interesante para su utilización en formulaciones alimentarias. Sin embargo, este residuo, actualmente no ha sido muy estudiado. El objetivo del presente trabajo, fue realizar una comparación de bagazos, obtenidos a partir de la elaboración de distintos estilos de cerveza artesanal (Dorada, Scottish y Hazy APA), realizando una caracterización proximal y una posterior caracterización funcional de los componentes presentes en dichos subproductos. Los resultados obtenidos mostraron diferencias significativas entre los bagazos. Los principales componentes de la caracterización fueron, fibras estructurales (como fibra detergente neutro, FDN) y proteína bruta. La proteína bruta presentó una variación entre 13,61 y 22,30% en base seca (b.s.), dependiendo el bagazo y la FDN entre 36,92 y 46,87 %b.s. y libre de grasa. El contenido de aceite osciló entre 1,9 y 5,0 %b.s., siendo el componente minoritario. En la caracterización funcional se determinó la digestibilidad de las fibras y la solubilidad de las proteínas, donde se observó que los residuos de maltas Dorada presentaron una mayor digestibilidad, indicado por la relación fibra:proteína y por la menor proporción de hemicelulosa en su composición. Por otra parte, los residuos de malta Dorada también presentaron, mayor solubilidad de las proteínas otorgándole mejores características funcionales.

Palabras claves: grano gastado, bagazo de cerveza, fibras, proteínas.

1 Introducción

La industria alimentaria genera anualmente grandes cantidades de desechos agroindustriales en todo el mundo a partir del procesamiento y la fabricación de alimentos y bebidas [1]. Los subproductos y desechos de los alimentos están formados por componentes altamente complejos, muchos de los cuales pueden tener un alto valor

como proteínas, polisacáridos, fibras, saborizantes, fitoquímicos, etc. Estos pueden ser extraídos, purificados, y caracterizados por las tecnologías existentes y emergentes, lo que conduce al desarrollo de nuevas aplicaciones comerciales en sectores alimentarios y no alimentarios como la industria farmacéutica, biomédica, cosmética, etc. [2,3]. Los cereales, sus derivados y los efluentes provenientes de su industrialización, son considerados especialmente atractivos como materia adecuada debido a su abundancia y disponibilidad [4,5].

La cerveza es una bebida alcohólica que resulta de fermentar, mediante levadura seleccionada, el mosto de cebada malteada, sola o mezclada con otros productos amiláceos (adjuntos). Todas las cervezas se elaboran con cuatro ingredientes básicos que son: malta, agua, levadura y lúpulo, pero se diferencia según el proceso de elaboración en cerveza artesanal y cerveza industrial, las calidades de los ingredientes y en la fórmula que el maestro cervecero ha creado [5,6]. Puede contener otros granos de cereales malteados como trigo, centeno o sorgo, o sin maltear como arroz, maíz e incluso cebada, dependiendo del tipo de cerveza que se produce. La malta es el ingrediente más significativo y el que le confiere color a la cerveza, así como también contribuye al aroma, al sabor, y al cuerpo de la misma. Las diferentes maltas aportan azúcares, los cuales la levadura fermentará posteriormente. A su vez, la espuma de la cerveza obtiene estructura gracias a las proteínas de los granos de los distintos tipos de malta.

La elaboración de cerveza produce varios residuos que incluyen: granos agotados (bagazo), lúpulo agotado y levaduras agotadas. Por cada 100 litros de cerveza elaborada, se generan aproximadamente, un 14-20 kg de grano agotado durante el filtrado y 0,2-0,4 kg de lúpulo agotado, generado durante la ebullición del mosto y la adición del lúpulo (por la coagulación y formación de complejos de proteínas de alta masa molar y compuestos fenólicos oxidados). Además, la levadura residual es el resultado de la multiplicación celular durante la fermentación [7].

El bagazo, correspondiente a la parte insoluble del grano de cebada germinada, es el subproducto más abundante generado a partir del proceso de elaboración de la cerveza. Después del proceso de maceración, el grano agotado es desechado y representa alrededor de un 85 % del total de subproductos obtenidos. Su composición puede variar según la variedad de grano empleado, su época de cosecha, las condiciones de malteado y maceración, y la calidad y tipo de complementos agregados al proceso de elaboración. Durante la elaboración de cervezas, en general se utiliza la combinación de dos o tres tipos de maltas y otros adjuntos para lograr los diferentes estilos. El grano agotado contiene alrededor de un 30-50 % de fibra, 19-30 % de proteína y 2-10 % de lípidos [8].

A nivel industrial todos los residuos son agrupados como un único residuo y son los responsables de las pérdidas en el proceso de elaboración de la cerveza, proporcionando pérdidas de mosto, extracto y también cerveza, según de qué fase se extraiga el residuo, lo que conduce también a la generación de cantidades significativas no solo de residuo sólido, sino también de efluentes líquidos [7]. Actualmente, este residuo es utilizado principalmente como alimento animal, pero también presenta otros usos como producción de biocombustibles y etanol, biogás, materiales de construcción, materiales de fabricación de papel y adsorbentes, entre otros. También, se han realizado varios intentos para emplear el grano agotado en la producción de compuestos de valor agregado (xilitol, ácido láctico, etc.), cultivo de microorganismos o simplemente como

materia prima para la extracción de compuestos como azúcares, proteínas, ácidos, antioxidantes y en la producción de enzimas [9]. Sin embargo, estos usos han sido poco estudiados aún.

La composición del grano agotado de la cebada hace que este material resulte atractivo para la industria de alimentos, pudiendo proporcionar recursos proteicos verdes, innovadores y de alta calidad, que podrían satisfacer las necesidades de salud de los seres humanos [8]. En este contexto, una de las principales áreas de explotación de este tipo de residuos sería la recuperación de componentes valiosos como materias primas para la obtención de productos de valor agregado. Las proteínas del bagazo posiblemente se puedan utilizar como fuente proteica, no solo para animales, sino también en la dieta humana. Los hidrolizados de proteínas han sido, durante algún tiempo, el punto focal de la investigación nutritiva, ya que se ha demostrado que los hidrolizados de proteínas de fuentes vegetales, tienen efectos antiinflamatorios y actividad antioxidante [10,11]. Por otra parte, el material lignocelulósico del bagazo está constituido por una estructura compleja de celulosa, hemicelulosa y fibras de lignina.

La utilización de estos residuos por parte de los grandes productores de cerveza (industrial) ha sido investigada, sin embargo, el conocimiento acerca de la utilización de éstos entre los cerveceros artesanales (*craft brewers*) es incipiente [7,11]. Para una evaluación adecuada del bagazo, como fuente de productos de valor agregado, y su potencial aplicación en tecnologías de bioprocesos, la caracterización de los diferentes componentes presentes es de gran interés. Sin embargo, estudios previos se han ocupado principalmente de la composición y obtención de carbohidratos, lignina, y ácidos p-hidroxicinámicos del bagazo cervecero, y en menor medida de la composición y obtención de lípidos y proteínas. A pesar de los estudios existentes, aún no existen antecedentes sobre la comparación entre los bagazos provenientes de diferentes estilos de cervezas, los cuales podrían diferir significativamente en su composición y calidad, debido a que los distintos estilos de cervezas son elaborados con diferentes tipos de maltas [13-15]. En el presente trabajo se realizó una comparación de la composición de diferentes bagazos, obtenidos de la elaboración de distintos estilos de cerveza artesanal y posteriormente se analizó la funcionalidad de los componentes mayoritarios (fibras estructurales y proteínas).

2 Materiales y métodos

Los bagazos se obtuvieron de la elaboración de cervezas realizadas por la cátedra de Laboratorio de Procesamiento de Alimentos, del Departamento de Ingeniería Química (UNS). Los tipos de cervezas empleados fueron Dorada, Scottish y Hazy APA (American Pale Ale) y en la Tabla 1 se resumen las especificaciones de las maltas utilizadas en su elaboración. Los bagazos fueron secados en un secadero rotativo con aire a 60°C, hasta alcanzar un contenido de humedad menor al 14%, para acondicionarlos hasta su reutilización.

Se determinó en los bagazos secos el contenido de humedad, lípidos, proteínas, fibra detergente neutra (FDN), fibra detergente ácida (FDA) y hemicelulosa.

El contenido de humedad se determinó según técnica IUPAC 1.121 [16], por secado en estufa de vacío a 100 ºC hasta peso constante. La determinación del contenido de aceite

se llevó a cabo en un equipo Soxhlet, empleando n-hexano grado comercial como solvente, siguiendo la norma IUPAC 1.122 [16]. El contenido de proteína cruda se determinó utilizando el método de Kjeldahl [17], empleando un digestor y destilador Büchi. Para el análisis de las fibras estructurales, se siguió el método de Van Soest [18]. Este método de análisis separa la pared celular del contenido celular y sus componentes: celulosa, hemicelulosa y lignina. Empleando un simple balance se calculó el contenido de hemicelulosa entre el valor de FDN y FDA.

Tabla 1: Tipos de maltas y adjuntos según el estilo de cerveza**.**

Maltas	**Tipo**	**Temperatura de horneado (°C)**	**Dorada**	**Scottish**	**Hazy APA**
Base	Pilsen	80-85	x	x	
	Pale	80-85			x
	Munich	100-108			x
	Trigo	80			
	Viena	90-100	x		
Especiales	Caramelo 60	64-71		x	
	Chocolate	220		x	
Adjuntos	Copo de Trigo				x
	Copo de Avena	---			x

El contenido de humedad y lípidos fue expresado en base seca (% b.s.) y el contenido de FDN, FDA, hemicelulosa y proteínas se expresó en base seca desgrasada (% b.s.d). Por otra parte, se realizó una caracterización funcional de los residuos, determinando la digestibilidad de la materia seca (DMS), la energía digestible (ED) y la energía metabolizable (EM), a través de estimaciones en las muestras desgrasadas, según ecuaciones de predicción de National Research Council (N.R.C.,1998). El porcentaje de DMS fue determinado por la ecuación predictiva (1) a partir del contenido de FDA [19]:

$$\%DMS = 88{,}9 - 0{,}779\ \%FDA \quad (1)$$

El contenido de energía metabolizable (EM) del residuo fue estimado, según las normas inglesas de alimentación [20] con la siguiente ecuación (2):

$$EM = 3{,}61\ \%DMS \quad (2)$$

La caracterización funcional se realizó sobre las proteínas y las fibras. La solubilidad de las proteínas se determinó en función del pH, las muestras se dispersaron en agua destilada con una relación sólido:líquido de 1:20. El pH de las suspensiones se ajustó a los valores de: 1,4; 3,6; 4,5; 5,7; 7,1; 10,1 y 12,3 utilizando HCl 0,1 M y NaOH 0,1 M. Las suspensiones se agitaron durante 1 hora a temperatura ambiente y se midió su pH. Los contenidos de proteínas en los sobrenadantes, obtenidos después de la centrifugación (3115 g; 25 min), se determinaron por el método colorimétrico de Lowry, calibrado con una curva estándar de albúmina de suero bovino (BSA). La

solubilidad de las proteínas se expresó como el porcentaje de proteína soluble extraído en relación contenido total de proteína presente en los distintos bagazos [21-22].

2.2. Análisis estadístico

El análisis estadístico de los resultados se llevó a cabo por medio del Análisis de Varianza (ANOVA) usando el software Infostat [23]. La comparación de medias se realizó mediante el test de Tukey con un nivel de significancia de $p \leq 0,05$.

3 Resultados y discusión

3.1. Determinación del contenido de humedad, lípidos y proteínas.

La Tabla 2 presenta el contenido de humedad final de las diferentes muestras (luego del secado). Las mismas presentaron valores menores a 11 % b.s. El bajo contenido de humedad permitió mantener la estabilidad de los materiales y la calidad microbiológica para su posterior uso.

Tabla 2: Contenido de humedad, lípidos y proteínas de los bagazos en estudio.

Bagazos	Humedad (% b.s.)	Aceite (% b.s.)	Proteínas (% b.s.d*)
Dorada 1	10,8 ± 0,10	1,94 ± 0,05[a]	16,23 ± 0,16[a]
Dorada 2	11,6 ± 0,07	2,05 ± 0,03[a]	15,25 ± 0,15[b]
Scottish	7,81 ± 0,09	3,01 ± 0,14[b]	18,26 ± 0,18[c]
Hazy APA	3,37± 0,03	4,68 ± 0,07[c]	23,02 ± 0,23[d]

Los datos son valores medios ± error estándar n=3. Los valores en la misma columna con la misma letra no son significativamente diferentes (p>0,05) por método Tukey.
*b.s.d: base seca desgrasada.

El contenido de aceite osciló entre el 2 y 5 % en peso del bagazo seco (b.s.). El análisis estadístico arrojó diferencias significativas entre las maltas Doradas respecto de la Scottish y Hazy APA ($p < 0,05$). Los valores encontrados en bibliografía presentan una amplia variabilidad en la composición lipídica, con valores que llegan hasta un 10 % b.s. de lípidos totales. Faulds et al. [13] reportaron un contenido de lípidos similares a los presentados en este trabajo para la malta Hazy APA (5,4 % b.s.). Del Rio et al. [24], por su parte, reportaron un contenido de lípidos de 9,2 % b.s., un valor superior, pero acorde a valores informados previamente en otros documentos [5,25,26]. Esta variabilidad en el contenido de lípidos, depende principalmente de las distintas variedades de maltas en cada residuo. A pesar del contenido de lípidos de dichos residuos, los estudios sobre la composición de los mismos, aun son relativamente escasos y limitados.

El contenido de proteínas presentó diferencias significativas para todos los residuos analizados ($p < 0,01$). Los residuos de malta Dorada 1 y Dorada 2 fueron los que presentaron el menor contenido, con valores de 13,6 % y 14,7 % b.s.d, respectivamente. Otros autores han reportado contenidos de proteínas, con valores de 22-24 %,

presentando concordancia con los resultados obtenidos para el residuo de malta Hazy APA [25-28]. Esta variabilidad en la composición, depende principalmente del uso de diferentes maltas y del proceso al que fueron sometidas. Cada residuo derivado de un estilo de cerveza, es elaborado con una o más variedades de maltas, las cuales son el producto del grano germinado bajo condiciones controladas. Esta germinación modifica la composición química del grano, produciendo cambios en la composición del mismo. El grado de transformación durante el malteado se conoce como modificación y es debidamente controlado con el manejo de las condiciones de crecimiento a las cuales es expuesto el grano. Los cambios esenciales que ocurren durante la modificación del grano son tres, comenzando con el aumento en la cantidad de enzimas hidrolíticas presentes en el grano, mediante liberación o síntesis; la degradación de las paredes celulares, gomas, proteínas y almidón por parte de estas enzimas y, por último, una reducción en la fuerza estructural del tejido del grano. Las cervezas con diferentes sabor, color, aroma, suavidad y espuma utilizan maltas producidas por estos diferentes procesos, que en particular difieren principalmente en el tiempo y temperatura de secado y tostado posterior al malteado. Estas etapas desarrollan sabor y color de diferentes grados de intensidad para la preparación de diferentes cervezas [29].

3.2. Determinación del contenido de fibras estructurales

El bagazo cervecero es de naturaleza lignocelulósica. Los polisacáridos en el bagazo están representados por celulosa (formada por unidades repetitivas de b-D-glucopiranosa) y hemicelulosa (heteropolímero formado por azúcares no celulósicos como manosa, xilosa, galactosa y arabinosa) y comprenden casi el 45 % del peso seco total. La lignina, un polímero ramificado, forma el resto de la composición del bagazo [5,29].
Los cuatro residuos analizados presentaron un contenido de FDN (celulosa, hemicelulosa y lignina) entre 36 % y 48 % (Tabla 3). Según el análisis estadístico, los residuos de bagazos de Doradas fueron significativamente diferentes respecto de los de Scottish y Hazy APA ($p<0,05$). Sin embargo, los bagazos de Doradas presentaron menor contenido de fibra que lo reportado hasta el momento en bibliografía [26,30].

Tabla 3: Contenido de FDN, FDA y Hemicelulosa de los cuatro bagazos analizados.

Bagazo	FDN (% b.s.d)	FDA (% b.s.d)	Hemicelulosa (% b.s.d)
Dorada 1	$42,04 \pm 0,42^{a}$	$14,91 \pm 0,14^{a}$	$27,13 \pm 0,27$
Dorada 2	$41,20 \pm 0,41^{a}$	$16,13 \pm 0,16^{b}$	$25,07 \pm 0,25$
Scottish	$48,03 \pm 0,48^{b}$	$17,73 \pm 0,17^{c}$	$30,30 \pm 0.30$
Hazy APA	$49,41 \pm 0,49^{b}$	$18,93 \pm 0,18^{d}$	$30,48 \pm 0,30$

Los datos son valores medios ± error estándar n=2. Los valores en la misma columna con la misma letra no son significativamente diferentes ($p>0,05$) por método Tukey. *b.s.d: base seca desgrasada.

Por otra parte, se encontraron valores similares a los de Hazy APA, en otros trabajos previos. Yu et al [26] reportaron un contenido de fibra detergente neutra de 51,0 ± 0,7 % y Shen et al. [30] obtuvieron valores de 46,6 %.

Mussato et al. [31] asociaron las diferencias en la composición del bagazo, no solo a los diferentes tipos de maltas sino también al país de producción y al proceso de elaboración de cerveza y concluyó que independientemente de las variaciones reportadas en la cantidad de cada constituyente en la composición del bagazo, este material está compuesto principalmente de fibras (celulosa, hemicelulosa y lignina) y proteínas (como se muestra en la Tabla 3). La hemicelulosa y la celulosa son fracciones constituidas por azúcares, siendo los más abundante en el bagazo la xilosa, la arabinosa y la glucosa. Los azúcares corresponden a aproximadamente la mitad de la composición del bagazo en peso seco, lo que representa una fracción muy importante.

En comparación con otros productos agroindustriales, el bagazo presenta un contenido elevado de hemicelulosa, más alto que el que presentan otros subproductos de cultivos, incluyendo cáscara de arroz, de trigo, cebada y avena. Por otra parte, el bagazo presenta menor contenido de celulosa, pero posee un contenido de lignina similar frente a estos subproductos.

3.3. Estimaciones de digestibilidad de la MS (DMS), energía digestible (ED) y energía metabolizable (EM)

Desde un punto de vista económico y ambiental, se ha hecho un esfuerzo por encontrar una reutilización del residuo generado durante la elaboración de la cerveza. El bagazo cervecero es el subproducto más abundante de la industria de la cerveza y aunque tiene un bajo costo, hasta el momento, sus aplicaciones son muy limitadas. Actualmente, se lo utiliza en alimentación animal a pesar de su alto valor, principalmente como fuente de moléculas bioactivas. El contenido de fibra en el forraje juega un papel muy importante dentro de la alimentación y nutrición de ganado bovino y rumiantes en general. La calidad y cantidad de fibra afectan la capacidad de consumo voluntario y la cantidad de energía que puede aportar una ración [32]. A medida que el forraje madura, aumenta su contenido de fibra detergente neutra, lo cual determina una más lenta tasa de digestión con mayor tiempo de retención ruminal. En términos prácticos, la fibra detergente neutra es inversamente proporcional a la capacidad de consumo que los animales tendrán sobre ese alimento (a más FDN, menor consumo voluntario). Las determinaciones de FDA, buscan cuantificar las fracciones de celulosa y lignina del alimento. Al igual que en el caso anterior, estos compuestos se incrementan con el avance de los estadios fenológicos de las forrajeras. Ello implica una correlación negativa con la digestibilidad de la materia seca y un menor contenido energético aprovechable [33].

La Tabla 4 muestra las estimaciones de digestibilidad de la materia seca (DMS), la energía digestible (ED) y la energía metabolizable (EM). Para la realización de las estimaciones fue necesario conocer el contenido de FDN y FDA (Tabla 2).

Tabla 4: Estimaciones de digestibilidad de la MS (DMS), energía digestible (ED) y energía metabolizable (EM) de diferentes tipos de bagazos de cerveza.

Bagazos	**DMS %**	**ED** Mcal/kg MS	**EM** Mcal/kg MS
Dorada 1	78,44	3,45	2,83
Dorada 2	77,68	3,42	2,81
Scottish	76,09	3,36	2,75
Hazy APA	74,61	3,30	2,71

La digestibilidad es una forma de medir el aprovechamiento de un alimento, en otras palabras, es la facilidad con que el alimento es convertido en el aparato digestivo en sustancias útiles para la nutrición. Comprende dos procesos, la digestión correspondiente a la hidrólisis de las moléculas complejas de los alimentos, y la absorción de pequeñas moléculas, como aminoácidos y ácidos grasos, en el intestino. La digestibilidad, a su vez, puede constituir un indicador de calidad de la materia prima que a veces varía notablemente, de una especie a otra; a priori deberían esperarse valores muy distintos en las especies carnívoras, herbívoras u omnívoras [34]. Independientemente de la metodología utilizada para evaluar la calidad, se considera que un subproducto tiene alta calidad cuando tiene aproximadamente 70 % de digestibilidad de la materia seca (DMS) o más, menos de 50 % de fibra detergente neutra (FDN) y más de 15 % de proteína bruta (PB) [20]. De acuerdo a lo mencionado, se puede observar que los residuos de malta Scottish y Hazy APA podrían ser considerados de alta calidad. Mientras que los bagazos obtenidos de las maltas Dorada, presentan un menor contenido de proteínas. Cuando se ofrece un residuo con menor contenido de proteínas y elevado contenido de fibras, existe una depresión parcial en la digestión de la fibra. La digestibilidad es afectada por varios factores, siendo la fibra cruda el principal componente que afecta de manera negativa la digestibilidad de un insumo o dieta. Por otra parte, los mayores valores de energía digestible se presentan para los bagazos de maltas Dorada, según algunos autores esto se explica por la menor cantidad de fibra cruda presente en el residuo [35].

El contenido de energía digestible (ED), correspondiente a cada una de los residuos estudiados, se consignan en la Tabla 4, donde se observa que la energía digestible de los residuos de maltas Doradas fueron los valores superiores a los encontrados entre todos los residuos. Los mayores valores de energía digestible de los residuos de malta dorada, en comparación a los demás bagazos, podría ser explicado por la menor cantidad de fibra presente en las mismas (36,9 y 37,8 %) y posiblemente por una mayor cantidad de extracto libre de nitrógeno, en este caso, la energía es mejor aprovechada [35]. Por otra parte, cabe destacar que todos los valores de energía digestible fueron superiores a los informados por otros autores para distintos forrajes, los cuales no superan valores de 2,5 Mcal/kg MS. Esto podría dar indicio de la calidad de los residuos estudiados, los cuales presentan ciertas características (tanto nutricionales como funcionales) que hacen del bagazo un buen subproducto de valor agregado.

La energía metabolizable (EM), es la cantidad de energía retenida por el organismo para las diferentes necesidades, y se utiliza en la actualidad como unidad básica para expresar los valores energéticos de los alimentos y las necesidades del animal [36]. La energía metabolizable presentó valores similares en todos los residuos, estos valores se encuentran en concordancia con los reportados por otros autores para diferentes subproductos utilizados en alimentación animal [36].

3.4. Solubilidad de las proteínas

La solubilidad de las proteínas es una de las propiedades fisicoquímicas y funcionales más importantes. El grado de solubilidad de las proteínas varía en función de diversos factores: pH, concentración salina, temperatura, etc. En general las proteínas globulares son solubles en agua debido a los radicales R que están colocados en la superficie de la proteína y que establecen enlaces por puente de Hidrógeno con el agua. Varios investigadores han demostrado que la mayoría de las proteínas vegetales tienen la solubilidad proteica más baja en su punto isoeléctrico y luego aumenta hacia los valores de pH básicos. En general, las proteínas del bagazo son poco solubles en agua (menos del 10 %) [37].

En el presente trabajo, el estudio de solubilidad se realizó modificando el pH del medio desde 1,5 hasta 12,3. En un perfil típico de solubilidad proteica en agua en función de pH, se observó que la solubilidad es máxima a pHs muy ácidos (2-3) o muy alcalinos (9-11). En dichas zonas, las proteínas poseen cargas neta positivas o negativas, respectivamente y las fuerzas repulsivas son la causa del incremento en su solubilidad. También fue posible observar un mínimo de solubilidad en las cercanías del pH isoeléctrico (pI), a pH=3-5 (dependiendo el tipo de muestra), donde la carga neta de las proteínas es cero, por lo que disminuye la repulsión electrostática y se promueve la agregación [22].

La Fig. 1 muestra la solubilidad de las proteínas, expresada como porcentaje, g Proteína solubles/100 g de proteínas totales, de los distintos bagazos en función del pH. En todos los casos, la menor solubilidad se obtuvo a valores de pH inferiores a 4. Al aumentar el pH a valores superiores, se produjo la precipitación consecutiva de las proteínas, encontrándose que los residuos de maltas Dorada, a un pH de 4,2, son casi completamente insolubles (0,206 y 0,335 % b.s., Dorada 1 y 2, respectivamente). Luego en cercanías del pH neutro, la solubilización de las proteínas se vio favorecida, presentando un aumento significativo a valores superiores a 5. A pH alcalino se observó que alrededor de un 25-35 % del total de las proteínas de los bagazos, pueden solubilizarse en agua. Por otra parte, se pudo determinar que el punto isoeléctrico fue a pH cercanos a 3,6 para todas las muestras. Este valor se encuentra en concordancia con los reportados por Arauzo et al. [38] y Connolly et al. [39] para proteínas de bagazo.

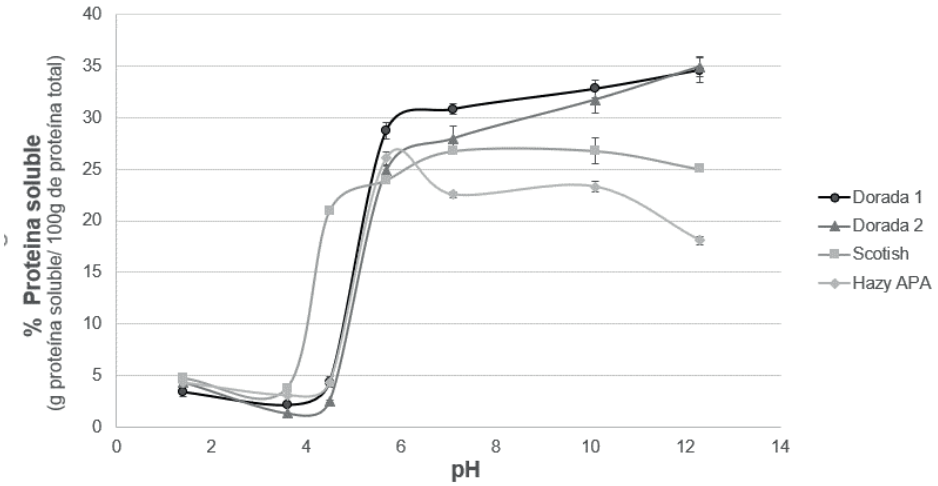

Fig. 1: Perfil de solubilidad de las proteínas de cuatro bagazos obtenidos de la elaboración de tres estilos de cerveza artesanal.

Los residuos de malta Dorada presentaron un aumento significativo de la solubilidad de las proteínas cuando el pH aumentó a 5,7, en ambos residuos. A partir de este pH, el aumento de la solubilidad fue menos significativo con el ascenso de pH hasta valores de 12,3. El residuo de bagazo de Dorada 1, incrementó la solubilidad de las proteínas en un 6 % pasando de un pH de 5,7 a 12,3. Mientras que el residuo de bagazo de Dorada 2 presentó un incremento del 10 % para un mismo intervalo de pH. Por su parte, el residuo de Scottish presentó su menor solubilidad a pH 3,4 con un 4 % de proteína solubilizada, mientras que alcanzó su máxima solubilización a pH 7,1 (28,8 %) no observándose variación con un aumento de pH hasta 12,3. El residuo de bagazo de Hazy APA, presentó la menor solubilidad de las proteínas a un pH de 3,5, mientras que el aumento significativo de solubilidad se alcanzó a un pH de 5,7 alcanzando un 27 % de solubilización del total de la proteína presente en la muestra, a partir de este pH la curva se vuelve asintótica para dicho residuo.

Si bien, el residuo de Hazy APA presentó el mayor contenido de proteína bruta, la solubilidad de la misma fue menor que para el resto de los residuos. Los residuos de maltas Doradas contenían proteínas con una solubilidad significativamente mayor que los demás bagazos. También se pudo observar que las proteínas del bagazo Scottish mostraron una mayor solubilidad sobre el rango de pH más ácido. Algunos autores consideran un pH de 3,8-4,0 como el pH de precipitación para la recuperación de proteínas de bagazo extraídas con álcali [22,39].

El aumento de la solubilidad de las proteínas podría estar afectado por la versatilidad de las muestras y por los diferentes tratamientos a los que se sometieron las maltas previo uso en la elaboración de las cervezas. Por otra parte, el aumento de la solubilidad

de las proteínas puede deberse, también, a la disminución de peso molecular y al despliegue de proteínas. Tanto los grupos de aminoácidos no polares como algunos polares, encerrados dentro de las moléculas de proteínas, podrían quedar expuestos en la superficie de las moléculas después del despliegue. Estos aminoácidos polares expuestos pueden interactuar con las moléculas de agua a través de enlaces de hidrógeno e interacciones electrostáticas, lo que resulta en un aumento de la solubilidad proteica [22].

Para aumentar las aplicaciones potenciales de las proteínas insolubles, se podría aplicar hidrólisis química y enzimática. La hidrólisis enzimática es leve y no destruye los aminoácidos. Los efectos sobre las propiedades nutricionales, aun resultan poco estudiados. Además, las enzimas son específicas en su acción y esto permite un procesamiento controlado. Los hidrolizados formados por diversas enzimas pueden tener diferentes funcionalidades. La hidrólisis de proteínas cambia el peso molecular, la carga y la exposición de grupos hidrófobos, además de las cadenas laterales reactivas de aminoácidos. Estas transformaciones moleculares resultan en cambios en la solubilidad, viscosidad, propiedades sensoriales y comportamiento emulsionante y espumante de las proteínas [22].

4 Conclusiones

Los esfuerzos crecientes hacia la reutilización de subproductos agroindustriales, tanto desde el punto de vista económico como ambiental han ido en aumento en los últimos años. El bagazo es un subproducto abundante producido en cervecerías de todo el mundo. Sin embargo, a pesar de la amplia gama de posibles aplicaciones, todavía se restringe su uso y actualmente, es utilizado principalmente como alimento para animales.

En el presente trabajo se pudo realizar una comparación de distintos bagazos obtenidos a partir de diferentes estilos de cervezas artesanales, realizando una caracterización proximal y una posterior caracterización funcional de fibras y proteínas. Los residuos presentaron una amplia gama de componentes y diferencias en la funcionalidad de los mismos. En este estudio se observó que los bagazos provenientes de diferentes estilos de cervezas no presentaron una misma composición y dependiendo del tipo de malta utilizada, se diferenciaron tanto en la cantidad como en la funcionalidad de los componentes. Este estudio podría contribuir a la búsqueda de potenciales usos de los bagazos discriminando los residuos según su composición para potenciar su empleo. El conocimiento de dichos componentes y su funcionalidad resultan de gran interés para la industria de alimentos. Desde el punto de vista nutricional, el alto contenido de fibra y proteína del bagazo lo hace muy interesante para su aplicación en la dieta humana, tanto en aplicaciones alimentarias como en biotecnológicas. Este subproducto también podría representar una valiosa fuente de componentes bioactivos.

Resumen. La presencia de mohos en la cebada cervecera representa un inconveniente para la industria maltera, debido a la pérdida de calidad de esta materia prima en cuanto a sus propiedades tecnológicas y de inocuidad por la presencia de micotoxinas. El ozono (O_3) es una tecnología emergente que puede aplicarse para la reducción de la carga microbiana de esta matriz. La etapa de remojo en el proceso de malteado proporciona condiciones favorables para el tratamiento de los granos de cebada con ozono en fase acuosa. El objetivo de este trabajo fue evaluar el efecto de la aplicación de diferentes dosis de ozono en fase acuosa sobre la inactivación fúngica en cebada cervecera contaminada artificialmente con *Fusarium graminearum*, utilizando una columna de burbujeo a escala de laboratorio. Se realizaron tratamientos de ozonización en una etapa (a diferentes tiempos de exposición) y en tres etapas (durante 45 min por etapa) a 20 ± 1 °C, y se determinó su efecto sobre el porcentaje de granos infectados, incubados a 15, 20 y 25 °C. Los resultados se compararon con controles de lavado, además del control. El tratamiento con ozono en 3 etapas redujo significativamente la contaminación de *F. graminearum*, evidenciándose el efecto positivo de la ozonización con respecto a sólo el proceso de lavado cuando la incubación se realizó a 20 y 25 °C. A 15 °C no hubo un efecto adicional significativo del ozono sobre el efecto mecánico del lavado.

Palabras clave: Cebada, Malteado, Ozono, Contaminación fúngica

1 Introducción

Uno de los principales ingredientes en el proceso de fabricación de la cerveza es la malta, que se obtiene a través del malteado de la cebada cervecera. Mediante el malteado se logra un grano de cebada rico en enzimas, con una estructura del endospermo que permite la hidrólisis del almidón, el cual será la fuente de energía de las levaduras durante la fermentación [1, 2]. En el proceso industrial de malteado, la cebada cervecera, al ser recibida en la maltería, pasa por un proceso de limpieza y clasificación, y luego es almacenada en silos. Las etapas siguientes son el remojo, la germinación y el secado. Durante el remojo de la cebada, se sumergen los granos en agua (36-52 h a 12-20 °C) para aumentar el contenido de humedad del grano hasta un nivel que permita su germinación (alrededor de 45%); esta etapa involucra varios pasos de inmersión en agua (en condiciones aerobias) seguidas de descansos para aireación. Posteriormente se elimina el agua de remojo y se lleva a cabo la germinación de los granos en una atmósfera de aire humidificado (15-20 °C). Durante esta etapa ocurren diversas modificaciones bioquímicas y morfológicas en los granos, evidenciadas por la formación de raicillas. Para detener la germinación, los granos se secan con aire caliente (hasta 90 °C) hasta alcanzar un 5% de humedad. Es en esta etapa donde se definen el color, aroma y sabor de la malta. Finalmente se eliminan las raíces y se almacena la malta [2].

La contaminación de la cebada cervecera por hongos filamentosos (mohos), principalmente *Fusarium*, representa un problema para la industria de la cerveza [2, 3]. El desarrollo de los mohos es posible durante algunas de las etapas (remojado y germinación) que constituyen el proceso de malteado debido al aumento de la actividad de agua en el grano, y las consecuencias negativas de su desarrollo afectan tanto al proceso de malteado como a la calidad de la malta, y, por lo tanto, a la calidad de la cerveza. Algunos de los efectos negativos del desarrollo fúngico son: la reducción de la velocidad de germinación de la cebada; el *gushing* (exceso de presión del gas al abrir la cerveza envasada y posterior derrame del líquido), la alteración del color de la cerveza, y la producción de *off-flavors* en la misma [2, 4]. Por otra parte, los mohos pueden producir micotoxinas (metabolitos secundarios tóxicos, como deoxinivalenol, hallado frecuentemente en cerveza [5]), las cuales tienen efectos negativos sobre las levaduras que se emplean en la fermentación, y por lo tanto la eficiencia en esa etapa puede disminuir [2]. Teniendo en cuenta que la contaminación por micotoxinas puede ocurrir también durante el cultivo de la cebada [6, 7], y que durante el malteado no se reduce en forma importante el contenido de las mismas [3, 5], su presencia en el producto final afecta la inocuidad de la cerveza.

En las últimas décadas han surgido agentes físicos y químicos de destrucción microbiana (comúnmente denominados “factores emergentes de conservación”) alternativos a los tratamientos tradicionales para incrementar la inocuidad de alimentos manteniendo su calidad sensorial, nutricional y/o funcional, tanto en productos de consumo directo como en materias primas y productos intermediarios antes de su industrialización. Entre ellos pueden mencionarse altas presiones hidrostáticas, pulsos eléctricos de alto voltaje, ozono, ultrasonido, radiación ultravioleta y luz pulsada [8].

El ozono es un oxidante potente que se utiliza para la purificación de agua y el tratamiento de efluentes [9], y ha sido aprobado como GRAS (Generally Recognized as

Safe) en USA para su uso en el procesamiento de alimentos [10]. Debido a su corta vida útil (se descompone espontáneamente en oxígeno), no queda ozono residual en el producto [11]. El ozono puede ser utilizado para la inactivación de varios microorganismos y la degradación de sustancias químicas en alimentos, en fase líquida o en fase gaseosa [12–14]. En el caso de los cereales, ha sido utilizado en fase gaseosa para la reducción de la carga microbiana, la desinsectación y la inactivación de micotoxinas [15–19]. Por otra parte, al ser burbujeado en agua, el ozono se disuelve parcialmente, formando radicales hidroxilo que pueden oxidar contaminantes con mayor eficiencia que el ozono molecular [14]. La etapa de remojo en el proceso de malteado proporciona condiciones favorables para el tratamiento de los granos de cebada con ozono en fase acuosa, con la finalidad de la inactivación microbiana, dado que la matriz a tratar se encuentra sumergida en agua. Así, el objetivo de este trabajo fue evaluar el efecto de la aplicación de diferentes dosis de ozono en fase acuosa sobre la inactivación fúngica en cebada cervecera contaminada artificialmente con *Fusarium graminearum*, utilizando una columna de burbujeo a escala de laboratorio.

2 Materiales y Métodos

2.1 Muestras

Se utilizó cebada (*Hordeum vulgare* L) de la variedad comercial Andreia, de calidad cervecera. Se desinfectó la cebada sumergiéndola en una solución de NaClO al 5% (v/v) y agitando la mezcla durante 1 min. Se enjuagó la muestra dos veces con abundante agua estéril, agitando cada vez la mezcla por 1 min. Finalmente, se secó la muestra exponiéndola a flujo laminar de aire, en cabina, durante 15 min. La cantidad de cebada utilizada en cada tratamiento fue de 50 g, cantidad que se pesó en recipientes individuales para su posterior inoculación.

2.2 Cepa fúngica e inoculación de las muestras

Se utilizó la cepa 257 del moho *Fusarium graminearum*, productora de deoxinivalenol y zearalenona [20]. Esta cepa pertenece a la colección del laboratorio MICA (Departamento de Industrias de la Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires). El moho se cultivó en medio sólido favorable para la producción de conidios (1 g KH_2PO_4, 1 g KNO_3, 0.5 g KCl, 0.5 g $MgSO_4 \cdot 7H_2O$, 0.2 g glucosa, 0.2 g sacarosa, 20 g agar agar, 20 g cebada molida, 1 L H_2O), y fue incubado a 25 ± 1 °C durante 21 días. Para obtener una suspensión de conidios con la cual inocular las muestras, se agregó agua sobre el cultivo y se removió suavemente con espátula de Drigalsky. El líquido remanente fue filtrado a través de gasa y recolectado en un recipiente estéril. La concentración de conidios de la suspensión se determinó utilizando una cámara de Neubauer (Marienfeld, Alemania), y fue ajustada a 10^6 conidios/mL.

Cada muestra de cebada (50 g) fue inoculada con 10 mL de la suspensión de conidios. Las muestras inoculadas se homogeneizaron mediante agitación manual y se almacenaron a 8 °C hasta el día siguiente, cuando se realizaron los tratamientos. La contaminación de las muestras de cebada inoculada se determinó mediante la técnica de

recuento en placa (Agar Extracto de Levadura, Dextrosa y Cloranfenicol; Biokar Diagnostics, Francia), y fue del orden de 10^4 UFC/g.

2.3 Sistema de ozonización y tratamientos

Se utilizó un equipo generador de ozono por descarga en corona UTK-O-4 (Unitek, Argentina) conectado a una columna de burbujeo de 2 L de capacidad. El ozono fue generado a partir de oxígeno seco de elevada pureza, a un caudal de 5 L/min, y una concentración de 19.58 ± 1.44 mg ozono/L. En este sistema de tratamiento, el gas proveniente del generador ingresa por la parte inferior de la columna de burbujeo, y es dispersado en el líquido a través de un difusor ubicado en la sección posterior a la entrada del gas. Luego de atravesar la columna de burbujeo, y antes de ser liberado al ambiente, el gas es inactivado al entrar en contacto con una solución de KI al 2% (p/v). Este sistema se encuentra instalado dentro de una campana de extracción de gases. Los tratamientos de ozonización se realizaron colocando en la columna de burbujeo la muestra inoculada y 500 mL de agua, y burbujeando el gas en una o en tres etapas según lo descripto a continuación:

Tratamientos en una etapa. La duración de estos tratamientos fue de 5, 15, 30, 45 o 60 min.

Tratamientos en tres etapas. Se realizaron tratamientos de más de una etapa teniendo en cuenta que en el proceso industrial de malteado de la cebada, la etapa de remojo involucra más de un paso de inmersión de los granos en agua. El tiempo de ozonización en cada etapa se eligió en función de los resultados de los tratamientos en una etapa, y fue de 45 min. Una vez finalizada cada etapa, la muestra fue retirada de la columna, el agua fue descartada, se tomó una pequeña cantidad de cebada para llevar a cabo los análisis correspondientes y, posteriormente, se colocó la muestra en la columna junto con otros 500 mL de agua para iniciar la siguiente etapa.

Control. Se denominó de esta manera a las muestras inoculadas que no fueron sometidas a ningún tratamiento.

Controles de lavado. Se llevaron a cabo burbujeando sólo oxígeno (con el generador de ozono apagado), de la misma manera en que se realizaron los tratamientos de ozonización en una o en tres etapas.

Las experiencias se llevaron a cabo a 20 ± 1 °C, y se realizaron tres réplicas por tipo de tratamiento, cada una de ellas en diferentes días, con sus respectivos controles. Las réplicas de los tratamientos en una etapa se llevaron a cabo en días distintos, realizando o bien tratamientos de ozonización, o bien controles de lavado por día. En el caso de los tratamientos en tres etapas, en cambio, fue posible realizar una réplica de ozonización y una de control de lavado en el mismo día.

2.4 Determinación del porcentaje de granos infectados

Se colocaron 10 granos de cebada de cada muestra control o tratada sobre placas de Petri de 90 mm de diámetro con el medio de cultivo Agar Extracto de Levadura, Dextrosa y Cloranfenicol (Biokar Diagnostics, Francia). Las muestras fueron incubadas por separado a tres temperaturas (15, 20 y 25 ± 1 °C), y el recuento de granos infectados se realizó cada 24 h y como máximo hasta 72 h después del inicio de la incubación, o hasta que se hubo observado el 100% de infección en los granos (lo que ocurriera primero). Se contó como positivo el desarrollo de micelio en cada grano a la inspección visual, y se lo expresó como porcentaje de granos infectados (% GI). Las temperaturas de incubación fueron seleccionadas teniendo en cuenta la temperatura óptima de desarrollo del moho (25 °C) y dos temperaturas en las que se lleva a cabo industrialmente el remojo de la cebada (15 y 20 °C). Cada determinación se realizó por triplicado y los resultados se expresaron como el promedio de las réplicas (%) ± desviación estándar.

2.5 Análisis estadístico

Se evaluó la normalidad de las distribuciones de los resultados por tratamiento mediante el test de Shapiro-Wilk ($\alpha = 0.05$). Los resultados del test indicaron que no todas ellas pertenecían a una distribución normal. Por ello, se utilizaron tests no paramétricos de Kruskal-Wallis y de múltiples rangos para evaluar las diferencias entre tratamientos ($\alpha = 0.05$).

3 Resultados y Discusión

3.1 Tratamientos en una etapa

En el primer día de incubación a 20 y 25 °C, el porcentaje de granos infectados (%GI) fue del 100% cuando las muestras fueron tratadas con ozono durante 5 y 15 min, y para todos los controles de lavado. A partir de los 30 min de tratamiento, el %GI de las muestras ozonizadas fue menor (entre 80 y 90%) que el observado para los correspondientes controles de lavado, aunque no significativamente diferente (Fig. 1). En estudios complementarios se observó que el contenido de humedad (en base seca) de los granos llegó al 44,2 y 45,3% a los 30 min de exposición al oxígeno y ozono, respectivamente, hasta un 47,8 y 47,0% a los 60 min. Cuando la temperatura de incubación fue de 15 °C, el %GI de todas las muestras fue inferior al 100%, incluidos los controles. La incidencia de la infección por *F. graminearum* en granos control fue significativamente diferente y superior a la observada en todos los granos ozonizados ($P < 0,0001$), y a la observada a partir de 15 min en el caso de los controles de lavado ($P = 0,0060$). Este es un resultado esperable, puesto que tanto los controles de lavado como las muestras tratadas fueron sometidos a agitación mecánica.

Puede observarse en la Fig. 1 que los %GI de las muestras ozonizadas y sus controles (también en el primer día de incubación a 15 °C) fueron superiores a los correspondientes a los controles de lavado: la causa de estas diferencias pudo deberse a que los ensayos en una etapa se llevaron a cabo en diferentes días, como se indicó en la sección de

Materiales y Métodos, y por lo tanto se partió de un inóculo diferente cada día. Si bien la concentración de conidios de las suspensiones utilizadas para inocular las muestras fue la misma en todas las réplicas, las diferencias en los %GI de los controles pudieron estar relacionadas con la heterogeneidad de la superficie de los granos de cebada, y por ello la forma en que los conidios fueron retenidos en los granos.

El recuento de granos infectados al segundo día de incubación fue del 100% para todos los tratamientos de ozonización y controles de lavado, a las tres temperaturas de incubación. Por lo tanto, si bien se observó un retraso en el desarrollo fúngico en las muestras tratadas al primer día de incubación, al día 2 la incidencia del moho no fue afectada por los tratamientos.

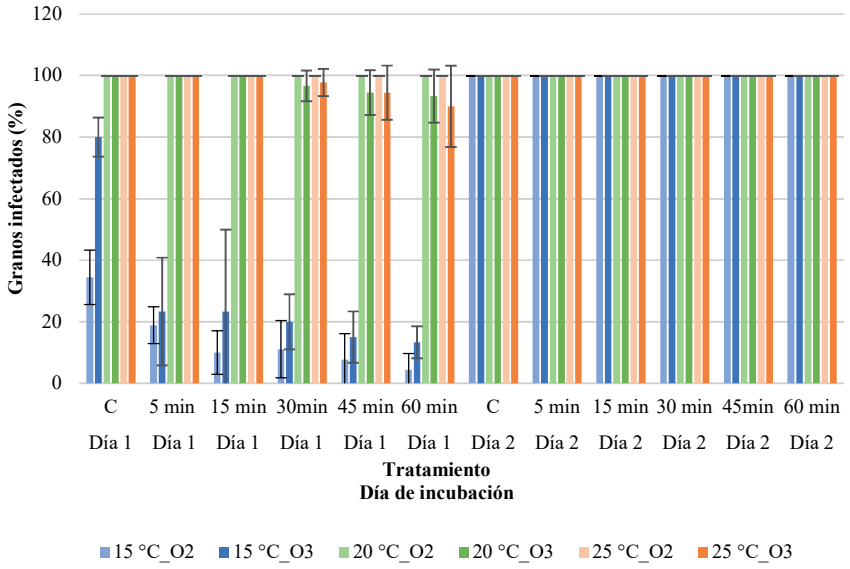

Fig. 1. Porcentaje de granos infectados en control (C), controles de lavado (O_2) y en muestras tratadas con ozono (O_3) durante diferentes períodos de tiempo (5, 15, 30, 45 y 60 min) e incubados a diferentes temperaturas (15, 20 y 25 °C). Las barras corresponden a los valores promedio de las determinaciones, y las barras de error corresponden a ± la desviación estándar.

3.2 Tratamientos en tres etapas

Para la selección del tiempo de ozonización en los tratamientos en etapas, se tuvieron en cuenta los resultados de %GI del primer día de incubación a 20 y 25 °C. Dado que hubo una reducción del %GI respecto de los controles de lavado a 30, 45 y 60 min, se evaluaron las diferencias entre estos tratamientos para cada temperatura. Éstas resultaron no significativas en ambos casos (P = 0,7173 y P = 0,476 para 20 y 25 °C, respec-

tivamente). Sin embargo, el mínimo en el rango de los valores de %GI para los tratamientos de 30 min fue de 90% mientras que para los tratamientos de 45 y 60 min, el mínimo fue de 80%, para ambas temperaturas de incubación. Por lo tanto, se seleccionó entre estos dos últimos, el tratamiento de menor duración (45 min). Los promedios del %GI a 20 °C para 30, 45 y 60 min fueron 96,7 ± 5,0; 94,4 ± 7,3 y 93,3 ± 8,7, respectivamente; y a 25 °C fueron 97,8 ± 4,4; 94,4 ± 7,8 y 93,8 ± 7,4, respectivamente.

De manera similar a lo observado en los tratamientos en una etapa, el %GI fue menor cuanto más baja fue la temperatura de incubación de los granos (Fig. 2). A las 72 h de incubación, no se observaron desarrollos fúngicos adicionales a los observados al segundo día, por lo que la Fig. 2 muestra solo los resultados hasta el día 2. Al segundo día de incubación, el %GI fue del 100% para las muestras de la primera etapa, mientras que, para las muestras ozonizadas de la segunda etapa, los %GI variaron entre 50 y 90%, y entre 45 y 80% para las muestras de la tercera etapa, a las diferentes temperaturas de almacenamiento. En cuanto a los controles de lavado, también se observó una disminución en el %GI a partir de la segunda etapa, aunque los valores de %GI fueron mayores que los observados en las muestras ozonizadas.

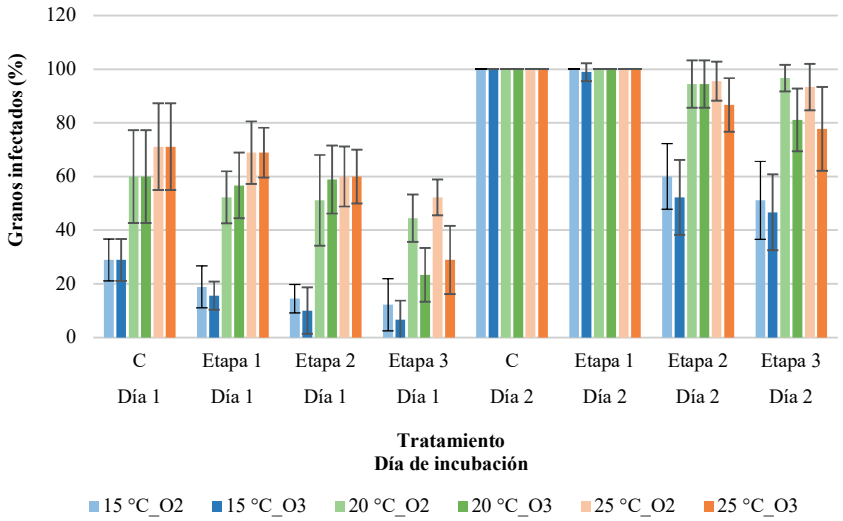

Fig. 2. Porcentaje de granos infectados en control (C), controles de lavado (O_2) y muestras tratadas con ozono (O_3) en etapas (1, 2 y 3) e incubados a diferentes temperaturas (15, 20 y 25 °C). Las barras corresponden a los valores promedio de las determinaciones, y las barras de error corresponden a ± la desviación estándar.

Las tablas 1 y 2 indican la significancia de las diferencias entre el control y las muestras ozonizadas o entre el control y los controles de lavado en las distintas etapas, respectivamente; mientras que la tabla 3 indica la significancia de las diferencias entre el control, las muestras ozonizadas y los controles de lavado en cada etapa. Tanto en el

primer día de incubación como en el segundo, y para las tres temperaturas, no se observaron diferencias significativas entre los %GI del control y la primera etapa de tratamiento, para muestras ozonizadas como para controles de lavado (Tablas 1 y 2). Las muestras ozonizadas en tres etapas presentaron %GI significativamente diferentes a la mayoría de las tratadas en menor número de etapas, según lo observado a ambos días y para algunas temperaturas de incubación (Tabla 1). Este resultado no se repitió en el caso de los controles de lavado, donde sólo se observaron diferencias significativas a 25 °C el primer día de incubación, y a 15 y 25 °C el segundo día (Tabla 2).

En cuanto a las diferencias entre muestras ozonizadas y controles de lavado en la misma etapa, para las observaciones de %GI en ambos días de incubación, a las temperaturas de 15 y 20 °C no hubo diferencias significativas entre los %GI de las muestras ozonizadas y de los controles de lavado. A 25 °C, los valores correspondientes a las muestras ozonizadas en la segunda y tercera etapa fueron significativamente diferentes ($P < 0,05$) y menores, que los %GI de los controles de lavado (Tabla 3).

La ozonización en tres etapas de cebada inoculada con *F. graminearum* permitió reducir la contaminación inicial del moho, a pesar de no haberse alcanzado la completa inactivación del mismo. Si bien se observó un efecto del lavado, el ozono fue más efectivo para lograr la reducción de la contaminación fúngica, sobre todo a las mayores temperaturas.

Tabla 1. Diferencias significativas ($P < 0,05$) entre control (C) y etapas (1, 2 y 3) de tratamientos de ozonización al primer y segundo día de incubación de las muestras a diferentes temperaturas (15, 20 y 25 °C). Los grupos homogéneos se encuentran alineados en la misma columna.

4 Conclusiones

El estudio de la ozonización en una etapa a diferentes dosis de tratamiento permitió la selección de la dosis de ozonización para los tratamientos multietapa, que se asimilan a los diferentes pasos de la etapa de remojo de la cebada cervecera en el proceso industrial de malteado. El tratamiento con ozono en 3 etapas redujo significativamente la contaminación de *F. graminearum* durante 72 h, evidenciándose el efecto positivo de la ozonización con respecto a sólo el proceso de lavado cuando la incubación se realizó a 20 y 25 °C. A 15 °C no hubo un efecto adicional significativo del ozono sobre el efecto mecánico del lavado. Así el ozono es una alternativa ambientalmente amigable de interés para reducir la contaminación fúngica de la cebada durante el malteado cuando el mismo se realiza a temperaturas en el rango óptimo de desarrollo del moho.

Están en curso investigaciones acerca del efecto de los tratamientos de ozonización en 3 etapas sobre la capacidad germinativa de la cebada, parámetro fundamental para el proceso de malteado. Estudios preliminares han mostrado que la misma no se altera en tratamientos de hasta 60 min en condiciones operativas similares.

Agradecimientos

Resumen. El proceso de salado-madurado de anchoíta (*Engraulis anchoíta*) genera en nuestro país un gran volumen de residuos, que no pueden ser destinados a la obtención de harina y aceite de pescado por su alto tenor salino. En este trabajo se busca caracterizar este residuo y evaluar la posibilidad de aplicar un proceso de desalado que permita su posterior reprocesamiento. Se aplicó un proceso de desalado con agua corriente en tres etapas, evaluándose el efecto sobre la retención de macronutrientes. Se determinó que los residuos contienen un 17,6% NaCl, con un 14,8% proteína y 3,5% de lípidos, de los cuales el 20,3% corresponden a ácidos grasos poliinsaturados, representados principalmente por EPA y DHA. El desalado propuesto permitió reducir el contenido de NaCl hasta 1,6%, sólo con 1,3% y 0,35% de pérdida de proteína y lípidos hacia la solución, respectivamente. Los residuos de anchoíta salada-madurada sometidos a un proceso sencillo de desalado, presentaron componentes con alto valor biológico, que los hace interesantes para reintegrar a distintos ciclos productivos.

Palabras Clave: Subproductos de la pesca, Desalado, Propiedades Fisicoquímicas, Ácidos grasos poliinsaturados.

1 Introducción

El pescado es una de las fuentes más importantes de nutrientes como proteínas, vitaminas y minerales, considerándose la mayor reserva de ácidos grasos poliinsaturados, especialmente omega-3 [1]. Los residuos generados por su procesamiento pueden representar entre 30 y 70%, con un volumen en aumento debido a la demanda creciente de los consumidores [2]. Particularmente, la anchoíta (*Engraulis anchoita*) constituye uno de los principales recursos pesqueros de nuestro país, destinado principalmente a la producción de anchoíta salada-madurada. Esta industria genera alrededor de 7.000 ton/año de residuos, que no pueden aprovecharse en la producción de harina o aceite de pescado debido a su alto contenido de sal (NaCl), que puede alcanzar 55 % dependiendo de las particularidades del proceso. Por este motivo, estos residuos son desechados al predio de disposición final, con el consecuente impacto ambiental asociado. Para

su reintegración a los ciclos productivos es necesario previamente realizar un tratamiento que reduzca el contenido de sal a niveles compatibles con los distintos procesos.

En este contexto, se propone el estudio del desalado de residuos de la elaboración de anchoíta salada-madurada y su efecto sobre la retención de macronutrientes, aportando de esta forma estrategias que favorezcan el agregado de valor y el uso integral de los recursos pesqueros comerciales.

2 Metodología

2.1 Procedimiento de desalado

Se utilizaron residuos del proceso industrial de salado-madurado de *E. anchoíta* (Mar del Plata, Argentina), constituidos principalmente por cabezas y parte de las vísceras. El desalado consistió en la inmersión en agua corriente (16 ± 2 °C) durante un tiempo total de 5 horas, con dos renovaciones de agua a 1,75 y 3,75 h y una relación solución-residuo 2:1. Se extrajeron muestras (20 g) a distintos tiempos de desalado, se homogeneizaron y almacenaron a 5 ± 1 °C para su análisis.

2.2 Análisis fisicoquímicos

La composición química proximal de los residuos fue determinada según AOAC [3] y el contenido de NaCl mediante el método de Mohr [4]. En el agua de desalado se determinó proteína soluble por Lowry et al. [5] y contenido de lípidos como sustancias solubles en éter etílico. El perfil de ácidos grasos (AG) se determinó por cromatografía gaseosa (Shimadzu GC-17^{A}, Japón). Los análisis se realizaron por triplicado.

Los cambios en el contenido de macronutrientes durante el tratamiento se evaluaron a partir de ANOVA y test de Tukey para comparación de medias (R Development Core Team, Version 4.2 2020), $p<0.05$.

3 Resultados y discusión

3.1 Caracterización de los residuos

La composición de los residuos sin tratar fue: 62,5 ± 0,5% de agua, 23,1 ± 0,2% de cenizas, 14,8 ± 0,5% de proteínas y 3,5 ± 0,2% de lípidos con un tenor salino de 17,6 ± 0,2%. Los datos disponibles en bibliografía se refieren en general a la porción comestible, habiéndose reportado en músculo de anchoíta salada un contenido de agua en el rango 55-60 g/100g y un contenido de NaCl entre 17 y 47 g/100g [6]. Los residuos presentan una CQP diferente debido a la gran proporción de cabezas, piel, vísceras y escamas. En cuanto a la composición de AG (**Tabla 1**), se determinó en los residuos una predominancia de ácidos grasos saturados (AGS), mayormente representados por el palmítico (16:0) (0,233 ± 0,003 g/g_{grasa}); seguido por los monoinsaturados (AGMI), siendo el oleico (18:1 n9) el de mayor proporción (0,101 ± 0,000 g/g_{grasa}). Los ácidos grasos poliinsaturados (AGPI) representaron el 20,3%, con los porcentajes más altos

para la familia omega-3 (EPA y DHA). Esto se contrapone con los datos disponibles para productos de anchoíta, que presentan una prevalencia de AGMI y AGPI con menor proporción de AGS [6]. De acuerdo a estos resultados, resulta evidente el efecto del salado sobre la fracción AGPI, explicado por su alta sensibilidad a la oxidación combinada con la presencia de factores pro-oxidantes durante el proceso, como enzimas y restos de sangre.

3.2 Proceso de desalado

El proceso de desalado permitió reducir el contenido de NaCl en los residuos, alcanzando valores finales de 1,6% con un contenido de humedad de 75,1% (**Figura 1**). Se observa que las mayores modificaciones se produjeron durante la primera etapa (1,75h), disminuyendo el contenido de NaCl un 70% con respecto al valor inicial.

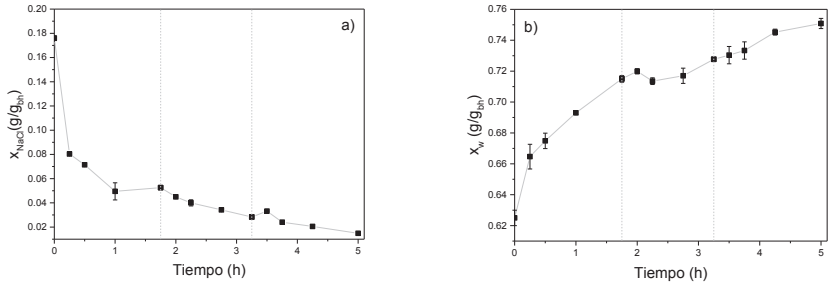

Fig. 1. Evolución del contenido de NaCl (a) y del contenido de agua (b) durante el desalado de residuos del salado-madurado de anchoíta.

Tabla 1. Contenido de proteínas, lípidos (g/g) y perfil de ácidos grasos (g/g de grasa) en el residuo y solución de desalado durante el proceso.

	Tiempo de desalado			
	0 h	1,75 h (Etapa 1)	3,75 h (Etapa 2)	5 h (Etapa 3)
RESIDUO				
Proteínas	0,148 ± 0,005 [a]	0,128 ± 0,006 [a]	0,148 ± 0,005 [a]	0,142 ± 0,014 [a]
Lípidos	0,035 ± 0,002 [a]	0,038 ± 0,003 [a]	0,051 ± 0,003 [b]	0,047 ± 0,001 [c]
AGS	0,486 ± 0,007 [a]	0,424 ± 0,015 [b]	0,518 ± 0,008 [a]	0,437 ± 0,019 [b]
AGMI	0,231 ± 0,002[a]	0,324 ± 0,021[b]	0,228 ± 0,012[a]	0,280 ± 0,011[c]
AGPI	0,203 ± 0,003[a]	0,193 ± 0,005[a]	0,201 ± 0,007[a]	0,209 ± 0,009[a]
EPA+DHA	0,141 ± 0,002	0,156 ± 0,003	0,161 ± 0,005	0,158 ± 0,005
SOLUCIÓN DE DESALADO				
Proteínas	-	0,0089 ± 0,0005[a]	0,0027 ± 0,0004[b]	0,0014 ± 0,0002[c]
Lípidos	-	0,0022 ± 0,0005[a]	0,0005 ± 0,0000[b]	0,0008 ± 0,0001[b]
AGS	-	0,225± 0,019[a]	0,367 ± 0,018[b]	0,320 ± 0,034[b]
AGMI	-	0,136 ± 0,013[a]	0,199 ± 0,028[a]	0,176 ± 0,029[a]
AGPI	-	0,308 ± 0,016[a]	0,211 ± 0,022[b]	0,183 ± 0,015[b]
EPA+DHA	-	0,070 ± 0,003	0,090 ± 0,007	0,026 ± 0,007

Letras diferentes en una misma fila indican diferencias significativas ($p<0,05$).

De acuerdo a la **Tabla 1**, las mayores pérdidas hacia la solución de desalado ocurrieron durante la primera etapa. Luego de 5 h, sólo el 1,3% y 0,35% de proteínas y lípidos, respectivamente, se perdieron en el agua de desalado (porcentaje acumulado). En la etapa 1, se determinó un mayor aporte de AGPI en la disolución, sugiriendo una hidrólisis preferencial de esta fracción, que se encuentra en estado líquido a temperatura ambiente, favoreciendo la acción de las lipasas [7]. En forma global, el tratamiento no llevó a una pérdida significativa de proteínas desde los residuos hacia el agua de desalado, así como tampoco a una modificación en la proporción de los distintos grupos de AG.

4 Conclusiones

Los residuos del salado-madurado de anchoíta presentaron un contenido considerable de biomoléculas de alto valor biológico, como proteínas y lípidos, reforzando la idea de la importancia de su recuperación como subproducto y del diseño de tratamientos adecuados que permitan su reincorporación a los ciclos productivos, como la obtención de harina de pescado u otros productos con valor agregado tales como hidrolizados proteicos y obtención de extractos ricos en ácidos grasos omega-3. El desalado propuesto podría servir de base para el diseño de procesos, considerando la reducción del contenido de NaCl alcanzada y la alta retención de macronutrientes.

Arsénico en agua y alimentos: determinación del perfil de riesgo en Argentina

Perez, Silvina[1,2] [0000-0001-7104-6995]a; Marchetti, Marion D.[1,2] [0000-0002-0801-8083]; Tomac, Alejandra[1,2] [0000-0003-3391-6771]

Abstract. El Arsénico (As) es un elemento que se encuentra ampliamente distribuido en la naturaleza. Los compuestos de As inorgánico (iAs) son los más tóxicos y, clasificados como agentes cancerígenos, ocasionan múltiples efectos negativos sobre la salud. La exposición humana al As se da principalmente por la ingesta de agua y alimentos. Argentina presenta vastas zonas con aguas con altas concentraciones de As, superiores al límite recomendado de 0,01 mg/L. En alimentos, pescados y mariscos, arroz y algas marinas tienen naturalmente los niveles más altos de As. En este trabajo se realizó el Perfil de Riesgo de As en agua y alimentos, mediante la revisión sistemática de más de 100 documentos científicos y normativa relacionada, encontrándose que la ingesta de As en Argentina podría suscitar una preocupación de Salud Pública. Es de crucial importancia el conocimiento certero de los riesgos asociados a la baja exposición al As, el contenido de iAs en diferentes matrices alimenticias y el efecto del procesamiento tecnológico y culinario sobre la especiación y concentración, que permitan la elaboración de informes fehacientes y con visión a futuro sobre el estado de contaminación.

Keywords: Análisis de Riesgo, Peligro Químico, Agua, Alimentos, Inocuidad.

1 Introducción

El arsénico (As) se encuentra naturalmente en las aguas subterráneas y las actividades antropogénicas contribuyen a su incremento, por lo que existen valores superiores al límite (0,01 mg/L) en aguas de bebida. El As ingresa al organismo por consumo de estas aguas, de cultivos regados con agua contaminada y de organismos filtradores o sus predadores. Las formas inorgánicas (III) y (V) son las más tóxicas, clasificadas como agentes carcinógenos [1], [2]. En Argentina existen vastas zonas con agua con niveles de As perjudiciales para la salud. Si bien en el siglo XX se confirmó que la exposición a las mismas daba lugar al Hidroarsenicismo Crónico Regional Endémico (HACRE), aún existe incertidumbre sobre la magnitud de la población expuesta, siendo necesario un programa permanente de vigilancia de los niveles de As en recursos hídricos.

El Perfil de Riesgo es una etapa preliminar del Análisis y la Gestión de Riesgos para la inocuidad de los alimentos, siendo la base para iniciar una evaluación de riesgo. Provee información relevante acerca de la combinación peligro/alimento, la caracterización del peligro y el riesgo existente en la cadena alimentaria [3]. El objetivo fue describir mediante el Perfil de Riesgo el problema de inocuidad de alimentos y del agua con altas concentraciones de As, a fin de identificar los elementos de relevancia para la gestión de riesgos.

2 Metodología

Se realizó un Perfil de Riesgo del peligro químico Arsénico, en agua y en alimentos de acuerdo a los lineamientos de FAO [3]. Para ello se describió la combinación peligro/alimento, se identificó y caracterizó el peligro y se analizó la exposición del ser humano al mismo a través de la ingesta, los posibles riesgos asociados a la misma y sus consecuencias para la salud, mediante la recopilación y revisión sistemática de más de 100 fuentes de documentos científicos y normativa relacionada.

3 Resultados y Discusión

3.1 Identificación del peligro: Arsénico

La toxicidad del As varía según su forma arsenical, valencia, solubilidad, estado físico, pureza y tasas de absorción y eliminación. Los arsenitos y arseniatos son formas de iAs altamente solubles en agua, generalmente más tóxicas que el As orgánico que se elimina rápidamente del organismo. Los compuestos arsenicales de mayor a menor toxicidad son: inorgánicos trivalentes > orgánicos trivalentes > inorgánicos pentavalentes > orgánicos pentavalentes > As elemental [4].

En la naturaleza, el As cuenta con ciclos asociados a actividades geológicas y antropogénicas, entre estas últimas, pigmentos, componentes electrónicos, aleaciones de cobre o plomo, minería, plaguicidas, herbicidas, fertilizantes. La presencia natural se asocia a la corteza terrestre, suelos, sedimentos, aire, agua, organismos vivos, polvo volcánico y continental y quema de vegetación [4]. Las actividades humanas y eventos naturales transfieren As al ambiente, de éste a la atmosfera, precipitando con el agua de lluvia y llegando a la superficie continental, sedimentos oceánicos y agua; y en general a través del agua a los alimentos [4], [5].

3.2 Normativa nacional

De acuerdo con las recomendaciones de la OMS, en 2019 la normativa argentina estableció un valor máximo de 0,01 mg/L de As en agua potable de suministro público y uso domiciliario, en aguas de bebida o potabilizadas envasadas y en aguas mineralizadas [6]. Sin embargo, en agua mineral natural y sus productos, se admite un valor muy superior (0,2 mg As/L). En alimentos se establecen límites máximos de contaminantes inorgánicos en un rango de 0,01-1 mg/kg (Art. 56) [6].

3.3 Caracterización del peligro

La vía de ingreso más importante del As es por la ingesta, acumulándose en hígado, bazo, riñones, pulmones y tracto gastrointestinal. Los efectos en la salud dependen de la dosis y duración de la exposición[4]. Semanas o meses de exposición a altas dosis de As (0,04 mg/kg/día) resulta en efectos inespecíficos reversibles. Cuando se trata de exposición crónica, la variedad de problemas en la salud se conoce en Argentina como HACRE. Se caracteriza por efectos dérmicos, como hiperpigmentación luego de 5-15 años de ingestión de bajas dosis (≥ 0,01 mg/kg/día) o 6 meses a 3 años de altas dosis (0,04 mg/kg/día). Además, se asocia a enfermedad vascular, diabetes, hipertensión y efectos sobre los sistemas inmune y respiratorio. El As ha sido clasificado como cancerígeno (grupo I) por el IARC y como cancerígeno (grupo A) por la USEPA [1].

3.4 Exposición al peligro: Arsénico/agua

Investigaciones en Argentina demostraron la existencia de una gran área con aguas con más de 0,05 mg As/L, la cual se extiende en un continuo noroeste-sureste desde el Altiplano hacia la Costa Atlántica, subdividiéndose en zona cordillerana, pericordillerana y pampeana. El origen del As es principalmente natural, debido a la actividad volcánica e hidrotermal de la cordillera de los Andes [1]. Las provincias más afectadas son Córdoba, Santiago del Estero, Chaco, Salta, Tucumán, Santa Fé y La Pampa. Actualmente, la cifra de argentinos que vive en áreas contaminadas (>0,05 mg As/L) asciende a cuatro millones [7], [8].

3.5 Exposición al peligro: Arsénico/alimentos

En general, la proporción de iAs en alimentos comprende el 50-100% del As total [5]. El iAs predomina en carnes, lácteos y cereales, pero también está presente en vegetales y frutas [9]. El contenido de As en alimentos de origen terrestre es generalmente bajo, por lo que la cantidad de iAs es también baja. Excepción es el arroz con importante contenido de iAs [5]. Por otro lado, los pescados y mariscos pueden tener elevado contenido de As pero proporción relativa de iAs usualmente muy baja [10]. De arroz y pescados se han reportado exceso de los limites nacionales permitidos. Los vegetales contienen en su mayoría (>40 %) iAs [11]. La principal fuente de iAs para los argentinos, considerando la ingesta y el porcentaje de iAs respecto del total, correspondería a harina de trigo y derivados y luego el arroz, cuyo consumo es bajo, pero la cantidad de iAs en el mismo es elevada. La contribución de la carne de res resultaría importante debido a su alto consumo [5].

4 Conclusiones

La exposición al As a través del agua y alimentos en Argentina podría suscitar una preocupación de Salud Pública, principalmente debido a la existencia de zonas con

contenidos de As en agua mayores al límite establecido. Pescados y mariscos, carnes y arroz presentan valores más elevados, por lo que la cuantificación de As total, iAs y As orgánico debe ser más exhaustiva en los mismos. Es necesario el continuo relevamiento de las regiones con HACRE y con fuentes de agua contaminadas, ya que la información disponible actualmente no posibilita una evaluación del riesgo completa. Se debe continuar trabajando para que los organismos pertinentes puedan elaborar informes fehacientes y con visión a futuro sobre el estado de contaminación con As en Argentina de forma de poder tomar medidas preventivas y decisiones de mejora.

Abstract. El proceso de salado-madurado permite el desarrollo de una gran diversidad de procariotas halófilos. En Latinoamérica este método de preservación se utiliza para la especie *Engraulis anchoita*. En el presente estudio se analiza el microbioma de dos muestras de este producto. Se encontró mayor abundancia de OTUs de bacterias (>97%) con una baja proporción de arqueas. Los OTUs con una abundancia mayor al 5% correspondieron a bacterias de los géneros *Marinobacter* (SA1 17,5% y SA2 14,3%), *Thalassospira* (SA1 15,5% y SA2 17,7%), *Alcanivorax* (SA1 14,5% y SA2 10,7%) y *Parvibaculum* (SA1 6,6% y SA2 12,0%), de las familias *Flavobacteriaceae* (SA1 11,2% y SA2 15,3%) y *Rhodospirillaceae* (SA1 6,3% y SA2 6,1%) y 9,4% y 5,8% de los OTUs de SA1 y SA2, respectivamente, que se pudieron clasificar solo hasta la *clase Gammaproteobacteoria*. Esto indicaría que las bacterias podrían adaptarse mejor como cultivos iniciadores del proceso para mantener las características típicas del producto. Además, se determinó que este producto es fuente de microorganismos novedosos, con el potencial biotecnológico que esto representa.

Keywords: Microbioma, Procariotas halófilos, Anchoíta, Fermentación.

1 Introducción

Diferentes especies pesqueras se pueden conservar mediante salado-madurado, práctica adoptada en América Latina utilizando *Engraulis anchoíta* que alcanza un alto contenido de NaCl (14–20% w/w) y baja actividad de agua (a_w~0.75) [1], lo que contribuye a prevenir el desarrollo de microorganismos patógenos y deteriorantes típicos del pescado fresco. La fermentación de alimentos involucra microorganismos que modifican características sensoriales mediante una diversa gama de actividades enzimáticas. Cuando se realizan en presencia de altos contenidos de sal, resultan en el desarrollo de una gran diversidad de microorganismos autóctonos halófilos o halotolerantes capaces de sobrevivir y crecer en ambientes hipersalinos. Pese a que estos productos se encuentran en constante estudio [2]–[4], el microbioma de la *Engraulis anchoíta* salada-madurada no ha sido analizado hasta el momento. Por lo antedicho, el objetivo del presente

estudio se enfoca en el estudio del microbioma de la anchoíta salada-madurada enfocado a aplicaciones tecnológicas.

2 Metodología

Se colectaron dos muestras (SA1 y SA2) de anchoíta (*Engraulis anchoita*) de diferentes capturas, salada, descabezada y parcialmente eviscerada, de la etapa de maduración en barriles de una planta procesadora en Mar del Plata, Argentina; cuyo proceso de elaboración constó de una etapa de salado-húmedo de los ejemplares enteros seguido de la maduración de troncos de anchoíta acondicionados con sal en barriles [4]. Se homogeneizaron 50 g de muestra en caldo salino estéril (NaCl, 150 g/L; peptona de carne, 3 g/L; extracto de carne, 3 g/L) y se dejó reposar por 30 min [5]. La matriz del alimento se separó por centrifugación a 3.000 g por 5 min. El sobrenadante obtenido se centrifugó a 10.000 g por 10 min y los pellets se resuspendieron en etanol 70% (v/v) y almacenaron a 4°C hasta la extracción de ADN [6]. Para el análisis del microbioma se utilizaron los primers 15F(Parada)-806R(Apprill): FWD:GTGYCAGCMGCCGCGGTAA; REV:GGACTACNVGGGTWTCTAAT enfocado a regiones altamente conservadas en procariotas y a la región hipervariable V4 del 16S rARN. Los resultados se analizaron de acuerdo al paquete QIIME version 1.9.1 [7]. Las secuencias con más de un 97% de similitud fueron agrupadas en unidades taxonómicas operacionales (operational taxonomic units, OTUs). Las secuencias representativas se analizaron con la base de datos SILVA 132 (versión 132, publicada en abril de 2018) utilizando el Naïve Bayesian Classifier [8].

3 Resultados y Discusión

Se determinó la composición de la secuenciación de amplicones Illumina del gen 16S ARNr dirigido a la región hipervariable v4, obteniendo datos de secuencias de 300 pb en promedio con 96664 lecturas para SA1 y 96306 para SA2. El patrón de la composición total se puede observar en la Fig. 1. Se detectaron múltiples OTU que contribuían con al menos un 0,1% a la composición del microbioma del consorcio. En este sentido, hubo 34 OTUs para SA1 y 28 en SA2, sin cambios en las OTU predominantes. La abundancia de las arqueas fue minoritaria, siendo que el 97,8% y 99,5% de las lecturas de SA1 y SA2, respectivamente, correspondieron a eubacterias. Los OTUs con una predominancia mayor al 5% fueron en ambos casos bacterias de los géneros *Marinobacter* (SA1 17,5% y SA2 14,3%), *Thalassospira* (SA1 15,5% y SA2 17,7%), *Alcanivorax* (SA1 14,5% y SA2 10,7%) y *Parvibaculum* (SA1 6,6% y SA2 12,0%), de las familias *Flavobacteriaceae* (SA1 11,2% y SA2 15,3%) y *Rhodospirillaceae* (SA1 6,3% y SA2 6,1%) y 9,4% y 5,8% de los OTUs de SA1 y SA2, respectivamente, que se pudieron clasificar solo hasta la clase *Gammaproteobacteria*. Entre las arqueas, la mayor presencia se dio en SA1 con 2,66% de los OTUs pertenecientes a *Halobacteriaceae*, dentro esta familia encontrando los géneros *Haloquadratum* (0,25%), *Halorhabdus* (0,02%) y *Haloarcula* (0,01%). Muchos miembros de estos géneros y familias se han encontrado halófilos en pescado y ambientes marinos, y algunos de ellos en productos

pesqueros salado-madurados. Cabe destacar que múltiples OTUs no pudieron atribuirse a una taxonomía precisa de género/especie con una secuencia de referencia similar (> 97%) a una cepa tipo, indicando la presencia de especies potencialmente novedosas, como todas las OTU de nueva referencia y las OTU provenientes de cepas donde la taxonomía máxima que infirió solo a nivel familiar.

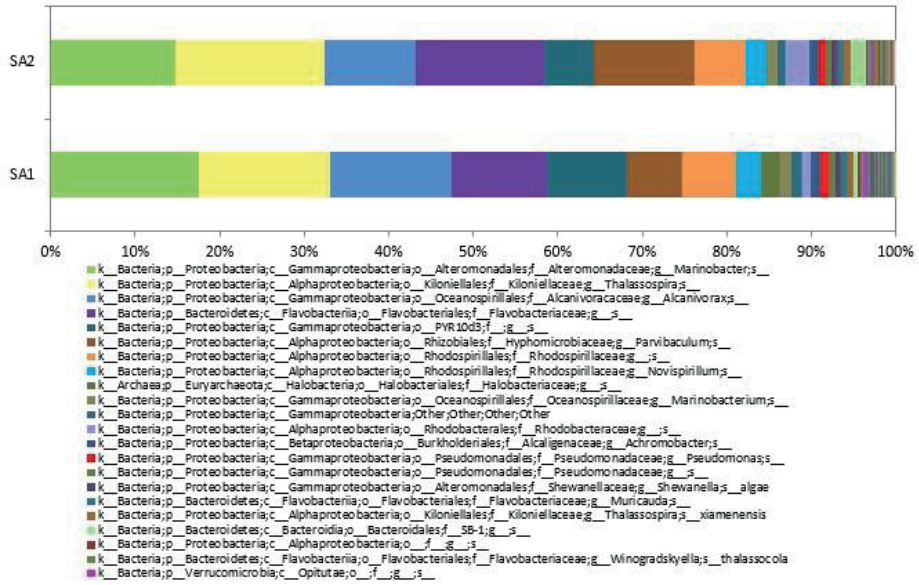

Fig. 1. Composición del microbioma de las muestras de anchoíta salada-madurada.

Dado que el proceso de elaboración de *Engraulis anchoíta* salada-madurada puede proporcionar las condiciones necesarias para la formación de aminas biogénas, para los humanos [1], resulta de interés evaluar la presencia de OTUs próximos a géneros de procariotas degradadores de histamina asociados a previamente a este producto a fin de controlar su presencia. La histamina puede causar una intoxicación alimentaria similar a una alergia, que es la enfermedad transmitida por los alimentos más común relacionada con los productos pesqueros, por lo que su contenido está regulado en estos alimentos [1]. En este sentido, se encontraron cepas pertenecientes a los géneros *Halobacterium*, *Halomonas* y *Halovibrio* capaces de degradar histamina [9]. En las muestras analizadas en el presente estudio, la abundancia de OTUs de *Halomonas* fue 0,09% en SA1 y 0,28% en SA2, mientras que los otros géneros no fueron encontrados.

4 Conclusiones

Se encontró que en este alimento la abundancia predominante corresponde a bacterias con una muy baja incidencia de arqueas. El conocimiento del microbioma puede contribuir a la toma de decisiones para la mejora del proceso de salado-madurado de anchoíta. De particular importancia resultan estos hallazgos para la selección de microorganismos iniciadores de la maduración, indicando que las bacterias podrían adaptarse mejor como cultivos iniciadores del proceso considerando también mantener las características típicas del producto. Además, se determinó que este producto es fuente de microorganismos novedosos, con el potencial biotecnológico que esto representa.

Resumen. El tratamiento con ozono es una alternativa de procesamiento mínimo para aumentar la vida útil de frutas, con reducido impacto en la calidad global. El objetivo de este trabajo fue evaluar los cambios en las propiedades ópticas y en las ceras epicuticulares (CE) de arándanos expuestos a 5,1 $mg.L^{-1}$ de ozono en fase acuosa durante 10 min y almacenados a 4 ± 1 ºC durante 15 días. Se adquirieron espectros de frutos con CE (fruto entero), frutos sin CE y sólo CE tanto de frutos ozonizados como control. Los espectros fueron preprocesados utilizando distintos métodos (primera y segunda derivada y normalización de vectores) para eliminar la variabilidad no deseada, y se utilizó un análisis de componentes principales (PCA) para agrupar las muestras. La primera derivada permitió explicar la variabilidad de las muestras y obtener una buena separación de los diferentes grupos de espectros (frutos con CE, frutos sin CE y sólo CE), además de una buena clasificación de las muestras tratadas con ozono y sin tratar. Los espectros FT-IR revelaron varias señales asignadas a las CE y la cutina. El efecto del ozono en las CE se manifestó con la aparición de nuevas bandas (estiramiento de C=O a 1701 cm^{-1}, debido a la oxidación de alcoholes a carbonilos, o 1542 cm^{-1}), y desplazamiento de otras (1464-1472 a 1468 cm^{-1} para el tijereteo de CH_2 o 730 a 724 cm^{-1} para el balanceo de CH_2). Sin embargo, estos cambios en CE no afectaron significativamente el color de los arándanos ozonizados.

Palabras clave: Arándano, Ozono, Espectros FT-IR

1 Introducción

El cultivo de arándano es relativamente joven en Argentina, siendo su principal ventaja la contra-estacionalidad con el hemisferio norte, lo cual permite que el 95 % del fruto fresco sea exportado a los Estados Unidos. Las principales variedades plantadas en el país son Misty y O'Neal, siendo esta última la predominante en la provincia de Buenos Aires. En la actualidad el Comité Argentino de Arándanos desarrolla estrategias para incrementar el consumo de esta fruta en el mercado local y posicionar el arándano como una alternativa de consumo de fruta fresca y natural, destacando sus beneficios a la salud asociados con su alto contenido de vitamina C y compuestos fenólicos, que califican a esta fruta como un "superalimento". Esta baya es altamente propensa al deterioro postcosecha debido principalmente a cambios fisiológicos, daños físicos y contaminación por bacterias y hongos, pérdida de agua, y ablandamiento, entre otros [1,2].

Varios estudios destacan la importancia de las ceras epicuticulares (CE) en diferentes bayas (arándanos, uvas, ciruelas). Las CE contribuyen a inhibir el ataque fúngico en estos frutos y constituyen una barrera para la pérdida de agua, además de ser consideradas un parámetro de calidad desde el punto de vista comercial: la ausencia de éstas resulta en una apariencia poco atractiva y dan impresión de mala calidad [2-6]. Los frutos de arándano cv. O'Neal tiene un contenido de cera cuticular de alrededor de 100 $\mu g/cm^2$, constituidas principalmente por triterpenoides pentacíclicos (especialmente ácido urólico, ácido oleanólico y lupol) y β-dicetonas (principalmente hentriacontan-10,12-diona), que representan el 64,2 % y 16,4 % del total de las CE, respectivamente [7].

En la actualidad, la creciente demanda por parte de los consumidores de productos naturales o símil frescos ha llevado al estudio y desarrollo de nuevas tecnologías que permitan extender la vida útil de frutos y vegetales, sin ocasionar un impacto negativo en las características organolépticas y nutricionales de los mismos. Entre las principales tecnologías de procesamiento mínimo estudiadas, se encuentra el ozono [8,9] que se caracteriza por su alto poder oxidante y corta vida útil, que se traduce en propiedades bactericidas y viricidas sin dejar residuos en el producto. En el año 2002, la FDA aprobó su uso en el tratamiento postcosecha de frutas y vegetales. Diversos estudios han establecido la efectividad del uso de agua ozonizada para el lavado de frutos finos previamente inoculados con patógenos como *Escherichia coli* O157:H7 y *Salmonella enterica* [10,11]. En estudios previos del grupo se demostró la efectividad de tratamientos de ozono en fase acuosa (3,0 y 5,1 mg $O_3.L^{-1}$) durante 10, 15, 20 y 30 min en la reducción de la micobiota nativa durante el almacenamiento refrigerado. Estos tratamientos no produjeron alteraciones en los parámetros mecánicos de los frutos, pero incrementaron la pérdida de peso en comparación con el fruto sin tratar. En particular, el tratamiento de ozonización que causó la menor pérdida de peso fue 10 min de exposición a 5,1 mg $O_3.L^{-1}$ [12]. En función del rol que cumplen las CE en la pérdida de peso y, ante la escasez de estudios sobre la caracterización de las ceras epicuticulares de frutos de arándano o sus cambios como consecuencia de los tratamientos con ozono, el objetivo del presente trabajo fue evaluar el efecto del tratamiento con ozono en fase acuosa (5,1 mg $O_3.L^{-1}$, 10 min) en la superficie del fruto mediante la

adquisición de espectros FT-IR(con énfasis en las ceras epicuticulares), y mediante la evaluación del color a los 0 y 15 días de almacenamiento a 4 ± 1 ºC.

2 Materiales y métodos

2.1 Materia prima

Se utilizaron frutos orgánicos de *Vaccinium corymbosum* (arándano alto) cultivar O'Neal provenientes de la provincia de Buenos Aires, Argentina. Para evitar la variabilidad debido al estadio de madurez, se trabajó con un lote homogéneo. Para la selección de los frutos se tomó en cuenta el tamaño, la forma, el color y la ausencia de infección microbiológica o daño físico. El tamaño de los frutos fue de 1,8 ± 0,2 cm de diámetro y su peso 2,0 ± 0,2 g. Los frutos fueron mantenidos bajo refrigeración (3 ± 1 ºC) hasta 30 min antes de los tratamientos.

2.2 Tratamiento de ozono en fase acuosa

Las muestras fueron ozonizadas en un equipo provisto de un generador de ozono UTK-O-4 (Unitek S.A., Argentina), una columna de burbujeo con difusor incluido y un tanque de oxígeno. Los frutos fueron ozonizados con una concentración de ozono en la corriente gaseosa de entrada a la columna de burbujeo de 18 ± 2 mg $O_3.L^{-1}$ durante 10 min. El ozono se burbujeó en forma continua en 1500 mL de agua destilada a 20 ± 1 ºC. La concentración de ozono disuelto en la fase líquida fue determinada por el método colorimétrico Índigo [13]. Luego de 5 min de exposición, la concentración de ozono fue de 5,1 ± 0,1 mg $O_3.L^{-1}$, la cual permaneció constante hasta el final del proceso.

Se consideraron dos controles: el fruto fresco (FF, fruto sin lavar) y el fruto sumergido en agua destilada burbujeada sólo con oxígeno (generador de ozono apagado) durante 10 min (control O_2 10 min) para diferenciar el efecto del ozono *per se* respecto al lavado ocasionado por la agitación de los frutos dentro de la columna.

2.3 Almacenamiento de las muestras

Inmediatamente después de los tratamientos los frutos fueron secados con papel absorbente y almacenados en bandejas plásticas con tapa de polipropileno de alta densidad (permeable al aire) a 4 ± 1 ºC durante 15 días.

2.4 Medición del color

El color de los frutos de arándano fue medido con un espectrofotómetro triestímulo de reflectancia (Minolta Co., Modelo CM-700-d, Japón), con un iluminante D65 y 2º de ángulo de observador. Se utilizaron 30 muestras independientes para cada tratamiento y se tomaron dos mediciones en dos posiciones diferentes de la zona ecuatorial del fruto. Luego se calculó el valor promedio para obtener un valor para cada fruto. Se registraron los valores de las coordenadas de color del espacio CIE (X, Y, Z)

y los parámetros L*, a* y b* del espacio CIELab donde L* indica luminosidad, a* indica cromaticidad sobre el eje que va del rojo (+) al verde (-), y b* indica cromaticidad sobre el eje que va desde el amarillo (+) hasta el azul (-). A partir de estos valores numéricos, se calcularon las funciones de color "croma" (C*) y "ángulo de tono" (h*).

2.5 Obtención de los espectros por Espectroscopía Infrarroja por Transformada de Fourier (FT-IR)

Esta técnica fue utilizada para evaluar posibles modificaciones y/o interacciones en las ceras y/o la cutícula del fruto ocasionados por el tratamiento con ozono. Las mediciones fueron realizadas en un espectrómetro Spectrum 400 FT-IR/FT-NIR (Perkin Elmer Inc., Estados Unidos) con un accesorio de Reflectancia Total Atenuada (ATR) con cristal de ZnSe de tres reflexiones, con ángulo de incidencia de 45º.

Para cada grupo experimental (FF, control O_2 10 min, 5,1 mg $O_3.L^{-1}$ 10 min), se obtuvieron espectros de tres sets de muestras: frutos sin cera, frutos con cera (frutos enteros) y espectros únicamente de ceras.

Para la obtención de los espectros de los frutos sin cera, las muestras fueron limpiadas al menos dos veces con un algodón empapado en cloroformo dentro de una campana de ventilación y dejados en reposo 10 a 12 h para evaporar por completo el solvente. Por otro lado, los espectros de los frutos (con y sin cera) fueron obtenidos comprimiendo cada fruto (sin provocar la rotura del mismo) con una punta plana de manera tal de garantizar un contacto íntimo entre la muestra y el cristal. Finalmente, los espectros únicamente de ceras fueron obtenidos frotando varias veces el fruto sobre el cristal de ZnSe, de modo tal que la cera quedase adherida al mismo. Para cada condición se analizaron 12 (frutos completos) o 6 frutos (ceras y frutos sin cera) y los espectros fueron adquiridos en el modo reflectancia, entre 600 y 4000 cm^{-1}, de un promedio de 32 escaneos y con una resolución de 4 cm^{-1}. Se adquirió un espectro en aire (sin muestra) previo a la medición de cada sistema.

La localización y obtención de los números de onda de los picos, así como la corrección de la línea de base de los espectros se realizó mediante el programa Spectrum versión 6.3.5 (Perkin Elmer Inc., Estados Unidos). Dado que el cristal utilizado muestra una región de muy alta absorción entre 1900 y 2250 cm^{-1}, ésta fue substraída en todos los casos.

Los estudios mediante FT-IR se realizaron inmediatamente después de los tratamientos con ozono (día 0) y luego de 15 días de almacenamiento a 4 ± 1 ºC.

2.6 Análisis estadístico

Para el análisis quimiométrico se utilizó el programa The Unscrambler v9.7 (Camo Software AS, Noruega). Todos los espectros fueron pre-procesados utilizando la primera y segunda derivada, corrección de dispersión multiplicada (MSC) y normalización de vectores (NV). El análisis de datos se realizó mediante un análisis de componentes principales (PCA) donde en un primer paso se analizaron todos los espectros juntos: frutos con cera, frutos sin cera y sólo ceras, correspondientes a frutos frescos (FF), control O_2 10 min, 5,1 mg $O_3.L^{-1}$ 10 min (n=150). Posteriormente y para cumplir el objetivo de este trabajo, se utilizaron solamente los espectros de los frutos con

cera correspondiente a los FF, control O_2 10 min y 5,1 mg $O_3.L^{-1}$ 10 min (n=85). En todos los casos la calibración se llevó a cabo con el 75% de los datos, y el test de validación con el 25% de los datos restantes. Se utilizó la prueba t de Student para comparar la predicción predictiva del modelo.

Los datos correspondientes a la evaluación del color se analizaron mediante un análisis de varianza multivariado (MANOVA) mediante el programa Infostat v.2008 (InfoStat, Argentina). Se utilizó la prueba Hotelling corregida por Bonferroni en caso de encontrar diferencias significativas. Previo al análisis, se verificaron los requisitos de normalidad y homocedasticidad y se detectaron los valores anómalos mediante el análisis de las distancias de Mahalanobis. El nivel de significancia utilizado en todos los análisis fue 0,05.

3 Resultados

3.1 Color

En la Tabla 1 se presentan los valores promedio ± desviación estándar de los parámetros colorimétricos (L*, a*, b*) y funciones de color (C*, h*) de los frutos tratados y control durante el almacenamiento. Al día 0, la fruta fresca (FF) presentó un color azul y la presencia de CE se evidenció por su superficie opaca. Los valores negativos de b* indicaron un predominio del color azul, mientras que los valores de C* indicaron una baja saturación de color que explicaría el aspecto grisáceo del arándano, y el ángulo de tono (h) ubicó los frutos en la región azul. No se observaron diferencias significativas entre FF, control O_2 10 min y 5,1 mg $O_3.L^{-1}$ 10 min, mientras que los frutos sin CE mostraron valores significativamente menores de L* y mayores de a* y b*, asociados principalmente a la ausencia de la capa de ceras. Las diferencias entre frutos enteros ozonizados (5,1 mg $O_3.L^{-1}$ 10 min) y no ozonizados (FF y control O_2 10 min) no resultaron en general significativas en el período de almacenamiento estudiado, excepto en los frutos a los que se les removió previamente las CE.

Después de 15 días de almacenamiento, los parámetros de color de los FF mostraron cambios leves, pero no significativos respecto al día 0. Sin embargo, el almacenamiento refrigerado afectó significativamente el color de la fruta sin CE, control O_2 10 min y 5,1 mg $O_3.L^{-1}$ 10 min. Los cambios más severos se observaron en los frutos sin CE, mientras que el control O_2 10 min y los frutos ozonizados mostraron un comportamiento intermedio.

En general, el tratamiento con ozono no afectó negativamente el color superficial de los arándanos con respecto a los frutos sin tratar (FF), ya sea inmediatamente después del tratamiento (día 0) o después de 15 días de almacenamiento.

Tabla1. Valores promedio y desviación estándar de los parámetros colorimétricos y funciones de color de arándanos control y tratados con ozono en fase acuosa almacenados 15 días a 4 ± 1 ºC. Se incluye a modo comparativo los valores correspondientes a frutos frescos (sin tratar) a los cuales se les removió las ceras epicuticulares (FF sin CE). Diferente letra entre filas indican diferencias significativas (n=30).

3.2 Espectros FT-IR de arándanos tratados y control: análisis de componentes principales

Como se mencionó anteriormente, se estudiaron tres grupos de espectros (fruta completa, fruta sin cera y ceras epicuticulares) para cada tratamiento (FF, control O_2 10 min y 5,1 mg $O_3.L^{-1}$ 10 min). En la Figura 1 se muestra la variabilidad explicada y el número de componentes principales luego de aplicar las distintas metodologías de pre-procesamiento de los espectros. La normalización vectorial mostró un mejor rendimiento, ya que con sólo 3 componentes principales logró explicar el mayor porcentaje de la variabilidad en la calibración y validación.

La Figura 2 muestra las dos componentes principales más significativas de los espectros procesados mediante normalización vectorial (a) y la primera derivada (b). Ambas técnicas lograron separar los espectros de las ceras. Sin embargo, la normalización vectorial no logra una buena separación entre los tres grupos de muestras (Figura 2a). En cambio, con la primera derivada se obtuvo una buena separación entre los grupos experimentales, aunque para ello implicó una componente principal adicional.

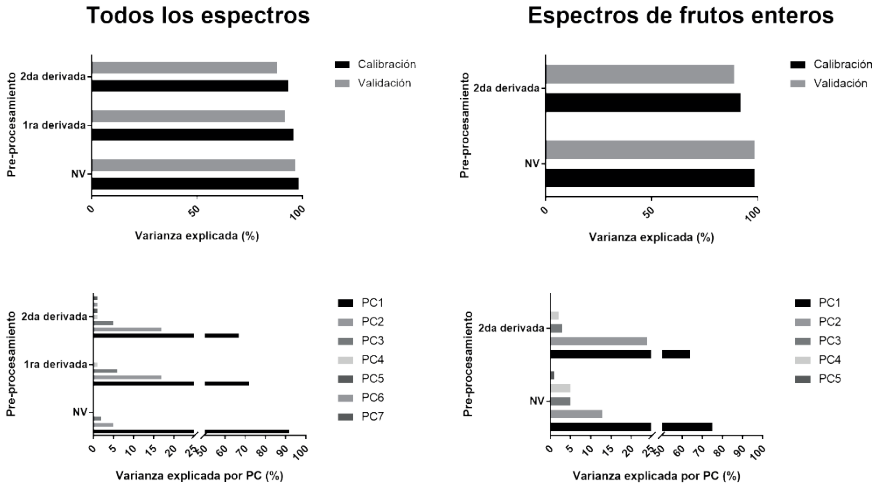

Fig.1 Efecto del pre-procesamiento en la explicación de la varianza y número de componentes principales (PC) de los espectros de fruta entera, ceras epicuticulares (CE) y fruta sin ceras de frutos sin tratar (FF), control O_2 10 min y ozonizados (5,1 mgO_3.L^{-1} 10 min). *NV: normalización vectorial. Se utilizaron entre 3048 y 3084 variables.

Por otro lado, la Figura 2b reveló que las diferencias entre los grupos de muestras (frutos enteros, sin ceras y sólo ceras) eran mucho mayores que las diferencias producidas por los tratamientos (FF, control O_2 10 min y 5,1 mg O_3.L^{-1} 10 min). Luego, se realizó un segundo PCA incluyendo sólo las frutas enteras de arándanos frescos (FF), control O_2 10 min y 5,1 mg O_3.L^{-1} 10 min, utilizando los dos mejores métodos de preprocesamiento; estos resultados se muestran en la Figura 3. Una vez más, la normalización vectorial explicó un mayor porcentaje de variabilidad que la primera derivada, a pesar de utilizar una componente principal más. Sin embargo, la Figura 3 reveló que la normalización vectorial no pudo separar la fruta ozonizada de las muestras FF y de control O_2 10 min (Figura 3a). En cambio, la primera derivada diferenció claramente entre las muestras tratadas con ozono, control O_2 10 min y FF, estas dos últimas comparten características espectrales comunes (Figura 3 b). Al analizar las cargas de las muestras procesadas mediante la primera derivada, se identificaron algunos números de onda, cuya mayor contribución correspondería al estiramiento asimétrico y simétrico de CH_2 a 2917 y 2850 cm^{-1}, respectivamente.

El alto poder oxidativo del ozono podría afectar las ceras epicuticulares, lo cual se evidenciaría en las diferencias encontradas en los espectros y revelado en el análisis de PCA (Figura 3b). Sin embargo, es interesante resaltar que el ozono no eliminó/removió completamente las ceras epicuticulares como puede observarse en las Figuras 2 y 4, en donde se muestra una buena superposición entre las muestras ozonizadas, control O_2 10 min y FF, coincidentemente con los resultados obtenidos en el estudio de color (Tabla 1).

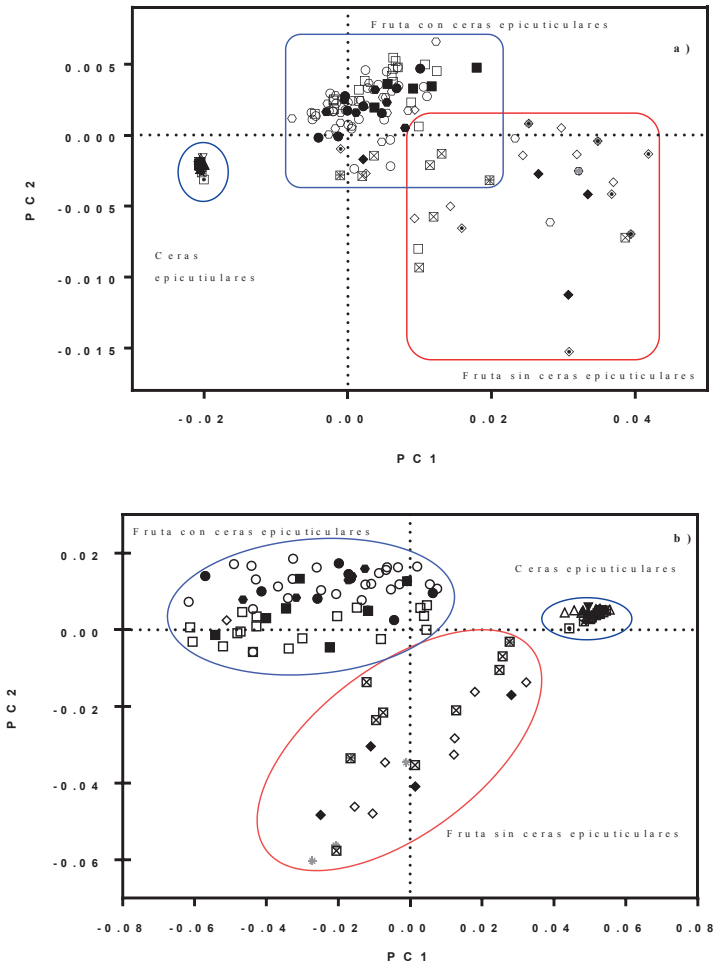

Fig.2. Análisis de componentes principales (PCA) luego del pre-procesamiento por medio de normalización vectorial (a) y 1[ra]derivada (b) de los espectros. Frutos enteros: frescos (○,●), control O_2 10 min (⬭,⬬), tratados 5,1 $mgO_3.L^{-1}$ 10 min (□,■). Ceras epicuticulares: frescos (△,▲), control O_2 10 min (▽,▼), tratados 5,1 $mgO_3.L^{-1}$ 10 min (▣,★). Frutos sin CE: frescos (◇,◆), control O_2 10 min (◈,✳), tratados 5,1 $mgO_3.L^{-1}$ 10 min (☒,⨯), siendo (calibración, validación), respectivamente. Los datos incluyen días 0 y 15 de almacenamiento.

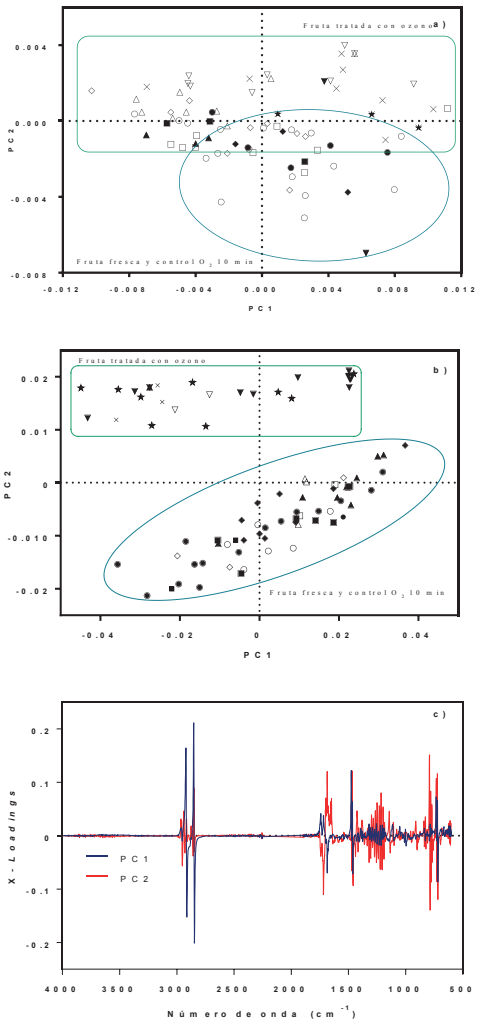

Fig.3.PCA de espectros de fruta entera: sin tratar (FF), control O_2 10 min y tratadas 5,1 $mgO_3.L^{-1}$ 10 min a los 0 y 15 días de almacenamiento a 4 ±1 ºC, pre-procesados mediante normalización vectorial (a) y 1ra derivada (b,c).Puntajes de las componentes principales que explican el mayor porcentaje de variabilidad (a,b); X-puntajes vs número de onda de las componentes principales (PC1 y PC2, líneas gris y negra, respectivamente) (c). Para a y b: sin tratar (○●,△▲), control O_2 10 min (□■,◇◆) y 5,1 $mgO_3.L^{-1}$ 10 min (×★,▽▼) [a los 0 y 15 días de almacenamiento a 4 ±1 ºC, siendo calibración (símbolos sin relleno) y validación (símbolos rellenos), respectivamente].

3.3 Estudio FT-IR de las modificaciones moleculares ocasionadas por el tratamiento con ozono en las ceras epicuticulares de arándanos

En la Figura 4 se muestra una comparación detallada de los espectros de ceras epicuticulares y de frutos enteros tanto del control lavado y de los frutos ozonizados (control O_2 10 min y 5,1 mg $O_3.L^{-1}$ 10 min), al día 0. Los espectros de CE mostraron bandas características mencionadas en la Tabla 2. Las más importantes corresponden a triterpenoides pentacíclicos, β-dicetonas, aldehídos, alcoholes primarios y ácidos grasos (compuestos alifáticos de cadena larga), según lo reportado por [7] para ceras cuticulares de arándanos cultivar O'Neal. Las flechas de la Figura 4 indican las regiones de mayores diferencias entre los espectros de los frutos ozonizados y control O_2 10 min. El estudio mediante FT-IR reveló cambios ocasionados por el ozono en las ceras epicuticulares como así también en otros componentes de la cutícula: aparecieron nuevas bandas y hombros (1701, 1542, 801 cm^{-1}), como se señala en la Tabla 2; mientras que también se observaron corrimientos de algunas señales asignadas a CE (1464-1472 a 1468; 730 a 724; 1055 a 1101-1109; y otras desde 884-904 a 887-910; 762 a 755 cm^{-1}). Los alquenos son uno de los principales objetivos a ser oxidados por el ozono siguiendo el mecanismo de Criegee [14], los alcoholes primarios son oxidados a cetonas y los secundarios, a los aldehídos y grupos carboxílicos. En particular, la banda a 1701 cm^{-1} evidenciada en los frutos ozonizados podría atribuirse a la oxidación de alcoholes de cadena larga. Los alquenos, ácidos carboxílicos y cetonas no reaccionan con el ozono o bien, lo hacen de manera más lenta [14,15].

Los espectros de los frutos enteros mostraron grandes diferencias tanto en intensidad como en bandas con respecto a los espectros de las CE, en ambos casos frutos ozonizados o control (Figura 4). Estas contribuciones nuevas surgen de la presencia de otros componentes de la cutícula como la cutina. La cutina es un polímero lipídico y componente principal de la piel de las frutas y berries, que junto a las CE constituyen una barrera entre la planta y el ambiente [16,17]. Las principales diferencias con los espectros de las CE se observaron en las regiones: 2800-2500, 1700-1660, 1660-1500, 1428-1450, 1330-1170 y 1075-950 cm^{-1}. Sin embargo, también se observaron bandas en común, indicando la presencia de ceras en la membrana cuticular del fruto entero.

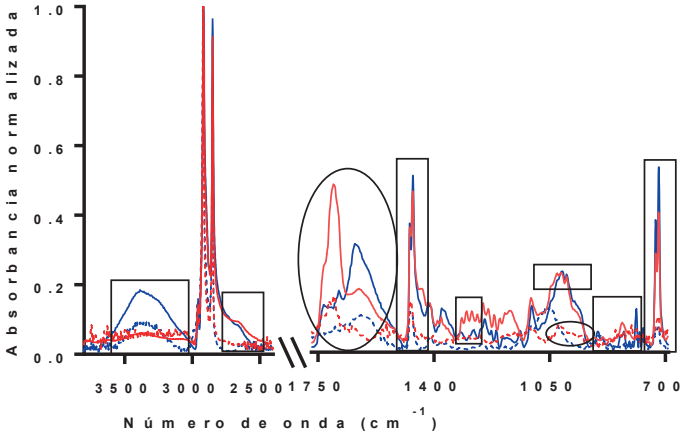

Fig.4. Espectros FT-IR de frutos ozonizados a (5,1 $mgO_3.L^{-1}$ 10 min) (líneas grises) y control $O_2$10 min (líneas negra). Las líneas continuas corresponden a espectros de los frutos enteros y las líneas punteadas a los espectros de ceras epicuticulares (CE). Los datos corresponden al día 0 de almacenamiento.

Tabla2. Asignación de señales a ceras epicuticulares (CE) y ceras + cutina de los espectros FT-IR obtenidos de ceras epicuticulares y de frutos enteros, respectivamente para control O_2 10 min y 5,1 $mgO_3.L^{-1}$ 10 min. h: hombro, +: aumento de intensidad relativa, a: ancho, d: doble. En negrita: por efecto del ozono (corrimiento, o aparición de nuevo pico u hombro)

4 Conclusiones

El tratamiento con ozono en fase acuosa (5,1 mg $O_3.L^{-1}$, 10 min) produjo cambios químicos en las ceras epicuticulares de los arándanos, como revelaron los espectros FT-IR. El efecto del ozono en las ceras se evidenció por la aparición de nuevas bandas asociadas al estiramiento del grupo carbonilo de la oxidación de alcoholes (1701 cm^{-1}), y corrimiento de otras asociadas al tijereteo (1464-1472 a 1468 cm^{-1}) y balanceo de grupos CH_2, entre otros. Estos cambios químicos podrían atribuirse de forma directa al ozono y no al efecto de lavado del proceso, ya que los espectros correspondientes al controlO_2 10 min mostraron características similares a la de los frutos sin tratar (FF) tanto al día 0 como después de 15 días de almacenamiento. Sin embargo, estas modificaciones podrían ser sutiles desde la óptica del consumidor ya que los cambios ocasionados por el ozono en las CE no afectaron el color de los frutos.

Resumen. En este trabajo se evaluó a escala piloto la aptitud enológica de levaduras autóctonas de la región patagónica y su influencia sobre el color y *flavour* del vino. Mostos patagónicos Malbec se inocularon con cultivos puros de cepas de *Saccharomyces cerevisiae* autóctonas Sc F8 y Sc M16 y comercial Sc F15 (control), y con el cultivo mixto autóctono Sc F8 y *Pichia kudriavzevii* P15 (Sc F8+P15, cocultivo) durante las vendimias 2015 y 2017. Las cinéticas fermentativas se siguieron por evolución de los ºBmé, la evaluación fisicoquímica de los vinos y los parámetros relacionados con el color (intensidad y tinte) se realizaron siguiendo los métodos del INV y espectrofotometría UV-V y el sensorial mediante análisis descriptivo y prueba de preferencias de consumidores. Todos los vinos resultaron normales y secos, pero los elaborados con los cultivos puros autóctonos mostraron diferencias con los del comercial en sus parámetros de color que pueden relacionarse con un mayor contenido de copigmentos (hipercromía, vendimia 2015) y de pigmentos resistentes al SO_2 (hipsocromía, vendimia 2017). Adicionalmente, los cultivos autóctonos puros potenciaron los aromas a frutos rojos y especiados, propiedad que conservó el cocultivo. La inclusión de P15 en el cultivo iniciador adicionalmente mejoró la sensación en boca (acidez y dulzor) resultando sus vinos (vendimias 2015 y 2017) y los elaborados con el cultivo mixto Sc F8 (vendimia 2017) preferidos por los consumidores. Los cultivos iniciadores autóctonos F8 y F8+P15 constituyen una valiosa herramienta para la diferenciación y el agregado de valor de los vinos regionales.

Palabras clave: ***Saccharomyces cerevisiae*, *Pichia kudriavzevii*, color, aroma, gusto.**

1. Introducción

El vino es, exclusivamente, la bebida resultante de la fermentación alcohólica (FA), completa o parcial, de uvas frescas, estrujadas o no, o de mosto de uva [1] y su composición química es la base de sus atributos sensoriales y en consecuencia de su calidad.

De los numerosos factores que afectan la calidad del vino, el sustrato y la biota microbiana imperante durante el proceso de vinificación, son en ese orden, los de mayor significación [2].

La vinificación es un proceso ecológicamente complejo que involucra una fermentación primaria, la alcohólica (FA), conducida por las levaduras y una fermentación secundaria y opcional, la maloláctica (FML), llevada a cabo por las bacterias del ácido láctico (BAL) [3]. Las numerosas interacciones celulares/bioquímicas que se establecen entre individuos de las diferentes especies de levaduras y BAL participantes de la vinificación [4] pueden producir vinos redondos y de gran complejidad aromática, pero también ocasionar metabolitos o efectos indeseables, como *off flavors*, compuestos perjudiciales para la salud y paradas o retrasos de la fermentación [5]. Esta impredecibilidad es la mayor desventaja de la elaboración de vinos por fermentaciones naturales a nivel industrial [6]. El control de la biota microbiana asociada al proceso fermentativo mediante la inoculación del mosto de uva con cultivos iniciadores es una práctica enológica de rutina en bodega tendiente a resolver este problema [7].

Por la importancia de la FA, la tecnología de los cultivos iniciadores centró inicialmente su atención en las levaduras, especialmente en la biodiversidad intraespecífica de *Saccharomyces cerevisiae,* la levadura vínica por excelencia [7]. Más recientemente la búsqueda se orientó a otras especies de levaduras pertenecientes a géneros diferentes de *Saccharomyces,* asociadas a la fase inicial de la fermentación espontánea de los mostos y denominadas colectivamente levaduras non-*Saccharomyces* [8]. Por sus características metabólicas particulares, individuos de estas especies utilizados en la forma de cultivos adjuntos de *S. cerevisiae* pueden proporcionar soluciones tecnológicas a problemas específicos (reducción de la acidez, del contenido alcohólico, desarrollo de color, entre otros) así como mejorar la calidad sensorial y /o sanitaria del producto [8-10].

En la enología actual, la tendencia mundial es el uso de cultivos iniciadores de la fermentación alcohólica (FA) constituidos por cepas de levaduras autóctonas de la propia región productora. Estos cultivos autóctonos, adaptados a las características agroecológicas de su región y respetuosos de su *terroir* microbiano, presentan mayor capacidad de competencia que los cultivos foráneos para controlar exitosamente el proceso [11]. Adicionalmente, utilizados en la forma de cultivos múltiples (más de una

cepa de *Saccharomyces*) o mixtos (cepas *Saccharomyces* y non-*Saccharomyces*) son capaces de otorgar a los vinos características sensoriales de aquellos elaborados por fermentaciones espontáneas/naturales exitosas, aunque bajo condiciones controladas del proceso [6], permitiendo expresar en los vinos las notas organolépticas distintivas de su terroir [12].

La región del Comahue (Patagonia norte) conforma la región vitivinícola más austral de la Argentina y una de las más australes del mundo; la formulación y aplicación de cultivos iniciadores regionales, hoy inexistentes en el mercado, permitirá resolver problemáticas del sector vitivinícola regional, favoreciendo la elaboración de productos de calidad controlada y diferencial, en los que se expresen las características de su terruño, muy ventajosas para el desarrollo de una viticultura de calidad enológica *premium* [13]. En este trabajo se presentan y discuten resultados relacionados con las calidades de vinos tintos de la variedad Malbec elaborados a escala piloto (200 L) mediante vinificaciones conducidas por cultivos puros y mixtos constituidos por levaduras autóctonas de esta región de las especies *S. cerevisiae* y *Pichia kudriavzevii* [14] poniendo el foco en los atributos color y *flavour* (aroma y gusto), los más apreciados por el consumidor al momento de la elección de un vino [15]. La capacidad de la cepa de *P. kudriavzevii* de consumir ácido L(−) málico [16] podría, adicionalmente, ayudar a resolver la elevada acidez relativa de los vinos de la región del Comahue respecto de aquellos elaborados en las otras regiones vitivinícolas del país debido al alto contenido de éste ácido en los mostos de uva patagónicos [17].

2. Materiales y métodos

2.1 Microorganismos

Se utilizaron cepas autóctonas de la Patagonia de las especies *S. cerevisiae* F8 (Sc F8) y M16 (Sc M16) y *P. kudriavzevii* (ex *Issatchenkia orientalis*) I15 (P15) seleccionada por sus características metabólicas de interés enológico [14] (del Mónaco *et al*. 2016) y la cepa comercial *S. cerevisiae* F15 (Sc F15) de Laffort, mayoritariamente usada en bodegas patagónicas para vinificaciones en tinto.

2.2 Vinificaciones

Se realizaron a escala piloto (200L) durante las vendimias 2015 y 2017. Mostos industriales Malbec se inocularon con cultivos puros de la cepa autóctona Sc F8, y de la

comercial Sc F15 y con el cultivo mixto F8 + P15 en la forma de cocultivo (CoC, inoculación simultánea en una relación 1/100 cél/mL) durante la vendimia 2015; en la vendimia 2017 adicionalmente se ensayó la cepa autóctona Sc M16 en la forma de cultivo puro. Las densidades celulares iniciales de los inóculos en los mostos estuvieron en el orden de ~10^7 cél/mL. Las FAs se desarrollaron a 23±2°C hasta sequedad de los mostos (azúcares reductores totales ≈2 g L^{-1}). En las vinificaciones 2015 la FML se desarrolló espontáneamente controlándose la evolución mediante la determinación enzimática del contenido del ácido L (-) málico. En las vinificaciones 2017 se inhibió el desarrollo de la FML por adición de elevadas concentraciones de SO_2 (100 ppm). Los vinos jóvenes se estabilizaron, se ajustaron en su concentración de SO_2 y se embotellaron. Con el fin de realizar análisis microbiológicos y fisicoquímicos se tomaron muestras de mostos en los estadios iniciales, medios y finales de las FA y de la FML, cuando correspondió (Vendimia 2015).

2.3 Análisis de los vinos

Fisicoquímico. La evaluación fisicoquímica de los vinos se realizó utilizando la metodología oficial del Instituto Nacional de Vitivinicultura (INV). El análisis estadístico de los datos se realizó mediante ANOVA y ensayo de Tukey HSD considerándose significativas diferencias con $p<0,05$. El análisis de parámetros de color en los vinos obtenidos al finalizar la FA se llevó a cabo en base a las medidas de absorbancia realizadas a tres longitudes de onda λ_{420nm}, λ_{520nm} y $\lambda_{620\ nm}$,. A partir de dichos valores pueden determinarse diferentes parámetros relacionados al atributo del color: Intensidad de Color ($A_{420nm}+A_{520nm}+A_{620nm}$), Tinte ($A_{420nm}/A_{520nm}$) e Índice de color IC = (intensidad de color/tinte *1000). En los vinos 2017 los parámetros de color se evaluaron antes y 48h después del sulfitado.

Sensorial. Con el objetivo de describir las muestras en forma cualitativa y cuantificar la intensidad de los distintos atributos sensoriales se realizó un análisis sensorial descriptivo de los vinos utilizando para ello una escala de 1=no intensidad a 10=intensidad extrema. Participaron nueve (9) evaluadores altamente entrenados. Cada evaluador recibió una muestra etiquetada con un código de tres (3) dígitos elegidos al azar. La presentación de las muestras se realizó en forma monádica para evitar comparaciones entre muestras. Se utilizó un diseño estadístico de bloques completos al azar en donde cada

evaluador ofició de bloque. Cada panelista recibió las muestras en un orden preestablecido y diferente al de los demás. Se realizaron tres (3) repeticiones en dos días diferentes en donde se varió tanto el orden de presentación para cada evaluador como los códigos de tres dígitos para reducir la posibilidad de resultados tendenciosos y el efecto posicional. Las muestras fueron servidas en copas normalizadas de color negro [18] a temperatura ambiente de 20±2ºC. En cada copa se sirvieron 30 ml de vino. Se instruyó a los evaluadores que indicaran la intensidad de cada atributo sensorial tanto de la fase visual, olfativa y gustativa. A fin de ayudar a los evaluadores a recordar los atributos pautados, se utilizaron estándares preparados en un vino base Malbec 2017 elaborado en el laboratorio de microvinificación de la EEA INTA Alto Valle [19]. Para reducir la variabilidad en la medición de las intensidades de los atributos, se utilizaron patrones de los atributos de acidez, dulzor, amargor, astringencia cuyas intensidades fueron consensuadas por el panel en trabajos previos realizados en 2018. Para interpretar los resultados se determinaron las medias de los valores asignados a la intensidad de los atributos sensoriales y se realizó un análisis de la varianza (ANOVA) y un análisis de componentes principales utilizando el software Infostat [20].

2.4 Prueba de Preferencia de Consumidores

Se realizaron en Bariloche a la Carta 2016 (vinos 2015) y durante la 39 Edición de Fiesta de la Vendimia 2018 (vinos 2017). En estas pruebas los diferentes vinos elaborados se identificaron con diferentes letras A, B, C, D debiendo el consumidor asignarle a cada vino un valor 1, 2, 3 o 4 según su preferencia. Uno, el preferido en primer lugar, dos en segundo lugar, etc. En esta degustación a ciegas, el promedio obtenido para cada vino es más cercano a uno cuanto mayor es su preferencia por el consumidor. El análisis estadístico de los datos se realizó utilizando un modelo lineal generalizado y prueba de comparaciones múltiples de Di Rienzo, Guzmán y Casanoves (DGC) [21]. El análisis se realizó a través del software INFOSTAT [20] como interfaz gráfica para el paquete NLMER de R [22].

3. Resultados y discusión

La Tabla 1 muestra los parámetros fisicoquímicos de importancia enológica de vinos Malbec elaborados con cultivos iniciadores puros Sc F8 y Sc M16 y mixto F8+P15 autóctonos, así como con el cultivo comercial Sc F15 durante la Vendimia 2015.

Todos los vinos resultaron normales y sus contenidos en azúcares reductores totales (ART) se encuentran dentro de los límites aceptados para ser clasificados como vinos secos (ART≤2g/L). Las concentraciones de metanol en los vinos fueron siempre <0,25 mg/L y las de carbamato de etilo en todos los casos estuvieron por debajo del límite de detección de métodos utilizado por el INV (15µg/L) (datos no mostrados), no observándose diferencias significativas de los parámetros evaluados entre vinos excepto en los relacionados con el color, evidenciando una influencia significativa de las cepas conductoras de la FA sobre este atributo.

Consistente con lo reportado en investigaciones previas con las variedades Pinot noir y Merlot [23], los vinos elaborados en el 2015 con la variedad Malbec (Tabla 1) y el cultivo indígena Sc F8 presentan un índice de color (IC) significativamente mayor (efecto hipercrómico) que los elaborados con su control Sc F15. Esta hipercromía se explica por un aumento de la absorbancia de estos vinos a 520 nm y 620 nm (efecto batocrómico) sin cambios en la absorbancia a 420 nm (datos no mostrados), que determinan un aumento significativo en la intensidad de color y concomitantemente una disminución del tinte (Tabla 1).

Tabla 1. Caracterización fisicoquímica y evaluación sensorial de vinos obtenidos a partir de mostos tintos regionales variedad Malbec- vendimia 2015, conducidas por cultivos puros de *S. cerevisiae* F8 (Sc F8) y F15 comercial (Sc F15) y cultivo mixto Sc F8 + *P. kudriavzevii* P15 (CoC)

El origen del color rojo de los vinos tintos proviene de las antocianinas (antocianidinas glicosiladas en el C3), compuestos particularmente inestables en sus formas libres [24, 25]. La estabilización del color se logra por asociación de moléculas de antocianinas consigo mismas o con otros constituyentes del vino, mayoritariamente compuestos fenólicos flavonoides y no flavonoides, a través de interacciones no covalentes (copigmentación), por formación de enlaces covalentes (pigmentos poliméricos) y por formación de nuevos pigmentos colorantes (piranoantocianinas) [25]. En general, la copigmentación es el mecanismo más importante de estabilización del color en los vinos jóvenes y está asociada con un incremento de la intensidad (efecto hipercrómico) y a un viraje hacia tonalidades más azuladas (efecto batocrómico) del color rojo del vino tinto (disminución del tinte). La concentración de copigmentos depende de la composición fenólica y de las relaciones molares de copigmento/pigmento que de forma particular se establecen en un vino. Si bien los complejos de copigmentación se forman con mucha facilidad [26], también se disocian fácilmente ante ciertas condiciones del medio (aumento de la proporción de ciertos co-solventes como el etanol y otros alcoholes del vino o el ácido acético) derivados de las actividades metabólicas de las levaduras [25]. En este contexto, la hipercromía de los vinos elaborados con la levadura autóctona Sc F8 podría estar relacionado con un mayor contenido de pigmentos promovido por las condiciones del medio vino generado por un metabolismo particular de esta cepa que favorece la extracción de antocianinas y copigmentos o la estabilización de éstos.

Por su parte, los vinos elaborados con el CoC (F8+P15) mostraron IC e intensidad de color significativamente menores que sus vinos controles (ScF8), perdiéndose el efecto hipercrómico como el batocrómico producido por el cultivo puro. Esta pérdida de color es consistente con pérdidas en el material colorante atribuible a la actividad β-glucosidasa (β-GL) del cultivo adjunto *P. kudriavzevii* P15 [16].

Estas diferencias químicas en el color fueron consistentes con la apreciación de este atributo en el análisis sensorial cualitativo (Figura 1) que reportó una mayor intensidad en los vinos elaborados con la cepa de *S. cerevisiae* autóctona que en los elaborados con la cepa comercial y una disminución de la misma por el agregado del cultivo adjunto P15. Las tablas 2 y 3 muestran los autovectores y las correlaciones de los componentes principales con las variables originales de la Figura 1.

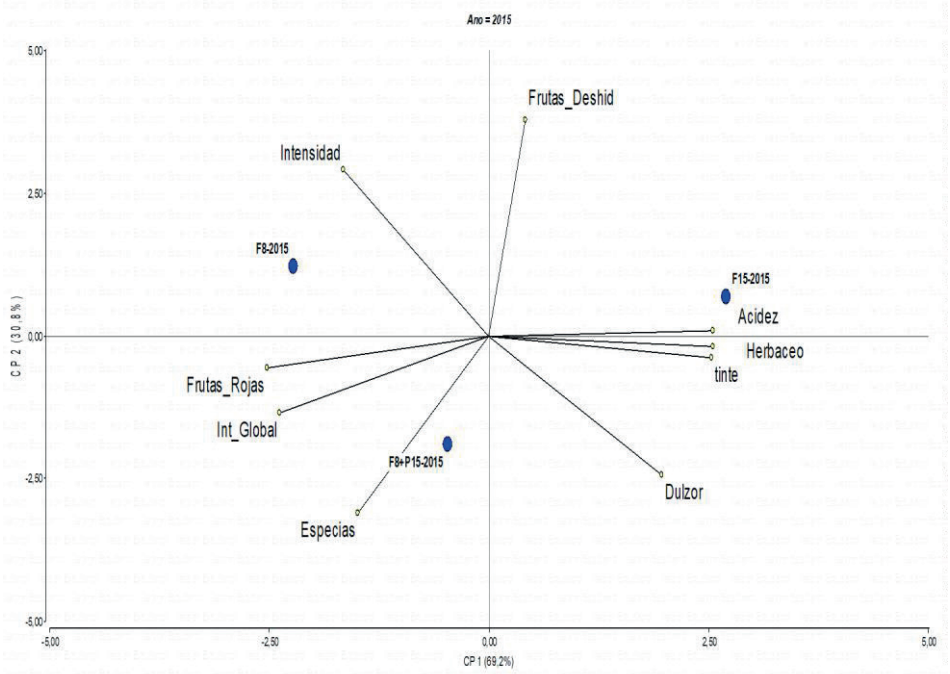

Figura 1: Componentes principales del análisis sensorial descriptivo de los vinos 2015. Intensidad: intensidad de color. Int_Global: intensidad global aroma; Frutas Rojas, Frutas Deshid (Deshidratadas) Especias, Herbáceo: notas aromáticas. Acidez y Dulzor, gusto. Las variables graficadas presentaron diferencias significativas (ANOVA $p<0,05$).

Medias con una letra común no son significativamente diferentes (p > 0,10), n=71

La calidad sensorial de los vinos jóvenes de variedades aromáticamente neutras como los aquí presentados está significativamente influenciada por la calidad de la biota de levaduras, pero también y aunque en menor grado, por las BAL. Los contenidos de ácido málico, sin diferencias y relativamente bajos en los tres vinos, y el pH elevado de todos éstos (Tabla 1) indican un desarrollo espontáneo de la FML en todas las vinificaciones, no pudiéndose descartar una potencial influencia de la biota BAL sobre las propiedades sensoriales de los vinos 2015. Con el objeto de inhibir el desarrollo espontáneo de la FML y obtener resultados conclusivos respecto de influencia de los cultivos

de levaduras autóctonas y comerciales sobre la calidad sensorial de los vinos, durante la Vendimia 2017, una vez finalizada la FA los vinos fueron sulfitados.

Todos los perfiles fisicoquímicos de los vinos obtenidos en la vendimia 2017 corresponden a vinos normales y secos (Tabla 5), pero la sulfitación deliberada realizada para impedir el desarrollo de la FML determinó que los vinos elaborados con los tres cultivos puros presentaran una mayor acidez titulable y un menor pH que sus homólogos 2015, diferencias que pueden relacionarse con su mayor contenido de ácido málico. Por el contrario, los vinos elaborados con el cultivo mixto presentaron un contenido de ácido málico significativamente menor y un pH significativamente mayor que su control (Sc F8) y similares a los obtenidos en los vinos 2015 elaborados con el mismo CoC. Este resultado es consistente con la capacidad de la cepa P15 de asimilar ácido málico, propiedad señalada en la Introducción y por la que fuera seleccionada [16]. El cultivo mixto representa una herramienta valiosa y alternativa a la FML para la deacidificación biológica de los vinos.

En relación al contenido de glicerol (Tablas 1 y 5) y a la calidad aromática de los vinos, los resultados obtenidos en el 2017 son consistentes con los del 2015 (Figuras 1 y 2) por lo que estas características pueden relacionarse con la calidad de las cepas de levaduras responsables de conducir la FA. Los vinos elaborados con los cultivos iniciadores puros autóctonos (Sc F8 y Sc M16) y mixto presentaron notas aromáticas a frutos rojos y especias significativamente mayores y herbáceas significativamente menores que los elaborados con el cultivo comercial, y de intensidad similar a las observadas en el 2015. Adicionalmente, el vino elaborado con el CoC presentó la menor acidez y el mayor dulzor entre los vinos evaluados, propiedades que pueden relacionarse con un menor contenido de ácido L(-) málico y mayor contenido de glicerol en este vino que en el control (Sc F8) y en el elaborado con Sc M16, respectivamente (Tabla 5).

Tabla 5: Caracterización fisicoquímica de los vinos elaborados con cultivos iniciadores indígenas puros Sc F8, Sc M16 y mixto F8 +P15 en la forma de CoC y con el cultivo foráneo comercial Sc F15 en la Vendimia 2017 con la variedad Malbec

En relación al atributo color, en los vinos 2017 sin sulfitar los efectos de las cepas autóctonas Sc F8, y Sc M16, sobre el IC (índice de color) y la intensidad de color fueron similares a los descritos en la vendimia 2015 (efecto hipercrómico), aunque los vinos 2017 también mostraron un aumento de la absorbancia a 420nm (efecto hipsocrómico) que determinó un aumento significativo de sus tintes respecto del control (Sc F15) (Tabla 5). Por otra parte, el sulfitado de estos vinos derivó en una pérdida significativa de la intensidad de color la que fue más significativa en los vinos elaborados con las levaduras autóctonas (10-20%) que en la comercial (5%). En todos los vinos, la perdida de intensidad de color estuvo asociada a una significativa disminución de la absorbancia (aproximadamente 30%) a 520nm (dato no mostrado). Mientras 520nm es la $\lambda_{máx}$ de absorción de la antocianina mayoritaria de los vinos tintos, malvidina 3-glucósido sensible al SO_2, el resultado evidencia que la estabilización del color en los vinos jóvenes ocurre mediante la formación de copigmentos sensibles al SO_2 y que la hipercromía observada en los vinos elaborados con los cultivos puros de Sc autóctonos está relacionada con mayor contenido de estos pigmentos en sus vinos. Al igual que lo observado

en la vendimia 2015, la inclusión de P15 en el cultivo iniciador disminuyó significativamente la intensidad de color de los vinos. Adicionalmente, todos los vinos elaborados con los cultivos iniciadores autóctonos mostraron una menor pérdida del material colorante capaz de absorber luz a los 420nm (13%) que los elaborados con el cultivo comercial (20%) (datos no mostrados) y como consecuencia un aumento significativo en sus tintes (Tabla 5, datos sombreados). Aunque debe corroborarse experimentalmente, este resultado es consistente con el supuesto de un mayor contenido de pigmentos poliméricos de tipo A-T y/o piranoantocianinas [25]

Los pigmentos poliméricos y las piranoantocianinas, son pigmentos rojo anaranjados (absorben luz a λ<500nm, efecto hipsocrómico) resistentes a la decoloración por SO_2 que otorgan al color del vino el matiz rojo teja típico de los vinos añejados [29]. Existe evidencia que el acetaldehído, un metabolito secundario de las levaduras, acelera la formación de estos pigmentos antociánicos poliméricos, actuando de nexo de unión entre los antocianos y los taninos [25, 26], y que tanto el acetaldehído como el ácido pirúvico (otro metabolito fermentativo de las levaduras) intervienen en la formación de piranoantocianinas [25].

Al igual que en el 2015, el vino elaborado en la vendimia 2017 con el cultivo mixto autóctono Sc F8+P15 fue el preferido de los consumidores, aunque en esta oportunidad la preferencia estuvo compartida con el vino elaborado por el cultivo puro autóctono Sc F8 (Tabla 8).

Tabla 8: Prueba de Preferencia de Consumidores para los Vinos 2017 elaborados con la variedad Malbec y FAs conducidas por los cultivos iniciadores autóctonos puros (F8 y M16) y mixto (F8+P15) y por el comercial (F15)

Cultivo iniciador FA	Media	E.E	
F15	2,96	0,24	A

Medias con una letra común no son significativamente diferentes (p > 0,05), n=96

4. Conclusiones

La regularidad en la calidad fisicoquímica de los vinos elaborados durante las vendimias 2015 y 2017 pone en evidencia la estabilidad genética de las cepas de levaduras autóctonas de la Patagonia *S. cerevisiae* F8 y *P. kudriavzevii* P15, validando su aptitud

para ser usada en enología, en particular para vinificaciones tintas de la variedad Malbec.

Los cultivos iniciadores autóctonos Sc F8 y M16 impactan positivamente sobre la calidad sensorial de los vinos, intensificando significativamente su color, un atributo de preferencia al momento de la elección de un vino y que establece, junto con el contenido alcohólico, el valor comercial de éste.

Los cultivos iniciadores autóctonos puros y mixto potencian el aroma frutal y especiado de los vinos regionales, diferenciado positivamente su calidad y su preferencia por parte de los consumidores.

El cultivo autóctono mixto representa una herramienta alternativa a la FML para la deacidificación biológica de los vinos

fsalaberria@hotmail.com

Resumen. En el presente trabajo se estudiaron las propiedades de emulsiones de aislado proteico de soja, cera de abeja y glicerol (reología, estabilidad y distribución de tamaño de partícula). Además, se determinó la velocidad de transferencia al vapor de agua, espesor y propiedades mecánicas de las películas biodegradables obtenidas a partir de dichas emulsiones mediante el método de casting. Los resultados indicaron que la emulsión se corresponde con el comportamiento de un fluido no-newtoniano con un tamaño de gota promedio igual a 3,79 µ, siendo altamente estable durante el periodo de tiempo necesario para la fabricación de la película. Las películas obtenidas presentaron un espesor promedio igual a 148 µm y aquellas películas con cera presentaron menor velocidad de transmisión al vapor de agua, probablemente por las propiedades hidrofóbicas de este componente.

Keywords: Emulsión, aislado proteico de soja, cera de abeja.

1. Introducción

Una de las áreas de aplicación de las ceras de abeja, y que en la actualidad se investiga intensamente, es el campo de las películas y recubrimientos comestibles. Una película comestible es una capa delgada y continua, hecha de materiales que pueden ser ingeridos por el consumidor, y que proveen una barrera contra la humedad, oxígeno y otros solutos [1]. Para conseguir una funcionalidad óptima de los recubrimientos, es especialmente importante la selección de los materiales que los forman, ya que sus propiedades están fuertemente afectadas por la naturaleza de sus componentes, composición y estructura final. Parámetros como distribución de tamaño de partículas, estabilidad, interacción de sus componentes, entre otros, determinan la estructura de las emulsiones filmogénica y afectan notablemente a las propiedades de los films resultantes.

Muchas biomoléculas, incluyendo proteínas, carbohidratos y lípidos han sido ampliamente utilizados para la elaboración de films comestibles. Las proteínas de soja son uno de los materiales mayormente utilizando debido a que presenta una excelente capacidad de producir films comestibles [2]. La combinación de proteínas de soja con lípidos y mezclas de lípidos es una alternativa interesante para optimizar las propiedades del film, debido a que algunos componentes tal como el ácido oleico brinda flexibilidad a través de sus propiedades plastificantes, mientras que otros como las ceras

de abeja pueden mejorar la eficiencia de los films como barreras a la permeabilidad del vapor de agua [3].

Sobre esta base en el trabajo realizado se planteó el estudio de emulsiones filmogénicas a base de aislado proteico de soja y cera de abeja.

2. Materiales y métodos

2.1. Elaboración de emulsiones

Se prepararon formulaciones en base a aislado proteico de soja (P) (90.8% proteínas, 6.58% humedad, 0.5% grasas, 5% cenizas), glicerol (G) (Anedra, pureza: 98-99%, reactivo grado analítico), ceras de abeja (W) y ácido oleico (AO). La cera de abeja fue provista por Ceras Argentinas S.R.L. (Buenos Aires, Pigüé). Antes de su uso, la misma fue purificada mediante extracción Soxhlet utilizando hexano como solvente.

Las emulsiones formuladas presentaron una relación proteína:lípidos de 1:0,50 y 1:0,75, distribuidos como G:W:AO 1:0,5:0 (PGW-0,75) y 1:1,6:0 (PGW-0,5), G:W:AO 0,33:0,33:0,33 (PGW-AO) y G:W:AO 1:0:0 (PG).

Las emulsiones fueron preparadas mediante la hidratación de la cantidad necesaria de proteína de soja en agua destilada a temperatura ambiente y posteriormente el pH fue llevado a 10 utilizando NaOH 1 M. La solución fue calentada a 90 °C en un baño de agua con agitación constante durante 30 minutos hasta lograr la disolución completa; luego se adicionó el glicerol como agente plastificante [4, 5]. Para obtener las formulaciones PGW-0,5 y PGW-0,75 las ceras de abeja (W) fueron añadidas a la mezcla y luego homogeneizada utilizando un mixer de mano (14500 rpm) durante tres ciclos de 30 segundos cada uno, transfiriéndola inmediatamente a un baño de hielo con agitación. Finalmente, la emulsión obtenida fue filtrada con un paño de gasa para eliminar la espuma residual acumulada en la superficie. El mismo procedimiento fue realizado para obtener PGW-AO, incorporando AO para evaluar el efecto del agregado de otro componente lipídico, y PG, sin incorporar lípidos a la fórmula.

2.2. Caracterización de emulsiones

2.2.1. Distribución de tamaño de gotas.

El tamaño de partícula y la distribución del tamaño fueron caracterizado mediante un láser de dispersión Horiba LA-910 analizador de tamaño de partículas (Horiba Ltd., Kioto, Japón). El tamaño de partícula fue calculado por el analizador basado en el valor medio de la longitud geométrica de las partículas medido a través de diferentes orientaciones de dispersión incidencia de luz.

2.2.2. Propiedades reológicas.

El análisis del comportamiento reológico se realizó utilizando un reómetro Paar Physica (modelo MCR 301, Anton Paar GmbH, Austria) con una geometría de conos (diámetro 50 mm) y un sistema de adquisición de datos computarizado (Rheoplus / 32 V3.40). La emulsión se colocó sobre la base inferior de la geometría y la prueba de barrido de velocidad de cizallamiento ($\dot{\gamma}$) se realizó a 20 °C variando este parámetro entre 0.1 y 100 1/s. Los datos experimentales se ajustaron de acuerdo a la ley de la potencia para fluidos no newtonianos de acuerdo a la siguiente ecuación:

$$\tau = K\dot{\gamma}^n \quad (1)$$

Donde K es el índice de consistencia (Pa s^n), n el índice de comportamiento de flujo (adimensional) y τ el esfuerzo de corte (Pa s).

2.2.3. Estabilidad.

La estabilidad de las emulsiones se determinó utilizando un analizador macroscópico de barrido vertical, Turbiscan (TurbiScan MA 2000, Toulouse, France). Aproximadamente 7 mL de cada emulsión fueron colocados en tubos de vidrio, el porcentaje de cambio en backscattering (ΔBS%) fue medido aproximadamente cada 20 minutos durante la primera hora. luego cada una hora y luego de manera más espaciada durante al menos 25 horas. La formulación PGW-0,5 fue monitoreada a tiempos superiores para evaluar su estabilidad en un tiempo más prolongado. Las emulsiones en estudio fueron opacas, por lo que sólo los perfiles backscattering se utilizaron para evaluar la estabilidad físico-química de las emulsiones.

2.3. Elaboración de películas

Las biopelículas fueron elaboradas mediante el método de casting utilizando placas de Petri de 10 cm de diámetro y moldes rectangulares de 5x12 cm empleando papel film de plástico para alimentos como superficie de contacto. Aproximadamente 18 y 16 g de la cada formulación fueron vertidos en cada placa circular y rectangular, respectivamente. Se realizaron 3 réplicas de cada placa. Las mismas se dejaron secar en una estufa con flujo de aire convectivo a 40 °C durante aproximadamente 24 h. Cuando se logra la evaporación del agua, una película fina de proteínas, o de proteína y lípidos queda depositada sobre la superficie de la placa. Las películas se extrajeron de las placas y se acondicionaron en ambientes de humedad relativa conocida (NaBr 0,577% HR) a 25 °C antes de las determinaciones pertinentes.

2.4. Caracterización de películas

2.4.1. Espesor

El espesor de los films se determinó utilizando un micrómetro manual con una precisión de 5 µm. Se realizaron cinco mediciones sobre cada película, cuatro en el perímetro y una central. Se tomó el promedio como valor del espesor en los cálculos de permeabilidad.

2.4.2. Velocidad de transferencia al vapor de agua.

La velocidad de transmisión al vapor de agua (VTVA) se determinó de acuerdo a la norma E 96-00 [6]. Para ello se utilizó una cámara de permeación con agua en su interior. La tapa superior de la cámara presenta un orificio, el cual fue sellado por la película en estudio. A su vez, dicha cámara se colocó dentro de un desecador en presencia de una atmósfera a aproximadamente 50% HR, la cual se logró empleando una solución saturada de nitrato de calcio tetrahidrato (Anedra, grado analítico). Las celdas de permeación se pesaron diariamente para registrar la cantidad de agua que permeó a través de la película, y abandonó la celda. Al finalizar el ensayo se realizó una regresión lineal entre los pesajes de la celda y el tiempo transcurrido. La VTVA (g/ s m^2) se calculó como la pendiente de dicha regresión sobre el área expuesta de la película. La determinación se realizó por duplicado.

2.4.3. Propiedades mecánicas.

Las propiedades mecánicas de determinaron mediante el método S 882 [7]. Las mismas incluyen el porcentaje de elongación (E%), tensión de rotura (TS) y el módulo elástico o módulo de Young (Y). Los ensayos se realizaron empleando un texturómetro TA-Plus (Lloyds Instruments, UK). El tamaño de la muestra fue un rectángulo de 12 cm de largo y 2.5 cm de ancho. La muestra es estirada longitudinalmente, a velocidad constante (20 mm/min), mediante dos grampas que sujetan los extremos de la misma. El ensayo finaliza una vez que la muestra cede ante la fuerza y se rompe. La separación inicial entre las grampas fue igual a 9 cm. Los ensayos fueron realizados por triplicado.

3. Resultados y discusión

3.1. Caracterización de emulsiones.

Tamaño de gota. La Figura 1 muestra la frecuencia del tamaño de partículas de las diferentes emulsiones Se puede observar tamaños de gotas esperables para el modo en que se realizó la homogenización (~2,0 µm) [8] Si bien las emulsiones PGW-AO tuvieron el tamaño de gotas más pequeñas (moda:2,114 ± 0,001), no difieren notablemente de la emulsión PGW-0,75 (moda: 2,779 ± 0,002). El incremento en el contenido de lípidos no afectó la distribución final de las partículas en las emulsiones.

La incorporación de AO redujo el tamaño de gota durante el proceso de emulsificación. Esto puede justificarse por la naturaleza hidrofílica del AO que facilita las interacciones polares con la proteína incrementando la dispersión [9]

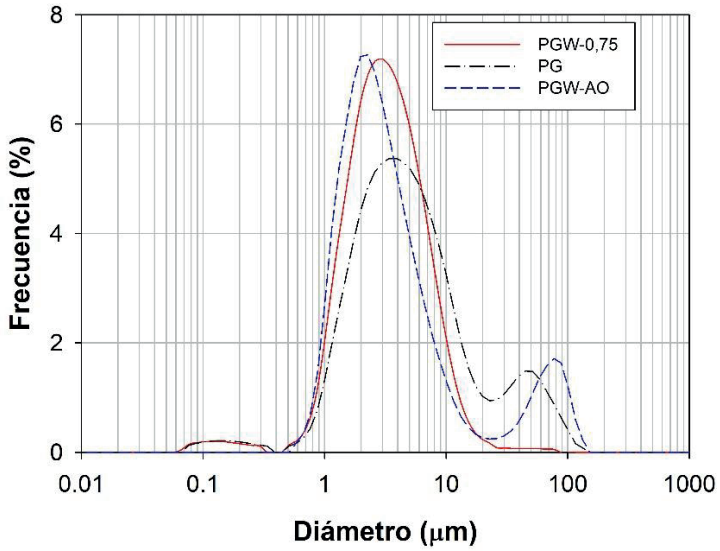

Fig. 1. Distribución de tamaño de gota de las emulsiones PGW-0,75, PG y PGW-AO

Reología. El análisis reológico de las emulsiones se muestra en la Fig. 2 Todas las emulsiones tuvieron un comportamiento pseudoplástico. Los índices de flujo para las emulsiones PGW-AO, PGW-0,5 y PGW-0,75 fueron 0,93, 0,89 y 0,96 respectivamente. Estudio similar de emulsiones con caseinato de sodio con AO y cera de abeja arrojó comportamiento Newtoniano excepto con el agregado de ácido esteárico (índice de flujo 0,79). Si comparamos las emulsiones con una relación de proteínas:lípidos 1:0,5, podemos observar las emulsiones con AO poseen una mayor viscosidad debido a un menor tamaño de partículas y a una mayor interacción entre lípidos-proteína. Comportamiento similar se registró para emulsiones caseinato de sodio-cera de abeja-ácido oleico [9]. Por otra parte, la emulsión con mayor cantidad de ceras (PGW-0,75 y PGW-0,5) presentó menor viscosidad y esto podría explicarse porque su incorporación de dejaría más solvente libre en el sistema [9].

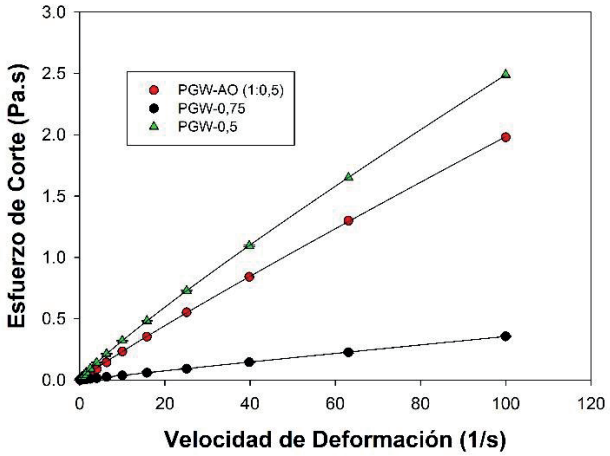

Fig. 2. Comportamiento reológico de las emulsiones PGW-0,75, PGW-0,5 y PGW-AO

Estabilidad. En la Figura 3 se observan las emulsiones colocadas en los tubos que luego fueron analizados en el TurbiScan. Las mismas exhibieron un color blanquecino. Los perfiles de transmisión no se presentan, ya que las emulsiones son opacas y no permiten el paso de la luz, haciendo que los valores de Transmission sean 0%.

Fig. 3. Tubos de ensayo con las emulsiones para ser analizadas mediante el equipo TurbiScan MA 2000.

En la Figura 4 se observan los perfiles de backscattering de las diferentes emulsiones elaboradas. En la figura 4-a se observa el perfil obtenido para la emulsión PG, en el fondo del tubo se produjo un desplazamiento hacia arriba de los perfiles, inicio del proceso de sedimentación, mientras que el en centro del tubo permanecen iguales. La Figura 4-b corresponde a las emulsiones PGW-0,5, se observa que el agregado de ceras provoca en el fondo del tubo un desplazamiento de los perfiles hacia abajo, indicando que se presenta el proceso de cremado. En el centro del tubo los perfiles comienzan a desplazarse hacia abajo, indicando un aumento del tamaño de las partículas. La figura 4-c corresponde a las emulsiones PGW-AO, en el fondo del tubo se observa que los perfiles se desplazan hacia arriba inicialmente, presentando el mismo comportamiento

que las emulsiones PG, sin embargo, a las 23 horas de medición el perfil presenta un desplazamiento hacia abajo, comenzando el proceso de cremado. El agregado de AO a la emulsión provoca que el inicio del proceso de cremado se vea retrasado, con respecto a la emulsión sin agregado de AO.

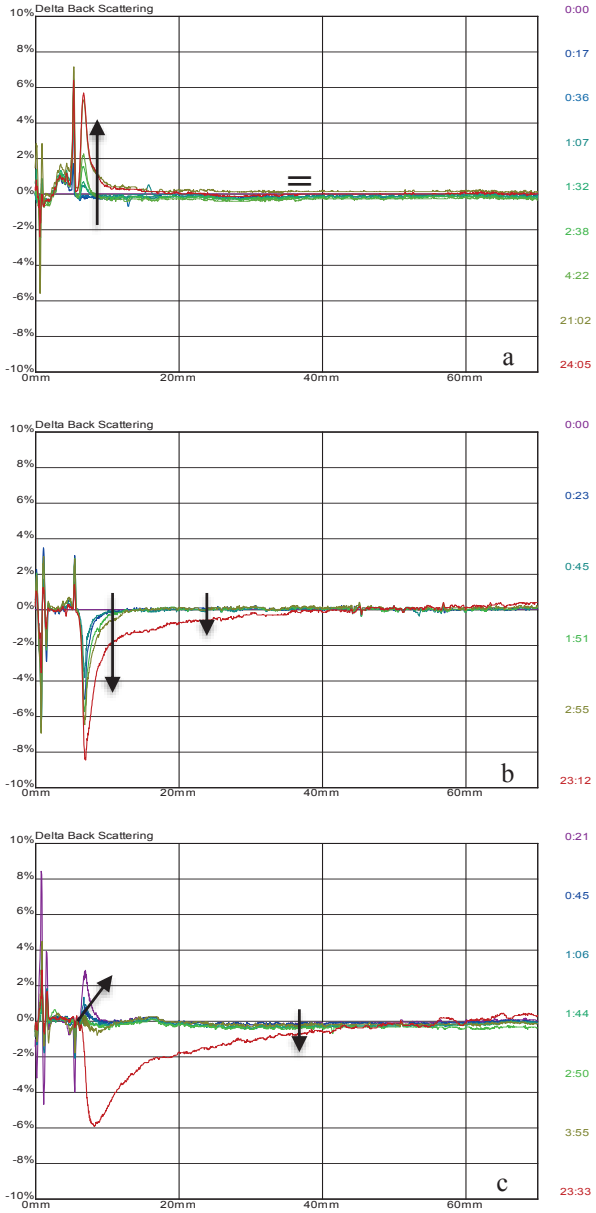

Fig. 4. Datos de backscattering de las emulsiones elaboradas, a) PG, b) PGW-0,5, c) PGW-AO, TurbiScan MA 2000.

Al no observarse alteraciones importantes puede afirmarse que las emulsiones formadas en todos los casos fueron estables en el tiempo considerado necesario para la elaboración de los films (24 horas).

En la Figura 5 se observan los perfiles de backscattering de emulsiones elaboradas con diferente relación lípido/proteína (PGW-0,5 y PGW-0,75). En ambas puede observarse un desplazamiento hacia debajo de los perfiles en el fondo del tubo, sin embargo, cuando la proporción de lípidos fue mayor (Fig 5-b), el desplazamiento fue mayor, indicando que el aumento del contenido de lípidos en la emulsión promueve los procesos de desestabilización.

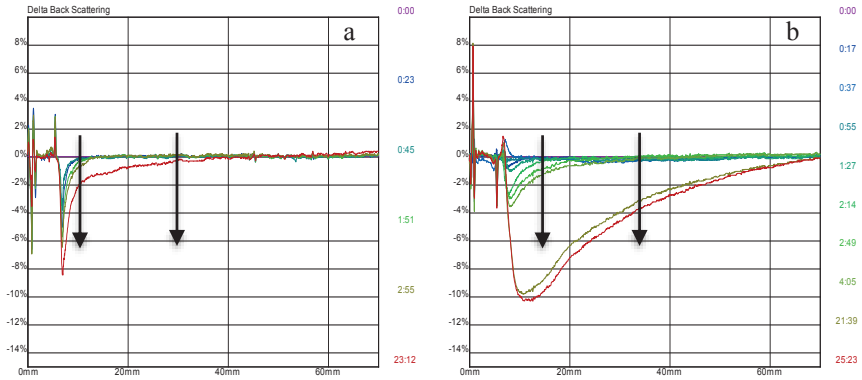

Fig. 5. Datos de backscattering de las emulsiones elaboradas con diferente relación lípidos/proteína, a) PGW-0,5, b) PGW-0,75, TurbiScan MA 2000.

Con el objetivo de evaluar la estabilidad de las emulsiones a tiempos superiores la formulación PGW-0,5 fue monitoreada durante aproximadamente 20 días, en la Figura 6 se presentan los perfiles de backscattering obtenidos. Puede observarse que la señal de BS% en el centro de los tubos presenta una disminución a lo largo del tiempo, indicando que hay un aumento del tamaño de partículas. También se observa que la señal en el fondo del tubo aumenta y mientras que en el tope disminuye, indicando que ocurren procesos de sedimentación.

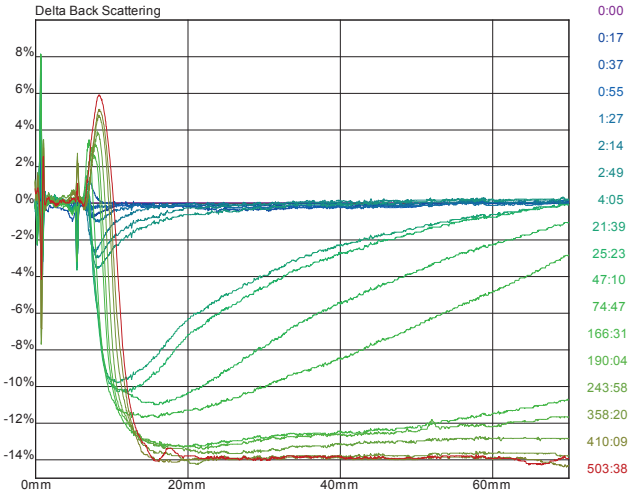

Fig. 6. Datos de backscattering de emulsiones elaboradas PGW-0,5 medidas a tiempos superiores, TurbiScan MA 2000.

3.2. Caracterización de películas.

En la Figura 7 se presentan imágenes de los films obtenidos a partir de las diferentes formulaciones elaboradas. En las fotografías puede observarse que todas las películas fueron opacas, y que el agregado de ceras y de AO no provocaron cambios en su apariencia. Las películas obtenidas con las emulsiones más concentradas en ceras fueron rugosas y no uniformes, y las películas obtenidas utilizando ceras y AO (PGW-AO) fueron frágiles y difíciles de manipular. Debido a esto solo pudieron ser analizadas las propiedades de los films elaborados con las formulaciones PG y PGW-0,5.

El espesor promedio de las películas obtenidas fue 148 ± 9 µm. La VTVA correspondiente a la película obtenida con la formulación PGW-0,5 fue 7.981 ± 0.001 g/ s m^2, mientras que para la película obtenida a partir de PG se obtuvo un valor de 9.47 ± 0.001 g/ s m^2, siendo esta última significativamente superior a la primera ($p<0.05$). Esto indica que las ceras aportan hidrofobicidad al film ayudando a retener la humedad del lado interno del film.

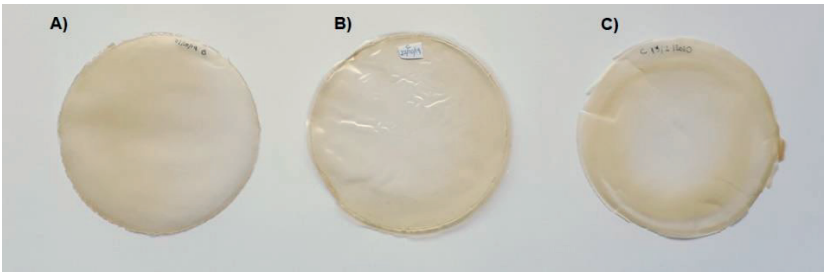

Fig. 7. Imágenes de los films obtenidos con las emulsiones: A) PGW-0,5, B) PG y C) PGW-AO.

La Tabla 1 muestra las propiedades mecánicas de las películas con y sin cera (PGW y PG). Se puede observar que tanto el parámetro TS como E% fueron significativamente mayores para el film sin cera indicando que la adición de cera produce una reducción en la elasticidad del film y requiriendo una menor fuerza para alcanzar la ruptura del mismo. La deseabilidad de algún valor predeterminado de alguna de estas propiedades dependerá exclusivamente de la aplicación específica de la película.

Table 1. Propiedades mecánicas promedio de las películas PGW y PG: porcentaje de elongación (E%), tensión de rotura (TS) y el módulo elástico o módulo de Young (Y).

	PGW	PG
TS (MPa)	$0.827^{a} \pm 0.183$	$1.282^{b} \pm 0.191$
E%	$6.11^{a} \pm 0.74$	$59.15^{b} \pm 19.72$
Y (MPa)	$17.92^{a} \pm 1.28$	$21.27^{a} \pm 2.44$

Subíndices con letras diferentes dentro de una misma fila indican diferencias significativas ($p<0.05$).

4. Conclusiones

En el presente trabajo se analizaron las propiedades de emulsiones compuestas de aislado proteico de soja, cera de abeja y glicerol, como también de las películas biodegradables obtenidas con las mismas. Como conclusiones generales se puede mencionar que las emulsiones resultaron altamente estables dentro del período de tiempo necesario para fabricar los films. Además, se observó que el agregado de las ceras produjo una disminución en la velocidad de transmisión al vapor de agua, probablemente causado por las propiedades hidrofóbicas de las mismas. Estos resultados los resultados alientan a profundizar las investigaciones sobre este tipo de emulsiones, con el objetivo de elaborar películas comestibles.

Resumen. El presente trabajo se centra en la caracterizaron de un total de veintiséis (26) muestras de propóleos crudos provenientes de diferentes localidades de la provincia de Buenos Aires y Valle de Río Negro y Río Colorado cosechados mediante los métodos de malla y raspado. La fracción de cérea contenida en el propóleos actualmente representa un residuo de la industria apícola que podría presentar compuestos bioactivos de interés, por lo que también fue parcialmente caracterizada. En general, los resultados indicaron que todos los propóleos cumplen con los requisitos impuestos por el Código Alimentario Argentino. Se determinó que el método de cosecha (malla o raspado) afecta la composición del propóleo en cuanto a su contenido de ceras y resinas. El contenido de compuestos fenólicos de los propóleos estuvo en un rango entre 1,5 y 2,9 % (p/p). El contenido de ceras de los propóleos analizados varió entre 12,3-48,9 % (b.s.), y se determinó que aproximadamente el 30% de los compuestos fenólicos presentes en el propóleo original son retenidos por las ceras. Estos resultados alientan la investigación del potencial uso de las ceras de propóleos en aplicaciones comerciales, como podrían ser el desarrollo películas biodegradables con contenidos de componentes bioactivos para el recubrimiento de alimentos.

Palabras clave: Propóleos, ceras de propóleos, método de cosecha, caracterización.

1 Introducción

El propóleos es un producto apícola que se compone mayormente de resinas que las abejas colectan de diferentes plantas, procesándolas y mezclándolas con su propia cera, para luego utilizarlo como protección de la colmena frente a diversos agentes patógenos. La fracción resinosa de este producto apícola es extraída y utilizada en la produc-

ción de múltiples formulaciones alimenticias debido al elevado contenido de compuestos bioactivos con efectos antimicrobianos y antioxidantes [1], siendo la fracción cérea desechada. Además, los estándares de aceptabilidad para el procesamiento de propóleos requieren un contenido de cera inferior al 40% [2], descartando aquellos propóleos que no cumplen con dicha especificación. En base a esto, el objetivo principal de este trabajo se centró en la caracterización de las ceras extraídas de propóleos provenientes de diferentes localidades bonaerense, valle del Río Negro y valle del Río Colorado, obtenidas por el método de raspado y malla, con el objetivo de evaluar su aplicación en diversas formulaciones alimentarias.

2 Materiales y métodos

Se estudiaron veintiséis (26) muestras de propóleos cosechadas entre los años 2016-2020, dieciséis de ellas recolectadas por el método de malla y las restantes por el método de raspado. Se establecieron cinco sitios de muestreo: valle inferior del Río Negro (muestras de Patagones y Viedma), valle bonaerense del Río Colorado (muestras de Villalonga, Pedro Luro e Hilario Ascasubi), la cuenca del Río Salado (muestras de Rauch) y la costa atlántica (muestras de Villa Gesell).
La caracterización del propóleos se realizó de acuerdo a la norma IRAM-INTA-15935 del Instituto Argentino de Normalización y Certificación. Se determinaron contenido de resinas [3], humedad, impurezas mecánicas, cenizas [4] y contenido de ceras.

Las ceras extrajeron con *n*-hexano mediante equipo Soxhlet [3]. Todas las determinaciones se realizaron por duplicado y se expresaron en % base seca (bs) de propóleos.

El color del propóleos crudo molido fue determinado mediante los parámetros de color CIELAB en un colorímetro Hunterlab a 25 ºC.
El análisis cualitativo de las ceras se realizó por comatografía TLC, utilizando una mezcla solvente de hexano, dietil éter y ácido acético en una relación 85:15:2, respectivamente y atmósfera de iodo como revelador. Se utilizaron como estándares [8]: alcoholes, hidrocarburos, ácido oleico, metil ésteres de ácidos grasos y colesterol. Se analizaron dos muestras de cera pertenecientes a propóleos con diferente método de cosecha (raspado y malla).

El punto de fusión de las ceras se determinó mediante calorimetría diferencial de barrido en un calorímetro Q20 TA Instrument. El rango de temperatura analizado fue 25-80 °C a una velocidad de 5°C/min.

Los compuestos fenólicos de las muestras de propóleos y ceras fueron extraídos en sistema agitado con metanol a temperatura ambiente por 24 h. El contenido de fenoles totales en el propóleo crudo y la cera recuperada fue determinado empleando el método de Folin-Ciocalteu (λ=765 nm, ácido gálico como estándar) y los flavonoides totales se determinaron en la cera mediante el método espectrofotométrico (λ=425 nm) empleando $AlCl_3$ [6, 7] y quercetina como estándar.

Los resultados se analizaron aplicando técnicas estadísticas de comparación de medias (prueba t de Student) con un nivel de significancia del 95% y análisis de varianza (ANOVA).

3 Resultados y discusión

En relación a lo establecido por el Código Alimentario Argentino [2], el contenido de humedad se encuentra por debajo del máximo establecido por dicho organismo (11% bs). El contenido de cenizas excedió el máximo permitido en solo dos muestras y el máximo registrado corresponde a propóleos recolectado en la localidad de Pedro Luro mediante el método de mallas (13,1%, bs). Solo tres muestras superaron levemente el contenido máximo de cera permitido por el CAA (40%). Todas las muestras presentaron un contenido de resinas (30%) y de fenoles totales (mínimo 5%) superior al mínimo establecido por el CCA.

En comparación con fuentes bibliográficas que reportan la caracterización de propóleos de la provincia de Buenos Aires [3], se puede mencionar que todos los parámetros reportados son similares a excepción del contenido de fenoles, el cual fue aproximadamente la mitad que el reportado por otros autores (22%). En general, se podría decir que la caracterización del propóleos de la provincia de Buenos Aires se ha mantenido relativamente constante a través del paso de los años.

En relación al color, la luminosidad (L) promedio de las muestras fue 53 ± 5. Considerando que el CV% fue inferior al 10% se podría decir que es un valor representativo para todo el conjunto de muestreo. Por otro lado, los parámetros a* y b* presentaron coeficientes de variación del 30 y 17%. A pesar de esto, todos los propóleos mostraron una coloración combinada entre rojo (valores positivos del parámetro a*) y amarillo (valores positivos del parámetro b*). Al agrupar las muestras de acuerdo al método de recolección, aquellas obtenidas mediante malla presentaron un valor de L y b* superior a aquellas correspondientes al método de raspado ($p<0.02$). Esto indica que los propóleos provenientes de mallas son levemente más luminosos y de un color amarillo más intenso. No se encontraron diferencias significativas en relación al parámetro a* ($p>0.07$).

Un parámetro importante que determina la calidad del propóleos es el contenido de resinas en relación al contenido de ceras, ya que la resina es la fracción del propóleos que contiene los compuestos bioactivos beneficiosos para la salud [9]. Por este motivo, se realizó la comparación entre las muestras recolectadas mediante el método de malla y raspado. Los resultados mostraron que el propóleos obtenido mediante el método de recolección por raspado presentó una mayor relación entre estos componentes ($p<0.05$).

El punto de fusión promedio de la cera de propóleos fue 61,3 ± 0,9 °C. Al comparar grupos de muestras provenientes de diferentes métodos de recolección, aquellas provenientes de mallas presentaron su punto de fusión 1 °C mayor que las de raspado ($p<0.04$).

El contenido máximo de fenoles en la cera de propóleo fue 2,9% (bs), mientras que el mínimo fue 1,5%. Si se utiliza el contenido de cera y fenoles promedio de las muestras, es posible determinar que aproximadamente el 30% de los compuestos fenólicos presentes en el propóleo crudo quedaron retenidos en la fracción de cera. Este resultado es de importancia ya que incentiva el desarrollo de nuevas aplicaciones para este residuo de la industria apícola. Además, al comparar muestras obtenidas mediante diferentes métodos de recolección, aquellas correspondientes al método de malla (2,4 ± 0,4% bs) presentaron un promedio significativamente mayor a las de raspado

(1,9 ± 0,3%, bs). Por último, las ceras presentaron un contenido de flavonoides entre 0.30 y 0.64% (bs).

El análisis cualitativo por TLC arrojo que las ceras contienen todos los compuestos de referencia: hidrocarburos, ésteres de ácidos grasos, alcoholes y colesterol [10].

4 Conclusiones

En el presente trabajo se realizó la caracterización de propóleos proveniente de diferentes regiones de la provincia de Buenos Aires, Valle del Río Negro y Valle del Río Colorado, así como también la fracción cérea presente en el mismo. Si bien en general todas las muestras respetan las normativas establecidas por el Código Alimentario Argentino, se encontró que la proporción de resina:cera es diferente de acuerdo al método de cosecha implementado, siendo la misma superior en los propóleos recolectados mediante el método de raspado. Además, se detectó que aproximadamente el 30% de los compuestos fenólicos presentes en el propóleo crudo quedan retenidos en la fracción cérea. Estos resultados alientan el estudio de las posibles aplicaciones para este residuo de la industria apícola.

Resumen. El complejamiento del calcio con péptidos y su impacto en la biodisponibilidad de este mineral tiene mucha vigencia. El calcio es un mineral esencial para la correcta salud ósea, pero su absorción en el intestino es baja debido a la formación de sales insolubles. Por otro lado, el caseinomacropéptido (CMP) es un péptido con propiedades bioactivas obtenido de la hidrólisis enzimática específica de la κ-caseína por acción de la pepsina o quimosina durante la elaboración del queso. Para incrementar la ingesta y bioaccesibilidad del calcio en la población es importante analizar tanto la afinidad como el modo de interacción del CMP por el calcio. Se evaluó, el efecto de la incorporación de $CaCl_2$ sobre la asociación molecular del CMP mediante la técnica de dispersión dinámica de luz láser. Adicionalmente, se analizaron los espectros infrarrojos con transformadas de Fourier. Las modificaciones observadas en los espectros de CMP y $CaCl_2$ a pH neutro confirmaron que el CMP interacciona con el calcio a través de los residuos carboxílicos que corresponderían al Asp y Glu. Los cambios en la zona de amidas indicaron cambios en la estructura secundaria del péptido. Por otro lado, los resultados de DLS mostraron la formación de estructuras asociadas por pares de moléculas de CMP (dímeros, tetrámeros, hexámeros) en presencia de $CaCl_2$, alcanzando un grado máximo de asociación, el hexámero, para la relación 1,2 mmol $CaCl_2$/g de CMP. Dada la potencialidad del CMP como péptido ligante, este trabajo plantea un nuevo ingrediente funcional con alto valor agregado.

Palabras clave: caseinomacropéptido, $CaCl_2$, DLS, FTIR, interacción

1 Introducción

El Caseinomacropéptido (CMP) es un péptido de origen animal, que proviene del suero de queso luego de la escisión de la κ-caseína por vía enzimática y posee numerosas

propiedades bioactivas. El CMP es afectado por el pH ya que contiene dos residuos de Asp, siete u ocho de Glu (dependiendo de la variante B o A del CMP, respectivamente), una Ser fosforilada y tres residuos de Lys. A pH 7,0 y en ausencia de sales, tiene una fuerte carga negativa siendo su ξ de -24,12 mV [1]. Teniendo en cuenta sus propiedades funcionales y sus características bioactivas, resulta de gran interés su estudio para el desarrollo de nuevos ingredientes funcionales, especialmente caracterizar si el CMP presenta cierta capacidad ligante de calcio. Para incrementar la ingesta y bioaccesibilidad del calcio en la población es importante analizar tanto la afinidad como el modo de interacción del CMP por el calcio. A diferencia de otros péptidos, el CMP se destaca también por su abundancia como subproducto de la quesería. La interacción entre el CMP y el calcio puede observarse a nivel molecular. Sin interacción entre el CMP y el calcio se esperaría que los tamaños de partícula característicos para el CMP se mantengan y, al contrario, un cambio en el tamaño sería indicativo de una interacción molecular. Esta metodología se ha utilizado con este fin en diferentes trabajos [2-6]. El objetivo de este trabajo fue caracterizar a nivel molecular las interacciones entre el CMP y el $CaCl_2$ en solución a pH neutro. Se evaluó en primer lugar, el efecto de la incorporación de $CaCl_2$ sobre la asociación molecular del CMP mediante la técnica de dispersión dinámica de luz láser (DLS, en inglés). Adicionalmente, se analizaron los espectros infrarrojos con transformadas de Fourier (FTIR). Esta técnica es especialmente útil para el estudio de compuestos orgánicos ya que la abundancia de bandas de absorción específicas garantiza poder identificar compuestos puros o modificaciones. A través de esta técnica se pueden observar modificaciones a nivel molecular e identificar cuáles son los grupos funcionales que intervienen en las interacciones.

2 Materiales y métodos

2.1 Materiales

Se utilizó caseinomacropéptido BioPURE-GMP® de Davisco Foods International (USA). Su pureza, según el proveedor, fue (en base seca): 90,0 ± 3,0% (p/p) de CMP (N x 7,07). Su contenido mineral fue (100 g de muestra): 950 mg de Na; 125 mg de K y 682 mg de Ca determinados mediante espectrometría de absorción atómica Analyst 200 Perkin Elmer (USA). Se utilizó $CaCl_2$ anhidro (Merck, Alemania) de calidad analítica. El agua utilizada para preparar las soluciones fue ultrapura (Thermo Scientific Barnstead, modelo Easypure RF) y su conductividad fue 1,8 ± 0,1 μS/cm.

2.2 Métodos

2.2.1. *Preparación de las soluciones.* Se utilizaron concentraciones de CMP del 1 y 5% (p/p). Las soluciones de CMP se prepararon como en Loria et al. [7] hasta alcanzar la concentración de sal deseada (entre 0 y 250 mM) de $CaCl_2$. El CMP es muy soluble en agua y no se formó ningún precipitado después de añadir las soluciones salinas. El pH se ajustó a 7,0 con NaOH (c).

2.2.2 *Dispersión Dinámica de Luz (DLS).* Las mediciones de tamaño de partícula fueron realizadas en un equipo de DLS Zetasizer Nano–Zs de Malvern Instruments (Malvern, Inglaterra) provisto de un láser He–Ne (633 nm) y un correlador digital, modelo ZEN3600 según la técnica descrita en [8]. Las mediciones fueron realizadas a un ángulo fijo de dispersión de 173º. El rango de medición del equipo es 0,6–6000 nm. Los ensayos fueron realizados por triplicado y a temperatura ambiente. Las muestras fueron previamente filtradas a través de microfiltros Whatman International Ltd. (Maidstone, Inglaterra) de 0,45, 0,22 y 0,02 μm.

2.2.3. *Espectroscopía FTIR*. Las muestras en solución fueron almacenadas en freezer a una temperatura de -80ºC durante 24 hs y posteriormente liofilizadas (Labconco® freezone 12). Los espectros fueron registrados a temperatura ambiente en un espectrofotómetro infrarrojo Shimadzu® (modelo IR Prestige-21, Japón) en un rango de longitud de onda de 4000 nm^{-1} a 500 nm^{-1}. Se utilizó 1 mg de muestra liofilizada mezclada con 100 mg de KBr, pulverizada en un mortero de ágata y luego presionada a 20 Bar para obtener una pastilla. Cada muestra se sometió a 40 scans con 2,0 cm^{-1} de resolución. El registro de datos se realizó con el software LabSolution IR®, y el análisis de los espectros y los picos con el software OriginPro® 8 SR0, V8.0724, USA.

2.2.4. *Análisis estadístico.* Se utilizó el software GraphPad Prims v7.0 (GraphPad Software, San Diego, CA, USA) para el análisis estadístico. Los datos fueron analizados a través de un análisis de varianza (ANOVA). Las diferencias fueron determinadas por la prueba de Tukey para $P < 0,05$.

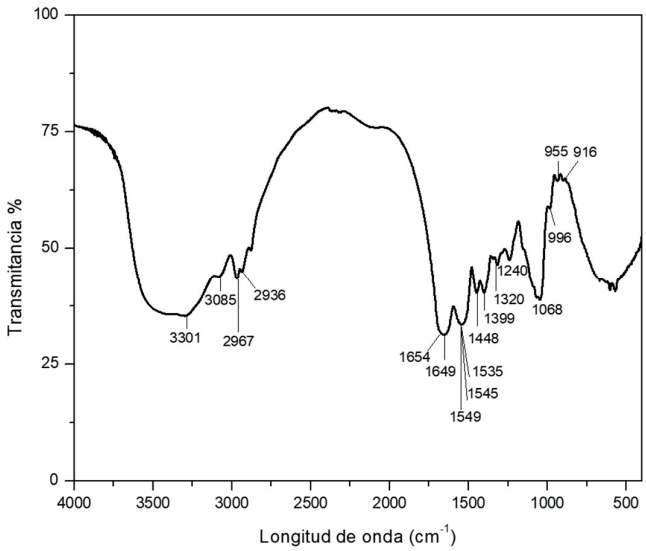

Fig. 1 Espectro FTIR del CMP a pH 7.

Tabla 1 Asignación de picos en los espectros FTIR del CMP en ausencia de sales y con 1,2 mmoles de $CaCl_2$/g CMP a pH 7,0. Se marcan en negrita las discrepancias con respecto al espectro de CMP sin sales.

Las asignaciones del espectro fueron adaptadas de Wang et al. [9]

3 Resultados y discusión

3.1. Espectro FTIR del CMP a pH neutro.

El espectro FTIR del caseinomacropéptido (Fig. 1) fue similar al obtenido por Burgardt et al. [10], quienes utilizaron un material del mismo proveedor. En un espectro FTIR se distinguen principalmente dos zonas: una región de huella digital o fingerprint (1300 - 600 cm^{-1}) y otra región correspondiente a los grupos funcionales (4000 - 1300 cm^{-1}). Esta última región da información para identificar el tipo y carga de los grupos, mientras que la región de la huella digital indica las características estructurales de la molécula [9]. Las asignaciones se muestran en la Tabla 1.

En el espectro de la Fig. 1 se puede observar una banda ancha e intensa entre 3400 y 3300 cm^{-1}. Se debe a un solapamiento de bandas correspondientes a la vibración de los estiramientos O–H, libre o unido [10]. Las absorciones de tensión N-H tienen lugar a frecuencias ligeramente más bajas que las absorciones de tensión del O-H. Las bandas de las amidas secundarias A y B se encuentran a 3300 cm^{-1} y 3080 cm^{-1}, respectivamente [10]. La banda de la amida A corresponde al estiramiento del enlace N–H en la formación de la unión puente hidrógeno N–H mientras que la amida B resulta de la resonancia de FERMI de la vibración del estiramiento N-H con el sobretono de la vibración de la amida II [11]. Según Burgardt et al. [10] estas bandas también están relacionadas con el aminoácido prolina, que es abundante en el CMP. Las bandas observadas en 2970 y 2940 cm^{-1} refieren a vibraciones simétricas y asimétricas del grupo metilo ($-CH_3$) [12]. La vibración de la amida I, que es causada principalmente por los estiramientos del enlace C=O, se mide en el rango de 1700 a 1600 cm^{-1}, mientras que, la vibración de la amida II, que se produce por la deformación de los enlaces N-H y por los estiramientos de los enlaces C-N, se mide en el rango de 1600 a 1500 cm^{-1} [13]. Estos son los modos vibracionales más importantes de las amidas. Las frecuencias exactas a las que estos enlaces absorben dependen de la estructura secundaria de las proteínas o péptidos. En el espectro del CMP estas bandas se observan en 1649 cm^{-1} y 1549 cm^{-1}, y se atribuyen a las vibraciones de amida I y II respectivamente. La banda de amida III a 1240 cm^{-1} representa la combinación entre la vibración del estiramiento C-N, la flexión del enlace N-H de la amida y las vibraciones de los grupos CH_2 del esqueleto de la glicina y de las cadenas laterales de la prolina [14].

Una de las bandas especialmente significativas en el CMP es la correspondiente al grupo funcional carboxilato (COO^-). Los carboxilatos producen una vibración a los 1400 cm^{-1} que caracteriza la coordinación de los iones metálicos divalentes [15]. La banda a 1320 cm^{-1} es atribuida al grupo CO-N (amina) [10]. El CMP está glicosilado, y la señal de absorción en la región de la huella digital se encuentra entre 1200 y 1000 cm^{-1} [16]. Según Lewis et al. [17] el ácido siálico tiene una señal característica a 1024 cm^{-1}, la N-Acetilglucosamina (GlcNAc) a 1025 cm^{-1} y la N-Acetilgalactosamina (GalNAc) a 1038 cm^{-1}. Los sitios fosforilados del CMP (Ser 149 y 127) dan una escasa señal a 990 cm^{-1} [18]. Las bandas presentes a 935 y 900 cm^{-1} estarían relacionadas con la galactosa (Burgardt y col., 2014).

3.2 Efecto de la adición de $CaCl_2$ sobre el estado de asociación del CMP por DLS

Con el propósito de analizar el efecto de la concentración de CMP con el tamaño molecular en presencia de $CaCl_2$ se realizaron las mediciones de tamaños de partícula por DLS para dos soluciones de CMP de diferente concentración (10 g/L y 50 g/L) y concentraciones variables de $CaCl_2$ a pH 7,0 y 25 ºC. En ausencia de $CaCl_2$, las distribuciones fueron bimodales para 10 g/L y trimodales para 50 g/L. Sin embargo, la concentración de CMP no influyó en la posición del primer pico, 2,3-2,5 nm. El software del equipo Zetasizer Nano-Zs permitió estimar el grado de asociación molecular en cada caso considerando a la forma monomérica del CMP (aproximadamente 7,5 kDa) de un valor de *d(H)* de 2,6 nm [8]. La Fig. 2 muestra el valor máximo del *d(H)* del pico predominante y los correspondientes estados de asociación obtenidos en presencia de distintas cantidades de $CaCl_2$ para soluciones de CMP con diferente concentración: 10 y 50 g/L. Se observó para las dos concentraciones que el *d(H)* se desplazó hacia tamaños mayores hasta alcanzar un valor máximo (5,6 nm). Es decir, el péptido en presencia de $CaCl_2$ se autoensambló desde monómeros a dímeros, tetrámeros y finalmente hexámeros dependiendo de la concentración de $CaCl_2$ presente en el medio.

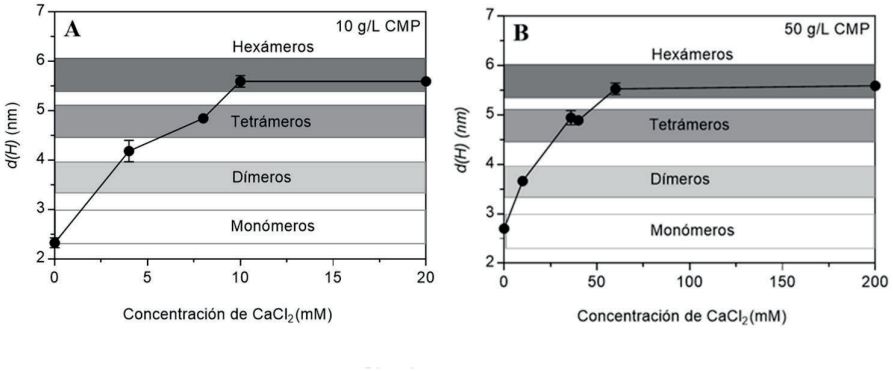

Fig. 2 Valor máximo del *d(H)* del primer pico de la distribución (intensidades) de soluciones de CMP en función de concentraciones crecientes de $CaCl_2$ a pH 7 y 25 ºC. Concentración de CMP: A) 10 g/L y B) 50 g/L. Se indica el estado de asociación predominante estimado mediante el software del equipo Zetasizer Nano-Zs. Las barras representan el desvío estándar.

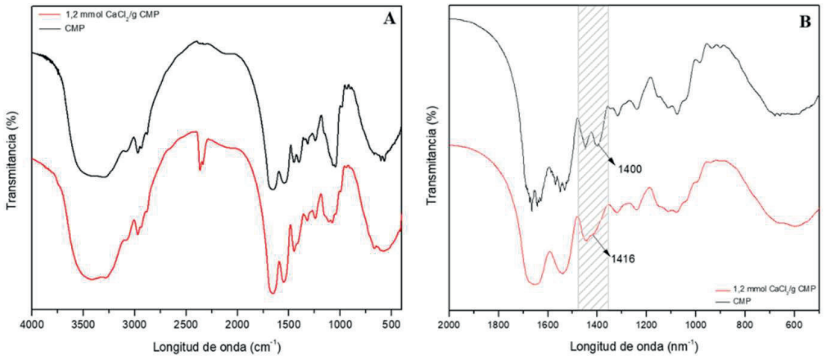

Fig. 3 Espectro FTIR del CMP en ausencia de sales (–) y en presencia de 180 mM de $CaCl_2$ (–). Relación 1,2 mmol $CaCal_2$/ g CMP (A). Vista ampliada entre 500 y 2000 cm^{-1} (B).

Basados en nuestros hallazgos, se puede afirmar que la forma de asociación del CMP en presencia de $CaCl_2$ sigue un mecanismo desde los monómeros hasta los dímeros (0,3 - 0,4 mmoles $CaCl_2$/g de CMP), luego tetrámeros (0,7 - 0,8 mmoles $CaCl_2$/g de CMP), y finalmente hexámeros (1 - 1,2 mmoles $CaCl_2$/g de CMP que equivale a 7,5 -9 mol/mol CMP), donde alcanzó su estado de asociación máximo indicando que esta relación es su máxima capacidad ligante.

3.3 Espectro FTIR del CMP a pH neutro en presencia de $CaCl_2$

Los espectros del CMP en ausencia y presencia de cloruro de calcio se muestran en la Fig. 3 y las asignaciones en la Tabla 1. Se eligió la concentración óptima que se observó previamente en los estudios previos de DLS de 1,2 mmoles de $CaCl_2$/g CMP. Al comparar los dos espectros (con y sin $CaCl_2$) de la Fig 3A, se distinguen diferencias que brindan información en la estructura molecular, por ejemplo, desplazamientos hacia el rojo o hacia el azul, incremento o reducción de picos. La absorción a alta frecuencia de 3301 cm^{-1} (Amida 2º A) que se atribuye a la vibración de estiramientos N-H cambió a 3283 cm^{-1} y el de la Amida 2º B de 3080 a 3088 cm^{-1}. Este cambio podría deberse a que los grupos N-H se reemplazarían por uniones N-Ca como describieron Peng et al. [19] y Wang et al. [9] para otros péptidos. La banda de Amida I a 1649 cm^{-1} para el CMP/$CaCl_2$, se debería a que los grupos C-O participarían en la interacción del péptido con el Ca^{2+} [20]. En la región de la Amida II han desaparecido los picos correspondientes al número de onda 1535 y 1545 cm^{-1}, encontrándose un valle en el espectro del CMP/$CaCl_2$. Fundamentalmente, la banda de 1400 cm^{-1} correspondiente a los grupos carboxílicos (COO^-) se desplazó hacia frecuencias mayores (1416 cm^{-1}) en el espectro del CMP/$CaCl_2$ (Fig. 3B).

Wang et al. [9] estudiaron a través de espectroscopía FTIR el efecto de la interacción del $CaCl_2$ y un péptido proveniente de la fermentación con *B. subtilis* de semillas de pepino. Los autores hallaron, al comparar el espectro en ausencia y presencia de calcio, cambios similares a los de esta tesis. Encontraron un pico a 3416 cm^{-1} que se desplazó a 3424 cm^{-1} que atribuyeron a la participación de los grupos -NH en la coordinación con el Ca^{2+}. Los autores observaron un desplazamiento desde 1402 cm^{-1} en el espectro del péptido libre hacia frecuencias mayores (1420 cm^{-1}) en presencia de calcio y lo atribuyeron al estiramiento del grupo carboxilato $–COO^-$ por la combinación con Ca^{2+} para formar –COO-Ca. Finalmente, concluyeron que los principales sitios de coordinación entre el calcio y el péptido estudiado fueron los grupos –COOH, -OH, $-NH_2$ y –CO-NH.

Por otro lado, Peng et al. [19] estudiaron la afinidad por el $CaCl_2$ de un péptido proveniente del colágeno de hueso de pescado (*Gadus macrocephalus*). El espectro FTIR del péptido con calcio mostró que la banda de 3381 cm^{-1} se desplazó a 3361 cm^{-1}, la banda correspondiente a la vibración de amida I (1646 cm^{-1}) se desplazó a 1658 cm^{-1} y la de amida II (1558 cm^{-1}) a 1549 cm^{-1}. Además, la banda de 1455 cm^{-1} se desplazó a 1411 cm^{-1}. Los autores concluyeron, a partir de los cambios observados por esta técnica, que ese péptido quela iones calcio principalmente a través de interacciones con los átomos del nitrógeno del grupo amino y los átomos de oxígeno del grupo carboxílico. Los péptidos con gran afinidad por el calcio típicamente contienen una gran cantidad de Glu y Asp, ya que contribuyen a la unión del calcio posiblemente al generar un ambiente ácido para que los cationes se coordinen [19]. Las proteínas del hueso de pescado contienen altas proporciones de Gly, Glu y Arg, que tienen una alta afinidad por el calcio. En la secuencia aminoacídica de la variante A del CMP se encuentran 10 de estos aminoácidos ácidos: 8 residuos de Glu y 2 de Asp. Otras investigaciones [21, 22] muestran que los aminoácidos básicos también tienen afinidad con el calcio principalmente causada por los grupos $–NH_2$ o –NH que pueden participar en la coordinación con el calcio. Los aminoácidos básicos son: Lys, Arg y His, de los cuales el CMP contiene 3 residuos de Lys.

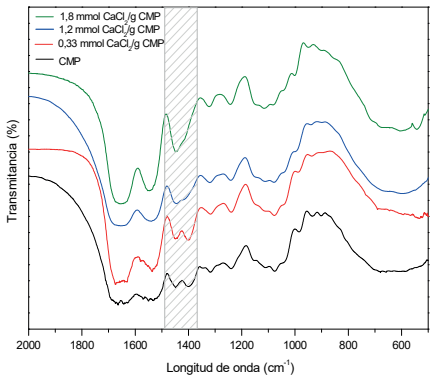

Figura 4. Espectro FTIR del CMP con diferentes relaciones $CaCl_2$/CMP, desde 2000 a 500 cm^{-1}.

En la Fig. 4 se muestran los espectros FTIR del CMP con diferentes concentraciones de $CaCl_2$. Las relaciones entre el $CaCl_2$ y el CMP están informadas en cada uno de los espectros y son: 0,33; 1,2 y 1,8 mmol de $CaCl_2$/g de CMP. Se eligieron estas relaciones a partir de los resultados hallados en DLS, buscando analizar la interacción molecular del CMP y el calcio en una relación por encima y por debajo de la hallada como óptima (1,2 mmol de $CaCl_2$/g CMP). En los espectros superpuestos de la Fig. 4 puede apreciarse que el corrimiento del pico de 1400 cm^{-1} a 1416 cm^{-1} sólo se observa para una relación $CaCl_2$/CMP igual o superior a 1,2 mmoles de Ca^{2+}/g. Esto indica que debe existir una cierta cantidad de iones Ca^{2+} en el medio para propiciar la unión con el CMP.

4. Conclusiones

A pH 7,0, el CMP se encuentra formando moléculas individuales (monómeros), pero si se adiciona $CaCl_2$, las cargas electroestáticas se apantallan y los residuos hidrofóbicos de la molécula de CMP pueden interaccionar. Los resultados de DLS indicaron que cuando la concentración de cloruro de calcio es superior a una relación 1,2 mmol $CaCl_2$/g de CMP, se alcanza el máximo estado de asociación, un hexámero. Este cambio en el tamaño es indicativo de una interacción molecular con el $CaCl_2$. Los espectros FTIR de CMP/$CaCl_2$ confirmaron que en presencia de calcio iónico se evidencia principalmente un corrimiento en la posición de los grupos carboxilatos (COO-) desde 1400 cm^{-1} a 1416 cm^{-1} que indicarían interacción para la misma relación de 1,2 mmoles de $Ca^{2+/}$g CMP o superior. Dada la potencialidad del CMP como péptido ligante, este trabajo plantea un nuevo ingrediente funcional con alto valor agregado.

Abstract. Technology development projects are constantly subject to risks and uncertainties and their performance are key to deliver the organizational value. Failing to meet project goals and objectives is critical, therefore, projects must be able to cope with an environment of complexity and pressure. This paper aims to assess and improve project resilience by using the Functional Resonance Analysis Model (FRAM) to look at project review process, a stage-gate milestone typical to Systems Engineering process. FRAM is supported by the Resilience Engineering perspective that things go wrong by the same reasons they go right, and everyday work is subject to variability and small adjustments, which is key to address such project environments. After assessing sources of variability and aggregating them, means to manage variability are proposed order to increase process resilience.

Keywords: Project Management, Resilience Engineering, FRAM.

1 Introduction

Technology-intensive projects are subject to complex environments and high levels of risk and uncertainty and require multidisciplinary approaches to meet their strategic objectives [1]. Resilience engineering focuses on helping people to achieve success while coping with complexity under pressure [2]. If risk management is entirely associated with Project Management and Systems Engineering [3], project resilience is one of the emerging topics in the area [4] and, along with Resilience, Resilience Engineering is described by Aven [5] as recent advances in the foundations of risk assessment and management.

This work aims to assess and improve project resilience in the context of the Institute of Aeronautics and Space (Instituto de Aeronáutica e Espaço, IAE), an organization from the Brazilian Air Force that defines its mission as "to develop technological and scientific solutions to strengthen Brazilian Aerospace power through research, development, innovation […] in aeronautical, space and defense systems" [6]. IAE, as a project-oriented organization, uses Systems Engineering, a process-oriented product life cycle management approach that enable developers to evolve from customers' needs to product delivery [7]. Systems Engineering may be seen either as a function within the

Project Management process [8], or a whole process that intersect with Project Management functions [9]. Project reviews, or design reviews, are gates that set decision-making milestones and determine whether the project is heading towards its original goals and the design has met criteria for the corresponding Systems Engineering process phase, aiding project control process and reducing risks and uncertainties during the development [10]. This work aims exclusively on project reviews.

All these processes are subject to variability and small adjustments, given that every project is unique. Functional Resonance Analysis Method (FRAM) aims to describe everyday performance model performance variability in complex dynamic socio-technical systems [11] and may be used in order to assess and find ways to manage variability and improve resilience within an interest system. Although originally imagined by Eric Hollnagel for modelling socio-technical systems [12], in this work FRAM will be applied in an essentially organizational process: the project review process.

This paper is divided into 6 sections. In section 2, a brief introduction to Resilience, Variability and FRAM will set the scene for the case study, the project review process in IAE, which will be discussed in section 3. Initial steps of FRAM will be applied for modelling work-as-done and assessing variability in section 4, then different scenarios for instantiations will be considered for later steps to establish ways to manage and improve resilience management of the process in section 5. Finally, an overview of the work as done in the conclusion and some insights for future works are provided.

2 Resilience, Variability and FRAM

2.1 Resilience and Resilience Engineering

Resilience and Resilience Engineering address issues with respect to the safety of systems, not by looking to things that go wrong, as usually do traditional approaches to safety, but by also looking to things that go right. It emerges as a consequence of understanding that both situations derive from the same circumstances: performance in sociotechnical contexts vary with time [13] and, as a conclusion, Resilience Engineering defines safety as “the ability to succeed under varying conditions” [14]. The perspective given by resilience is key to address modern context, in which traditional risk frames alone may not be enough and, therefore, both approaches should be considered together [15].

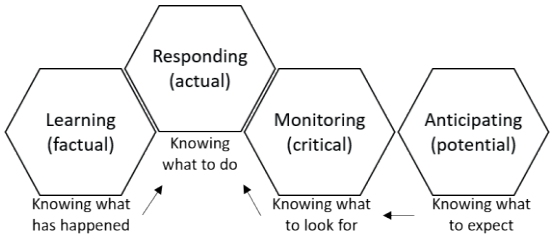

Fig. 1. The four cornerstones of resilience engineering [14, p. xxxvii]

Resilience is supported upon four cornerstones, as seen on Fig. 1, that can be improved within the context of a system [14]: responding (actual), which is dealing with what is already expected or considered normal behavior within minimal adjustments; monitoring (critical), that is observing the environment and the system in order to find threats; anticipating (potential): expecting potential developments, opportunities, and threats; and learning (factual): acquiring the right experience from both successes and failures.

2.2 Functional Resonance Analysis Method – FRAM

Functional Resonance Analysis Method (FRAM) was proposed by Erik Hollnagel in 2004 and developed in congruence with the principles of Resilience Engineering [11]. It introduces two key concepts: work-as-imagined (WAI) and work-as-done (WAD). Work-as-imagined can be understood as the task list or the process flowchart, in which things must be done the way it was meant to, in a linear thinking. Work-as-done perspective, on the other hand, provides the understanding that operators adjust their everyday operation with variations and small adjustments conditioned to the environment and other circumstances and, therefore, perform their work not necessarily according to the WAI, yet do not incur in a failure, from a traditional safety perspective [12].

FRAM defines system as "a set of coupled or mutually dependent functions" [12, p. 17] and model the relationship between these functions from a systemic perspective, which means properties may emerge from variability and resonate within the system. Functions in FRAM are coupled to each other through six aspects: input (the which is processed through the function), time (which determines a temporal constraint), preconditions (which must be met for the function to be performed), resources (which are consumed during the performance), control (which determines control or monitoring conditions during the performance), and the output (which may be an entity or a state change). Fig. 2 shows how a function is represented when modelled with FRAM.

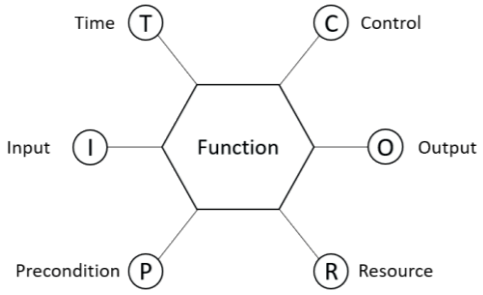

Fig. 2. A hexagon representing a function [12, p. 48]

FRAM is built upon four principles [12]: "equivalence of failures and successes": things go wrong by the same reason they go right; "approximate adjustments": everyday performance adjusted to match its conditions; "emergence": in the systemic sense, that the outcomes, predicted or not, must be described as emergent rather than resulted; and "resonance": relations and dependencies among functions are not cause-effect links, but they develop from a specific situation and context.

Hollnagel proposes four steps for using FRAM and one, which is necessary prior to the analysis, called "Step 0", in which the purpose of the analysis is determined. FRAM may be used either for event investigation (to look at what have happened) or for risk assessment (to predict what may happen in the future). Step 1 identifies the functions and describes how something is done through connecting the functions' aspects, then Step 2 will characterize potential and actual variability in FRAM. Then, Step 3 will aggregate variability by looking at specific instantiations of the model and, finally, Step 4 allows the user to propose ways to manage performance variability.

2.3 Evaluating the Process Performance Variability

Hollnagel proposes in step 3 a method for the aggregation of variability as a result of the upstream-downstream couplings for the aspects of every function [12]. His method, however, was essentially qualitative. In 2010, Luigi Macchi [16] proposed an increment for Hollnagel's approach for agregating variability through an application of the FRAM giving integer scores for aspect's qualities. For every function, its upstream aspects are assessed with respect to its quality, then this is related to how performance variability may be dumped or amplified. Table 1 links temporal and precision to quality of aspects, and Fig. 3 relates quality of aspect to potential for increasing or decreasing variability.

Table 1. Characterization of functions' output [16, p. 73]

		Temporal characteristics		
		Too early	On time	Too late
Precision	Precise	**A:** output to downstream functions is precise but too early	**B:** output to downstream functions is precise with the right timing	**C:** output to downstream functions is precise but delayed, reducing available time
	Appropriate	**D:** output to downstream functions is appropriate but too early	**E:** output to downstream functions is appropriate with the right timing	**F:** output to downstream functions is appropriate but delayed, reducing available time
	Imprecise	**G:** output to downstream functions is imprecise and too late	**H:** output to downstream functions is imprecise but correctly timed	**I:** output to downstream functions is imprecise as well as delayed, reducing available time

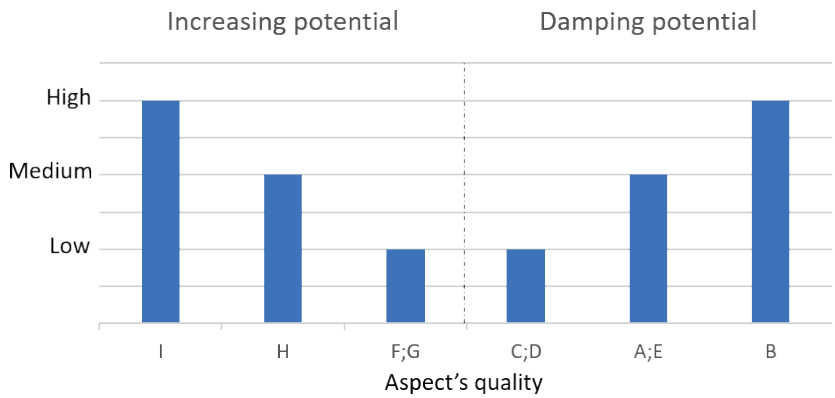

Fig. 3. Increasing and damping potential as a function of the aspect's quality [16]

Scores corresponding to the potential for increasing are positive (+) and, for damping, are negative (-), and the values for high, medium, and low are respectively +/- 3, +/- 2 and +/- 1. The quality of the output of a function would, then, be determined by the median of the quality of the *n* aspects provided by functions upstream as in (1).

$$q_o = \text{median}\left(q_{a_1}, q_{a_2}, \ldots, q_{a_n}\right) \quad (1)$$

For this work, another factor considered was complexity of a function, rather than precision and timely aspects. Complexity will be a source of variability if operator is not well trained or used to the function they are supposed to perform. Scores are also given considering low, medium, or high potential for damping or increasing variability.

3 Case Study: Systems Engineering Project Reviews in IAE

3.1 Systems Engineering Process in IAE

The Instituto de Aeronáutica e Espaço, as a project-oriented organization, has developed its own processes for Project Management and Systems Engineering, aligned with standards and good practices and the procedures for product lifecycle [17] and project lifecycle [18] at the Brazilian Air Force. The results are two internal standards for project and product lifecycle phases, and one for project review procedures. For aeronautical and defense systems, the phases of product development and their main project reviews are described in Fig. 4.

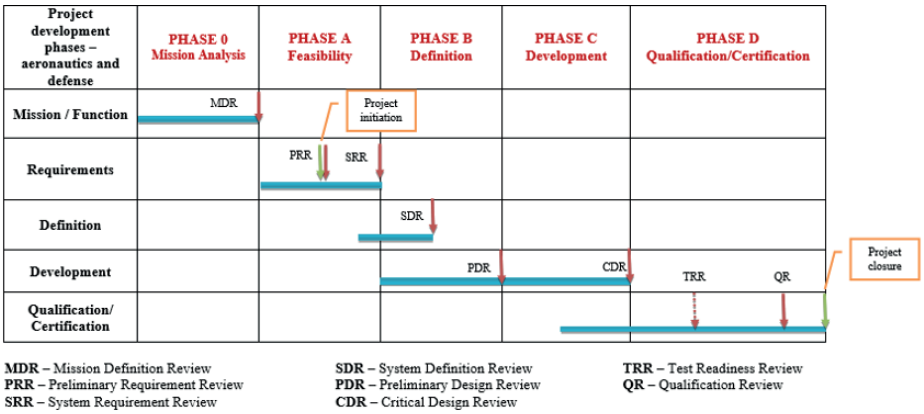

Fig. 4. Phases of product development and typical project reviews in IAE [19].

3.2 Project Review Process

Project reviews are milestones in which an independent group of experts evaluate whether the project is heading towards its original goals and meeting the phase criteria or not [20-21]. If the project meets the requirements as stated in the standards, or a subset of requirements, justified by a tailoring process, the project is considered approved to proceed to the next phase. If the project fails to meet all the requirements, it may either be approved, conditioned to meeting the requirements in time for the next milestone, or it is considered reproved and review must be retaken.

The "Project Review Procedures" internal standard [22] was developed by the Systems Engineering Office (SEO), derived from some international standards and procedures [23-25], and it represents a description for the work-as-imagined (WAI). Its last appendix shows a process flow using Business Process Model Notation. As already discussed in section 2.2, this is a result of a straight linear thinking and likely not to describe the real work-as-done (WAD), but it is helpful when modelling the WAD.

There are 3 main groups or actors involved with the process: the Project Review Team (PRT), who will be responsible for representing the whole project team and giving all the information necessary; the Review Committee (RC), which consists of invited and independent experts, who will be responsible for assessing the project and the evidence provided by the PRT; and the Review Authority, who acts as a moderator and is responsible for process quality assurance and ensuring that Review Committee (RC) works independently and free of political pressure.

The Project Review Process consists of 4 subprocesses:

1. *Prepare project review*: consists of assigning the Project Review Team (PRT), gathering the evidence that the criteria for the selected milestone were met, inviting experts for the Review Committee (RC), communicating to the SEO the intention of conducting a review and planning the next steps (communications, meetings, etc.)
2. *Assess evidence*: PRT discloses the initial data pack with documents and evidence, which shall be assessed by the RC. Comments and questions are issued in

"Comments and Questions Register" (CQR), which will be relied by an appointed PRT member. This goes on until register is scheduled to be consolidated by the PRT.
3. *Assess project*: RC presents its initial conclusions at a Coordination Meeting. From RC's considerations, they issue Review Item Discrepancies (RIDs), to be addressed by the PRT. Answers to the RIDs are assessed by the RC, who will consider whether answers are adequate or not to fix the discrepancies.
4. *Close review process*: RC shall present its final conclusions after evaluating RID's answers and approve if all milestone criteria were met, recommend conditional approval, or deny approval. Conditional approval needs Portfolio manager's approval. After Review Authority consent, review process shall be evaluated by its participants and a final report is issued.

4 Modelling the Work-as-Done

Before initiating Step 1, it is necessary to determine the purpose of the analysis. As stated in the introduction, this work aims to assess and find ways to improve the resilience by looking at the project review process. Therefore, the purpose is to predict what may happen in the future, but with a particularity: project reviews process are supposed to happen several times during a project life cycle, so monitoring work actually "as-done" will give further information and provide feedback to validate the model.

4.1 Step 1: Identifying and Describing Functions

FRAM modelling of the process was aided by the process flow given by the project review standard [22] and by monitoring the Mission Definition Review (MDR) for the Project IFF Mode 4 NSM, which is currently under development by IAE [26]. The model was done using the FRAM Model Visualizer (FMV) [27].

All four subprocesses described in section 3.2 were modelled from work-as-imagined (WAI) into work-as-done (WAD) and their functions were collapsed into a high-level perspective, as seen in Fig. 5. Functions in green are the 4 subprocesses, and functions in purple and red are background functions, which are not a direct part of the main process, yet they are sources of variability and must be considered for the next steps.

4.2 Step 2: Characterizing potential and actual variability

From the observed MDR process, subprocess 2, "Assess evidence" raised a flag and, therefore, was taken into consideration for further analysis. The interaction between PRT and RC did not work as imagined, which considered a loop of comments and questions continuously being replied. Although the interaction happened, there was little feedback to the process, and few comments and questions were reassessed by RC. Fig. 6 shows WAI for subprocess 2, and Fig. 7 show its WAD, modelled with FRAM, in which green functions are organizational considered in WAI model, yellow functions are human functions considered in WAI, red functions are human functions not considered in WAI and grey functions are background functions.

Fig. 5. FRAM model of the high-level project review process.

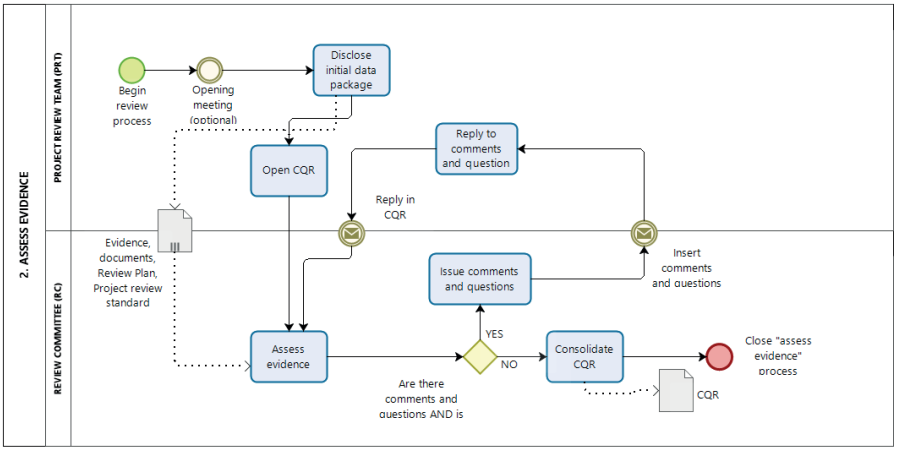

Fig. 6. Work-as-imagined (WAI) for subprocess "2. Assess evidence".

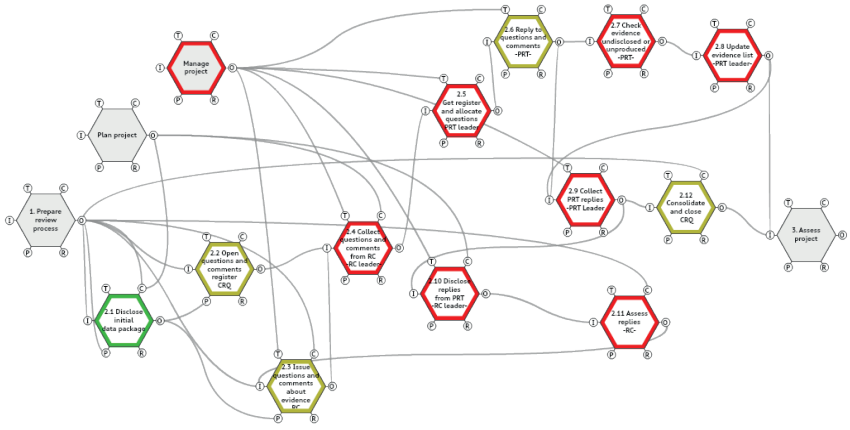

Fig. 7. FRAM model for subprocess "2. Assess evidence" work-as-done (WAD).

Functions, with their respective outputs, are described in Table 2. The output flow goes downstream up to a feedback, as seen in the WAI, in which replies are assessed by the RC and give them more information to interactively assess the evidence.

Table 2. Functions in subprocess 2 and their outputs

Nº	Function	Output	
2.1	Disclose initial data package	Data package disclosed	
2.3	Issue questions and comments about evidence	Comments and questions	
2.4	Collect questions and comments from RC	CQR with questions and comments	
2.5	Get CQR and assign questions to PRT	Questions and comments allocated	
2.6	Reply questions and comments	Questions and comments replied	
2.9	Collect PRT replies	CQR with replies	
2.10	Disclose replies to RC	CQR with replies disclosed	
2.11	Assess replies	Replies assessed	
2.12	Consolidate and close CQR	CQR consolidated	

FEEDBACK

Here is a brief description of each function:

- 2.1 – Disclose initial data package: as the review process begin, the RC shall receive the data package to assess the evidence. Review plan helps to set a deadline for disclosing, but this may vary. RC members should also sign a confidentiality agreement if the project data access is restricted, which is the case for most projects in IAE.
- 2.3 – Issue comments and questions about evidence: RC members, experts invited due to their experience with other development projects, shall assess the evidence. Usually, there is a need for clarification, therefore comments and questions are issued. The quality of this process depends on the RC members expertise, which is defined in subprocess 1. Prepare Review.
- 2.4 – Collect questions and comments from RC – Review Committee leader shall gather every RC members' comments and questions and send them to the Project Review Team leader.
- 2.5 – Get CQR and assign questions to PRT: PRT leader shall assign questions and comments to be replied by the project team member that deals with the matter.
- 2.6 – Reply questions and comments: PRT member assigned by the PRT leader shall reply to their comments and questions and send them back to the PRT leader.
- 2.9 – Collect PRT replies: as PRT members reply to their assigned questions and comments, PRT leader shall collect them to send a new version of the CQR to RC leader.
- 2.10 – Disclose replies to RC: RC leader discloses the latest CQR version to the other RC members.

- 2.11 – Assess replies: RC members assess replies given by PRT members, considering if further information is required and, so, issuing new comments or questions.
- 2.12 – Consolidate and close CQR: Review Plan defines, in its schedule, a deadline for the subprocess 2, whether assessment had been successfully done or not. After the deadline, review process proceeds to the next step, at the Coordination Meeting.

Background functions must also be considered for the resilience assessment. In this organizational process, they play a major role as a source of variability with respect to the quality of their outputs, either from a precision/timely (P/T) perspective or from a complexity (C) perspective. Table 3 gives further detail on background functions and quality of their outputs and Table 4 relates background functions and functions of subprocess 2 with respect to their aspects (I – input, P – precondition, R – resource, T – time, and C – control).

Table 3. Background functions and their outputs

Function	Output	Description
0.1 Manage project	Pressure upon review schedule (C)	Determined by Project Manager's expertise and approach to the team. A healthy pressure may lightly damp variability (-1), whereas lack of expertise or excessive pressure may amplify variability (+2 or +3).
	A. Project Review Plan (C)	Project Review Plan has little effect over the process, although it establishes a schedule and enlightens stakeholders with respect to their roles and responsibilities, which may be regarded as a low damp factor (-1).
	B. RC members expertise (C)	Depending on the expertise of the invited members of RC, good knowledge of the industry or with past similar projects damp variability (-1 or -2), whereas lack of expertise or knowledge of the subject of the review, or even the review process itself, may be a factor that amplifies variability (+1 or +2).
1. Prepare review	C. Initial list of evidence (P/T)	Usually delivered on time (D, -1). If project manager is unexperienced or do not pay attention to producing the evidence prior to the milestone, then output quality may be imprecise (H, +2).
	D. Signed confidentiality agreements (P/T)	Usually, delivered too late. There is no record of inappropriate output, which would mean RC member would not take part in the process. (F, +1).
	E. Data package ready for distribution (P/T)	Usually, delivered on time, but not usually precise, because typically there is a need to add new information to the initial data package (E, -1). Level of access may couple and delay the distribution (F, +1).
0.2 Plan project	Documentation level of access (C)	R&D projects at IAE usually are classified and this adds complexity to the process, especially regarding data transmission. Medium or high potential to amplify variability (+2 or +3).

5 Improving the Process Resilience

5.1 Step 3: Aggregating variability

After steps 1 and 2, step 3 will aggregate variability and step 4 will propose ways to manage variability. Once it was possible to monitor one round during the Project IFF Mode 4 NSM Mission Definition Review, one of the scenarios for aggregating variability will be the work-as-done. Other four scenario will be considered, using two variables: Project Manager expertise, which impacts output of background function 0.1, and RC members expertise, which impacts output B for background function 1. "Prepare Review". Both variables will have a "best-case" and a "worst-case" scenario. For instantiation where both are "best-case" scenario, a "worst-case" scenario will be added for level of access, adding more complexity to the process through output of background function 0.2. Table 5 gives all five instantiations scenarios and Table 6 gives relative scores with respect to potential for damping or amplifying variability for each scenario. Using the variability aggregation method as in section 2.3, scores were propagated through the functions and the results can be seen in Fig. 8.

Table 5. Instantiation scenarios

SCENARIOS	PM expertise & attitude		RC expertise		Level of access
	BEST	WORST	BEST	WORST	
WAD	WORK AS DONE				
Scenario 1		X		X	REGULAR
Scenario 2	X		X		HIGH
Scenario 3	X			X	REGULAR
Scenario 4		X	X		REGULAR

Table 6. Scores for the instantiation scenarios

Function / output		Scenario				
		WAD	1	2	3	4
0.1	Schedule pressure	2	3	-1	-1	3
1.A	Review plan	-1	-1	-1	-1	-1
1.B	RC expertise	-1	2	-1	2	-2
1.C	Initial data list of evidence	1	2	-1	-1	2
1.D	Confidentiality agreements	1	1	1	1	1
1.E	Data pack ready	1	1	1	1	1
0.2	Level of access	2	2	3	2	2

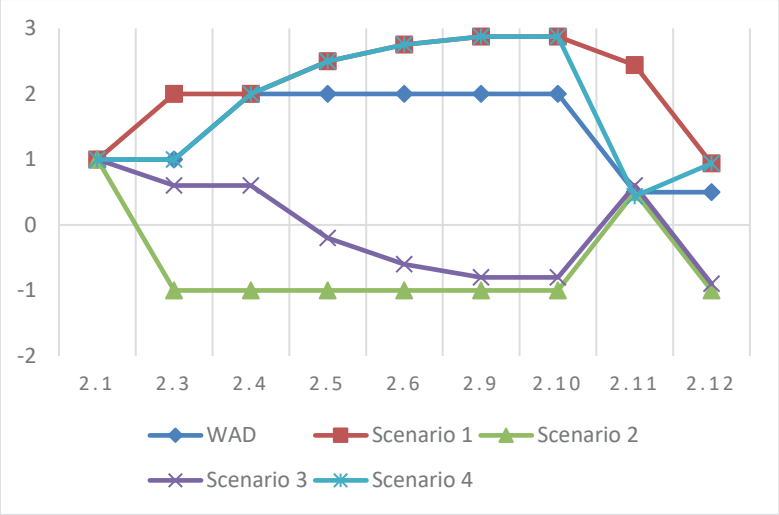

Fig. 8. Aggregation of variability and propagation through the process

5.2 Step 4: Managing variability

From the results in Fig. 8, three main findings may be drawn. Firstly, the results from the WAD scenario reflect how the process was performed. As stated in section 4.2, there was little interaction after comments and questions were replied by the PRT. This was partially due to the comments being issued with precision, but too late (F, +1), which is exactly the model quality output for function 2.3. Functions downstream were performed out of time or not even performed, which is in accordance with the results given by the model.

Secondly, Comments and Questions Register (CQR) consolidation is an event with a clear deadline, given by the Review plan, and is a pre-requisite to execute the Coordination Meeting, a mandatory event within the process. Output quality score of function 2.12 drops in almost every scenario (except in scenario 4), which was expected.

Output quality +1 may indicate issues with precision, which can be translated into information quality. This is the case for both scenarios in which RC expertise is at worst-case scenario, and, hence, justified.

Finally, the Project Manager attitude and expertise play a major role in the variability aggregation. A skilled, well-trained project manager, with a good attitude, will cope with adjustments necessary after planning is done and help their team towards meeting the process objectives with more ease. This impacts other functions, mostly related to the Project Management processes, such as risk management and leadership, which will keep team motivation and readiness levels high. If, on the other hand, the project manager is unexperienced, lack of attitude or puts too much pressure on their team, variability will be amplified, as seen in scenarios 1 and 4. This last conclusion could have been found in other sources that discuss the role of the project manager and good project management practices [4, 28-29], but it shows that the model gives results that are coherent with the main bodies of knowledge.

In order to close step 4 and the whole FRAM analysis, there are two actions which are suggested to manage variability. Firstly, to provide better training and environment for Project Managers. Well trained PM can manage their own team and to oversee the whole process from both project management and systems engineering, which will help them to increase the whole Systems Engineering process resilience. Also, good PMs will allow room for small adjustments to the original plans, should things work differently than expected (which they do). The second action, which is coupled to the first, is to give clearer instructions to participants within the project review process. This will help participants to clearly understand their roles and responsibilities, especially those external experts invited to the Review Committee, who may not be familiar with the whole review process. Resilience principles, however, must be considered: there must be room for small adjustments whenever they arise.

6 Conclusion

After going through the four steps of FRAM, plus its step 0, the project review process may now have its resilience improved by the findings of the last step, such as investing in Project Management qualification and providing an environment where project may adapt within the circumstances of their execution, therefore reaching the work's objective as stated in the Introduction. The Functional Resonance Analysis Method, although imagined to modelling social-technical problems, proved to be fit to model an organizational problem and provided interesting insights that are coherent with good practices, such as investing in Project Managers' training and career, in order to improve their capability to cope with variability, and establishing clearly to participants their roles and responsibilities. Everyday work is subject to variability and minimal adjustments, so it is important to determine ways to manage this variability and avoid resonances that would crush system stability.

For future works, it would be interesting to expand the scope of the analysis and assess relationship between Systems Engineering and Project Management processes, respectively product and project life cycle management tools. In an organization such

as IAE, technology development projects are its day-to-day operations, which are subject to variability, and may have its resilience improved with the help of FRAM.

Medios de pago electrónicos y evasión tributaria: el caso argentino

Florencia Verónica Pedroni[1][0000-0002-8896-4001], Gabriela Pesce[2][0000-0003-4043-5503], Anahí Briozzo[3][0000-0002-7865-2821]

Resumen. Este trabajo compara los costos de medios de pago e impositivos asociados a ventas cobradas bajo diferentes modalidades (efectivo, medios bancarios y billeteras virtuales) y sensibiliza estos resultados ante incrementos de actividad o subdeclaración de ingresos. Metodológicamente se efectúa un análisis de caso simulado (microempresa de Bahía Blanca, Argentina) para dos regímenes tributarios: general y simplificado. Para ambos tipos de contribuyentes, el efectivo, el envío de dinero mediante billeteras virtuales y las transferencias son los medios de pago más económicos; mientras que las tarjetas de crédito, el *point* y el *link* de pago resultan los más onerosos. En términos relativos, la empresa adherida al régimen general afronta menores costos por medios de pago y mayores costos tributarios, respecto a la suscrita al régimen simplificado. La subdeclaración del 30 % de los ingresos en efectivo reduce a la mitad los costos impositivos por peso de ventas. El principal limitante a la adopción de medios electrónicos de pago en firmas pequeñas se asocia a la informalidad y no a los costos de transacción.

Palabras claves: informalidad, costos de transacción, regímenes tributarios.

1 Introducción

En la actualidad, a la tradicional opción de cancelación de una transacción en efectivo, se suman diferentes medios electrónicos de pago[1] cuya variedad y nivel de utilización experimentan desde hace tiempo un importante proceso de crecimiento, en algunos casos debido a la obligatoriedad de uso establecida por organismos fiscales. Dichos medios pueden ser bancarios -integrados por las modalidades más clásicas como las transferencias y las tarjetas de débito y crédito- o no bancarios –constituidos por las

[1] Este trabajo analiza diferentes modalidades de cobro. Sin embargo, se emplea el concepto "medios electrónicos de pago" por ser la terminología más difundida y utilizada por el BCRA, entendiéndose como inclusiva de formas electrónicas de pago o cobro. Asimismo, los adjetivos electrónicos, digitales y virtuales se emplean como sinónimos en el presente manuscrito.

alternativas ofrecidas por las billeteras virtuales: *link* de pago, envío de dinero, *point*, código QR (del inglés *Quick Response code*). La multiplicidad de opciones existentes para el pago de las operaciones implica una tarea adicional –tanto por parte de compradores como de vendedores- de evaluación de los costos y las ventajas de cada medio electrónico, y su comparación con el tradicional efectivo, a fin de optar por el más conveniente o acorde a las necesidades.

Si bien la comparación de los medios de pago disponibles puede parecer una tarea sencilla, la complejidad del análisis radica en la cantidad de factores que intervienen y la interacción entre ellos. En primer lugar, cada medio de pago conlleva costos y beneficios asociados. Las ventas en efectivo tienen bajos gastos directos, mientras que las cobradas por modalidades electrónicas implican mayores costos de transacción, pero permiten incrementar los niveles de actividad si se combina con operaciones *online*. En segunda instancia, adquiere importancia el componente impositivo porque, dependiendo de la tipología tributaria del contribuyente, los impuestos se calculan luego de deducir los gastos financieros de la modalidad de pago y, adicionalmente, ciertos medios electrónicos están sujetos a regímenes de retención.

Como tercera cuestión, en un país donde cerca de un tercio del Producto Bruto Interno (PBI) se genera en las sombras [1] y con bajos niveles de educación financiera de la población [2], resulta difícil desalentar el uso del efectivo para la instrumentación de transacciones, por tratarse de un medio de que es fácil de usar y difícil de rastrear [3]. Esta situación agrega al análisis un factor adicional: la flexibilidad que brinda el efectivo a fines de evasión tributaria por subdeclaración de ventas. Incluso, la evaluación se complejiza aún más porque los tres aspectos mencionados (costos de los medios de pago, impositivos[2] y ahorro fiscal por subfacturación) dependen a su vez del régimen tributario al que pertenece el contribuyente.

Además, es necesario destacar que la irrupción de la pandemia causada por el COVID-19 y las medidas de aislamiento social dictadas en consecuencia, han provocado importantes transformaciones en los factores descriptos anteriormente: se produjo un incremento exponencial del comercio electrónico y de los medios de pago digitales; y, al mismo tiempo, se redujo el uso de efectivo tanto por razones vinculadas a la modalidad de venta (plataformas en línea) como por cuestiones de higiene.

Como se describe en los párrafos precedentes, la relación entre medios electrónicos de pago, aspectos impositivos, preferencia por el efectivo, e informalidad empresarial es compleja y la interacción entre sus componentes resulta afectada por la actual pandemia. En este contexto, el presente artículo tiene por objetivo comparar los costos de medios de pago e impositivos asociados a ventas cobradas bajo diferentes modalidades (efectivo, medios bancarios y alternativas ofrecidas por billeteras virtuales) y sensibilizar estos resultados ante incrementos en el nivel de actividad o subdeclaración de parte de los ingresos. En especial, se examinan tales costos para los distintos regímenes tributarios vigentes en la Argentina (general y simplificado). Metodológicamente se trabaja sobre un estudio de caso simulado representado por una microempresa de la industria alimenticia de la ciudad de Bahía Blanca y, a partir de una serie de parámetros

[2] A lo largo del trabajo el adjetivo impositivo se emplea como sinónimo de tributario, siendo inclusivo de los diferentes tipos de tributos: tasas, impuestos y contribuciones.

y supuestos, se estiman los costos y resultados netos de 11 medios de pago diferentes para dos tipologías tributarias: responsable inscripto (RI) y monotributo (MT).

El artículo se considera de relevancia pues representa un análisis microeconómico desde la perspectiva de la oferta de los aspectos vinculados a la implementación de los medios digitales de pago considerando: sus costos -en relación al uso efectivo-, los aspectos impositivos, los beneficios esperados por el incremento de la actividad y los niveles de declaración de ingresos de la compañía. Si bien se reconocen investigaciones sobre el tema, se trata de análisis macroeconómicos realizados en el contexto europeo. Según tales estudios la tasa de penetración de los métodos de pago electrónico se relaciona de negativamente con la economía informal [3] y de forma positiva con el crecimiento económico global [4-5] o la actividad macroeconómica en la región europea [6]. Incluso se verifica que la crisis financiera de 2008 y el nivel de informalidad de un país son factores que potencian el vínculo positivo entre métodos de pago y PBI [6].

Además de este apartado introductorio, el trabajo se estructura como se describe a continuación. En la sección 2 se exponen los conceptos referidos a formas de venta, medios de pago e informalidad empresarial y se analiza la relación entre los mismos. En el punto 3 de metodología se explica el diseño del caso de estudio y se listan los parámetros y supuestos usados para calibrarlo. En la cuarta sección se exhiben los resultados descriptivos para cada sujeto tributario estudiado y los correspondientes análisis de sensibilidad. Finalmente, en las consideraciones finales se sintetiza la evidencia obtenida, se discuten sus implicancias y se plantean futuras líneas de investigación.

2 Marco de antecedentes

2.1 Formas de venta, medios de pago e informalidad empresarial

Existen cuatro modalidades de concretar operaciones de compra venta dependiendo de la combinación del contexto (presencial, *online*) y del medio empleado para cancelar la transacción (efectivo, electrónico). La distinción entre las opciones se origina en dos cuestiones. Por un lado, el uso de un espacio físico o virtual para el encuentro entre vendedores y compradores e implica –bajo la modalidad *online*- la posibilidad de atender un mercado más amplio no limitado al lugar de emplazamiento del negocio, asumiendo costos logísticos. Por otra parte, el segundo factor diferencial corresponde al medio de pago/cobro usado y representa el objeto de interés este estudio: comparar los costos y resultados asociados a distintas modalidades de cobro y sus efectos tributarios.

Todos los instrumentos de pago tienen costos, aunque los vinculados al manejo del efectivo suelen ser subestimados o poco reconocidos porque dependen del volumen de ventas y no son tan visibles como los asociados a medios electrónicos. El empleo de efectivo conlleva costos de gestión originados en la infraestructura necesaria para el conteo de billetes y el registro de transacciones, que se suman a las potenciales pérdidas por robos, hurtos, errores y riesgo de falsificación [3]. Por su parte, en el caso de las modalidades electrónicas, aparecen costos de transacción como comisiones, mantenimiento de cuenta y alquiler de equipos, aunque dependiendo del medio digital utilizado también pueden generarse costos administrativos. Las transferencias bancarias o envíos de dinero mediante billeteras virtuales, por ejemplo, implican una tarea de seguimiento

entre la operación de compraventa y los fondos recibidos; mientras que los cobros con tarjetas, código QR, botón o *link* de pago requieren menores actividades de organización. Las retenciones impositivas -practicadas por las emisoras de tarjetas, administradores de billeteras virtuales o bancos en las liquidaciones efectuadas- también son un factor de peso al optar por una modalidad electrónica porque -si bien son un crédito impositivo- generan un costo financiero por inmovilización de los fondos retenidos.

Uno de los principales beneficios del uso de medios electrónicos de pago proviene del potencial incremento de operaciones, aunque ello depende de su combinación con modalidades de venta en línea y de factores externos como el nivel de penetración de las modalidades digitales en el contexto (país o región). El impacto de la pandemia en las cuestiones mencionadas se describe en la sección 2.2.

Respecto al efectivo, su utilización puede fundamentarse, siguiendo a Keynes [7], en la teoría de preferencia por la liquidez. Según ésta los individuos eligen contar con sus activos de forma accesible y líquida frente a otras posibilidades por tres motivos: transacción (tener el dinero en efectivo -en lugar de depositarlo en una entidad bancaria- facilita las operaciones básicas y cotidianas); precaución (para afrontar gastos imprevistos de diversos tipos) y especulación (mantener dinero en mano posibilita acceder a transacciones u oportunidades de inversión para obtener beneficios). Además de tales razones, su bajo costo y simplicidad, el uso del efectivo también puede vincularse al fenómeno de la informalidad empresarial dada la dificultad de trazabilidad de las operaciones respecto a las efectuadas por medios electrónicos. En este último caso las transacciones son susceptibles de ser verificadas por el cruzamiento de datos que realizan los organismos de recaudación con las entidades del sistema financiero.

La subdeclaración de ingresos en empresas registradas -o "informalidad parcial" [8]- representa una parte del sector informal y es al mismo tiempo una forma de evasión tributaria [9-10]. Para contextualizar el fenómeno, en el caso de la Argentina cerca de un tercio del PBI se genera en la informalidad [1]; mientras que estimaciones recientes indican que las tasas de evasión ascienden al 33,5 % en el Impuesto al Valor Agregado (IVA) y al 49 % en el Impuesto a las Ganancias (IG) [11-12]. Uno de los principales beneficios de la subfacturación radica en el ahorro fiscal obtenido sobre las ventas no declaradas, aunque también pueden mencionarse otras ventajas como la reducción de requerimientos burocráticos o el incremento de ventas por negociación de descuentos con consumidores finales. Asimismo, la informalidad genera ciertos costos: uso limitado de servicios públicos, dificultad de acceso al financiamiento, organización de sistemas de información desdoblados (operaciones registradas y no registradas), posibles sanciones en caso de detección, exposición a coimas de funcionarios, entre otros.

Parte de las exigencias normativas emitidas por los organismos fiscales de control apuntan a desincentivar las prácticas ilícitas de subfacturación e informalidad obligando a los contribuyentes a emitir comprobantes electrónicos y ofrecer medios de pago digitales. Por lo tanto, en algunos casos los medios de pago ofrecidos por las empresas responden al cumplimiento de una obligación formal y no a una estrategia comercial. En ese sentido, con un cronograma de adopción gradual iniciado en el año 2018, en la Argentina, la Administración Federal de Ingresos Públicos (AFIP) [13] ha generalizado la utilización obligatoria de factura electrónica y del controlador fiscal de nueva tecnología. Asimismo, en abril de 2018 finalizó la agenda de implementación que obligó a

todos los contribuyentes a contar con tarjeta de débito o algún medio electrónico de pago para operaciones de importe superior a $ 100 (pesos argentinos cien).

2.2 Impacto de la pandemia en las modalidades de venta y medios de pago

En el marco de la pandemia por COVID-19, la cuarentena y las medidas de aislamiento social, preventivo y obligatorio (ASPO) han acelerado el proceso de digitalización de las pymes, las cuales implementaron la venta en plataformas de comercio electrónico y el cobro *online*. Según el estudio de una consultora privada, el comercio electrónico en la Argentina registró un crecimiento en facturación del 84 % en el mes de abril -en comparación con un mes promedio del primer trimestre de 2020- y pasó de representar el 2 % de los ingresos por ventas de los negocios al actual 12 % [14].

Además del incremento del *e-commerce*, la pandemia motivó la reducción del uso de efectivo: si bien no existe evidencia médica de que el dinero transmita el virus, las percepciones de que los billetes puedan propagar los patógenos afectan el comportamiento de pago de usuarios y empresas [15]. Según una encuesta reciente de RTi Research en América Latina el 72 % de los consumidores prefiere el uso de tarjetas de débito, el 63 % elige tarjetas de crédito, mientras que el 44% opta por el efectivo [16].

De esta forma, la pandemia por coronavirus cambió significativamente el uso del *e-commerce* y fue un catalizador de pagos digitales tanto desde la oferta como de la demanda. De acuerdo a un estudio de Red Link, en abril de 2020 el Uso del Dinero Electrónico (UDE)[3] creció un 8,3 % respecto a marzo y un 19 % interanual [17]. Por su parte, según un relevamiento de la consultora D'Alessio IROL, durante el ASPO el 62% de los argentinos sondeados admitió haber aumentado el uso de pagos digitales. Las modalidades con mayor incremento fueron las tarjetas de débito (35%), las transferencias por *home banking* (31%), las tarjetas de crédito (22%) y Mercado Pago (17%) [16].

Desde el lado de la oferta, entre el inicio de la cuarentena y mediados de junio de 2020, se registraron 34.400 pymes que adoptaron alguna modalidad de cobro digital de Mercado Pago (web, código QR, *link* de pagos, entre otras) [18]. Específicamente, una de las formas de cobro *online* que más creció en dicha plataforma es el *link* de pagos: la cantidad de operaciones se duplicó en los días de ASPO y la cantidad de comercios creció 90 %. Por su parte, los pagos con código QR, que reducen el riesgo de contagio al evitar manipular billetes y tarjetas, también ganaron participación aunque en menor medida porque corren con la desventaja de la modalidad presencial, salvo cuando el código está en una plataforma digital o se envía por correo electrónico [19].

3 Metodología

3.1 Diseño del caso de estudio y métodos de análisis

Para abordar el objetivo propuesto se trabaja sobre un estudio de caso simulado representado por una microempresa de la industria alimenticia -con venta minorista a

[3] Uso del Dinero Electrónico (UDE Link) incluye los movimientos de dinero a través de cajeros automáticos, computadora o celular, y las diversas aplicaciones para operaciones financieras.

consumidores finales- radicada en la ciudad de Bahía Blanca, Buenos Aires, Argentina[4]. A partir de un conjunto de parámetros y supuestos predefinidos (descriptos en la sección 3.2), se efectúan dos análisis. El primero de carácter descriptivo donde se estiman los costos y resultados netos mensuales de 11 medios de pago diferentes para dos categorizaciones tributarias: régimen general (Responsable Inscripto [RI]) y simplificado (monotributo [MT]). Tales estimaciones contemplan: los costos tributarios y de medios electrónicos de pago -incluido el costo financiero por inmovilización de retenciones- y los beneficios impositivos por subdeclaración de ingresos. Sin embargo, no se incluyen los costos de organización administrativa de cada modalidad de pago (se plantea un nivel de operación bajo, donde los costos diferenciales serían escasos o nulos), ni tampoco se cuantifican otros resultados asociados a la informalidad (por ejemplo, multas, coimas, ventajas por menores requerimientos burocráticos).

En segundo lugar, se realiza un análisis de sensibilidad de los resultados estimados ante dos escenarios: (i) un incremento en el nivel de actividad por la implementación de medios electrónicos de pago; y (ii) la subdeclaración del 30 % de las ventas en efectivo. El porcentaje de subfacturación se define considerando las estimaciones más recientes del fenómeno para la Argentina: en 2016 la economía no oficial representó el 28,65% del PBI [1]. No se contempla otra forma de evasión (como la sobredeclaración de costos). Las sensibilidades calculadas permiten conocer para cada medio electrónico de pago analizado cuál es el incremento de ventas mensual necesario -respecto al nivel inicial- para cubrir: los costos de la modalidad digital (S1); los costos del medio de pago y el ahorro fiscal por subdeclaración del 30 % de las ventas originales en efectivo (S2); y el ahorro fiscal por subdeclaración del 30 % de las ventas de base en efectivo (S3).

3.2 Parámetros y supuestos del modelo

Los medios de pago analizados son los vigentes a mayo de 2020 en la Argentina [20]: efectivo y modalidades electrónicas (Tabla 1). Para las alternativas bancarias[5] se consideran dos opciones: que estén asociadas a una caja de ahorro (CA) –sin costos financieros ni aplicación de tributos por débitos y créditos- o a una cuenta corriente (CC), sujeta a un costo de mantenimiento mensual de $ 559,04 neto de IVA (promedio 10 primeras entidades bancarias según BCRA [20]). En el caso de tarjetas, se estima un importe mensual neto de $ 880 por alquiler de la terminal POS (*Point of Sale*).

Para los medios no bancarios, se seleccionan las opciones y los costos de Mercado Pago por ser la billetera virtual con mayor penetración en la Argentina. El único cargo de la plataforma es una comisión variable que depende del momento de acreditación de las ventas y del medio de pago seleccionado dentro de la billetera electrónica. El *point* se adquiere por única vez y no tiene gasto de mantenimiento mensual. Los porcentajes de comisiones de medios no bancarios de la Tabla 1 se corresponden con la alternativa

[4] Encuadra como microempresa según los límites de ventas anuales por sector de la Secretaría de Emprendedores y de la Pequeña y Mediana Empresa. Se identifica a la firma con ubicación y sector porque los tributos provinciales y municipales varían entre regiones y por actividad.

[5] No se incluye el cheque porque se analiza una empresa con venta minorista a consumidores finales y su uso por parte de éstos no es habitual en la Argentina. Sin embargo, los costos del cobro mediante cheques se corresponden con los de transferencias en cuenta corriente.

de disponibilidad de los fondos en el momento y con operaciones al contado (excepto en el *link* de pago que admite tarjetas de crédito o Mercado Crédito).

Tabla 1. Tipos de medios electrónicos de pago y comisiones para el vendedor

	Descripción	Comisión
Bancario	Transferencias (TR)	0 %
	Tarjetas de débito (TD), acreditación en 48 horas.	0,9 %
	Tarjetas de crédito (TC) en 1 cuota, acreditación: 10 días hábiles (máximo).	2 %
No bancario	*Link* o botón de pago (LP) enviado por aplicaciones de mensajería, redes sociales o insertos en una web.	5,99 %
	POS móvil o POINT (PO): transferencias iniciadas por medio del deslizamiento de una tarjeta por un dispositivo lector que se conecta al celular.	3,49 %
	Códigos QR (QR): pagos mediante el escaneo de un código QR desde una billetera electrónica en el celular.	0,6 %
	Envío dinero (ED) a través de una billetera electrónica.	0 %

Fuente: Datos de BCRA [20] y Mercado Pago [21]

Tabla 2. Parámetros tributarios

	RI	MT
IG	30 % sobre el resultado después de intereses y amortizaciones	Impuesto integrado (categoría según ingresos anuales): 5.392,44 (H:1.739.493,79); 10.220,77 (J: 2.348.316,62); 11.741, 58 (K: 2.609.240,69)
IIBB	1,5 % sobre ventas netas	
Tasa SH	0,59 % sobre ventas netas	
IDCB	0,06 % sobre movimientos en cuenta corriente bancaria	
	Pago a cuenta IG	No es computable como pago a cuenta
Retenciones	IIBB: tarjeta crédito 1 %, medios no bancarios 0,5 %. IIBB bancarias: 1,5 %	

Fuente: datos obtenidos de AFIP [13], ARBA [22], Municipalidad de Bahía Blanca [23].

En función a la actividad definida, la empresa resulta alcanzada por los tributos y regímenes de retención exhibidos en la Tabla 2 que varían en función a su calidad tributaria. En el RI no se considera el IVA por tratarse de un tributo trasladable a consumidores finales, mientras que en el MT dicho impuesto (21 %) se adiciona a los gastos dada su imposibilidad de traslación. La alícuota del impuesto a los Ingresos Brutos (IIBB) comprende las actividades de producción de bienes listadas en el inciso D del código fiscal 2020 de la provincia de Buenos Aires; mientras que la tasa por inspección de Seguridad e Higiene (SH) representa la moda del rubro 31 de la ordenanza fiscal de Bahía Blanca (industrias manufactureras de productos alimenticios, bebidas y tabacos). El Impuesto a los Débitos y Créditos Bancarios (IDCB) se calcula en 1,2 % considerando que comprende tanto la recepción de los fondos (crédito) como su uso (débito). Las alícuotas de retención se seleccionan considerando una categoría de riesgo fiscal e incumplimiento medio. Como se explica en el marco de antecedentes, si bien las retenciones son un crédito impositivo implican un costo financiero por los fondos inmovilizados que se calcula tomando el promedio de la tasa Badlar diaria para el primer semestre de 2020 (28,7973 %) [20] y un lapso medio de inmovilización de 15 días al mes. El mismo tratamiento se aplica para el IDCB cobrado a los RI que se computan contra los anticipos mensuales del IG, suponiendo que la empresa cuenta con el certificado

MiPyME. A fin de simplificar el análisis, no se incluyen los costos asociados al sistema previsional: pago de autónomos en RI y aportes jubilatorios del MT.

Los valores de alícuotas impositivas, gastos de comisión, y demás datos son los vigentes durante el año 2020 y son netos de IVA. Además de los parámetros mencionados, el modelo considera los siguientes supuestos. La empresa:

a) tiene un nivel de ventas máximo en efectivo de $175.000 en MT y $ 315.000 en RI y solo puede aumentarlo empleando medios de pago electrónico (en casos de operaciones *online* los costos de envío y *packaging* están a cargo del comprador);
b) cobra el 100 % de las ventas bajo la modalidad indicada en cada caso, es decir, no hay combinación de diferentes medios de pago;
c) presenta un margen de ganancias sobre ventas del 60 %, calculado con el resultado antes de costos comerciales por modalidad de pago e impuestos;
d) tiene capacidad instalada ociosa por lo que puede aumentar sus ventas sin incremento de costos fijos, solo cambian los variables;
e) se financia únicamente con fondos propios: no hay intereses por deuda por solventar capital de trabajo;
f) exhibe unidad de administración y propiedad, lo cual implica que los beneficios y costos de la evasión recaen sobre la misma persona.

4 Resultados

4.1 Resultados descriptivos

Las tablas 3 y 4 exponen las estimaciones de costos y rentabilidades para cada medio de pago por tipología tributaria. Las estimaciones muestran que, para ambos sujetos tributarios, los **costos de los medios de pago** son nulos en el caso de efectivo, transferencia a caja de ahorro (CA) y envío de dinero mediante billeteras electrónicas (BE); y alcanzan su máximo cuando se trata del *link* de pago. El ordenamiento de las formas de pago en función a su costo encuentra a las transferencias en cuenta corriente (CC), códigos QR y tarjetas de débito como las menos costosas, y continúa con las tarjetas de crédito y el *point*. Si bien dicho ranking es independiente de la tipología tributaria, en términos relativos los costos son mayores para el MT, dada su imposibilidad de trasladar el IVA de gastos y comisiones.

Además de los valores, es interesante analizar la diferencia en cantidad y tipo de ítems que componen el costo según se trate de medios bancarios o billeteras virtuales. Estas últimas sólo contienen comisiones variables, a diferencia de los primeros que también incorporan cargos fijos mensuales por mantenimiento de cuenta o alquiler de equipos. La distinción es importante en el caso de emprendimientos que adoptan un medio de pago electrónico no para atender la demanda comercial, sino para cumplimentar una obligación formal. Si este fuera el caso, para ciertos niveles de venta resulta más rentable optar por un *point*, por ejemplo, respecto a una terminal POS.

Respecto a los **costos impositivos,** para el caso del RI representan un 19,64 % de las ventas (en promedio para los diferentes medios de pago), con valores mínimos de 18,31 % en el *link* de pagos y máximos de 20,11 % en las transferencias a CA y envío de dinero. El menor costo tributario en las modalidades con mayores costos obedece al

efecto de deducción de gastos financieros en la base imposible del IG. En el caso del MT, el costo impositivo medio asciende a 8,28 %, oscilando entre 7,93 % (efectivo) y 9,17 % (tarjeta de crédito en CC) y la moda en 7,95 %. Para el MT, las modalidades bancarias asociadas a CC son las que implican un mayor costo tributario porque el IDCB representa un gasto, a diferencia del RI que lo computa como un crédito. Por ello, excepto que utilicen cheques en su operatoria financiera, los MT debieran desestimar el uso de CC o reemplazarlas por CA para evitar el cargo por IDCB. De todas formas, los contribuyentes del régimen simplificado también cuentan con la posibilidad de solicitar reducción de alícuotas de dicho impuesto.

Tanto para el RI como para el MT, los costos tributarios incluyen el efecto de las retenciones de IIBB efectuadas por quienes acreditan los fondos que, si bien son un crédito impositivo, se incluyen pues implican un resultado negativo generado por la inmovilización de los importes retenidos. Incluso tales costos pueden ser mayores que los estimados, en los supuestos de empresas que tienen saldos impositivos a favor (por lo que no hay deuda contra la cual computar el crédito y por ende es mayor el plazo de indisponibilidad de los fondos) o no categorizan como mypymes (estando sujetas adicionalmente a regímenes de retención de IVA e IG).

En especial, los resultados del ítem tributario muestran la notable diferencia de onerosidad entre el régimen general y el simplificado: los costos impositivos para el MT representan menos de la mitad que para el RI. Ello responde fundamentalmente a la estructura del IG: en el caso del RI es un porcentaje sobre el resultado después de intereses y amortizaciones; mientras que en el MT es un monto fijo por categoría de impuesto integrado (IG, IVA). Esas diferencias también se observan en el total de costos de medios de pago e impositivos por peso vendido para cada sujeto tributario.

En relación a la informalidad, se observan dos situaciones. Por un lado, en un análisis dentro de cada tipología tributaria, se tiene un efecto directo por subdeclaración de ventas en efectivo que reduce a la mitad los costos tributarios del RI (de 20,09 % a 10,46 %) y en poco menos de la mitad los del MT (de 7,93 % a 4,54%). Es decir, una subfacturación del 30 % de las ventas en efectivo (respecto a la declaración del 100 % por el mismo medio) genera un ahorro por evasión tributaria del 9,63 % y del 3,39 % de los ingresos en los RI y MT, respectivamente. Por otra parte, al comparar entre sujetos tributarios, se detecta un segundo efecto subyacente: el importante cambio de los costos impositivos para niveles de ingresos cercanos al punto de inflexión entre los regímenes incentiva la informalidad. Por ejemplo, si el MT bajo estudio incrementara sus ventas mensuales en más de $ 42.437 (un 24,25 %) quedaría categorizado como RI, con un aumento promedio del 11,36 % de sus costos impositivos. Es decir que incrementar su actividad en un 25 % aproximadamente, implicaría duplicar los costos tributarios por peso vendido (de 8,28 % a 19,64 %). En el mismo sentido, si el RI analizado -con un nivel de ventas mensual real de $ 315.000- subdeclarara más del 30,97 % de sus ingresos quedaría encuadrado como MT, reduciendo casi a la mitad sus costos impositivos.

4.2 Análisis de sensibilidad

La tabla 5 y la Fig. 1 muestran los resultados de los análisis de sensibilidad realizados. Los hallazgos para el S1 confirman los resultados descriptivos sobre los costos de los medios pagos. El *link* de pago es la alternativa más costosa y por ende requiere un mayor incremento de ventas para cubrir los costos asociados (11,80 % y 16,06 %, RI y MT en ese orden). Por su parte, la transferencia a CA y el envío de dinero -al ser las modalidades de menor costo- implican un escaso aumento de la actividad para afrontar su implementación (0,05 % y 0,03 %, RI y MT, respectivamente), que solo responde a cubrir el costo financiero por inmovilización de las retenciones. Estos resultados, junto con el ordenamiento de los medios de pago según S1, son semejantes para ambas categorías tributarias. Sin embargo, por la imposibilidad de trasladar el IVA de los gastos financieros, los coeficientes de sensibilidad resultan mayores en el MT, es decir, el RI necesita un menor incremento en las ventas para cubrir el costo de cada medio de pago (columnas celestes –S1 RI- son menores que las naranja claro –S1 MT- en Fig. 1).

Los valores mínimos y máximos de S2 (alto total de columnas en Fig. 1) corresponden a los mismos medios de pago identificados según S1, al igual que su ordenamiento. Sin embargo, en este caso, es interesante comparar los valores de S2 entre categorías tributarias (columnas azuladas versus anaranjadas en Fig. 1): los niveles de aumento de ventas que necesita el RI para cubrir los costos del medio de pago y el beneficio fiscal por evasión son sustancialmente superiores a los del MT. Incluso, las modalidades más económicas (transferencias bancarias, envío de dinero, tarjetas de débito vinculadas a CA o códigos QR) implican para el RI un aumento de facturación mensual que triplica el requerido para el MT; mientras que para las restantes alternativas ese incremento es del doble entre RI y MT (tarjetas de crédito, *point* y *link* de pago). La diferencia de S2 entre RI y MT es más alta en los medios de pagos menos costosos por el efecto del componente impositivo: es mayor el impuesto porque existen menos gastos deducibles de la base imponible del IG, entonces es menor el resultado neto y por ende se requiere un mayor incremento de ventas.

Tabla 5. Sensibilidades por categoría tributaria y medio electrónico de pago

Medios de pago		TR-cc	TD-cc	TC-cc	TR-ca	TD-ca	TC-ca	LP	PO	QR	ED
S1	RI	0,39%	2,50%	4,60%	0,05%	2,15%	4,24%	11,80%	6,57%	1,11%	0,05%

Nota. S1: incremento en ventas necesario para cubrir los costos asociados a la modalidad de pago y mantener el mismo resultado neto que cobrando 100 % en efectivo (sin evasión); S2: incremento en ventas necesario para cubrir los costos asociados a la modalidad de pago y mantener el mismo resultado neto que subdeclarando 30 % de las ventas en efectivo; S3= S2-S1 es el incremento en ventas necesario para cubrir solo los costos de la informalidad.

Fuente: elaboración propia

Por último, los valores de S3 expresan el incremento de ventas necesario para cubrir el ahorro fiscal "perdido" por la subdeclaración de ingresos que no posibilitan los medios de pago electrónicos, es decir, es el efecto puro de la evasión fiscal. Nuevamente los aumentos de actividad requeridos son más altos para los contribuyentes del régimen general. Este efecto diferencial de la informalidad para el RI respecto al MT, se refleja claramente en al comparar los tramos azules –S3 RI- y naranjas –S3 MT- de las columnas en la Fig. 1. La diferencia de magnitud entre tales secciones de las columnas muestra que el RI tiene muchos más incentivos a subdeclarar ingresos por los impuestos asociados linealmente al monto de ventas.

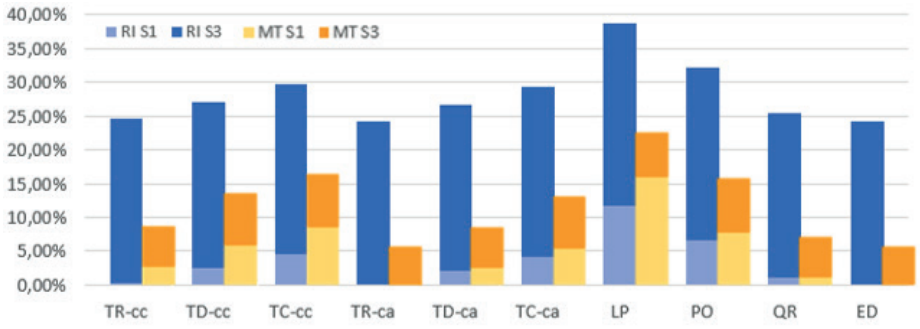

Fig. 1. Sensibilidades por categoría tributaria y medio electrónico de pago

5 Consideraciones finales

Además del efectivo, existen diversos medios electrónicos de pago cuyos costos son diferentes y, a su vez, impactan de forma disímil según la categoría tributaria de la empresa. En un esfuerzo por clarificar la relación entre modalidades digitales de pago, tributos e informalidad, a partir de un caso de estudio simulado, este trabajo compara los resultados asociados a 11 medios de pago para dos tipos tributarios (RI y MT), analizando la incidencia de la subdeclaración de ingresos sobre operaciones en efectivo.

Según los hallazgos, el ordenamiento de los medios de pago por su costo no varía entre RI y MT, aunque en términos relativos son mayores para el MT. El efectivo, el envío de dinero mediante billeteras virtuales y las transferencias a CA son los más económicos; mientras que las tarjetas de crédito, el *point* y el *link* de pago resultan los más onerosos. Asimismo, se destaca la importancia de conocer y evaluar la composición de los costos de medios bancarios y no bancarios a la luz de la organización del negocio y las disposiciones normativas vigentes a fin de seleccionar el más conveniente.

Analizando la onerosidad de los medios electrónicos de pago respecto al incremento de uso en el contexto de pandemia, se observa una tendencia al empleo de alternativas menos costosas (tarjetas de débito, transferencia, tarjetas de crédito, Mercado Pago [16]). Una excepción a esto es el *link* de pago por ser la modalidad de cobro que más creció en la plataforma [19] y en este estudio se reporta como la de mayor costo. Ello puede justificarse en que gran parte de las operaciones durante el ASPO fueron *online*, donde no existe la posibilidad de uso del *point* y el *link* resulta más cómodo frente a

otras opciones como el envío de un código QR. Sin embargo, su mayor uso también puede atribuirse a un desconocimiento de los vendedores de su costo.

Respecto los costos impositivos, la situación se invierte siendo mayores para el RI. En ese caso por la estructura del régimen, con porcentajes de IG vinculados a resultados, los medios de pago menos costosos derivan en mayores costos impositivos. Para el MT, las modalidades bancarias asociadas a CC son las que generan un impuesto más elevado, en especial por la imposibilidad de computar el IDCB como pago a cuenta de obligaciones fiscales.

En relación a la informalidad, el efecto directo muestra que una subdeclaración de 30 % de las ventas en efectivo reduce los costos tributarios en 9,63 % para el RI y en 3,39 % para el MT. Es decir, cuantitativamente y en términos relativos, los incentivos a evadir son mayores para el RI. Por su parte, el efecto subyacente indica la existencia de estímulos a subfacturar en niveles de ingresos cercanos al punto de inflexión entre los regímenes tributarios, evitando un cambio brusco en los costos por impuestos.

Todos los resultados descriptivos comentados, son confirmados y refinados por los hallazgos del análisis de sensibilidad: los incrementos de ventas necesarios para solventar los costos de los medios electrónicos de pago son mayores en el MT (S1), mientras que los incrementos de actividad requeridos para cubrir los gastos de modalidad digitales y el ahorro fiscal por subdeclaración son más altos en el RI (S2). Esto marca nuevamente la onerosidad del régimen general con su consecuente incentivo a mayor subfacturación. Incluso, analizando S3 respecto a S2 (Fig. 1), los resultados indican que el principal limitante a la adopción de medios de pago electrónicos en empresas pequeñas está mayormente asociado a la informalidad y no a los costos de transacción.

A nivel teórico, el estudio presentado contribuye a profundizar la comprensión del fenómeno de la evasión tributaria y el nivel de adherencia a los medios electrónicos de pago, colaborando con el diseño de políticas públicas tendientes a reducir la informalidad empresarial e incrementar la inclusión financiera en un contexto donde tales tópicos representan problemáticas actuales. Por ejemplo, podría pensarse en exenciones de IVA a MT sobre las comisiones por cobros electrónicos que desincentiven la informalidad y beneficien al Estado generando un potencial incremento de la recaudación fiscal. Desde el punto de vista práctico, los resultados del artículo resultan de interés para empresarios al momento de evaluar los efectos asociados a diferentes medios de pago.

Los hallazgos del presente trabajo provienen de un estudio de caso y, por ende, no pueden ser generalizados a empresas con actividades diferentes, radicadas en otros distritos o no sujetas a los supuestos del modelo. Además de tales limitaciones, puede mencionarse la falta de consideración de otros costos y beneficios asociados al fenómeno pero no cuantificados. Dentro de las futuras líneas de investigaciones se pretende estudiar los incentivos de los contribuyentes a la informalidad en el punto de inflexión entre los regímenes tributarios.

Abstract. Work design is being constantly transformed by technology and requirements for polyvalent workers piloting the work system instead of operating it. Performance no longer depends exclusively on working hours, but in multiple aspects that balance the vision of production systems results. The purpose of this paper is to investigate self-management teams' implementation and its effects on performance. A Brazilian cosmetics company case study of team development was used as a guidance for this investigation and company performance reports were the data source for descriptive statistics and multivariate analysis. Boxplot performance analysis was applied over team building stages along with One-way Variance Analysis to test average performance differences among stages' transitions. Tukey test was sequentially applied to identify its statistic differences in pairs. Results revealed team development reached the expected performance over team stages. Forming to storming, though, was the only transition with no performance average gains. Storming to norming was the highest improvement, which meets literature principles. The present research is limited to a single sociotechnical environment and performance measurement is based on average data. Therefore, specific conclusions imply further research to extend findings to other contexts. However, the present study identified empowerment best practices to achieve superior performance. The originality of this paper consists on providing consistent connection between team development theory and practice, exploring sociotechnical approach benefits through practices into performance.

Keywords: Work organization, Team performance, Self-managed teams, Empowerment.

1 Introduction

Work rationalization, born in the Classical School with Scientific Administration, indorsed critical specification for task execution, and little flexibility in the work posts. Taylor's organizational model consisted of a rigid hierarchy, that it was highly dictating specialized and standardized tasks (Weisbord, 2011; Batiz-Lazo, 2019). The

social scientist Elton Mayo was the first to reveal opposition to this work system. Hawthorne Experience, coordinated by the sociologist between 1924 and 1933, showed that Western Electric Company's productivity increased with the stimulus of social aspects in the work environment. The School of Human Relations contradicted Taylor's theory since it knocked down the preponderance of physiologic factors on the psychological ones (Zoller and Muldoon, 2019). Toyota's Japanese approach also brought revolutions when they started to consider the intellectual prospect of working members as a critical success organizational factor (Simonetti and Marx, 2010).

The models that came after Taylorism started to value the collective work, inside of activities that before were only mechanists. They tried to bring together the projection with the execution of tasks previously segmented by the classical approach (Joullié, 2018). Autonomous teams, however, presented a differentiation factor: the minimization of the hierarchical role figure, stimulating teams for high performance (Marx, 1997). The sociotechnical model was discovered, and subsequently, studied by Tavistock Institute researchers after observing the productivity's optimization in the English coal mines through self-management in 1949 (Salerno, 1994; Moreira and Marx, 2008).

Lee and Edmondson (2017) recently investigated current trends and expected benefits that motivate the development of self-managing organizations. Less-hierarchical organizations with employee empowerment initiatives stimulate brighter and faster responses in dynamic conditions. Also, Yin *et al.* (2018) argue that empowerment has been a mechanism to reduce traditional managing costs and proposed an economic perspective to explain how empowerment practices affect organizational performance indirectly through moderating the effect of the employee-employer exchange relationship.

The work with greater autonomy can increase productivity and work motivation providing competitive advantage for organizations (Manz and Sims, 1996). The implantation of autonomous teams according to the sociotechnical model, however, involves great and challenging organizational changes (Salerno, 1994). The introduction of these teams requires a new style of leadership and designates greater responsibilities to workers, and not everyone is willing to work in teams. The implementation of these teams is usually of medium to long term and involves high costs, demanding deeper organizational changes and there is not always a consensus between the hierarchies for political changes (Marx, 1997; Cunningham and MacGregor, 2000). Moreover, autonomy degrees must be consistent with strategic goals (Olsson and Bosch, 2018).

Based on the problems related to the organizational challenges of this work model described above, the following research question is proposed for this paper: Can self-managed teams bring performance improvement? A case study is used as a guidance for this investigation. The case study's company introduced sociotechnical work teams willing to reach high performance and this paper explores its approach with performance improvement over team-building stages. Therefore, this paper presents a meaningful relationship between team empowerment theoretical principles and practice.

2 Literature review

This section explores theoretical background of teams in three dimensions considered relevant to this paper: team building, empowerment and team performance measurement.

2.1 Team Building

Widely known as an effective team building design for the educational setting (Riebe *et al*., 2010; Aydin and Gumus, 2016; Weber and Karman, 2017), Tuckman approach (1965) remains famous for team development model and it is still known for its four-sequential stages (Kur, 1996; Largent, 2016; Manges *et al*., 2017). Forming is the first interaction of team members, when they become familiar with each other and try to find out which behaviors are acceptable regarding their tasks, feeling confused on how to act and unsure about the benefits of team participation. There is suspicion, fear and anxiety on the onward work and the common goal supported by the formed team. At storming stage, members start to show resistance and hostility towards each other and conflicts are often caused by miscommunication, what may lead them to disbelief in the collective power. These problems begin to be solved at norming stage, when the whole team effectively learn how to work together and internal differences are overcome. The focus on tasks, interpersonal relationship and mutual identification among members are fortified. Finally, performing stage comes and the responsibility shared is intensified, together with creativity and the expected productivity. Mutual cooperation and team self-identity provide exceptional results (Tuckman, 1965).

Tuckman and Jensen (1977) formally extended the original model and added a fifth stage, adjourning, to provide opportunity for acknowledgements. Since then, the model was studied, applied and successfully validated in many team development fields, remaining strongly accepted (Largent, 2016; Aydin and Gumus, 2016; Manges *et al*., 2017). An Indonesian research has recently used Tuckman model as a theoretical reference to investigate virtual team performance of Binus University e-learning student's capability of solving teamwork problems (Siregar *et al.*, 2018).

Manges *et al*. (2017) successfully used the model in the healthcare environment as a guiding framework to improve safe patient care delivery. Nurse leaders' behaviors changed over Tuckman stages and were critical to build high performance teams. At the performing stage, nurse leaders no longer coordinated team actions and focused mainly on empowering members that developed shared leadership in the work design.

Kuhrmann and Munch (2016) highlights Tuckman theory's importance and argue that project managers must be familiar with the theoretical stages because they do not only start during project beginnings, but also when new members join team projects. The authors applied group dynamics with graduate students at Munich Technical University and Blekinge Institute of Technology and reinforced the premise that performance drops after changing teams. Conjointly, the dynamics revealed that time pressure, team size and missing strategies are the factors that mostly impact performance while task complexity and communication aspects affect work efficiency. Additionally, Largent (2016) reinforces Tuckman pattern that team's skill level rises

over time and team enthusiasm starts high, drops and then returns to a high level. The author also emphasized the importance of team ability to recognize the team current stage because this awareness can provide knowledge to understand team progress and distinguish between normal and abnormal difficulties along team development.

On the other hand, Tuckman's model was also challenged by some researchers. Kur (1996) complemented that company teams can possibly transit from one stage to another during work execution. Miller (2003) argued that complex teams do not follow the linear team building performance suggested by the psychologist researcher. Rickards and Moger (2000) also criticized the theoretical model, claiming that not all teams go through all stages. According to the authors, storming stages can possibly never end and teams become dysfunctional, failing to pass a weak behavioral barrier before norming. Even though most teams overcome the weak barrier, fewer teams pass the strong performance one and do not achieve exceptional performance.

A similar model of team development was additionally proposed by Katzenbach and Smith (1993), projecting a performance curve that losses up to the team complete formation, integration and alignment of the members. Therefore, formation phase will undoubtedly need more time than a group run by a single leader to reach a desirable performance. According to Katzenbach and Smith (1993) it happens because a real team demands more from its members and team formation phase tends to be less effective. Formation requires difficult adaptation periods in the level of sharing experiences and distinct knowledge among members can bring disagreements and competition. Learning requires trust, as well as trust promotes learning. Therefore, learning and trust are not earned in a short period and only over time inevitable conflicts are solved.

Staniforth (1996) claims that many organizational practices and systems are more aligned to individuals, which inhibits team maturity growth and consequently teamwork performance. Castka *et al*. (2001) grouped successful factors of high performance teams implementation into two categories and seven subgroup categories: I) system factors: organizational impact; alignment and interaction with external entities; performance measures and defined focus II) human factors: knowledge and skills, individual needs and group culture.

2.2 Empowerment

High performance companies depend on internal policies and capabilities (Okoshi *et al*., 2019). Empowerment practices allow coworkers to gather relevant information from each other and prompt employees to work as teammates, which reduces communication and coordination costs. Unlike ineffective authority, autonomy can lead self-managed teams with consistent knowledge shared to make better decisions, contributing to organizational performance and reducing monitoring high costs (Yin *et al*., 2018).

Idris *et al*. (2018) found empirical evidence that employee empowerment strengthens job satisfaction for Malaysian capital local workers. Potnuru *et al*. (2019) recently identified that organizational learning culture remarkably influences the relationships of team building and empowerment on employee competencies in Indian cement

manufacturing companies. Another interesting finding is the interrelationship between enabling management controls and staff empowerment and their mutual beneficial effects on performance in Australian companies (Baird *et al.*, 2018).

Jian'an (2008) discussed how to build self-management teams through empowerment, proposing pushing and pulling power strategies to achieve the desired dynamic equilibrium between supply and demand of power along team evolution. Empowerment advances gradually with time, maturity and experience, consequently benefits are only obtained in long-term. Strategic guidance is a requirement to optimize business performance through previously established autonomy levels that meets organizational specific ambitions (Olsson and Bosch, 2018). Autonomy degrees are often low during team forming stage and increases along team life cycle, exerting influence on outcomes (Hess, 2018).

Even though moving away from a traditional hierarchical design is a demand, most organizations persist to inhibit and limit employee's participation and empowerment skills and shifting responsibilities are impossible if leaders at every level are not truly committed to empower their subordinates (Huusko, 2006; Attaran and Nguyen, 2000; Horner, 1997).

According to Hess (2018) and Brower (1995), hierarchy must be limited to offer only guidelines as well as the confidence required to work execution and autonomous team members' expectations for top leader involvement must be aligned with previously established empowerment degrees consistently further reinforced to ensure perceptions that autonomy given is a real purpose and not purely symbolic.

In order to accelerate autonomy progress, empowerment practices must be adapted. Some approaches are commonly implied, such as training development plans for motivation and knowledge improvement, along with performance assessments connected to the organizational learning programs (Brower, 1995; Holt *et al.*, 2000; Potnuru *et al.*, 2019). Employees' strengths must be intensified instead of focusing on their weaknesses, because complementary team members' skills compensate individual flaws to achieve common goals (Margulies and Kleiner, 1995). In addition, clear goal statements through effective communication channels are meaningful. Targets and decisions must also be appraised by managers to ensure that commitment and efforts are focused on expected directions. Performance results, acknowledgments and rewards must be afforded not only to individuals, but also to the whole team, to reassure teammates take responsibility for each other's performance. (Brower, 1995; Elmuti, 1997; Conti and Kleiner, 1997). In conjunction with open and frequent communication, all-inclusive recruitment and consistent resource allocation are other preconditions to be granted to autonomous team members (Hess, 2018).

2.3 Team performance measurement

Teams with greater autonomy demand performance measurement indicators to appraise autonomy progress and results achieved over time (Marx, 1997). In order to build high performance teams, it is exceedingly indispensable that team members are acquainted and in total consonance with the chosen performance measurement system. According to Aguinis (2013), there are some fundamentals for team performance

assessment. Firstly, it is essential to ensure that teams are actually teams sharing common goals and not simply small groups with individual targets. Secondary steps are the investment in measurement structures and clear establishment of performance goals. Further, the selection of multiple appraisal methods focused on processes as well as outcomes and, finally, long-term changes are assessed.

Macbryde and Mendibil (2003) propose a four dimensional model for team performance measurement. I) team effectiveness, the dimension which process' results satisfy team stakeholders; II) team efficiency, the dimension in which internal processes support the achievement of process outcomes; III) learning and growth, which consists on monitoring team progress. Some features of this assessment involve transferable skills, documented learning, best practices, tools, methods, process improvement and team innovation potential; IV) satisfaction of the members, which implies motivation and personal fulfillment measurements, quantifying how teamwork contributes to the growth and personal well-being of each teammate.

Work designs, team composition and direct or indirect factors influencing high performance are widely explored by researches to support team cohesion theories (Ferreira *et al.*, 2012; Wilsher, 2015; Moura *et al.*, 2019). Rezvani *et al*. (2019) recently applied partial least square regression analysis on construction project teams' surveys to measure emotional intelligence relationship with team performance. Emotional intelligence and trust as a mediate factor were positively related to team performance, while conflict mediate factor presented a negative relation. The study implies that relationship conflicts could be diminished, and trust can be reinforced by improving emotional intelligence to reach performance enhancement. Cha *et al*. (2014) also used the same statistical methodology with developed surveys based on literature to support member's psychological proximity has a critical effect on team performance.

Jaca *et al*. (2013) applied a teamwork effectiveness measurement structured by survey to investigate key performance factors employing Input-Mediator-Outcome methodology (Ilgen *et al*., 2005; Mathieu *et al*., 2005). Independence, autonomy, internal leadership, conflict management were some common highly rated and constantly measured in healthcare and manufacturing distinct environments.

Team performance measurements have been also consistently worked out to test work designs involving leadership styles to evaluate optimizing performance structures. Ciasullo *et al*. (2017) measured effectiveness, efficiency and satisfaction of members dimensions to compare a traditional top-down with a hybrid bottom-up team building approach. The authors used not only lead-time, an organizational performance indicator, but also applied external and internal surveys to quantify both, customer and employee's satisfaction. Bottom-up team development performed better across all three dimensions of this integrated performance assessment. Yang and Choi (2009) also identified that empowerment elements influence on team performance through linear regression.

Han *et al*. (2017) have indirectly explored some dimensions suggested by Macbryde and Mendibil (2003) in a survey research, testing the effect of shared leadership on team perceived performance. Statistical analysis performed have supported shared leadership indirectly increases performance through stimulating knowledge share, commitment to goals and activity coordination as team mediate factors. Complemen-

tary, Müller *et al*. (2018) have also found that shared leadership positively affects team performance on a laboratory team decision-making exercise. Statistical analysis showed not only that sharing leadership brought quality improvement, but also perceived task complexity strengthens this effect. Even with constant complexity, when recognized as harder tasks, shared leadership was intensified and fewer errors were made in work execution.

3 Research Design

This paper presents a case study of team building, introduced by a cosmetics Brazilian company with the purpose to reach higher performance with the development of shop-floor self-managed teams. Empowerment practices with technical and behavioral trainings were provided to gradually achieve the desired team autonomy degrees over time. This research consists on measuring quantitative team performance over team building stages and evaluate the team development project, that was segmented by five learning levels. These five progressive stages structured by the company, presented by Figure 1, involved all factory teams and each level was planned to last the period of a year. Leadership left coordination role and gradually started to act as internal coachers and consultants, limiting to provide only generic directions along with confidence for members to accomplish autonomy. An important procedure followed by the company is that, for each stage advancement, besides the mandatory approval after trainings, auditing carried out to reassure that behavioral and professional improvement were successfully achieved to certify team breakthrough.

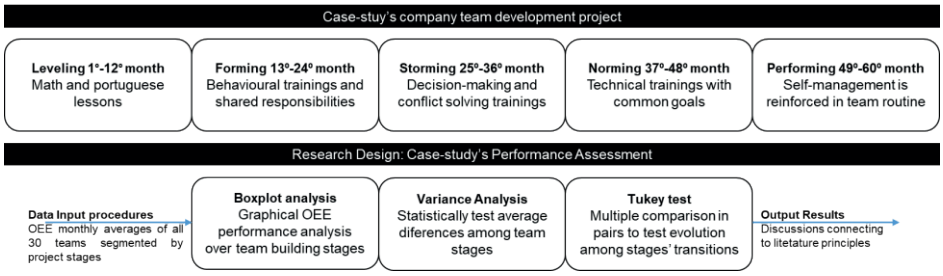

Figure 1. Research Design.

Quantitative performance reports provided by the company at the end of the project were the original data source for all the analyses. The main shop-floor performance indicator, overall efficiency, was chosen for the assessment. Overall line efficiency is measured through the formula Availability x Performance x Quality and team evaluation was applied by project consultants and team leaders. This indicator considers three percentage target dimensions, which only good parts are produced (100% quality), at the maximum cycle time speed (100% performance), and without equipment interruption (100% availability). Since the purpose is generic conclusions, team performance data of all 30 developed teams, were converted to monthly performance averages as a single team for all the following analyses described below.

1. Boxplot with all stages of overall efficiency's performance in a single chart was applied to graphically analyze performance over team learning stages.
2. One-way variance analysis was applied to statistically test performance average differences among team stages.
3. Tukey test was applied to test overall efficiency's multiple comparison in pairs to test performance evolution analysis between stages' transitions.

The performance assessment exhibited by Figure 1 was applied in academic environment to evaluate performance enhancement with the new intended work design and consequently answer the research proposed question regarding the ability of self-managing teams to bring high performance.

4 Results

Overall efficiency exhibits wide-ranging performance evolution over the stages, presented by Figure 2. It is perceptible forming to storming is the only particular distinguishable transition that did not present considerable difference in the average values. Performance staunchly had its greatest increase at storming to norming and repeatedly had another breakthrough at performing stage, when overall efficiency data is more concentrated, reaching persistent performance stability.

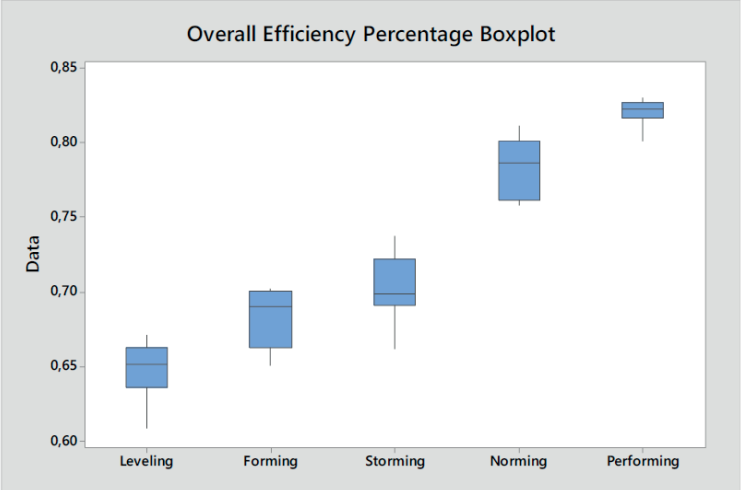

Figure 2. Boxplot analysis.

Performance behavior presented in boxplot reinforces some literature principles further explored in discussion section. Boxplot method provided graphical evolution overview, summarizing each stage's enhancement along team development. A single-factor variance analysis for overall efficiency was sequentially appropriate to test significant average difference among stages. Table 1 details the hypothesis test, performed with 95% confidence interval for this analysis.

Table 1. Hypothesis test.

Method	
Null hypothesis	All Means are equal
Alternative hypothesis	Not all means are equal
Significance level	α = 0,05
Equal variances were assumed for the analysis.	

Factor Information		
Factor	Levels	Values
Factor	5	Leveling; Forming; Storming; Norming; Performing

Analysis of Variance					
Source	DF	Adj SS	Adj MS	F-Value	P-Value
Factor	4	0,24884	0,062210	184,25	0,000
Error	55	0,01857	0,000338		
Total	59	0,26741			

Before conclusions, test premises were challenged. Since residues showed a large adherence to the standard normal distribution and residual variances were approximately equal, premises were ratified. Considering a 95% confidence level, H0 was rejected, since p-value < 0.05. Therefore, statistical evidence of significant average difference for at least a couple of overall efficiency's stages was found. Tukey's test was then conveniently useful to test average differences between stages in pairs, presented by Figure 3.

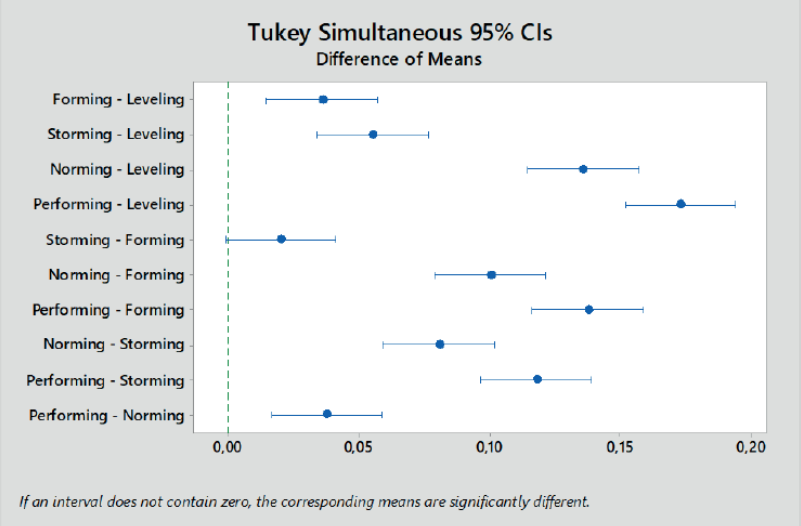

Figure 3. Tukey test.

By means of the 95% confidence interval for differences between averages, Tukey's test showed that only forming to storming stage had no significant difference, as

suspected upon boxplots descriptive analysis. In addition, it also implied a respective improvement for all the other transitions compared in pairs since the difference is always positive, hence, it essentially diagnoses overall efficiency gain over all other transitions, except forming-storming.

5 Discussion

The training development approach adopted by the company to introduce team development matches Tuckman's initial model (1965). The autonomy given was previously planned to attend organizational demands as highlighted in literature by Olsson and Bosch (2018) and autonomy was initially low (Hess, 2018). Both initial Boxplot and Variance Analysis approaches imply performance improvement along team autonomy progress.

Boxplot presented consistent performance breakthrough over team development, even though some stage transitions noticeably had different improvement scales. Although there was no performance loss from forming to storming as defended by theory (Tuckman, 1965; Katzenbach and Smith, 1993), it was the only transition with no performance average gains since Tukey's test showed no significant average differences between both stages. Storming to norming is highlighted by Tuckman theory as the greatest performance evolution, which also coincides with the case study's pattern. The highest improvement also corresponds to Katzenbach and Smith's theory (1993), that implies a huge evolution from potential team to real team. Tukey's test analysis also implies that teams have succeeded at passing both, weak behavioral and strong performance barriers, suggested by Rickards and Moger (2000).

Salerno (1994), Manz and Sims (1996), and Simonetti and Marx (2010) emphasized that self-managed teams, besides performance gains and commitment improvement, also reduces processes variability, which was an achieved result by the teams, since performing stage presented consistent lower variability in Boxplot analysis.

Learning and growth and team efficiency are some of the dimensions suggested by Macbryde and Mendibil (2003) related and explored in this case study. Team development brought the high performance expectation achievement in the long-term defended by sociotechnical researchers (Moreira and Marx, 2008). It is essential to recognize that empowerment practices applied are related to theoretical principles, such as training programs, open communication and shared leadership with previously designed individual responsibilities (Brower, 1995; Margulies and Kleiner, 1995; Hess, 2018).

This study also implies theoretical discussion related to future approaches of organizational work. Salerno (1994) defends that despite the autonomy given for decision-making during work execution, teams cannot be regarded as completely autonomous, after all even with great empowerment, members can't be completely independent since they belong to an organization with strategies of its own. However, Zarifian (1997) believes that this tends to change in the future, because according to the author, it is not possible to keep two management systems built on different principles for too long. Self-organizations do not only reduces coordination costs (Yin *et*

al., 2018) but remain studied because they also respond more effectively in dynamic scenarios (Lee and Edmondson, 2017).

This paper supports sociotechnical approach principles, bringing evidence that the case study's company achieved its ambition to reach high performance with the new work design with empowered teams (Salerno, 1994; Marx, 1997). Empowerment benefits remarkably appeared in the long-term, as implied by researchers (Jian'an, 2008; Olsson and Bosch, 2018). This study suggests that a team building prosperity has a connection to empowerment practices that meets literature suggestions (Margulies and Kleiner, 1995; Elmuti, 1997; Brower, 1995) such as internal alignment between managers and teams (Hess, 2018) and proper strategic guidance before team development to gradually introduce autonomy (Olsson and Bosch, 2018).

6 Conclusion

This paper strengthens the hypothesis that self-managed teams can reach high performance, since quantitative analysis showed performance evolution on the presented case study, and positively answered the research investigative proposed question. Team building academic contributors and sociotechnical researchers provided a strong theoretical background, making it possible to connect theory to practice identifying similarities and divergences shown in the discussion section. The consistency of this integration brings relevance and originality to this paper in work organizational field.

Limitations are also relevant to direct following research to cover some topics left unexplored in the present case study. For this reason, cost-exchange perspective must be a further study, to quantify managing costs reduction brought by empowerment practices defended by literature and examine the investment made on training programs comparing to team development's cost reduction. It is equally important to emphasize that we do not generalize and extend our conclusions to other realities because the present study was restricted to a single company case-study.

This paper focused on measuring team performance across team development, exploring learning and growth versus team efficiency dimensions. The unexplored dimensions could be further assessed by internal surveys to measure employee's satisfaction individually and inside their own teams, together with external surveys to evaluate customer satisfaction, as explored by team building research present in the visited literature. Complimentarily, empowerment measurement itself through external questionnaires along with internal learning and shared leadership mediate factors' influence on performance could be meaningful techniques to extend our case study's analysis.

Statistical analysis presented in research design were applied using team performance averages for general conclusions. Consequently, a further study exploring teams individually could also contribute to additional and more specific studies. It is also suggested the Myers-Briggs Type Indicator test application for team building and leadership development. Based on the ideas of analytical psychology, the test provides individual personality analysis and their behavior in different situations, consid-

ering specific preferences, values and motivations. Therefore, another complementary research involving members' personalities inside teams could be also an interesting following theme to test relations between team personality structure and performance.

Abstract

Teams are fundamental for innovation and efficient communication may be fundamental for team performance. The aim of this paper is to present the use of sociometric badges in real workplace teams to display how team structure communication patterns can be measured and analyzed. The selected method consists of four case studies of different organizations, where the unit of analysis is represented by a meeting team. Use of this emergent technology allowed the evaluation of vocalization distribution, turn taking frequency and overlapping speech metrics. Main results of the analysis showed that team vocalization tenure corresponds to performance results but vocalization distribution does not, which was unexpected. We found where the average speech segment was high, the meeting overcome the 100% of team vocalization tenure, and the total overlap time was also high. We identified different kinds of overlapping speech. Higher overlapping seems to occur more frequently when total overlap time is high but dominance is low than when total overlap and dominance are both high. Badges metrics also allowed a preliminary identification of three meeting stages. Finally, we identified possible future research lines.

Keywords: sociometric badges, team interaction, emergent technologies, human resources, innovation.

1 Introduction

Changes over the last three decades have been highly accelerated owing to the advent of technology and innovations in communications [1] so the role of technology in contemporary organizations plays an increasingly important place [2]. Organizations are called to adapt in order to stand effective, productive and competitive in a volatile, uncertain, complex and ambiguous environment. In this process, a vital feature of modern organizations is working under changing circumstances; they increasingly adopt

work teams to coordinate activities [3]. In particular, the development and introduction of innovations in an Industry 4.0 manufacturing environment poses some challenges to human resource management. Industry 4.0 require interdisciplinary project teams [4].

As teams became a common working unit for managing change [5], investigating teams in order to understand team communication patterns is essential. Similarly, comprehension of the collaboration dynamic is becoming more and more important to improve team performance. The role of teams is fundamental for innovation. One of the competences that may enhance innovation processes is communication, understood as creating fluid communication pathways [6]. However, while digital communication is important in the modern workplace, face-to-face interaction still represents a large and important share of organizational communication, information exchange, socialization and informal coordination [7].

Currently, a variety of devices and technologies are used for business administration as a way to guarantee that processes are producing the expected results [8]. Specifically, electronic devices can measure communication patterns among teams [9-14]. For example, it has been argued that a balanced vocalization in between team members can be considered as a good proxy in relation to team performance [12, 13]. Despite these advances mean enormous potential for the strategic role of human resources function [1], there is still a lack of research on the use of this emergent technology in real teamwork settings. Although direct and quantitative approaches are highly desirable [2], teams interaction patterns are still poorly understood [10]. Methods for accurate group dynamics measurement are critical issues to be solved [15].

This research aims to study how team structure communication patterns can be measured and analyzed, to extend current literature over the use of sociometric badges in real settings, and to present challenges and opportunities of this promising emergent technology. Research describe how sociometric badges were used in different kind of teams, such as hackathons competitors [12], recruited specifically for study proposes [15], a crew during mission simulation [16], from first-year undergraduate engineering design course [10], from graduate students [17] or master´s students [9]. We did not find studies that describe the use of sociometric badges in a real teamwork setting.

2 Background

In order to frame the underpinnings of this case study, we briefly mention theoretical and empirical findings around communication in work teams that seeks for innovation and the use of sociometric badges as a tool to measure that complex phenomenon.

2.1 The Use of Sociometric Badges

Traditionally, sociologists have employed human observers, questionnaires or surveys to understand group dynamics for successful intervention [3, 15]. In order to minimize subjectivity [3], the unconscious bias inherent in recording group interaction data [12], remain unobtrusive [7], and responding to the need for automatic tools to measure individual and group behavior in the social sciences [18], researchers have leaned on

technology for solutions. There have been used complex measurements like videos, audios, sensors or other methods to understand and enhance group dynamics, with a high cost in data processing and delay in feedback. For addressing the complexity of team and communication dynamics wearable devices are becoming a common research tool for studying social behavior [12].

Sociometric badges are wearable sensors that may measure body movements, interactions, and speech [11]. Sociometric badges can collect unbiased and richer data than traditional methods [15]. They also reduce the large amount of post-processing data and gives researchers a chance to efficiently examine human interaction in granularity that was previously impossible [10], they allow exploring the structure of verbal interactions and provide further insight into complex team interaction process [9]. They can automatically measure individual and collective dynamics in a quantitative way and guarantee privacy due to the fact it is impossible to determine the content of the conversation or identify the speaker from the sociometric data [3].

2.2 Team Performance Communication Metrics

Within the use of this emergent technology, we identify three main verbal communication metrics related to team performance in literature, namely vocalization distribution, turn taking frequency, and overlapping speech.

First, the critical factor in a group's dynamics is the extent to which members participate in developing shared ideas [19].Vocalization distribution is the proportion of the speaking time [9]. There is enough empirical evidence to support that a balanced vocalization distribution is positively correlated with team performance [9, 10, 12, 13].There is higher team performance when less centralized communication or more sharing of ideas among multiple team members rather than a single or a few members´ communication is displayed. Dominant behavior is a key determinant in the formation of a group's social structure, and consequently group communication and dynamics. A dominant participant may have a negative effect on group's dynamics by discouraging participation of other members or imposing their thoughts on the whole group [15]. Although conversely, in practical terms, Paulus and his colleagues [19] observe that typically one or two persons dominate team conversation.

Second, turn taking frequency was defined by Kim and her colleagues [15] as each instance a participant takes over in a conversation either from another participant or from silence, so every turn taking divides a speech segment. A speech segment is any continuous stream of speech from an individual, regardless of interruption or overlap from other participants. A segment will end either by an interruption caused by another participant that resulted in the speaker to stop speaking (which means a turn taking) or by a significant length of silence.

It is not clear how turn taking frequency correlates with results. A recent study by Zhou and her colleagues [17] indicates the contradictions. On one hand, disagreement may appear as a high level of turn taking in meetings, with participants interrupting each other or frequently speaking at the same time [12]. Turn taking was found to be negatively associated with perceived collaboration quality [17]. On the other hand, studies confirm that turn taking correlates positively with the results [4, 20, 21]. The

possibility of frequent exchange is closely linked to coordination and collaboration with positive impact on team performance. Higher turn taking rates contribute to better group cohesiveness and satisfaction, generate a higher number of quality ideas and have higher performance [10]. Turn taking was significantly and positively associated with creative fluency, which provides strong support for theoretical suggestions that elaboration is a process that directly enhances group creativity [17].

Third, overlapping speech is the time that two or more members are speaking at the same time [15], is the duration of speech that speaker A and B uttered simultaneously [17]. Overlapping speech may evidence lack of hearing or disagreement, when participants cut each other off or speaking at the same time, so correlates negatively with performance [12, 17]. However, we are cautious on this metric. To Lederman [12] it was difficult to identify if overlaps mean the configuration of subgroups and regarding brief overlaps, Endedijk and her colleagues [9] clarify in their study they could not define whether this consisted of a lot of brief interruptions (e.g., a confirmatory 'yes') or fewer long interruptions (which might be experienced as more disrupting than brief confirmations) and ask for more advanced algorithms to add measures that provide more insight into overlaps effects, i.e. in relation to the length and number of interruptions.

Kim and her colleagues [14] take this emergent technology a step further and develop a Meeting Mediator (MM), a real-time portable system that shows sociometric badge outputs. Their study concludes that the use of MM has a significant effect on overlapping speaking time and interactivity level without distracting the subjects. The sociometric badges also able to detect dominant players in the group and measure their influence on other participants. Most interestingly, they highlight in groups with one or more dominant people, MM effectively reduce the dynamical difference between co-located and distributed collaboration as well as the behavioral difference between dominant and non-dominant people. The authors suggest the system encourages change in group dynamics that may lead to higher performance and satisfaction.

3 Method

This is an exploratory research, and its strategy is the elaboration of four different case studies [22]. The unit of analysis is represented by a meeting where the team joint to solve a real problem in the organization setting. First, we describe the instruments used to measure communication metrics and team performance. Second, we present the pilot test and the description implemented to collect the data. Third, we detail how we calculate metrics with the data analysis software. Finally, we describe the team's organizations as teams´ context and the characteristics of the task and meeting under study.

3.1 Instruments

In order to measure team structure communication patterns and correlate results with team performance, we use two instruments, sociometric badges during a meeting and a questionnaire, after the meeting.

The MIT Media Lab facilitates information and layouts to develop an affordable wearable technology; the Rhythm badges [12]. The badges (Fig. 1) enable to extract vocalization signals highly undersampled, which means they do not record any speech content but are capable of recording whether the user is speaking or not. They can not identify the person who is speaking. The badges are connected to a base station, and send collected information via Bluetooth. This allows measuring the communication metrics described in the analysis section.

Fig. 1. Sociometric badges.

A questionnaire with a 6-level Likert scale based on Lewis [21] performance metric is used to identify each team member´s perception about what happened throughout the meeting from a referent-shift approach [23]. The questionnaire includes the following points: (a) The team's deliverables were of excellent quality, (b) The team managed time effectively, (c) The team met important deadlines on time (d) The team did a good job at meeting [the expected or client's] needs. The questionnaire is designed to be administered individually, considering that the aggregate perspective of the participants belonging to the group is usually an accepted measure in the literature to measure the collective-team level constructs [24].

3.2 Pilot Test

The project, protocol and instruments were studied and approved by the Bioethics Committee of the Municipal Hospital of Bahía Blanca (Argentina). The protocol requires each participant to sign a formal participation consent.

A pilot test was conducted in order to evaluate badges utilization, software recording parameters, and data processing. The questionnaire was validated. The pilot test was conducted in a team of 5 engineers' members at the Universidad Nacional del Sur, which aimed to verify a series of technical issues on a project. The meeting lasted 40 minutes and allowed to measured, for example, the time it took to sign the participation consent. This pilot case allowed us to adapt the data collection instrument. We have also checked devises functioning, such as if they identify false positives from the software. Improved versions were used in the four cases under study, following the next procedure.

3.3 Procedure Description

First, the meeting was planned. Having the organization and leader authorization, we anticipated potential user's details of the technology that was going to be used and sent the consent. The meeting was schedule by the team, as their activity demanded, and researchers were informed. Second, following Lederman [12] guides, we installed the base station in the meeting room, before the meeting. Third and while each member arrived to the meeting room, we asked for the consent signature, we shifted on and helped wearing the devices. This process took 2-4 minutes, depending on how many members the meeting had.

A researcher assisted during the meetings, who has no eye contact with any participant, focused on checking the data was being collected properly by the software and registered observable interactional dynamics, such as subgroups. Forth, a form was completed with data about the exact time the badges were turn on, the formal time of the beginning and end of the meeting and every event associated with studied metrics (for example, if a member went out of the room, used the phone or a subgroup was set up). Fifth and having finished the meeting, each member handed over the badges. While each member delivered the equipment, the effect of the presence of the researcher was consulted. In all cases they expressed they had had neither distractions nor discomfort. Finally, and after the meeting, the questionnaire was sent by email to all assistants in GoogleForms format.

3.4 Data analysis

In order to process the badges data, we developed a data analysis algorithm for this special purpose, which can recognize which participants were speaking every moment. First, for each participant we extracted a subset of data where we were sure that only that participant was speaking. Second, using statistical tools we studied that subset to define rules to detect in the entire data set when each participant was likely to speak. Finally, analyzing the correlation between the audio signals of each participant, we eliminated false detections due to crosstalk. The environment noise and researcher´s notes were considered, such as a bus passing by the window (case 2) or a mobile ringing (case 4). As Lederman´s explained [12] we met metric imperfections, due is mathematically impossible to be precise with this technology. However, the devises allowed to access to team dynamics representative metrics.

In order to analyze questionnaire results, we processed responses in an Excel spreadsheet. Considering its 6 level scale, we transform each case average result into percentage.

3.5 Metric Definitions

Based on background empiric literature [9, 10, 14, 12, 17] we define metrics and indicators (shown in Table 1 with an asterisk*). Having collected and processed the data, we develop a set of indicators that serve us to complement the analysis (shown in Table 1 with a double asterisk**). Table 1 also shows indicators´ calculation and unit of measurement.

Table 1. Metric definitions and calculations details

Metric ID	Definitions	Indicator Name & Calculation	Unit of measurement
Vocalization Distribution	Fraction of time per person that distributes total speaking time during which a member speaks, regardless of interruptions or overlap speech from others	**Vocalization Distribution*:** Total member speaking time divided the meeting time	**Minutes (per member)**
Team Vocalization Distribution	Level of homogeneity or heterogeneity in which the team distributes its vocalization	**Standard Deviation ** ** considering each member vocalization distribution	**Proxy:** the lower-closest to 0, the better team balance distribution
		Dominance:** the maximum participation level divided by the average participation of the other members	**Proxy:** the higher, the more difference is between the dominant speaker and the rest of the members
		Team Vocalization Tenure:** time speech occupation over total meeting time	**% of the meeting time:** can range from 0 (no one spoke throughout the meeting) to 100% multiplied the number of members (all spoke throughout the length of the meeting)
		Clean Vocalization:** team vocalization tenure subtracting total overlap time percentage	**% of the meeting time** during which a member speaks, without counting interruptions or overlap speech from others.
Turn Taking Frequency	A turn is the number of times a member speaks after another member. A turn divides a speech segment. More turn taking frequency means shorter speech segments per member.	**Turn Taking Frequency*** is the number for each member during the entire meeting	**Count (per member)**
		Team Turn Taking:** Total turn taking divided the meeting time	**Proxy:** the higher, the faster the speed of the exchange frequency in shifts
		Average Speech Segment:** Average of speaking time per member divided turn taking count per member	**Seconds:** the higher, the longer average duration in the meeting speech segment
Overlapping Speech	Fraction of time that two or more members are speaking simultaneously.	**Overlap Time*:** Fraction of overlap speech time divided the total meeting duration	**% (per member)**
		Overlap Count:** number of participation occasions in overlapping speech	**Count (per member)**
		Total Overlap Time:** the sum of the member overlap time associated to the meeting time	**% of the meeting time:** the higher, the greater presence of overlap throughout the meeting
		Average Overlap duration:** the average of each member difference between each overlap time and overlap count	**Seconds:** the higher, the longer average duration in meeting overlap

3.6 Description of case studies

We studied four team works, belonging to different organizations. Table 2 present each team organization characteristics.

Table 2. Organizations characteristics.

N°	Sector	Years in business	Staff number
1	**Consulting Services**	10 years	Less than 10
2	**Education**	55 years	More than 500
3	**Food**	15 years	More than 100
4	**Gas Distribution**	74 years	More than 1500

Organization 1 is an association of professionals that provide management and human resources consulting services in the region, especially to small and medium size firms. Their teams set up to respond to specific client´s demands, so flexibility is a valuable competence.

Organization 2 is a public national university, funded in 1956 and represent an educational hub. It must comply with laws, resolutions and administrative decisions issued by different government agencies. It has an independent government and budget. The university is organized in departments (17) and research centers (9). There are 23,619 undergraduate students, 1,761 postgraduate students, 3,099 academic staff, 60 undergraduate careers, 64 postgraduate careers, and 581 administrative and technical staff [25]

Organization 3 has emerged as a venture entrepreneurship in 2004. In its beginnings, the firm's activity was centralized in a single point of elaboration, sales and distribution. A short time later and, as a result of the great acceptance of the product proposal, the structure has expanded: it currently has a production factory and seven distribution and sales locations. It has well established itself as a regional leading gastronomic firm; it has diversified, and currently produces more than 40 products. The organization offers a delivery service to its clients.

Organization 4 is the largest natural gas distributor in Argentina in terms of volume, covering 45% of the country in two contiguous regions. With a complex system of transportation pipelines and distribution networks that exceeds 50,000 linear kilometers in length; they supply more than 2,000,000 users in seven provinces of the country.

4 Results

Cross-boundary meetings [26] are regular in organizations as a form to address and solve problems or discuss and define future directions. Each organization planned a meeting in order to solve a current and real problem. Table 3 briefly summarizes the task for which the members were called to the meeting under study and team member characteristics.

Table 3. Team Meetings

N°	Context	Objective	Duration	Number of team members	Educational level structure Without // With grade formation
1	A client asks for a recruitment and selection service for a difficult profile to fill, the regular working plan needed to be adjusted.	Re-define steps, responsible, schedules…	50 min	3	1 // 2
2	Academic management top team seeks for an ISO certification, monitoring indicators is mandatory to achieve this organizational goal.	Analyze annual KPIs and define next period objectives	1:45 hours	7	3 // 4
3	A new online delivery service is offered in the city. The questions were: What should we do? Should we incorporate these channel sales? What impact would this have over our own delivery personnel?	Analyze pros and conts. Take decisions. Define plan to respond.	1:15 hours	6	5 // 1
4	Digital transformation is an imperative in the organization. Some sectors are using paper-based and digital systems to process customers' claims.	Analyze change difficulties, synchronize sectors and organize faster migration.	40 min	8	6 // 2

Having collected and processed data, we first analyze each case separately. We highlight that the research observations show all four meetings were flowed smoothly and harmonically and no apparent conflict was shown during them. For space reasons, we only include the full description of case 4. We also present main descriptive results of the other three cases. Then, we present a synthesis and compare results in Table 4 and discuss results as preliminary interpretations.

4.1 Cases

The eight members meeting was vocally distributed unevenly. Even though member 18 dominated the participation (2,44 dominance) the standard deviation stand at 8,12. As Fig. 2 shows, there were 3 (if not 4) members that stood out. One of them, member number 1, was the facilitator and convener of the meeting, a person that opened the meeting with the agenda items, synthesized agreements achieved during the meeting and gave a formal finishing. Also, case 2 did not show a significant dominance member. In case 1 and 3, one member dominated the vocalization participation, the leader and convener of the meeting.

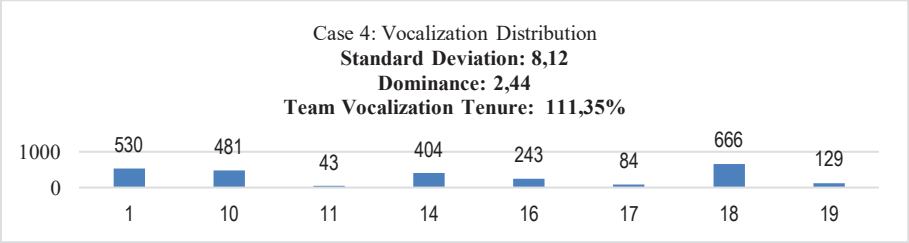

Fig. 2. Vocalization Distribution Indicators of Case 4.

Fig. 3 shows the dominance were both regarding vocalization and turn taking count –as in case 1. This feature was not present in case 2, where some members took shorter turn. The members' sum 111,35% of vocalization over the extent of the meeting, which correspond to the level of the total overlap time (36,43%). Differently, in case 1, the team vocalized among 80,7% of the meeting length, which leaves almost 20% of the meeting time to members silence.

Team turn taking speed arose up to 0,085. The slowest was case 2 (0,056) The average speech segment in case 4 was 14,10 seconds.

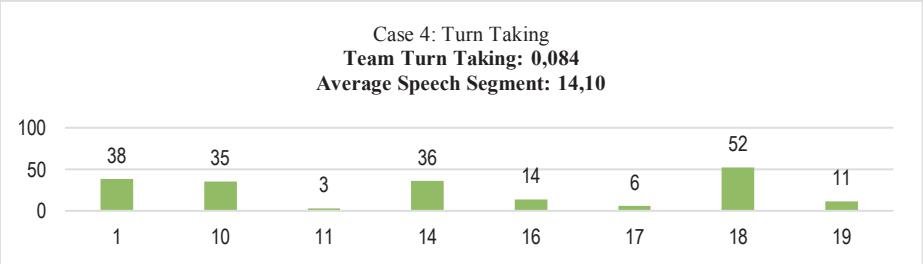

Fig. 3. Turn Taking Frequency Indicators of Case 4.

The average overlap duration of case 4 was 1,36 seconds. Besides vocalization, member 18 also contributed more than the other members to overlap count and time (see Fig. 4). The same occurred in case 1, where the member that contributed the more to overlaps was not the leader neither the facilitator. Differently, in cases 2 and 3, vocalization and overlap were balanced. In this case, the dominant member was the only that had an outstanding difference between overlap time and overlap count, meaning overlaps were longer than others´. Case 2 present this same feature among their 3 dominant members, their overlaps were also longer. Differently, in case 1 and 3 all members contributed similarly in times and duration. During case 2 meeting, the researcher observation registered one case of overlap that correspond to a member (n°5) that leaved the room in order to respond a phone call. Considering the data of the entire meeting, it seems this circumstance did not affect results significantly.

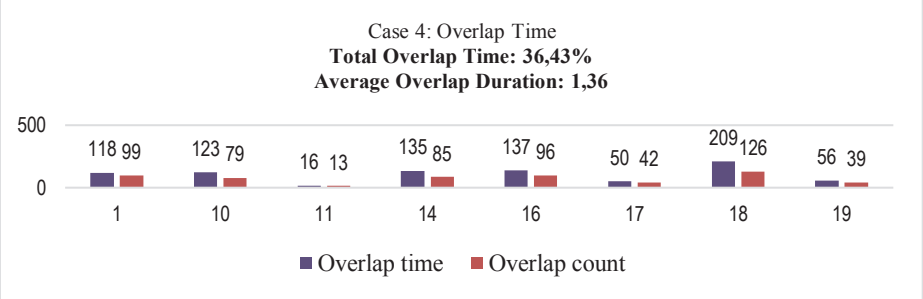

Fig. 4. Overlapping Speech Indicators of Case 4.

Thanks to observer records about case 4, we identified that in general, overlaps appeared as confirmatory interventions or short interruptions (yes, of course, in agreement, a name or reference) or as informal interactions (jokes, laughter). During the meeting, as in case 2 and 3, there were occasions when in dynamic interaction two or more members "compete" to take the turn and one managed to overcome the overlap at the cost of the other member's silence. Subsequently, the turn changed to whoever wanted to contribute. This feature mainly happened in case 3 where the flow of information run between the members quickly, team turn taking was the highest –faster turn- of the four cases (0,099).

The appearance of subgroups in short periods of time, which did not imply disruptive overlaps, was also recorded. In this case, members immediately returned, naturally and without being asked, to configure themselves as the only group. This phenomenon of subgroup assembly and natural return to the unique group was observed in this meeting of eight members, mainly. In case 3, when subgroups were sustained over time and its extent required greater concentration due to the vocalization volume increasing, the leader expressly requested to return to the single group configuration. In these situations, was registered a first functional overlapping speech moment (subgroup) and a second dysfunctional overlapping speech moment (lack of line, organization of speech and general understanding). During case 1 no subgroups were set –which in a meeting of three members would not be possible-. Still, this fact evidence case 1 overlap indicators do not correspond to subgroups.

4.2 Team Comparison and Preliminary Interpretations

Table 4 summarizes the four cases. The table includes performance indicator (members' perception about what happened throughout the meeting). According to this perception, all meetings were valued above 75%, the difference between the top (case 1) and the lowest (case 4) is 18,06%.

Table 4. Team Metric Results by Case

Metric ID	Indicator	Case 1	Case 2	Case 3	Case 4
Team Vocalization Distribution	**Standard Deviation**	15.82	7.42	7.34	8.12
	Dominance	2.95	1.63	2.38	2.44
	Team Vocalization Tenure	80.68%	108.59%	92.87%	111.35%
	Clean Vocalization	74.63%	72.84%	74.02%	74.92%
Turn Taking Frequency	**Team Turn Taking**	0.076	0.056	0.099	0.084
	Average Speech Segment (seconds)	9.68	18.73	8.99	14.10
Overlapping Speech	**Total Overlap Time**	6.05%	35.75%	18.85%	36.43%
	Average Overlap Duration (seconds)	1.10	2.00	1.29	1.36
Performance Result (scale 1-6)		5.63	5.13	4.88	4.54
		93.75%	85.25%	81.25%	75.69%

Based on the theoretical background, we understand that the lower the vocalization distribution standard deviation, the greater the homogeneity; which would indicate greater team efficiency. This indicator simplifies the comparison of the indicators related to the distribution in the vocalization [27]. Although it has been the most proven, we found it did not correlate positively in our four case studies.

The dominance indicator also contributes to this aspect of the meeting analysis, where it reflects the maximum participation level divided by the average participation of the other participants. We found no direct relationship between dominance indicator and meeting performance results neither. A series of factors could be attributed to our findings such as the size of the meeting team, if the meeting had or not a facilitator and the presence of a reference member with the technical knowledge needed to solve the meeting agenda. In addition, differently from what is indicated by the literature, we found up to 3 dominant members of the team conversation.

We found team vocalization tenure –the extent members use the meeting time to vocalize- were coherent with performance results. As long as the team vocally fits the meeting time (100% of the meeting time or less), the results hold high. To the extent the vocalization percentage exceed 100%, the perception of performance in results decreases. For example in case 4, members vocalized 111,35% and ranked last. Following this reasoning, it is interesting to connect team vocalization tenure with total overlap time percentage. We calculated clean vocalization indicator (vocalization without counting interruptions or overlap speech) This indicator itself did not display any correlation with performance results but, in our cases, where clean vocalization stood around 70-75%, performance results corresponded above 75%.

Similarly, we could not found a positive or negative direct relation in between speed frequency among members' turns nor the average speech segment duration with results. However, and considering the need to identify more clearly the explanation of overlapping speech, we could note that where the average speech segment was high (case 2 and 4) the meeting overcome the 100% of team vocalization tenure, and the total overlap time was also high. Our interpretation was that a faster turn taking could facilitate a better means of overlapping speech in team interaction.

We identified different kinds of overlapping speech, namely informal, disruptive, confirmatory, competitive for a turn and related to subgroups. Subgroups appeared when the meeting has 4 or more members. We found subgroups might have functional or dysfunctional moments; they may disappeared naturally or by demand.

In the four cases, overlapping speech metric did not correlate with performance results directly. However, we can approximate as an interpretation that when total overlap time was high but dominance was low (case 2) results were higher than when total overlap and dominance were both high (case 4). This may indicate that when vocalization was balanced, all members contributed to a synchronized and fluid conversation, meaning the interruptions and overlaps reflected this rhythm of interaction.

The average overlap duration holds below 1,36 seconds in three cases, and in case 2 it was 2 seconds. Considering the performance results and the observer notes regarding the fluidity of the meetings, this length was not disrupting in team interaction, with the exception of dysfunctional subgroups moments.

Considering team communication dynamics and thanks to the researcher observation, we offer a preliminary characterization of meeting stages. We identified a first stage, the starting one, where members arrived and located. This stage was characterized with icebreaker interaction, members exchanged informally. The interaction was not structured and dominant members appeared (for instance, the extrovert or the leader) and subgroups were dysfunctional. Disruptive and informal overlaps were observed and turn taking was faster. In a second stage, the developing stage, the group focused their activity on the convening meeting topics and defined a rhythm. Subgroups may appear and the overlapping speech was mainly disruptive, confirmatory or respond to the intention of winning a turn (competitive overlap). The speech segments were longer. Then, as the finishing stage of the meeting, the group returned to unstructured dynamics; commentaries that were not related to the convening meeting topic appeared. During this last stage, overlaps corresponded to informal interaction and turn taking got speed.

5 Conclusions and Future Research

Our study extends the understanding team structure communication patterns and provides an important contribution to research in the field of sociometric badges, being the first one that analyzed teams in real work settings. Focus on the use of the badges allowed to measure metrics that have been used previously (vocalization distribution, turn taking frequency and overlapping speech) and new indicators, built with the purpose of exploring the technological possibilities of the devices (dominance, team vocalization tenure and average speech segment, for example).

Based on previous literature, while one might argue that vocalization distribution is a good proxy for team performance, when we examined our four cases, we found that the metric should be analyzed as part of a set of indicators in context. For example, we identify subgroups and overlapping speech key mechanisms of team interactional dynamics.

We can identify at least four lines for future research using sociometric badges. First, the study of the evolution of the same team along different meetings. Second, it would be interesting to focus on technological possibilities of devises to identify and characterize more clearly different meeting stages. Third, the collection of data in a wider set of teams and organizations may allow better comparisons within cases and indicators. Fourth and finally, regarding available technology, there is great chance to incorporate artificial intelligence to give more precision to metrics.

Abstract. Course Timetabling at universities can be defined as the scheduling of different courses in specific time slots. To carry out this process it is necessary to take into account key factors such as: available courses, the distribution of time slots and lecturers' availability. In addition, there are resources that are essential for the model performance. For instance, the available classrooms and their capacity to completely satisfy the specific demand of students. In this study, a mixed integer linear programming model is presented to find the optimal schedule of the courses. Results show that the proposed model provides feasible solutions where all the proposed factors are considered.

Keywords: University Course Timetabling, Scheduling, Mixed Integer Linear Programming, Classroom Programming

1 Introduction

Scheduling has been widely used in educational institutions due to its importance for optimizing physical and human resources [1]. Institutions such as universities, which have a high demand for subjects and students, must organize each of these resources in the best way to comply with all the quality conditions they have offer and are accountable for. Not having a systematic methodology to generate feasible schedules efficiently may result in the use of human resources to carry out the task manually. This situation worsens when considering all the different conditions given to determine the viability of schedules to be used.

For educational institutions, organizing academic schedules is not an easy task. Moreover, it is not unusual that budget for these processes is scarse, meaning that an efficient planning schedule must be carried out by qualified staff and with minimum cost. Lawrie [2] and Tripathy [3] took that into consideration and defined the number of hours per week that were necessary for a course to prevent courses from overlapping, as main requirements. These generates the fulfillment of the estimated hours and the assignment of teachers without conflict. During the following years, different authors adapted these first models, adding specific

conditions for their institutions or some other general ones that could be applied to other studies. An example of this is the study by Schimmelpfeng [4], where the application of a Mixed Integer Programming (MIP) model was carried out at the German School of Economics and Administration, adding elements such as the capacity of the available rooms and establishing as a objective function the minimization of violation of planning constraints.

The aim of this paper is to propose a MIP model for the course timetabling in a Colombian University. In this case study, an academic program and its core courses are considered. The academic program consists in 10-semesters, 17 core subjects, each with a certain number of subgroups determined by the expected demand of students. The model focuses mainly on avoiding the overlapping of subjects from the same semester, guaranteeing that students can enroll the courses of the semester they are. The proposed MIP model also considers the classroom capacity, the assignment of professors to courses according to a subject ability and the type of contract to determine the maximum number of hours each professor can teach per week.

The rest of this paper is organized as follows. Section 2 presents a bibliometric analysis of related studies. Section 3 shows the MIP model formulation. Section 4 presents the computational results. Lastly, Section 5 drawns some conclusions of the study and provides some interesting avenues for future research.

2 Bibliometric Analysis

In order to delve deeper into schedule and timetabling problems, a bibliometric analysis was carried out. Bibliometric analysis helps one to understand who are the authors more interested on a specific topic, as well as which are the journals, countries and institutions that have worked more on it. (Sierra-Henao et al., 2019) [5]. In addition, citation and co- citation analysis help identify the most cited authors, articles and prevailing topics. According to Noyons et al. (1999) [6], bibliometrics combine two main procedures: scientific mapping and performance analysis. The importance of this type of analysis is to estimate how well the reviewed topics have been studied and draw conclusions from there, as mentioned by Solano, Castellanos, Rodríguez and Hernández [7].

Table 1 shows a summary of the methodology followed for the analysis. The bibliometric analysis was based on the literature collected from Scopus database (www.scopus.com) as it is defined as "the largest abstract and citation database, with over 1.4 billion cited references indexed from high-quality of peer-reviewed literature as scientific journals, books and conference proceedings" (Elsevier, 2020) [8].

Unit of analysis	Published
Period of analysis	2010 to 2020
Search engine	Scopus
Query string	TITLE-ABS-KEY((course OR class*) AND timetable AND schedul* AND optim*) AND (LIMIT-TO (PUBYEAR , 2020) OR LIMIT-TO (PUBYEAR , 2019) OR LIMIT-TO (PUBYEAR , 2018) OR LIMIT-TO (PUBYEAR , 2017) OR LIMIT-TO (PUBYEAR , 2016) OR LIMIT-TO (PUBYEAR , 2015) OR LIMIT-TO (PUBYEAR , 2014) OR LIMIT-TO (PUBYEAR , 2013) OR LIMIT-TO (PUBYEAR , 2012) OR LIMIT-TO (PUBYEAR , 2011) OR LIMIT-TO (PUBYEAR , 2010)) AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "cp") OR LIMIT-TO (DOCTYPE , "re")) AND (LIMIT-TO (LANGUAGE , "English")) AND (LIMIT-TO (SUBJAREA , "COMP") OR LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "MATH") OR LIMIT-TO (SUBJAREA , "DECI"))
Number of evaluated articles	1,059

Table 1. Research method.

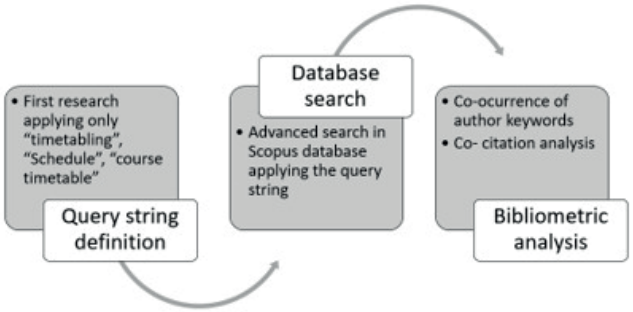

Figure 2. Summary of methodology used.

After having collected the search results from the query string, a software called VOSviewer was used. This software is a tool for building and visualizing bibliometric networks for better understanding and detect non relevant repeating terms to excluded them from the list. VOSviewer was developed by Van Eck and Waltman [9] where the software has the capacity to distinguish two types of bibliographic maps, one of them related between the investigated elements and the other facilitates the identification of groups of related elements.

First of all, an analysis of author keywords was performed. Figure 2 shows the 85 most frequent keywords with at least three occurrences for easier reading. Keywords are represented with circles, where the largest circles represent the keywords that have been used the most. As shown in figure 2, eight different clusters are separated by distinct colors. The green cluster identified as "timetabling", represents the prescriptive approaches for solving this type of problems.

Keywords related with "scheduling problem", such as "combinatorial optimization" and "course timetabling problem" appear in the yellow cluster. Other words such as "timetabling problem", "genetic algorithm", "high school timetabling problem", "exam timetabling" and "particle swarm optimization" appear in the purple, blue, orange, red and light blue clusters, respectively. In addition, the brown subgroup are linked with "robustness" and "course timetabling" topics.

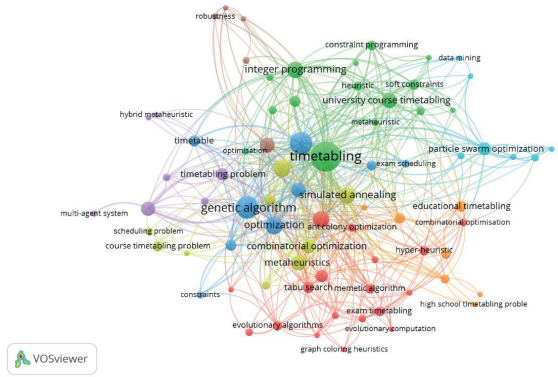

Figure 2. Co-occurrence of author keywords.

Additionally, in order to obtain a deeper insight into the gained results, figure 3 shows the timeline visualization overlay of the co-occurrence of author keywords on the evaluated contributors. In other words, it exhibits the evolution of the different keywords through the years. Considering what was mentioned above, new or trending concepts can be highlighted: university course timetabling, educational timetabling, bi-criteria optimization, , and integer linear programming. The latter has the highest average publication year among 85 keywords between 2018. At the other end of the spectrum, keywords as “course timetabling problem” and “school timetabling problem” have been less popular recently with an average publication year between 2012.

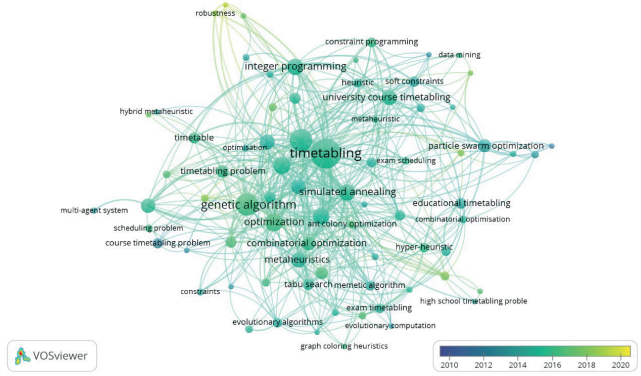

Figure 3. Evolution of co-occurrence of author keywords from 2010 to 2020.

For the co-citation of authors analysis, a minimum of 20 citations per author was considered. Out of the 8,702 authors within the analysis, 218 of them met the threshold. As shown in figure 4, authors were classified in 5 different clusters evaluating the strength of correlations between co-citations. Authors Burke, E.K, Mccollum, B. and Qu, R, are the most relevant and most cited for timetabling and scheduling related topics. Table 2 shows a summary on the top 10 most cited

authors, their total citations and the references to which citations are associated.

3 Problem Formulation

This section presents a MIP model to schedule a specific number of subjects, considering institutional policies and physical resources characteristics. The objective function and operational constraints aim to minimize the number of missed hours to fulfill professors workload while assuring that all classes are programmed and avoiding the overlapping of subjects from the same semester.

Therefore, the model considers students demand, professor availability, classrooms capacity, days and hours where classes could be programmed, and type of contract (full or part time) of the professors, seeking to generate optimal schedules for both students and professors. The following sections present the sets, parameters, decision variables, objective function and operational constraints of the model.

3.1 Indices

The following indices were defined for the proper development of the model:

i = timeslots (T1: 7-9, T2: 9-11, T3: 11-13, T4: 13-15, T5: 15-17, T6: 17-19, T7: 8-10, T8: 10-12, T9: 12-14, T10: 14-16, T11: 16-18, T12: 7-10, T13: 10-13, T14: 13-16, T15: 16-19, T16: 8-11, T17: 11-14, T18: 14-17, T19: 9-12, T20: 12-15, T21: 15-18). These are defined considering that courses may be offered in two- and three-hours spaces only.
j = days (Monday,..., Friday).
k = courses (C1,..., C59).
p = professors (1,...,25).
t = contract type (full time, part time).
s = semester (1,..., 10).
a = available classrooms (S1,..., S10).
m = number of days in which the class is taught. That is, a class needs either one day a week or two.

3.2 Parameters

The following parameters were defined for the development of the model:

$Hours_k$= Week hours for course k.
$Maxdays_m$= Days m per week required for course. Either one or two.
$Numberhours_i$= Hours for timeslot i.
$Capacity_a$= Student capacity of classroom a.
$Students_k$ = Expected demand of students for course k.
$Contract_{p,t}$= 0-1 Matrix indicating if professor p has contract type t.
$Semester_{k,s}$= 0-1 Matrix indicating if course k is offered in semester s.
$Timeslots_{i,i'}$= 0-1 Matrix indicating if timeslot i does not overlap with timeslot i'.
$Courseprof_{k,p}$= 0-1 Matrix indicating if course k can be taught by professor p.
$Courseday_{k,m}$= 0-1 Matrix indicating if course p requires m days per week.
$Disp_{p,k,i,j}$= 0-1 Matrix indicating if professor p is available for teaching course k during timeslot i on day j.
$Minhoursparttime$= Maximum number of teaching hours per week for part-time lecturers.
$Maxhoursfulltime$= Minimum number of teaching hours per week for full-time professors.
$Maxhoursfulltime$= Maximum number of teaching hours that can be allocated per day for each semester.
$BigM$= Very large integer value.

3.3 Decision Variables

The following decision variables were defined for the model:

$X_{p,k,i,j}$= 1 if professor p teaches course k in timeslot i of day j, 0 otherwise.
$Y_{k,i,j}$= 1 if course k is taught in timeslot i of day j, 0 otherwise.
$N_{a,i,k,j}$= 1 if course k is taught in timeslot i of day j in classroom a, 0 otherwise.
$W_{p.k}$= If professor p teaches course k.
$G_{k,j}$= If course k is taught on day j.
$DELTA_p$= Hours professor p misses to fulfill his workload.
$DELTA2_{p,k,i,j}$= Hours missed to assign all courses.

3.4 Objective Function

The model is aimed at minimizing the hours professor p misses to fulfill his workload:

$$min\ Z = BigM \cdot \sum_{p} DELTA_p \tag{1}$$

3.5 Constraints

The following constraints were considered for the problem:

$$\sum_i \sum_j Y_{k,i,j} \cdot Numberhours_i = Hours_k, \ \forall k \tag{2}$$

$$\sum_i Y_{k,i,j} \leq 1, \ \forall k, j | Courseday_{k,m} = 2 \tag{3}$$

$$G_{k,j} + G_{k,j+1} \leq 1, \ \forall k, j | j \neq Friday \tag{4}$$

$$\sum_j G_{k,j} \cdot Courseday_{k,m} \leq Maxdays_m, \ \forall k, m \tag{5}$$

$$\sum_k Y_{k,i,j} \cdot Semester_{k,s} \leq 1, \ \forall i, j, s \tag{6}$$

$$Y_{k,i,j} = 0, \ \forall k, i = \{T4, T5, T6, T10, T11, T14, T15, T18, T20, T21\}, j = Friday \tag{7}$$

$$\sum_k \sum_i Y_{k,i,j} \cdot Semester_{k,s} \leq Maxhoursday, \ \forall k, s \tag{8}$$

$$\sum_p W_{p,k} \leq 1, \ \forall k \tag{9}$$

$$\sum_p X_{p,k,i,j} \leq 1, \ \forall k, i, j \tag{10}$$

$$\sum_k X_{p,k,i,j} + \sum_k \sum_{i' | i' \neq i \wedge Timeslots_{i,i'} = 0} X_{p,k,i',j} \leq 1, \ \forall p, i, j \tag{11}$$

$$X_{p,k,i,j} \leq Courseprof_{p,k}, \ \forall p, k, i, j \tag{12}$$

$$\sum_k \sum_i \sum_j X_{p,k,i,j} \cdot Contract_{p,t} \geq Minhoursfulltime - DELTA_p, \ \forall p, t = Fulltime \tag{13}$$

$$\sum_k \sum_i \sum_j X_{p,k,i,j} \cdot Contract_{p,t} \leq Maxhoursparttime, \ \forall p, t = PartTime \tag{14}$$

$$\sum_p X_{p,k,i,j} = Y_{k,i,j} \ \forall k, i, j \tag{15}$$

$$X_{p,k,i,j} \leq disp_{p,i,j} + DELTA2_{p,k,i,j},\ \forall p,k,i,j \tag{16}$$

$$\sum_{a} N_{a,i,k,j} \leq 1,\ \forall i,k,j \tag{17}$$

$$\sum_{k} N_{a,i,k,j} + \sum_{k} \sum_{i'|i' \neq i \wedge Timeslots_{i,i'}=0} N_{a,i',k,j} \leq 1,\ \forall i,j,a \tag{18}$$

$$\sum_{k} N_{a,i,k,j} \cdot Students_k \leq Capacity_a,\ \forall a,i,j \tag{19}$$

$$\sum_{k} N_{a,i,k,j} = Y_{k,i,j},\ \forall i,j,k \tag{20}$$

$$DELTA2_{p,k,i,j} \leq 1,\ \forall p,k,i,j \tag{21}$$

$$W_{p,k} \leq 1,\ \forall p,k \tag{22}$$

$$G_{k,i} \leq 1,\ \forall k,j \tag{23}$$

$$X_{p,k,i,j} \leq W_{p,k},\ \forall p,k,i,j \tag{24}$$

$$Y_{k,i,j} \leq G_{k,j}\ \forall k,i,j \tag{25}$$

$$X_{p,k,i,j}, Y_{k,i,j}, N_{a,i,k,j} \in (0,1), \forall i,j,k,p,a \tag{26}$$

$$W_{p,k}, G_{k,j}, DELTA_p, DELTA2_{p,k,i,j} \geq 0, \forall j,k,p \tag{27}$$

Constraints 2 guarantee that all the hours of each class are scheduled. Constraints 3 guarantee that, if a course has more than one session per week (i.e., requires two or more days of the week), the sessions of the class cannot be scheduled on the same day. Constraints 4 apply to those subjects that require days between their sections, in this case at least one day in between. Constraints 5 guarantee that a class cannot be programmed in more days than it is permitted to. In addition, it is necessary to ensure that classes that belong to the same semester do not overlap, this is done by constraints 6. Considering the university, Friday afternoons are reserved for postgraduate courses, meaning that constraints 7 guarantee that no undergraduate classes are assigned during said timeslots. Constraints 8 limit the maximum number of hours a day that can be taught to each semester.

It is also considered that each of the courses may be taught by a single professor, just as they may teach only one class at a time. This is ensured with constraints 9, 10 and 11. Constraints 12 establish that professors will only be able to teach courses that they are able to teach. Additionally, according to the contract type, full-time professors must teach a minimum 6 hours of class per week, while part-time professors may dictate maximum 21 hours. This is done in constraints 13 and 14 respectively. Constraints 15 establish that professors can only be assigned to courses-slots that have already been assigned. Part-time professors have a certain availability according to their needs. Constraints 16 contemplate the availability matrix of all professors, both full-time and part-time professor, in order to assign them to courses that are available in time slots to teach the class.

For the last resource (i.e., classrooms), constraints 17 ensure that each class may be assigned to only one timeslot on a single day. On the other hand, constraints 18 guarantee that classrooms may have only one course allocated on each timeslot. Constraints 19 establish that all courses will be assigned to classroom that can support the expected student demand. Lastly, the number of classrooms assigned must correspond to the number of courses in each of the time slots of each day. This is given by constraints 20. Constraints 21 to 25 establish relationship conditions between variables, and constraints 24 and 25 indicate the nature of the variables of the model.

4 Results

The proposed model was coded and solved using GAMS (General Algebraic Modeling System) version 28.2.0 and solved using CPLEX on a laptop computer equiped with an Intel Core i5 processor, 8GB RAM and a 64-bit Windows 10 operating system.

For this particular project, it is important to consider, within the result analysis, different scenarios that provide useful information for decision makers. Despite the foundations of the model being exclusively on course timetabling, it is ideal to develop ideas that revolve on the impact that the model may have on other areas, such as economics or the optimization of resource utilization.

The structure of the scenarios considered is based on two variables: teachers' availability and courses' demand. Based on information shared by the University, the code states an initial expected students demand for each course and a specific amount of groups for dividing students in order to meet classrooms maximum capacity and a homogeneous distribution. For the problem analyzed in this paper, only ten classrooms of the university were considered, seven of them can accommodate 40 people while the other three have a capacity for 30. The academic program has 20 teachers, 12 of them are part-time, while the rest

are full-time teachers.

For evaluating different scenarios, eight indicators were selected, depending on classrooms, courses, teachers and time frames. The following indicators were defined: classroom usage hours per day (%HU), classroom average occupied capacity (%AVG CAP), scheduled and unscheduled courses (%CA and %UC, respectively), assigned full- and part-time professors, critical time slots, and number of classrooms used.

Three scenarios were examined. The first one with the normal expected student demand. The second one consideres a 10% demand increase. It is worth mentioning, that in this scenario classes still have a maximum number of 40 students, as this is the largest classroom capacity. The third one evaluates a 10% demand decrease. In addition, each scenario considers five possible professor availability (100%, 75%, 60%, 50% and 40%)

		100%	**75%**	**60%**	**50%**	**40%**
Classrooms	%HU	33.82%	33.82%	33.82%	33.27%	32.73%
	%AVG CAP	91.66%	90.06%	83.55%	88.98%	91.70%
Courses	%CA	100%	100%	100%	98%	97%
	%UC	0%	0%	0%	2%	3%
Professors Used	Full-Time	8	8	8	8	8
	Lecturers	10	12	11	12	12
Critical Hour		17-18	8-9	9-10	8-9	9-10
Classrooms Used		10	10	9	10	10
Used Resources Indicators		**100%**	**75%**	**60%**	**50%**	**40%**
Classrooms	%HU	33.82%	33.82%	37.58%	33.27%	32.73%
	%AVG CAP	91.66%	90.06%	92.84%	88.98%	91.70%

Table 3. Results with a students demand decrease of 10%.

This first scenario, represented in Table 3, is based on the usual expected demand for each course. It is very important to highlight the fact that with the 40% and 50% professors' availability the total courses were not assigned. Despite the latter, the percentage of average capacity used for the 40% scenario, is the best within this frame, mainly because of the use of classrooms 7 and 10, whose capacities were entirely used by one course in a time frame, this is why these spaces have the lowest percentage of hours used. It is important to point out that the teacher 19 is the only entitled to teach for 6 groups due to its subject speciality; therefore when the availability is less than 60%, the professor is not able to teach all of them, in the 40% he matches 4 out of 6 and 5 out of 6 in the

scenario with 50% of professor availability.

Once it is possible to teach all the courses due to professors' availability, an interesting phenomenon appears: the proposed schedule distributed the hours through the classrooms in a very similar way, resulting in an equal percentage of used hours. Nevertheless, it is interesting to see that the average capacity used increases as the availability does, stating the fact that when teachers have better availability, it is more likely to use resources better.

However, in the scenario with 60% of professor availability, there is a fact that needs to be taken into account: not all the classrooms are used, that is, there is at least one empty classroom which increases the usage percentage of the classrooms. That is the reason why the second part of Table 3 is important, because it takes into account only used resources. Therefore, analyzing the behavior of the results, the 60% scenario is the best possible, regarding average capacity used of the classrooms and the hours used. This is explained by the fact that, the model focuses mainly on avoiding the overlapping of subjects from the same semester and ensuring certain amount of hours for part-time professors.

Students demand increases 10%		**100%**	**75%**	**60%**	**50%**	**40%**
Classrooms	%HU	33.82%	33.27%	33.82%	33.09%	33.09%
	%AVG CAP	74.89%	82.40%	82.22%	80.46%	80.35%
Courses	%CA	100%	100%	100%	98%	97%
	%UC	0%	0%	0%	2%	3%
Professors Used	Full-Time	8	8	8	8	8
	Lecturers	9	10	10	11	11
Critical Hour		17 - 18	8 - 9	8 - 9	9 - 10	8 - 9
Classrooms Used		8	9	9	9	9
Used Resources Indicators		**100%**	**75%**	**60%**	**50%**	**40%**
Classrooms	%HU	42.27%	36.97%	37.58%	36.77%	36.77%
	%AVG CAP	93.61%	91.55%	91.35%	89.40%	89.27%

Table 4. Results with a students demand decrease of 10%.

The results for the second scenario are presented in Table 4. It can be observed that the best used hours percentage is achieved with a 100% professor availability. Basically, when demand increased there were only 2 courses that could be taught in less than 30 people capacity classrooms, each of them with 22 students demand. The model scheduled these two classes in one classroom, leaving low demands concentrated in one space and not distributed, saving the possibility of lowering the average of the rooms with a capacity of 40 people. This scenario is the best possible for all indicators: hours used, average classroom capacity, classrooms used and teachers scheduled. Nevertheless, all the instances

(i.e., 75%, 60%, 50% and 40%) for this scenario have a good performance in terms of average capacity used.

Students demand decreases 10%		**100%**	**75%**	**60%**	**50%**	**40%**
Classrooms	**%HU**	33.82%	33.82%	34.18%	33.27%	32.73%
	%AVG CAP	84.04%	84.34%	81.99%	83.96%	81.89%
Courses	**%CA**	100%	100%	100%	98%	97%
	%UC	0%	0%	0%	2%	3%
Professors Used	**Full-Time**	8	8	8	8	8
	Lecturers	10	12	11	12	12
Critical Hour		9-10	12-13	17-18	11-12	12-13
Classrooms Used		10	10	10	10	10

Table 5. Results with a students demand decrease of 10%.

For the last scenario, when demand decreases, the model tends to distribute equally the classes within the classrooms as it can be concluded after analysing Table 5. For the different variants of teachers' availability, the 10 classrooms were used; all of them with less than 85% capacity used. This is due to the use of all classrooms where the low and high students courses are mixed and the fact the demand itself decreased. It is really interesting the fact that when demand is lower the model tends to distribute almost equally teachers and classrooms. This could be explained by considering that a demand decrease would generate smaller groups and, therefore, a better usage could be achieved for the classrooms with capacity for 30 students.

5 Conclusions and Future Research

This paper studied a university course timetabling problem. The objective was to schedule the set of courses of an academic program while professors and classrooms were assigned. A set of data from a Colombian University was taken as a sample to carry out a mathematical model that meets the conditions of schedules, crossings of subjects from the same semester, the maximum number of hours that a professor can dictate and keeping in mind the demand of students for each of the courses to allocate classrooms.

The problem is solved and provides to the researchers a tool to assess and evaluate different scenarios. The computational results show that it is possible adapt the model to different educational scenarios that require the optimal use of resources. The initial conditions are very favourable for the University as classrooms and teachers are enough. Nevertheless, numbers may highlight the underuse of available classrooms and the possibility of leaving these spaces for

another purpose; for all scenarios at least 57% hours are free in the classrooms, meaning that other programs could take advantage of this spaces.

The results also show that the model can comply with the guidelines established by the board of directors and the quality standards necessary in the academic offer. This is clear as the scheduling conditions can be modified to meet specific requirements and make the assignment process more complete, while maintaining high levels of service for both students and teachers and for the institution.

As future research, the model can be considered to be applied with all academic programs of the university to coordinate efficiently the manage of resources and to deliver one system that take control of them. Also, the inclusion of distances between classrooms can be contemplated as part of a new optimization criterion. The route that students and teachers must take could be an objective to take into account when there are two or more consecutive classes, so the less distance they travel the more time they will have to arrive. Also, integrating other scenarios with alternate students demand. In addition, as in the result analysis, assigning an opening cost for each classroom and each time frame, could transform the programming into an optimization tool as well.

It is also possible to add preference conditions at specific times, determined by the institutions to give priority to other academic activities. This should contain a matrix with weights for each of the time slots where it will be possible to indicate which of them are more pertinent to specific interests. Finally, new ways of addressing the problem can be designed, such as heuristic methods, that allow finding feasible solutions comparable with the results obtained in this research and obtaining conclusions about the performance of the models and the management of resources for their optimization.

Resumo. A qualidade da energia elétrica é importante para todos os setores da cadeia de fornecimento, desde a geração até a transmissão e distribuição da eletricidade. O aumento do número de empresas resulta em um acréscimo de cargas na rede, tornando necessário um monitoramento adequado da qualidade de energia, tanto pelas distribuidoras quanto pelos consumidores. A baixa qualidade de energia elétrica independente da sua causa, pode gerar perdas significativas aos consumidores, sendo as indústrias as mais afetadas em razão do seu alto consumo para produção de bens. Os distúrbios e as perdas de energia podem ocasionar a queima ou mau funcionamento de equipamentos, afetando diretamente o processo produtivo. É necessário identificar através do monitoramento, medição e análise, as situações que afetam a qualidade da energia em todos os segmentos. Nessa perspectiva, o presente estudo tem como objetivo realizar uma revisão sistemática de literatura para identificar os fatores que mais influenciam na qualidade do fornecimento da energia elétrica. O conhecimento dos fatores torna possível às organizações traçar um plano de gerenciamento da qualidade, podendo gerar um maior investimento em tecnologias para melhoria da produção e diminuição de gastos advindos desse consumo.

Palavras-chave: Qualidade da Energia Elétrica, Revisão Sistemática, Fatores, Fornecimento de Energia, Setor Elétrico Brasileiro.

1 Introdução

Nos setores industriais, a energia elétrica é considerada um dos produtos mais caros necessários à produção de bens [1], sendo gastos aproximadamente um terço da energia disponível [2], o que leva as empresas a equacionarem seus gastos advindos desse consumo [3]. A Energy Information Administration (EIA) estima que até 2050 a nível mundial, haja um aumento de aproximadamente 50% no uso da energia [4], sendo a China responsável por um quarto do consumo mundial de eletricidade [5]. No Brasil, embora o setor residencial seja responsável por 86,1% das unidades consumidoras de energia elétrica, em relação ao consumo, fica atrás do setor industrial, sendo

consumidos 137.615 GWh e 169.625 GWh de energia respectivamente [6].Um fator que pode condicionar às empresas perdas financeiras significativas é a qualidade da energia [7], sendo seu fraco desempenho prejudicial a todos segmentos da organização. Seu impacto está associado a questões como perda de produção, falhas de equipamentos, custos adicionais de operação e investimentos [8].

Externas às organizações, as distribuidoras de energia elétrica são responsáveis pelo fornecimento confiável e de qualidade da energia elétrica às empresas. Como esse fornecimento em muitos países é um monopólio natural, os clientes insatisfeitos com a qualidade ou com os preços pagos, acabam sem alternativas de troca de fornecedor. Isso aumenta a importância do monitoramento do desempenho das concessionárias de energia por parte dos órgãos reguladores [9]. Embora cada país possua seus próprios padrões de qualidade da energia, há diretrizes internacionais, como a norma técnica EN 50160 aplicada na Europa e aceita por todos os países, garantindo uma maior compatibilidade de padrões [10]. No Brasil, criada pela Lei n° 9.427, a Agência Nacional de Energia Elétrica (ANEEL) é a organização responsável por regular e fiscalizar o mercado de energia, monitorando também sua qualidade até os consumidores.

A avaliação da qualidade da energia elétrica é uma área que abrange toda cadeia de fornecimento, sendo importante desde a geração até a transmissão e distribuição da eletricidade [7]. No entanto, deve-se considerar também, que o aumento do número de empresas resulta em um acréscimo de cargas na rede, o que torna necessário um monitoramento adequado da qualidade de energia tanto pelas distribuidoras quanto pelos consumidores [8]. Oprea e Andrei [10] destacam ainda que as empresas ao investirem no desenvolvimento de tecnologias e equipamentos, acabam perturbando a linearidade da rede, afetando diretamente na qualidade da energia.

Os autores Dang e La [9] apontam em seu estudo, que a confiabilidade da rede elétrica aumenta a probabilidade de investimentos no setor agrícola, além do número de dias úteis a serem utilizados. Os autores destacam ainda que uma melhoria de 1% na qualidade da rede elétrica aumenta em 3,6% a probabilidade de se investir nesse setor. Já os autores Rusinaru et al. [8] discutiram em suas pesquisas uma nova abordagem para avaliar a qualidade da energia nas redes de distribuição. Para isso, um relatório de informações foi discutido, onde os fenômenos relacionados a qualidade de energia são avaliados e exibidos de maneira unitária, possibilitando a criação de mapas de perturbações e simplificando informações para que as empresas de distribuição compreendam facilmente o estado da qualidade da energia em sua rede. Gheorghe et al. [11] destacam que o funcionamento do sistema de monitoramento da qualidade de energia deve integrar aspectos técnicos, regulatórios e gerenciais para todos os participantes do mercado de energia. Sendo os aspectos técnicos a identificação de perturbações que causam a degradação da energia. Regulatórios consiste em uma estrutura para o monitoramento e medição, estabelecendo padrões e indicadores que caracterizem a qualidade para cada perturbação. E os aspectos gerenciais são as estratégias ou políticas para se monitorar os indicadores de qualidade, garantindo os padrões impostos na regulamentação. Os autores ainda colocam que uma gestão da qualidade de energia compreende sete etapas principais, estas apresentadas na Fig. 1.

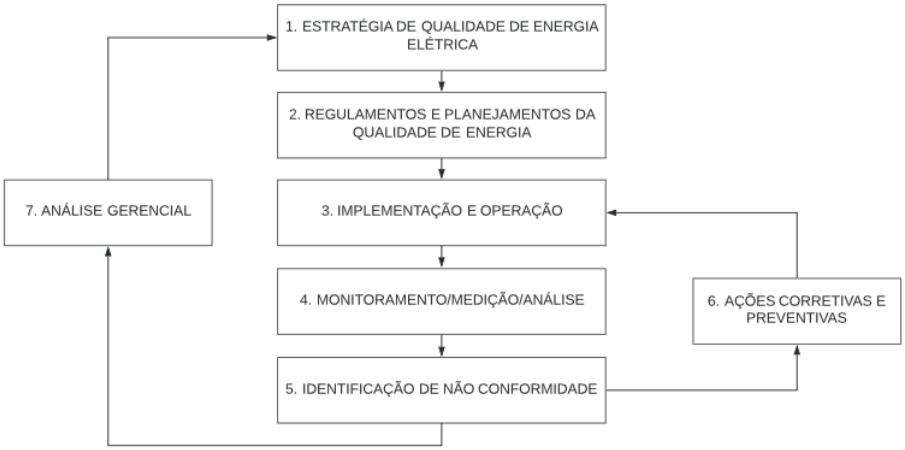

Fig. 1. Sete etapas da gestão da qualidade (Fonte: Gheorghe et al. [11])

É importante, porém, que os consumidores saibam identificar através do monitoramento, medição e análise, as situações que afetam a qualidade da energia em seus estabelecimentos. Com estratégias bem definidas, ter em vista não só os aspectos dependentes dos serviços das distribuidoras, mas também, aqueles relacionados ao meio ambiente e os vinculados aos seus processos, como equipamentos e tecnologias. Nesse sentido, o presente estudo tem como objetivo realizar uma revisão sistemática de literatura para identificar os fatores que mais influenciam na qualidade do fornecimento da energia elétrica utilizada, principal insumo dos processos industriais. Com essa abordagem, será possível a busca por soluções para mitigar tais impactos, proporcionando a redução de prejuízos advindos do consumo de energia elétrica aos consumidores, como a economia na fatura de energia elétrica e o aumento da produtividade das empresas.

2 Qualidade da Energia Elétrica

Neste capítulo serão apresentados conceitos fundamentais para contextualização e condução do estudo. O primeiro tópico apresenta os aspectos sobre os fenômenos que afetam a qualidade da energia elétrica e as percepções do mercado. Na sequência, o segundo tópico traz uma discussão sobre a sustentabilidade e o monitoramento da energia elétrica, abordando tecnologias e requisitos que permitem ao consumidor um melhor controle da qualidade da energia que recebem.

2.1 Fenômenos que afetam a qualidade de energia e as percepções do mercado

O fornecimento de energia elétrica confiável está relacionado com as questões de frequência das interrupções de energia. Assim, informações associadas as condições operacionais de equipamentos desempenham papel relevante no comportamento dos sistemas elétricos [12]. Uma vez que, existem eventos no sistema de energia que são associados ao baixo nível de qualidade de energia, como as oscilações, queda de tensão, cargas de desequilíbrio, distorção harmônica e menor fator de potência. Ao analisar historicamente os impactos de qualidade de energia mais prejudiciais para sociedade, conclui-se que estes são decorrentes de interrupções de longa duração, o que resulta em custo elevado. E, a substituição de equipamentos ineficientes juntamente com a análise das atividades de desperdícios contribuem com um aumento significativo na qualidade de energia [13,14].

Um estudo realizado por Pawawoi et al. [15] verificou o efeito de melhoria da qualidade para perda de energia nas linhas de distribuição de edifícios durante uma semana. Foi possível constatar que quando o consumo de eletricidade é relativamente pequeno, existe uma redução da perda de energia. Verificou-se que a redução de perdas de energia na linha de distribuição de cada edifício é proporcional ao nível de qualidade de energia da carga. Logo, o estudo apresenta que uma baixa qualidade da energia pode causar interferência no seu fornecimento.

Segundo Falchetta, Kasamba e Parkinson [16] na África subsaariana, a dependência da energia hidrelétrica representa um aspecto crítico para o desenvolvimento sustentável. Assim como na África muitas regiões carecem de meios acessíveis diante de perturbações temporárias causadas por fatores hidro climáticos como períodos prolongados de secas. As consequências desse fato são as quedas de energia e apagões recorrentes que implicam em questões comerciais, residenciais e perda de competitividade durante as anomalias de precipitação [17]. Ainda, observa-se que a interrupção de fornecimento aos consumidores ocasiona impactos diretos na produção econômica, através da perda de produção, matéria prima e horas trabalhadas, assim como também impactos indiretos, como perda de lazer e segurança [18].

Em relação as percepções do mercado, sabe-se que a energia elétrica apresenta o seu valor por MWh vendido ou consumido [18]. Onde, as variações na qualidade de energia que é fornecida podem acarretar em prejuízos para a sociedade, devido as alterações no seu fornecimento. Segundo a ANEEL [20], a distribuição de energia elétrica deve atender a dois conceitos de qualidade básicos como a qualidade de serviço prestados que compreende a avaliação de interrupções no fornecimento de energia elétrica e a qualidade do produto, que está relacionada à conformidade de tensão em regime permanente e as perturbações na forma de onda de tensão.

Assim, é possível entender que cada agente do setor elétrico apresenta uma percepção em relação ao custo de qualidade [21]. De maneira geral a distribuidora percebe apenas nas suas receitas e custos relativos a venda de energia com os investimentos na rede, somados ao custo de operação e manutenção desta. Uma perda decorrente da queda de consumo implica em custo para distribuidoras, que não ganham pela venda de energia, mas a receita esperada é baseada no consumo previsto. Já os

consumidores apresentam atividades afetadas pela energia elétrica, como preço de compra e prejuízos pela falta de energia como por exemplo uma parada total do processo produtivo. Por fim, o agente regulador é aquele que equilibra o mercado com regras e proporciona resultados para a sociedade [18].

2.2 Sustentabilidade de monitoramento da energia elétrica

Segundo Ferreira [23] a baixa qualidade de energia elétrica, independente da sua causa, pode gerar perdas significativas aos consumidores de energia, sendo as indústrias as mais afetadas, devido aos distúrbios que podem ocasionar um mau funcionamento e até mesmo queima de equipamentos. Esse cenário desperta preocupação por parte de concessionárias de energia elétrica em garantir a qualidade do produto. Conforme ANEEL [24], a qualidade percebida pelo consumidor de uma concessionária ou permissionária de serviço público de distribuição de energia elétrica é avaliada de acordo com o Módulo 8 do PRODIST, documento que fornece os procedimentos referentes à qualidade da energia elétrica, onde aborda a qualidade do produto e a qualidade do serviço prestado, enquanto que as Condições Gerais de Fornecimento, presente na Resolução Normativa nº 414/2010, apresentam os aspectos relacionados à qualidade do atendimento ao consumidor, do atendimento comercial, atendimento telefônico e tratamento das informações.

Ao mesmo tempo que este cenário desperta preocupação por parte de concessionárias, estimula também o interesse dos usuários de energia em monitorar a qualidade da energia elétrica o qual recebem. As principais atividades de monitoramento realizadas para a caracterização de problemas relacionados a qualidade de energia em um sistema de potência são detecções e classificações de distúrbios, além da compreensão dos dados, estimação e extração de parâmetros. Ainda, engloba fatores como localizar e identificar as fontes geradoras de distúrbios. Para tal, novas tecnologias em processamento digital de sinais, microprocessadores e dispositivos de armazenamento de dados, tornam possível o desenvolvimento de sistemas de monitoramento [22,25].

No mercado de energia elétrica, os sistemas de gestão de energia melhoram com a internet das coisas (IoT, do inglês Internet of Things). Empresas do setor de energia usam energias de fontes renováveis e estratégias baseadas na comparação de dados de indicadores de consumo dos equipamentos elétricos [26,27]. As tecnologias de energia considerada limpa e renovável promovem a sustentabilidade ambiental e os dispositivos inteligentes permitem um parecer imediato sobre o consumo de energia, o que aumenta a consciência sobre o estado da rede elétrica [27,28]. Segundo Golpîra e Bahramara [25] as redes inteligentes podem controlar os equipamentos de geração, transmissão, distribuição e consumo através da coleta de informações de indivíduos. Onde o desenvolvimento da tecnologia IoT torna possível transferir informações de demanda de energia do cliente para a nuvem, assim o banco de informações é armazenado em um servidor e toda rede de distribuição pode ser controlada.

3 Metodologia

A primeira fase da pesquisa parte da formação da *string*, o qual primou pelo desenvolvimento do protocolo de revisão e sua execução nas bases de dados. A partir da questão da pesquisa "Quais fatores influenciam na qualidade do fornecimento de energia elétrica utilizada em uma empresa? ", leituras iniciais auxiliaram para definição das palavras-chaves relacionadas ao desenvolvimento da *string* de busca. Duas bases de dados foram selecionadas: Spocus (Elsevier) e Web of Science (Clarivate Analytics). Essas bases, apresentaram as pesquisas mais relevantes da área de energia. Na estratégia de busca para a realização do estudo não foram especificados idioma e data de publicação, a única restrição aplicada foi a de artigos com acesso aberto. O desenvolvimento da pesquisa pode ser observado na Fig 2.

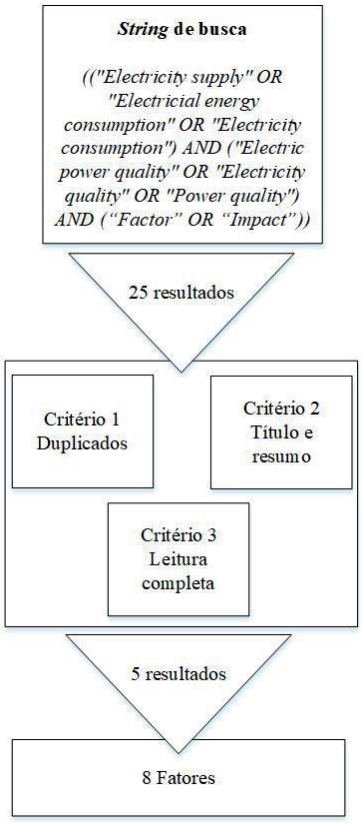

Fig. 2. Desenvolvimento da pesquisa

Na Fig. 2 é possível observar que a *string* de busca apresenta uma combinação de palavras presentes na questão da pesquisa, o que resultou em 25 artigos. A partir disso, foram aplicados os critérios de exclusão e extração. Primeiramente, no Critério 1, foram

excluídos os artigos duplicados, sendo identificado apenas um artigo. Na sequência, os demais critérios buscaram selecionar artigos de acordo com a questão da pesquisa.

No Critério 2 foram então selecionados 8 artigos a partir da leitura do título e resumo de todos os artigos. Já no Critério 3, foi realizada a leitura completa dos artigos selecionados no critério anterior, totalizando 5 artigos. Por fim, foi possível obter os fatores que influenciam na qualidade do fornecimento de energia elétrica utilizada em uma empresa. Assim, a metodologia empregada resultou em 8 fatores que respondem ao questionamento da pesquisa.

4 Resultados

Tendo em vista a importância da energia elétrica para a vida das pessoas, produção de bens e serviços em empresas, bem como a geração de empregos e contratos entre geradores e distribuidoras, a qualidade de toda essa energia consumida deve ser medida, analisada e monitorada. Para isso, faz-se necessário o conhecimento de fatores que influenciam este desempenho, sejam eles internos à organização, passíveis de melhoria como novas tecnologias e equipamentos, ou externos, como fatores ambientais ou ainda aqueles de domínio das empresas distribuidoras.

No Quadro 1 estão apresentados os cinco estudos encontrados e analisados, dos quais foram extraídos os 14 fatores que influenciam na qualidade do fornecimento de energia elétrica, com seus respectivos autores, título e ano de publicação.

Quadro 1. Estudos e fatores que influenciam na qualidade de energia elétrica

Título do Artigo	Autores	Fatores
Analysis of energy losses reduction potential on the distribution line of campus building through electric power quality improvement	Pawawoi et al. [15]	Perdas na linha de distribuição
		Equipamentos eficientes
		Investimento em automação
Analysis and identification of power blackout-sensitive users by using big data in the energy system	Shuai et al. [29]	Blecautes de energia
Performance analysis of methods at estimating insulated cables degradation	Velasco et al. [30]	Condições operacionais de equipamentos
Monitoring hydropower reliability in Malawi with		Mix de geração de energia

satellite data and machine learning	Falchetta, Kasamba e Parkinson [16]	Opções de backup
Analysis of the Spanish industry economical losses due to interruptions in the electricity supply	Coll-Mayor, Pardo e Pérez-Donsión [31]	Picos de consumo

Um dos principais fatores que afetam diretamente na qualidade da energia elétrica são as perdas de energia nas linhas de distribuição. Essas perdas reduzem significativamente a quantidade de energia que chega aos consumidores, reduzindo consequentemente, o seu consumo [15]. Essas perdas representam a diferença entre a energia injetada na rede de distribuição e a quantidade de energia que é faturada, sendo elas perdas técnicas e não técnicas [32]. As perdas técnicas ocorrem devido às perdas de calor nos componentes dos sistemas de transmissão e distribuição [33]. Já as perdas não técnicas, também conhecidas como perdas comerciais, dizem respeito as perdas não naturais e estão associadas a eletricidade não faturada e a faturada que não é paga, podendo ocorrer por erros na medição ou faturamento, ou comportamentos fraudulentos de consumidores [34], sendo muito difíceis de prever [35]. Com um plano de gerenciamento e investimentos em sistemas de automação é possível que consumidores e distribuidoras tenham um maior controle sobre essas perdas que ocasionam em desperdícios, sendo este um meio importante para aumentar a eficiência na distribuição e consumo [15].

Dispositivos inteligentes e sensores da Internet das Coisas, como medidores, terminais, equipamentos de monitoramento, dispositivos de telemetria e concentradores de dados, tem sido cada vez mais implementado nas redes de energia, fornecendo um grande suporte de dados para entender as características de cada usuário, proporcionando assim um aumento na qualidade da energia [29]. Esse ecossistema tecnológico, promete grandes redes de dispositivos conectados e coletando grandes volumes de dados e informações, monitorando fortemente os setores de energia [37]. Através do desenvolvimento e implementação desses dispositivos, os consumidores e as empresas responsáveis pela distribuição da energia, estarão mais preparadas para identificarem os motivos de uma queda na qualidade do fornecimento de energia elétrica, possibilitando um reparo imediato de eventuais falhas e evitando grandes perdas e prejuízos.

Outro fator que afeta a qualidade da energia, é o uso de equipamentos mais eficientes. Sendo de extrema importância que os consumidores se atentem a compra ou substituição de equipamentos ineficientes, isso trará um maior aproveitamento da energia elétrica, visto que a eficiência energética tem por definição a entrega de um trabalho considerando o mínimo de dispêndio possível [15]. A ineficiência energética está relacionada ao fato de os usuários utilizarem aparelhos antigos e ineficientes, sendo uma saída a este problema, o desenvolvimento de regulamentações que incentivem mudanças de hábitos por parte da população e à compra de novos equipamentos de alta eficiência [36].

Os chamados blecautes, ou quedas de energia, são outro fator que devem ser levados em consideração, pois afetam a qualidade da energia em todos os consumidores, sejam eles de maior ou menor curva de carga. Alguns aspectos devem observados, como tipos de sensores, duração de interrupções, perdas econômicas e localização como área urbana ou rural, afetarão no grau de sensibilidade de cada consumidor a esses blecautes de energia [29]. Essas quedas ou apagões de energia que afetam uma grande parte das redes de distribuição, são efeitos de falhas em cascatas, onde um componente afetado causa a falha de outros na sequência [38]. Esses apagões podem ser amenizados realizando investimentos para modernização dos elementos presentes na rede elétrica através do aumento de suas capacidades. Quedas de energia podem gerar extensas interrupções no fornecimento, gerando custos e prejuízos irreparáveis aos consumidores.

Os autores Velasco et al. [30] colocam que, garantir um fornecimento de energia confiável e de qualidade aos consumidores é um grande desafio, influenciando diretamente na melhoria de índices de continuidade da energia, como a duração e a frequência das interrupções. As condições operacionais dos equipamentos têm uma grande influência no sistema elétrico, como transformadores e cabos de energia. Sendo importante um sistema de monitoramento por software para realizar medições e o diagnóstico das condições operacionais dos equipamentos, objetivando reduzir interrupções de energia por falhas desses componentes.

Outro fator muito importante à qualidade da energia em um país é a diversificação da matriz elétrica. Países com grande dependência de recursos advindos de fontes renováveis para geração de energia, como ocorre por exemplo com o Brasil, o qual possui grande parte da energia proveniente usinas hidráulicas, acabam sofrendo com perturbações causadas por alterações climáticas, como longos períodos de estiagem ou enchentes, resultando em quedas de energia e apagões. Sendo assim, a capacidade adaptativa do país à novas fontes para geração de energia é de extrema importância para garantir qualidade de energia à toda população [16], possibilitando o suprimento de toda energia contratada mesmo que esses riscos e incertezas ocorram. Além disso, opções de backup seriam uma solução à países com o mesmo sistema de geração de energia brasileiro, viabilizando o armazenamento de parte ou de toda energia gerada para utilização em períodos de racionamento ou demais eventualidades, o que garantia qualidade no fornecimento de energia aos consumidores. Ainda externo às organizações, a quantidade de linhas de transmissão internacionais poderiam ser uma opção para garantir fornecimento de energia confiável, as importações de energia elétrica poderiam ser uma saída para eventuais problemas no sistema de abastecimento [16].

Por fim, os autores Coll-Mayor, Pardo e Pérez-Donsión [31] discutem em relação aos picos de consumo de energia elétrica nas indústrias, relatando que nesses períodos de máximo consumo ocorre uma maior perda de energia, afetando diretamente na qualidade. O estudo dos autores discute ainda sobre o desenvolvimento de uma metodologia que utiliza dados estatísticos para avaliar as consequências e perdas econômicas devido aos problemas de qualidade de energia, estes afetados por interrupções na fonte de alimentação ou quedas de tensão. Sendo as principais vantagens da nova metodologia a fácil aplicação, utilização de dados disponíveis,

desenvolvimento em diferentes países e o fornecimento de resultados para qualquer segmento de indústria.

5 Conclusões

Independente da sua causa, uma baixa qualidade de energia pode gerar perdas significativas aos consumidores. O termo qualidade na energia elétrica abrange toda cadeia de fornecimento e é importante desde a geração até a transmissão e distribuição da eletricidade. Com base nesse cenário, através da utilização do método de revisão sistemática de literatura foi possível identificar cientificamente fatores que afetam a qualidade da energia elétrica. Os autores citados neste estudo abordam metodologias que foram empregadas com a finalidade de avaliar problemas dentro do enquadramento de qualidade de energia elétrica.

Tendo em vista a importância do tema proposto e a carência de artigos que apontem aspectos gerais da falta de qualidade de energia nas organizações, este estudo foi realizado para elucidar e apontar soluções que auxiliem os consumidores no controle pela qualidade da energia elétrica. O conhecimento dos fatores internos torna possível às organizações traçar um plano de gerenciamento da qualidade, fazendo com que hajam investimentos em tecnologias, melhorando a produção e diminuindo gastos advindos desse consumo. Já a identificação de aspectos externos, como aqueles vinculados às empresas de distribuição e até mesmo climáticos, permite que as empresas saibam questionar aos responsáveis pelo setor de energia as medidas cabíveis para o melhoramento da qualidade da energia elétrica que chega até seus empreendimentos.

Km 7, Autopista Norte de Bogotá D.C., Chía, Cundinamarca, Colombia

Resumen. Este artículo tiene como objetivo la implementación de un modelo de localización de instalaciones para analizar el uso de los domicilios en el canal tradicional (tiendas de barrio) para mejorar la cobertura de la demanda de frutas y verduras con los cambios que ha supuesto la emergencia sanitaria causada por el COVID-19. Este tema presenta una gran relevancia dadas las restricciones de distanciamiento social y movilidad implementadas por muchos gobiernos para disminuir el contagio y garantizar la seguridad alimentaria de la población. El modelo busca la mejor configuración espacial de tiendas habilitadas para domicilios que incremente el acceso y la disponibilidad a las frutas y verduras. Se usó como caso de estudio los municipios de Chía y Cajicá en la región central de Colombia. Los resultados muestran que no es necesario más del 40% de tiendas habilitadas con servicio de domicilio para lograr la cobertura geográfica de las zonas críticas que son las áreas periféricas. Sin embargo, para incrementar la cobertura de la demanda si es necesario habilitar en más del 50% de tiendas el servicio de domicilio.

Palabras clave: Domicilios, problema de localización de instalaciones, logística de alimentos, tiendas de barrio, COVID-19.

1 Introducción

Desde que comenzó el brote del COVID-19 en enero de 2020 se han presentado más de 14 millones de casos y 597 mil muertes a nivel global. El brote se ha extendido por más de 200 países, siendo Colombia una de las naciones afectadas en donde hay más de 182 mil casos y 6 mil muertes [1]. Como solución para combatir la enfermedad, la mayoría de las naciones han reglamentado el confinamiento para disminuir la cantidad de contagios. Sin embargo, esto ha generado grandes impactos en la economía y el desarrollo del comercio [2], [3].

Las restricciones que ha impuesto la pandemia han representado un reto logístico sin precedentes y una gran disrupción en las cadenas de suministro (CS) [4]. Esto ha traído un gran riesgo para las operaciones, incluyendo cambios en la demanda, en la

distribución y en el abastecimiento [5]. El sector de "*retail*" ha sido uno de los más afectados; puesto que, para garantizar el acceso a los alimentos, ha tenido que buscar soluciones rápidas para responder a los cambios del comportamiento de los consumidores causados por las políticas adoptadas por los gobiernos durante la cuarentena [6].

De los factores que más han afectado la demanda a nivel general han sido el distanciamiento social y las restricciones de movilidad [7]. Específicamente, en el sector de alimentos, estas limitaciones han implicado la generación de las compras de pánico y el incremento de las compras online [8]. De hecho, este último efecto ha causado que muchos retailers hayan implementado el canal de domicilios para mejorar sus ventas por el efecto del COVID-19 [6]. Esto es debido a que se ha demostrado que la distancia es uno de los factores más importantes a la hora de que un cliente decida donde comprar sus alimentos [9], por ello garantizar el acceso y la disponibilidad es vital para sobrevivir a los efectos económicos de las restricciones antes mencionadas. Es así como los domicilios son una gran oportunidad para tratar con este problema [3].

Los domicilios son una parte importante del comercio electrónico, siendo especialmente complejo para los retailers al incrementar el ambiente tecnológico y así, las operaciones logísticas para la distribución de última milla [10]. Adicionalmente, la gestión de varios canales de ventas representa un reto para quienes solo han manejado las ventas presenciales. Es por lo que, la transformación inmediata a la que se tuvieron que someterse los retailers, dada la emergencia sanitaria, llevo a distintas ineficiencias [11].

Considerando lo anterior, el diseño de una red de domicilios se convierte en una decisión estratégica importante para que tenga el impacto deseado en el acceso a alimentos. Esto permite evaluar la disponibilidad que un hogar puede tener para abastecerse [12] y de esta manera, garantizar su seguridad alimentaria especialmente en tiempos de emergencia. Por estas razones, el presente artículo propone un modelo de optimización lineal entera mixta (MILP, por sus siglas en inglés) para diseñar una red de domicilios de tiendas que permita mejorar el acceso a alimentos frescos en los municipios de Chía y Cajicá, Colombia. Las tiendas en Colombia han sido el principal medio de abastecimiento en el tiempo de cuarentena. Estas han incrementado hasta en 96% sus ventas [13], [14]. Teniendo en cuenta esto y que el comercio online ha crecido significativamente [15], la red de domicilios garantizaría la supervivencia de este canal de retail a pesar de las implicaciones económicas de la pandemia; ya que, agrega valor a la CS [10]. Adicionalmente, se seleccionan los alimentos frescos, específicamente las frutas y verduras, teniendo en cuenta su importancia para garantizar la seguridad alimentaria del área de estudio; dado que, actualmente hay un bajo consumo de estas [30].

Este artículo está organizado como sigue. La sección 2 muestra los antecedentes de este trabajo con una breve revisión de los conceptos involucrados. La sección 3 presenta la definición formal del problema y el modelo matemático asociado. La sección 4 describe el caso de estudio de los municipios de Chía y Cajicá y el uso del modelo propuesto. La sección 5 presenta los resultados principales de la implementación en el caso de estudio. Finalmente, la sección 6 discute las conclusiones de este trabajo y sugiere algunos trabajos futuros.

2 Antecedentes

En esta sección se dará una breve revisión de los conceptos requeridos para el desarrollo de este trabajo.

2.1 Disrupción en CS causadas por pandemias

El efecto de las pandemias sobre las CS ha sido especialmente estudiado desde el punto de vista de logística humanitaria [16], [17]. No obstante, gran parte de estas investigaciones han sido enfocadas en mejorar la capacidad de respuesta para el suministro de dotaciones y recursos médicos. Por ejemplo, He et al. [18] presentaron un nuevo modelo de programación lineal para una rápida respuesta de los servicios médicos para tratar con emergencias sanitarias. Por otro lado, Anparasan et al. [19] propusieron un modelo de analítica de datos para asignar los recursos médicos en países en desarrollo usando información de la epidemia de cólera en Haití en 2010.

Sin embargo, hay pocas investigaciones asociadas al impacto económico y comercial de una pandemia sobre las CS. Chou et al. [20] son de los pocos autores que han investigado estos efectos con el virus del SARS en 2004 encontraron que el impacto más grande para Taiwán fue en el sector aéreo. Otros autores fueron Calnan et al. [21] quienes analizaron el efecto del virus del ébola en África en aspectos sociales y económicos concluyendo que construir un sistema de apoyo es importante para tratar los efectos de las pandemias.

Recientemente, con el brote del COVID-19 han aparecido nuevas investigaciones; dado que, muchos países cerraron sus fronteras causando grandes impactos en el comercio [5]. Un ejemplo de estos estudios son los llevados a cabo por Ivanov [5], [22] quien ha estudiado los factores que se requieren para tener una CS resiliente y predecir los efectos a largo plazo con simulación. Esto lo ha hecho a nivel general, mientras que Nicola et al. [8] han descrito específicamente los impactos en cada área económica. Para el caso del área de alimentos ha mencionado el incremento en los domicilios, siendo una parte importante para mantener la economía que debe ser regulada. Al respecto Li et al. [6] realizaron una encuesta en Wuhan en la cual se confirmó que el comercio online predominaba para abastecerse de alimentos. Sin embargo, está medida ha sido adoptada en distintos países sin una planeación previa teniendo en cuenta que es parte de una toma de decisiones estratégica.

2.2 Modelos de localización para el diseño de redes de domicilios

Habilitar los domicilios es una decisión estratégica importante, ya que implica un rediseño de la CS [12]. Una de las herramientas para tratar este problema son los modelos matemáticos de MILP, específicamente el problema de localización de instalaciones (FLP, por sus siglas en inglés). Este modelo consiste en la selección de la localización de una o más instalaciones para atender la demanda de un conjunto de consumidores [23]. Para el caso específico de los domicilios la mayor parte de los estudios se han concentrado en las decisiones tácticas de la distribución. Por ejemplo, Cagliano et al [24] utilizaron dinámica de sistemas para analizar el flujo en la CS

completa y optimizar la ruta de distribución según el tráfico en tiempo real. Los resultados mostraron la eficiencia de utilizar herramientas tecnológicas para la distribución de última milla. Autores como Pan et al. [25], Chen et al. [26] y Aktas et al. [27] usaron modelos matemáticos de ruteo de vehículos para disminuir costos operacionales, distancias y así tener mejor eficiencia en la distribución. En el alcance de esta investigación, solo se encontraron dos estudios que trataron con habilitar domicilios en los puntos de abastecimiento. El primero realizado por Zambetti et al. [12] quienes utilizaron un modelo de localización de instalaciones para asignar las localizaciones de los depósitos de las empresas intermediarias que prestan el servicio de domicilios. El segundo hecho por Hong et al. [28] también asignaba depósitos de envío desde donde se iniciaba el proceso de domicilio y adicionalmente optimizaban la ruta a seguir. No obstante, ninguno de estos modelos habilitaba el servicio de domicilio directamente en el punto de venta según la cobertura geográfica y por esta razón, es que este trabajo busca dar una solución al problema teniendo en cuenta las restricciones de movilidad dadas por la pandemia del COVID-19.

3 Propuesta

En esta sección se presenta en primer lugar la definición formal del problema del diseño de la red de domicilios y, en segundo lugar, se muestra el modelo matemático de programación lineal entera mixta (MILP, por sus siglas en inglés) asociado al problema.

3.1 Modelo MILP

La definición del problema es enunciada como sigue:

Un conjunto de clientes (hogares) $H = \{1...j\}$ se consideran geográficamente distribuidos dentro del área de estudio según la densidad residencial y deben abastecerse de alimentos frescos. Cada hogar $j \in H$ tiene una demanda d_j que debe ser satisfecha por una tienda $R = \{1...i\}$ dentro la máxima distancia de cobertura para el canal de ventas (presencial o domicilios) $V = \{1...k\}$ definido por el parámetro a_{ijk}. La capacidad de cada tienda $i \in R$ tiene un límite dado por el parámetro Q_{ik} para cada canal de ventas $k \in V$. Se considera que hay un ingreso P_1 por cada hogar $j \in H$ que este dentro del rango de cobertura de cada tienda $i \in R$ y otro ingreso P_2 por cada kilogramo de la demanda de un hogar $j \in H$ abastecido por la tienda $i \in R$. Adicionalmente, existe un costo C_k por habilitar el canal de ventas $k \in V$. Finalmente, tuvimos en cuenta un número máximo N de tiendas que pueden habilitarse para tener domicilios y un mínimo porcentaje β de la demanda total de alimentos frescos a cubrir.

3.2 Formulación del modelo

La siguiente notación es usada para formular el modelo de FLP:

Conjuntos

H conjunto de hogares; $j \in H$
R conjunto de tiendas potenciales para habilitar domicilios; $i \in R$
V conjunto de canales de ventas ofrecidos en las tiendas; $k \in V$

Parámetros

d_j demanda esperada para el hogar j
Q_{ik} máxima capacidad habilitada para cada tienda i en el canal de ventas k
a_{ijk} parámetro binario donde es 1 si la tienda i cubre al hogar j en el servicio k y 0 en otro caso
P_1 ingreso por cubrir espacialmente a un hogar
P_2 ingreso por kilogramo cubierto de la demanda de frutas y verduras
C_k costo por habilitar el canal de ventas k
N Porcentaje máximo de tiendas que pueden habilitarse para tener domicilios
t Total de tiendas que pueden habilitarse para tener domicilios
β mínimo porcentaje de la demanda total de frutas y verduras por cubrir
M número suficientemente grande para restricciones lógicas

Variables de decisión

$X_{ik} = \begin{cases} 1 \text{ Si la tienda } i \text{ utiliza el canal de venta } k \\ 0 \quad \text{En otro caso} \end{cases}$

$Y_{jk} = \begin{cases} 1 \text{ Si el hogar } j \text{ está cubierto en el canal de venta } k \\ 0 \quad \text{En otro caso} \end{cases}$

Z_{ji}= Proporción de la demanda del hogar j cubierto por la tienda i

La formulación es como sigue:

$$Max \sum_{j\in H}\sum_{k\in V} P_1 Y_{jk} + \sum_{i\in R}\sum_{j\in H} P_2 d_j Z_{ji} - \sum_{i\in R}\sum_{k\in V} C_k X_{ik} \quad (1)$$

Sujeto a:

$$\sum_{i\in R} a_{ijk} X_{ik} \geq Y_{jk} \quad \forall j,k \; ; \; j \in H, k \in V \quad (2)$$

$$\sum_{i \in R} a_{ijk} X_{ik} \leq M \, Y_{jk} \quad \forall j,k \; ; \; j \in H, k \in V \quad (3)$$

$$Z_{ji} \leq \sum_{k \in V} a_{ijk} X_{ik} \quad \forall i,j \; ; \; i \in R, j \in H \quad (4)$$

$$\sum_{i \in R} Z_{ji} \leq 1 \quad \forall j \; ; \; j \in H \quad (5)$$

$$\sum_{i \in R}\sum_{j \in H} d_j Z_{ji} \geq \beta \sum_{j \in H} d_j \quad \forall t \; ; t \in T \quad (6)$$

$$\sum_{j \in H} d_j Z_{ji} \leq \sum_{k \in V} Q_{ik} X_{ik} \quad \forall i \; ; \; i \in R \quad (7)$$

$$X_{ik} = 1 \ \forall i, k = 1 \ ; i \in H, k \ \in V \quad (8)$$

$$\sum_{i \in R} X_{ik} \leq N * t \ \ \forall k = 2 \ ; \ k \in V \quad (9)$$

$$Z_{ji} \geq 0 \ \ \forall j, i \ ; \ i \in R, j \in H \quad (10)$$

$$X_{ik} \ , Y_{jk} \ \in \{0,1\} \ \forall i, j, k \ ; \ i \in R, j \in H, k \ \in V \quad (11)$$

La función objetivo (1) maximiza la utilidad total de las tiendas teniendo en cuenta los ingresos por cubrir una tienda, los ingresos por las ventas de frutas y verduras y el costo que tiene habilitar el servicio de domicilios. El conjunto de restricciones (2) y (3) establece que un hogar puede estar cubierto en un canal de venta si este está dentro del rango de cobertura de una tienda que ofrece ese canal. El conjunto de restricciones (4) asegura que la demanda de un hogar solo puede estar cubierta por una tienda que tenga habilitado un determinado canal de venta y este dentro del rango de cobertura de esa tienda. El conjunto de restricciones (5) garantiza que la demanda de un hogar no se puede cubrir en más del 100% El conjunto de restricciones (6) asegura que la proporción cubierta de la demanda de frutas y verduras es mayor o igual que el porcentaje fijado previamente. El conjunto de restricciones (7) evita que las ventas de las tiendas sean mayores que sus capacidades. El conjunto de restricciones (8) habilita el servicio presencial para todas las tiendas, mientras que el conjunto de restricciones (9) limita el número de tiendas a las que se les puede habilitar el canal de ventas de domicilios. Finalmente, el conjunto de restricciones (10) y (11) hacen referencia a la naturaleza de las variables de decisión de no-negatividad y binarias.

4 Descripción del caso de estudio

Para este estudio se usaron datos recolectados de los municipios de Chía y Cajicá. Ambos son municipios colombianos los cuales pertenecen al departamento de Cundinamarca ubicados en la provincia Sabana Centro, a 10 y 17 km al norte de la ciudad de Bogotá (capital de Colombia), respectivamente. Chía tiene 142,302 habitantes [35], mientras que en Cajicá hay 62,862 habitantes [36]. Ambos municipios representan aproximadamente el 30% del territorio geográfico de la región.

En esta área la malnutrición prevalece evidenciándose en las tasas de niños nacidos con bajo peso, siendo de aproximadamente 11.2%, cifra que es preocupante [29]. Uno de los factores que más afecta es el bajo consumo de frutas y verduras [30] que en Colombia es de aproximadamente 190 gramos por persona, mientras que lo recomendado por la OMS es de 400 g [31]. El abastecimiento de alimentos en la zona tiene grandes fallas logísticas, por ejemplo los costos de transporte son elevados, el tiempo para abastecerse es alto al ir hasta Bogotá, la falta de planeación en el manejo de inventarios, entre otras [32]. Esa falta de planeación hizo que con la llegada del COVID-19 muchas tiendas no pudieran responder al incremento de la demanda y a la búsqueda de canales alternativos por el confinamiento [6].

4.1 Preparación de los datos

Los puntos demanda se establecieron ubicando la densidad poblacional del área a través de Google Earth™. Para Chía se tomaron 700 puntos de demanda, mientras que para Cajicá se tomaron 495 puntos. Con la información obtenida de la población de ambos municipios se asumió que cada punto en Chía representaba a 203.3 habitantes, mientas que para cada punto en Cajicá representaba a 127 habitantes. El consumo por persona se determinó mediante el Perfil Nacional de Consumo de Frutas y Verduras [37], en el cual, para el departamento de Cundinamarca, la media de consumo de frutas y verduras (alimentos frescos) fue de 107 gr y 107.8 gr respectivamente; por lo que, se asumió que el consumo total en los municipios de Chía y Cajicá es de 0.2148 Kg por persona. Con lo anterior se determinó que para cada punto de demanda el consumo es de 305.665 Kg por semana para el municipio de Chía y para Cajicá cada punto de demanda consume 190.948 Kg por semana.

Por otro lado, el número potencial de tiendas de barrio que existen en ambos municipios se determinó a través de las vistas panorámicas proporcionadas por Google Earth™ y Google Maps™. Se obtuvo que el municipio de Chía cuenta con un aproximado de 144 tiendas y el municipio de Cajicá cuenta con 104 tiendas aproximadamente. Las distancias fueron calculadas con la ecuación de Haversine, la cual da la distancia de dos puntos en una esfera según su la latitud y longitud [33]. Para considerar la estructura vial y otras condiciones geográficas se consideró un factor multiplicador [34]. El radio máximo de cobertura del servicio presencial es de 0.5 kilómetros mientras que el de servicio de domicilio es de 2 kilómetros.

Para conocer la capacidad de las tiendas, se realizaron 74 encuestas a tenderos. En la Tabla 1 se presentan los resultados de frecuencia y de cantidad de compra. Se puede observar que el 51% de los tenderos se abastecen de 2 a 3 veces por semana, y el 22% compran entre 151 y 180 kg cada vez que se abastecen. Por esta razón, la capacidad se determinó con el promedio del consolidado entre la frecuencia de compra y la cantidad de compra para cada municipio. A partir de esto se obtuvo un promedio total semanal de 672 Kg para todas las tiendas ubicadas en Chía y de 415 Kg para las tiendas ubicadas en Cajicá. Asumimos que para habilitar domicilios es necesaria una capacidad adicional de un 15%.

Tabla 1. Resultados de frecuencia y cantidad de compra de la encuesta aplicada a tenderos

Frecuencia de compra	%	Cantidad por cada compra	%
2-3 veces por semana	51%	Más de 180 kg	34%
Diariamente	27%	151-180 kg	22%
1 vez a la semana	16%	31-60 kg	19%
4-6 veces por semana	5%	91-120 kg	11%
Menos de una vez a la semana	1%	61-90 kg	7%
		Menos de 30 kg	4%
		121-150 kg	4%

El ingreso asociado a que un hogar se encuentra cubierto por alguna tienda es de $82,500 COP ($22.1 USD aprox.) y hace referencia al precio por semana de la canas-

ta básica familiar [38]. Por otro lado, el ingreso relacionado a la venta de frutas y verduras es de $3,500 COP ($1 USD aprox.) por kilogramo, el cual se tomó teniendo en cuenta el precio de abastos del boletín de precio diario [39]. Para el costo de habilitar un determinado tipo de venta, se asumió que para venta presencial es de $0 COP, al ya existir las tiendas, y para la venta por domicilio un costo asociado al tiempo que le tomaría a un domiciliario realizar el recorrido de la tienda hasta el punto de demanda según el salario mínimo legal vigente de Colombia año 2020 [40], obteniendo un costo de $714,000 COP ($192 USD).

5 Resultados

El modelo matemático fue implementado en el software GAMS. Probamos diferentes instancias con la variación del número máximo de tiendas N que se habilitarán para tener domicilios y el porcentaje mínimo a cubrir de la demanda total de frutas y verduras β. El parámetro N se varío de acuerdo con un porcentaje entre 20% y 70% del total de tiendas que hay en Chía y Cajicá.

La Fig. 1 muestra la cobertura real de la demanda de frutas y verduras en los casos evaluados con un β de 0.1 y 0.5. Se puede observar como el porcentaje de cubrimiento de la demanda varía principalmente por la cantidad de tiendas N habilitadas para prestar servicio de domicilio sin importar el porcentaje mínimo de la demanda β definido para cada prueba de experimentación. De hecho, para β entre 5% y 40% la curva obtenida es la misma que es la mostrada en la Fig. 1 con un β de 0.1.

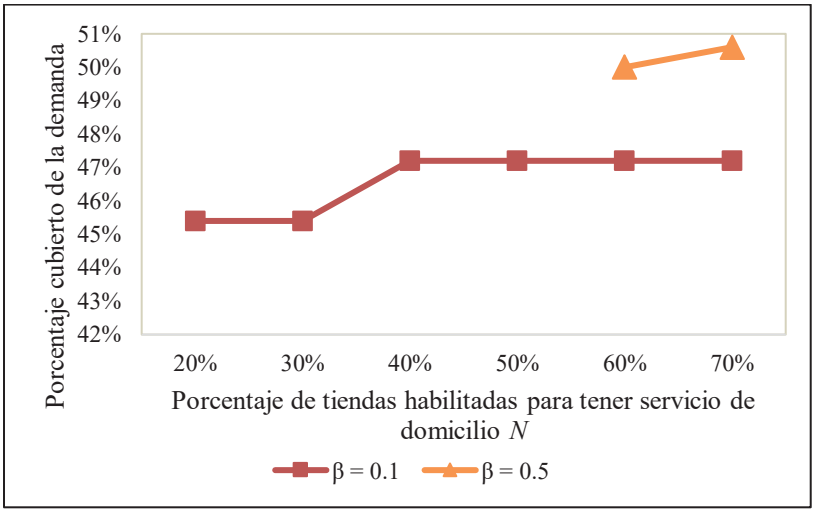

Fig. 1. Porcentaje real cubierto de la demanda de acuerdo con la cantidad de tiendas habilitadas para tener domicilios y el porcentaje mínimo a cubrir de la demanda total de frutas y verduras

Lo anterior se da debido a que la cobertura de la demanda que hay en cada uno de los casos depende de la capacidad con la que se cuenta acorde a las tiendas habilitadas

para tener servicio de domicilio. Observamos que el cubrimiento de la demanda se estabiliza luego de tener el 40% del total de las tiendas habilitadas para domicilios con un porcentaje mínimo de la demanda β de hasta 40%. Este es un resultado interesante que indicaría que el servicio de domicilio para más del 40% de las tiendas existentes no es necesario, ya que no varía el cubrimiento de la demanda. Sin embargo, para cubrir más del 50% de la demanda de frutas y verduras es necesario habilitar como mínimo un 60% de las tiendas existentes, lo cual implicaría mayores costos de implementación del servicio. Hay que tener en cuenta que no se están considerando los otros tipos de vendedores de frutas y verduras como supermercados mayoristas, mercados centrales, entre otros; por lo que, cubrir un 50% de la demanda estaría dentro de una buena solución al suponer que la cantidad restante es abastecida por los tipos de vendedores.

Por otro lado, el anterior patrón de estabilización del porcentaje real cubierto de la demanda se confirma con los resultados mostrados en la Tabla 2, en la cual se observa la cantidad de tiendas que es asignada para tener domicilios en cada caso evaluado. Podemos observar que el número de tiendas habilitadas para tener el canal de domicilios no supera las 75 para β menores a 40%. De hecho, este mínimo porcentaje de la demanda a cubrir no afecta el resultado hasta que se evalúa con 50%, donde se evidencia, tanto en la Fig. 1 como en la Tabla 2, que es necesario habilitar más de las 75 tiendas con el servicio de domicilio.

Tabla 2. Número de tiendas habilitadas para prestar el servicio de domicilios según las variaciones del parámetro N y el parámetro β

N	β =5%	β =10%	β =20%	β =30%	β =40%	β =50%
25%	9	9	9	9	9	
30%	9	9	9	9	9	
35%	75	75	75	75	75	
50%	75	75	75	75	75	
60%	75	75	75	75	75	148
75%	75	75	75	75	75	173

Por otro lado, frente al cubrimiento espacial, la Fig. 2 indica zonas con desabastecimiento en las periferias de ambos municipios (puntos rojos), exponiendo a los habitantes de esta zona al riesgo de contagio al tener que ir lejos de sus casas a hacer la compra de alimentos. Este cubrimiento es considerando solo el canal de ventas presencial en las tiendas.

Con las soluciones obtenidas con el modelo el cubrimiento espacial mejora. Por ejemplo, seleccionando la solución con un β de 40% y un N de 30%, se habilitan un total de solo 9 tiendas (Ver Tabla 2) con domicilios que se distribuyen geográficamente como se muestra en la Fig. 3 (a). Esta distribución logra el cubrimiento geográfico observado en la Fig. 4 en la cual se puede ver que se logra cubrir los puntos de demanda que no son cubiertos en el escenario actual en las áreas periféricas de ambos municipios (Ver Fig. 2) garantizando que todos los puntos de demanda están cubiertos

por al menos una tienda para abastecerse. Además, se obtiene una cobertura del 45.4% de la demanda de frutas y verduras.

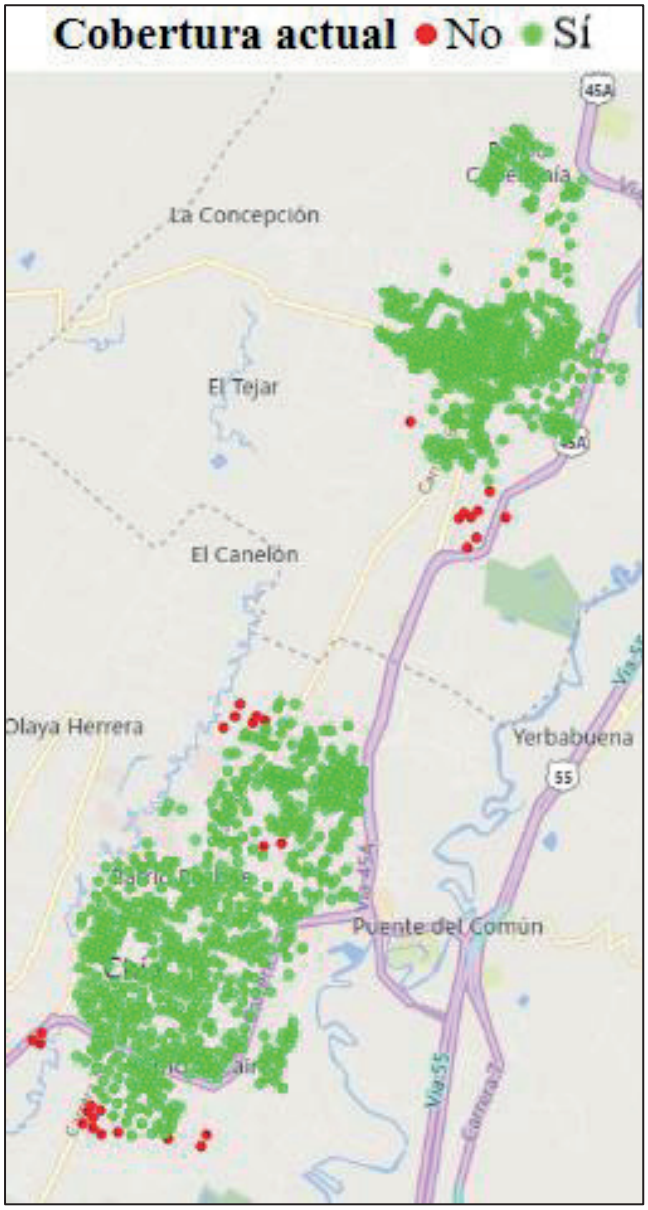

Fig. 2. Cobertura espacial actual de la demanda de frutas y verduras en Chía y Cajicá

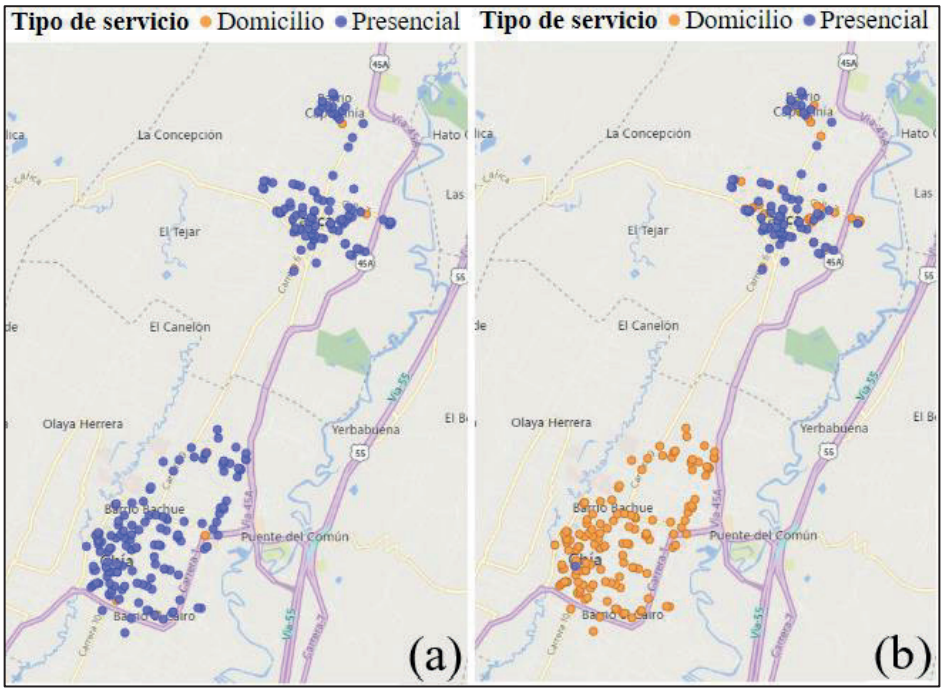

Fig. 3. (a) Tipo de servicio en cada tienda en escenario con un β de 40% y un N de 30%. (b) Tipo de servicio en cada tienda en escenario con un β de 50% y un N de 70%.

Seleccionando otro escenario para analizar la cobertura; por ejemplo, la solución con un β de 50% y un N de 70%, en la cual se habilitan un total de 173 tiendas con domicilios (Ver Tabla 2) que se distribuyen geográficamente como se muestra en la Fig. 3 (b), la cobertura que logra esta distribución es la misma mostrada en la Fig. 4. Es decir que, aunque se logre que todos los puntos de demanda queden cubiertos por al menos una tienda ya sea presencialmente o por medio de domicilios, el cubrimiento geográfico no mejora. Esto evidencia que, para tener un buen acceso espacial al abastecimiento de frutas y verduras, no se requiere un gran número de tiendas con domicilios. Sin embargo, la cobertura de la demanda con esta solución se incrementa a 50.6%, un 5% más en comparación mostrado en la Fig. 3 (a), lo cual mejora la disponibilidad de frutas y verduras para la población. Así que, aunque no se mejore la accesibilidad espacial si se mejora la disponibilidad de la cantidad ofertada para suplir la demanda. Adicionalmente, esta solución permite que las personas de ambos municipios tengan mayores opciones para poder abastecerse debido a que serían muchas más las tiendas las que prestarían el servicio presencial y de domicilios. No obstante, el habilitar más domicilios genera costos individuales a cada propietario.

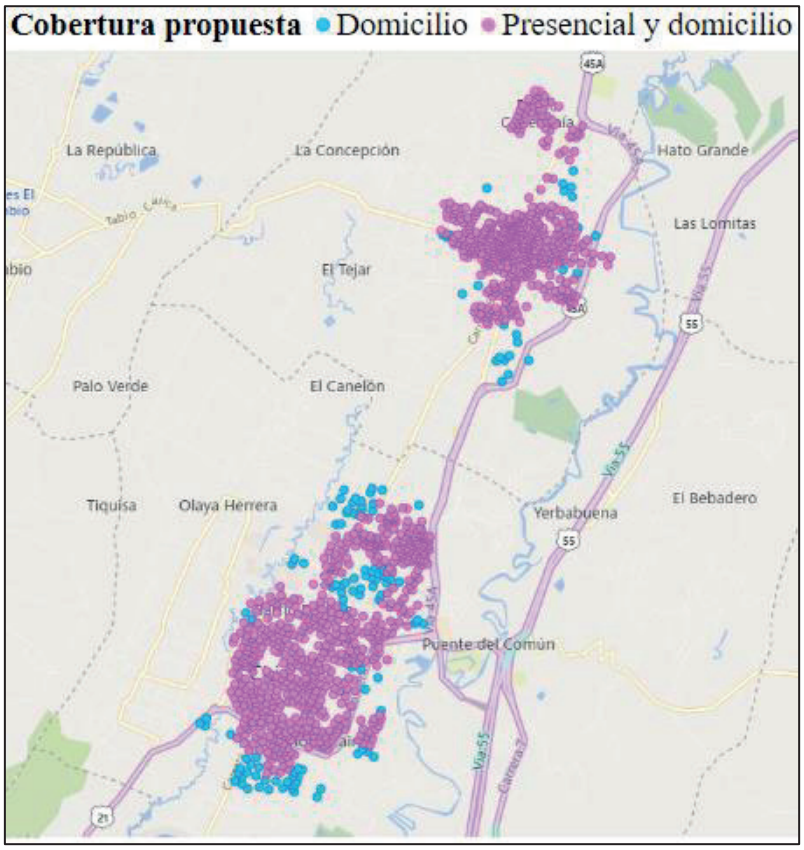

Fig. 4. Cobertura geográfica de la solución del escenario 1 y 4 según el tipo de canal de ventas para los municipios de Chía y Cajicá

6 Conclusiones y trabajos futuros

Esta investigación propuso una solución para la distribución de una red de domicilios de tiendas teniendo en cuenta la presencia del COVID-19 y las restricciones de confinamiento para evitar contagios. Con el modelo se logró determinar cuántas y cuáles tiendas son las que deberían ser habilitadas para prestar servicio de domicilio para que todos los puntos de demanda estuvieran cubiertos por lo menos por una tienda en cualquiera de sus modalidades (servicio presencial o domicilio).

Se observó que, a pesar de poder habilitar hasta el 70% de tiendas con domicilios, el modelo no lo hacía al obtener el cubrimiento geográfico de todos los hogares con solo el 40% del total de tiendas en las zonas de estudio. Esto se pudo observar en la Fig. 1, lo cual indica que no es necesario tener una red con más de 10 tiendas para mejorar la accesibilidad a frutas y verduras. No obstante, para cubrir más del 50% de la demanda total es necesario habilitar más de 140 tiendas con el servicio de domicilio, es decir que se requería mayor inversión para el aumento de la capacidad.

Considerando esto, dependiendo del enfoque de la necesidad que se desee suplir, ya sea en obtener la utilidad máxima o tener una mejor cobertura de la demanda total de frutas y verduras, se puede observar que una solución es mejor que otra a pesar de mantener la misma cobertura espacial. Hay que considerar los presupuestos limitados que pueden tener estas tiendas; ya que, las que se están analizando son tiendas de barrio que por su tamaño pueden restringirse de la posibilidad de prestar el servicio de domicilio. Para futuras investigaciones se puede considerar esa variación en el tamaño y presupuesto específico que tiene cada una de las tiendas; además de, la disposición de los hogares (clientes) a usar un tipo de servicio en lugar de otro.

Abstract. The Brazilian Navy's main mission is to control maritime areas, deny the use of the sea to the enemy and design the Naval Power, thus defending the Brazilian Jurisdictional Waters (BJW). For this, a robust naval force is needed to enable the fulfillment of its mission. The Brazilian Navy Fleet is located in the interior of Guanabara Bay, where the Port of Rio de Janeiro is also located. This fact weakens the National Defense since there is the possibility of carrying out, by ships, submarines, or mines enemies, a dam or blockade of the only exit to the sea. Therefore, this paper aims to select the most suitable city to be the headquarters of the Second Fleet of the Brazilian Navy. Several localities distributed throughout practically all navigable areas of the Brazilian territory were analyzed as possible headquarters for the Second Squadron. For the structuring of the problem, the Soft Systems Methodology (SSM) was used. For the decision-making process, hybrid modeling was used, with the SAPEVO-M method to obtain the weights of the criteria and the VIKOR method for the evaluation of alternatives. For the composition of the model, the criteria Distance to the Sea (KM), Width of Departure (KM), Distance from Rio de Janeiro (MN), Infrastructure for Repairs, and State of the Sea (Scale) were selected. After the application of the methods, the city of Belém was selected as the most indicated to be the headquarters of the new Brazilian Fleet.

Keywords: Management, Multicriteria Analysis, SAPEVO-M, VIKOR, Brazilian Navy.

1 Introduction

The National Defense Strategy (END), enacted in 2008 and updated in 2012, in order to ensure the security of the country both in peacetime and in crises, establishes guidelines for the proper preparation and training of the Brazilian Armed Forces (FFAA). The END was also developed to meet the equipment needs of the Military Commands, reorganizing the defense industry so that the most advanced technologies are under national control and instituting medium and long-term strategic actions aimed at modernizing the national defense structure [1].

Brazil's natural maritime vocation is supported by its extensive coastline, waterways, the magnitude of its maritime trade and the undeniable strategic and economic importance of the South Atlantic, which hosts the "Blue Amazon", an area that incorporates the high potential for living and non-living resources, such as Brazil's largest oil and natural gas reserves. The oceans are also important climate conditioners, besides serving as a cradle for submarine cables, whose data traffic is responsible for virtually all of the country's communication with the world [2].

The naval power must possess sufficient capacity and credibility to deter any adverse forces from conducting hostile actions in the AJB. The action of naval units in the South Atlantic, where the "Blue Amazon" is inserted, and in the Amazon and Paraguay rivers basins will be an essential factor for strengthening this deterrence. Thus, the Force must be prepared, both to act in an interstate crisis, and to monitor and suppress the actions of adverse groups practicing illegal activities in the AJB [2].

Over the past few years, much has been discussed about the constitution of the so-called Second Fleet, supported by a Naval Base capable of meeting the logistical needs arising. Numerous reasons justify a greater presence of the Brazilian Naval Power in the Blue Amazon [3].

With the survey of some points in the history of wars around the globe, there is a need to deal with some difficulties that Brazil may face if there is an armed conflict. An important point is a possibility of being carried out, by enemy ships or submarines, a dam or blockade at the exit to the sea. As Brazil has only one fleet headquarters – Rio de Janeiro – the country could go through serious problems due to the lack of a Second Fleet. Another important point, of great value to society, which justifies the Second Squadron, is the need for patrols and naval inspections, ensuring national sovereignty throughout the Blue Amazon.

However, the budgetary constraints are known and the need to prioritize the construction of submarines and corvettes, more essential to the Naval Power, led to the postponement of the Second Squadron project and its Naval Base [3].

In the study proposed by this paper, localities distributed through all navigable areas of the Brazilian territory are analyzed as possible headquarters for the Second Fleet.

In the decision-making process, Production Engineering becomes a fundamental mechanism in advising managers [4]. Part of this area, Operational Research (OR) is the comprehensive and multidisciplinary field that employs mathematical and analytical models for the solution of complex problems [5].

One relevant feature for a method of supporting decision-making is the availability of software implementing the method, as well as its graphical representation and

exploitation of results [6]. Considering the structure of the proposed problem and the availability of software, this article will use hybrid modeling composed of the SAPEVO-M method to obtain the weights of the criteria and VIKOR method for the evaluation of alternatives.

Taking into account that the country is undergoing a serious budgetary constraint, only cities that already have a previously established naval base structure will be evaluated, considering that the construction of a large maintenance complex requires a large amount to the public coffers.

2 Problem Structuring

Problems Structuring Methods (PSM) are one of the stages of the decision-making process that aims to organize issues, questions and/or dilemmas for which decision propositions are sought [7]. PSM is widely accessible in the OR and in the movement of systems for understanding and structuring complex problems [8].

Every model has validity only within a certain managerial context, which, in addition to taking into account the specificities of the organization studied, also has a "space-time" validity [9].

Among the most used PSM, this paper will use the Soft Systems Methodology (SSM) [10], which has been explored in a variety of research fields, as well as serves equally diverse practical interests.

SSM presents seven stages of application [10], which two will be addressed in this article for the problem structuring:

1 - explore an unstructured problematic situation; and

2 - express it by making a rich picture.

In the first stage, the brainstorming technique was used by the authors to demonstrate the perceptions of the group about all possible information, without interference or judgments to define the problem. In the second stage, a rich picture was constructed (Fig. 1) to express all relevant aspects of the problem.

The rich picture is a simple SSM tool, extremely useful for opening the discussion around individual perceptions towards a broad view of the different issues affecting the situation. They are created freely and unstructured to capture the participants' interpretation of a real situation [10,11].

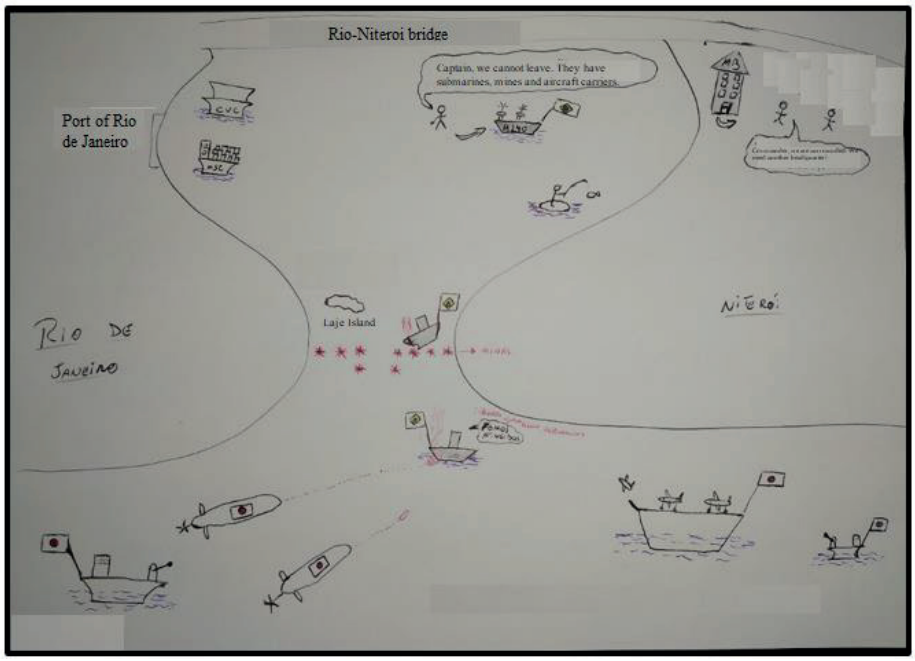

Fig. 1. Rich picture, entitled "Need for a second Fleet".

The rich picture shows that the Brazilian Navy Squadron is located inside Guanabara Bay, where the Port of Rio de Janeiro is also located. This fact weakens the national defense since there is the possibility of being carried out a dam or blockade of the only exit to the sea. This is considered a Political and Strategic movement that can lead Brazil to experience severe problems.

After analyzing the rich picture and consulting three Brazilian Navy officers with more than 20 years of experience, five criteria were established: Distance to the Sea (DS, Exit Width (EW), Distance from Rio de Janeiro by sea (DRJ), Infrastructure for Maintenance (IM) and State of the sea (SS).

Also, the alternatives of cities to be established as the headquarters of the second fleet were established, all of them with previously established naval base structure: Salvador/BA, Natal/RN, Rio Grande/RS, Ladário/MS, Belém/PA and Manaus/AM.

2.1 Presentation of criteria

The five criteria were chosen to compose the model are as follows:

I – Distance to the Sea (DS): It was considered to be the approximate distance of the existing Military Organizations, which could be reformulated to become the probable Second Squadron, to the point where it is considered the largest free area for maneuvering the naval means.

II – Exit Width (EW): The exit width to the sea is essential, since the smaller the maneuvering space, the greater the probability of applying some type of barrier or

blockade so that it is not possible to have access to the sea. Besides, a larger entry/exit width allows access to larger ships to the future second fleet headquarters.

III – Distance to Rio de Janeiro by sea (DRJ): Considering that the Brazilian coast is considerably extensive and taking into consideration the existence of a headquarter in Rio de Janeiro, the further away from this Second Squadron is, the better it will be for a larger area of operation concerning the protection of the entire Brazilian coast.

IV - Infrastructure for Maintenance (IM): It was considered as being the supply of specialized labor and bases for repairs of ships that will be crowded in the second fleet.

V - State of the sea (SS): Considered as being the general condition of ocean waves in a given locality and time. The state of the sea is characterized by statistics, which include wave height, frequency and spectral density. In this article, the data referring to the state of the sea were recorded by the official website of the Brazilian Navy Hydrography Center [12] through the Douglas Scale of the State of the Sea.

2.2 Presentation of alternatives

After the establishment of the criteria, and seeking to evaluate cities with previously established infrastructure, distributed along the Brazilian coast, six cities were selected to compose the model: Salvador - BA, Natal - RN, Rio Grande - RS, Ladário - MS, Belém - PA and Manaus - AM.

Table 1 presents the attributes of the cities in each criterion.

Table 1. Data from the cities evaluated.

Criterion	Feature	Salvador/ Ba	Natal	Rio Grande	Ladário	Belém	Manaus
DS (Km)	1st exit	1,7	5,5	18	No access	100	No access
	2nd exit	25	-	-	-	130	-
EW (m)	1st exit	450	200	500	200	1200	1500
	2nd exit	9000	-	-	-	1500	-
DRJ (NM)	In Nautical Miles	745	1233	755	-	2218	-
IM	Naval Base + City Structure	4	3	1	2	2	2
SS	Douglas Sea State Scale	2	2	5	1	1	1

3 Background

In this section, the SAPEVO-M and VIKOR methods will be described, which will be used in hybrid modeling as tools to support decision-making.

3.1 SAPEVO-M method

In general, the desired result in a given Multicriteria Decision Support problem can be identified among four types of reference problems [13]:

I - Problematic P.α - aims to clarify the decision by choosing a subset of alternatives as restricted as possible. Therefore, the desired result is a choice;

II - Problematic P.β - aims to clarify the decision by a screening resulting from the allocation of each alternative to a class (or category). Therefore, the desired result is a sort action;

III - Problematic P.γ - aims to clarify the decision by an organization obtained by the regrouping of part or all actions in equivalence classes, which are ordered partially or completely, according to the preferences of the decision-maker(s). Therefore, the desired result is a sort or ranking procedure;

IV - Problematic P.δ - aims to clarify the decision by a description of the actions and their consequences. Therefore, the desired result is a cognitive procedure or a description.

The Simple Aggregation of Preferences Expressed by Ordinal Vectors - Multi Decision Makers method (SAPEVO-M) represents a new version of the SAPEVO ordinal method [14], especially for problems of the P.γ type. This evolution of the original version extended the use of the method to multiple decision-makers [15].

The SAPEVO method unfolds the decision-making problem from three basic steps [15], which are:

1. Transforms the ordinal preferences of the criteria into a vector of criterion weights;
2. Transforms the ordinal preferences of alternatives for a given set of classification criteria into partial weights of alternatives; and
3. Determines the global weights of the alternatives.

The method has been applied in several areas, such as the selection of equipment for a bakery [16] and the selection of a troop landing ship for the Argentine navy [17].

SapevoWeb Computer System. The SapevoWeb system was developed from a partnership between the technical staff of the Naval Systems Analysis Centre (CASNAV), a research group of the Graduate Program in Production Engineering of the Fluminense Federal University (UFF) and a research group of the Graduate Program in Systems and Computer Engineering of the Military Institute of Engineering (IME) [15].

SapevoWeb code was developed in python language, using the Django framework, and HTML [18]. The program allows the inclusion of a sufficiently large integer of decision-makers, criteria and alternatives, limited only by the processing capacity of the server. The computational tool can be accessed at www.sapevoweb.com [15].

3.2 VIKOR method

The *ViseKriterijumska Optimizacija i Kompromisno Resenje* (VIKOR) method was developed as a method of commitment programming, to determine a ranking with weights of a set of alternatives [19]. To observe this weight that measures the ranking, a few steps must be followed [20,21] such as:

Step 1: Determine the highest values f_i^* and the lowest values f_i^- of all the alternatives in each criterion, i = 1, 2, ..., n.

$$f_i^* = max_j f_{ij}$$
$$f_i^- = min_j f_{ij}$$

Where f_i^* is the highest value presented by the alternatives in each criterion;
f_i^- is the lowest value presented by the alternatives in each criterion; and
f_{ij} is the value of the alternative in a given criterion.

Step 2: Calculate the values S (maximum utility group) (1) and R (minimum individual weight) (2), with j = 1, 2, ..., j, in the relationships; where W_i is the weight of the criteria.

$$S_j = \frac{\sum_{i=1}^{n} W_i(f_i^* - f_i^-)}{(f_i^* - f_i^-)} \quad (1)$$

$$R_j = max_j \left(\frac{\sum_{i=1}^{n} W_i(f_i^* - f_i^-)}{(f_i^* - f_i^-)} \right) \quad (2)$$

S_j: maximum utility group of the alternative j;
W_i: weights of the criteria obtained by calculating entropy;
R_j: the minimum individual weight of alternative j.

Step 3: Calculate the values of Q_j (3), with j = 1, 2, ..., j, by the ratio in which $S^* = min_j Sj$; $S^- = max_j S_j$ and $R^* = min_j R_j$; $R^- = max_j R_j$. Parameter v is entered as a strategy weight, commonly used as v = 0.5.

$$Q_j = \frac{v(S_j - S^*)}{(S^- - S^*)} + \frac{(1 - V)(R_j - R^*)}{(R^- - R^*)} \quad (3)$$

Where v = 0.5 and Q_j is the final score of an alternative j;

Step 4: Classify the alternatives in a decreasing ordination, using the values obtained by S, R and Q. The results are three classification lists. However, only the values obtained by Q can be considered.

Step 5: Once the Ranking on the decreasing values of Q_i is established, the analysis on the verifications of stability conditions C_1 and C_2, which are obtained through (4) and (5):

C_1 - Acceptable difference/advantage:

$$Q(A_2) - Q(A_1) \geq DQ \quad (4)$$

Where $DQ = \frac{1}{j-1}$ and j is the number of alternatives.

C_2 - Acceptable stability in decision-making: A_1 should be the best rated in S and/or R.

If one of the conditions (C_1 and C_2) is not met, then a cluster of compromise solutions is proposed, which consists of:

Alternatives A_1 and A_2, if only C_2 is not satisfied; or

Alternatives A_1, A_2, ... A_M, if only condition C_1 is not satisfied; The M value is determined for the maximum value of M that satisfies the equation (5):

$$Q(A_M) - Q(A_1) < DQ \tag{5}$$

4 Application of SAPEVO-M and VIKOR methods

First, the SAPEVO-M method will be applied to obtain the weights of the criteria, through the Software SapevoWeb [18]. After this, using the VIKOR method, through the Vikor software [22], the classification of cities will be obtained and stability conditions checked.

4.1 Evaluation of criteria

Three Navy officers with more than 20 years of experience have already been invited to evaluate the criteria that compose the problem. After registering the decision-makers (DM), criteria and alternatives of the cities, the DM will evaluate, one by one, the importance of the criteria and alternatives [15].

After evaluating the criteria chosen by the Navy Officers, the weights of the criteria are obtained, according to Table 2.

Table 2. Weights of the criteria, obtained by applying the SAPEVO-M method.

Criterion	Weight
DS	1,4185
EW	2,9473
DRJ	1,4135
IM	2,6040
SS	0,0131

Analyzing the weights of the criteria, it is observed that the exit width was the criterion that obtained the greatest weight in the evaluation, followed by the infrastructure for maintenance. The state of the sea was considered the least important by the DM.

The SAPEVO-M method allows to know how much an alternative and /or criterion was better ordered, in relation to another, passing additional information to the DM [15]. In other words, this means that the exit width criterion (Weight 2.9473) was

considered about 2 times better or more important than the distance from RJ by sea and distance to the sea.

4.2 Application of the VIKOR method

From the decision matrix demonstrated in Table 3 and including the weight vector (Table 3), acquired by SAPEVO-M, it is necessary to determine the best value f_i^* and the worst value f_i^- of each criterion:

Table 3. Decision matrix of the criteria with their respective weights and the values of f_i^* and f_i^-.

Weights	1,4185	2,9473	1,4135	2,6040	0,0131
	DS	EW	DRJ	IM	S
Salvador/BA	27	450	745	4	2
Natal/RN	5,5	200	1233	3	2
Rio Grande/RS	18	500	755	1	5
Ladário/MS	10000	200	0	2	1
Bethlehem/PA	100	1200	2218	2	1
Manaus/AM	10000	1500	0	2	1
fi*	5,5	1500	2218	4	1
fi-	10000	200	745	1	5

It is worth note the differentiation between the cost criteria (the lower, the better) - Distance to the sea and state of the sea - and benefit (the bigger, the better) - Exit Width, Infrastructure for Maintenance and distance from RJ by sea.

4.3 Obtaining S_i and R_i

After applying (1) and (2), Table 4 is obtained.

Table 4. Standard decision matrix and obtaining S_i and R_i.

	DS	EW	DRJ	IM	SS	S_i	R_i
Salvador/BA	0,0031	2,3805	0,9387	0,0000	0,0033	3,3256	2,3805
Natal/RN	0,0000	2,9473	0,6373	0,8680	0,0033	4,4559	2,9473
Rio Grande/RS	0,0018	2,2672	0,9323	2,6040	0,0131	5,8184	2,6040
Ladário/MS	1,4185	2,9473	1,4135	1,7360	0,0000	7,5153	2,9473
Bethlehem/PA	0,0134	0,6801	0,0000	1,7360	0,0000	2,4295	1,7360
Manaus/AM	1,4185	0,0000	1,4135	1,7360	0,0000	4,568	1,7360

Source: Authors (2020).

It is observed that the city of Ladário obtained the highest value of S_i, while Belém presented the lowest value in this parameter. In relation to the parameter R_i,, it is observed that Belém and Manaus obtained the lowest values, while Rio Grande and Natal presented the highest scores.

4.4 Calculating Q_i and ordering alternatives

Applying (3), Table 5 is obtained.

Table 5. Obtaining Q_i.

	S_i	R_i	Q_i
Salvador/BA	3,3256	2,3805	0,3541
Natal/RN	4,4559	2,9473	0,6992
Rio Grande/RS	5,8184	2,6040	0,6915
Ladário/MS	7,5153	2,9473	1,0000
Bethlehem/PA	2,4295	1,7360	0,0000
Manaus/AM	4,568	1,7360	0,2102
S*, R*	2,4295	1,7360	
S^- , R^-	7,5153	2,9473	

From the data obtained, the decreasing ordering is made, by S, R and Q values. For this, the results compose three classification lists, but only the Q values can be considered (Table 6).

Table 6. Ordering of alternatives.

	S_i	R_i	Q_i	Ranking
Salvador/BA	3,3256	2,3805	0,3541	3
Natal/RN	4,4559	2,9473	0,6992	5
Rio Grande/RS	5,8184	2,6040	0,6915	4
Ladário/MS	7,5153	2,9473	1,0000	6
Bethlehem/PA	2,4295	1,7360	0,0000	1
Manaus/AM	4,568	1,7360	0,2102	2

Analyzing the classification of the cities, it is observed that the best evaluated by the methods was the city of Belém/PA, which obtained the lowest Q value.

4.5 Analysis of results

After establishing the classification of alternatives, the stability conditions should be checked. First analyzing condition C_1 - Acceptable difference/advantage - applying (4), DQ equal to 0.2 is obtained. The difference between the second-placed (Manaus) and the first (Belém) must be greater than or equal to DQ for this condition to be met:

$Q(A_2) - Q(A_1) = 0.2102 - 0.0000 = 0.2102.$

Therefore, Condition C_1 is satisfied, since $0.2102 \geq 0.2$.

For condition C_2, it should be verified if the best-classified alternative also presents the best indices for R and/or S. It is observed that Belém, besides being the best alternative analyzing Q, presents the lowest values in R and S, also satisfying the stability condition C_2. As the two conditions were met, Belém can be considered as the most suitable city to be the headquarters of the Second Brazilian Squadron.

Analyzing Table which presents the normalized values of the alternatives in each criterion, it is observed that the first two placed in the proposed analysis (Belém and Manaus) present the best performance (note 0) in two criteria, which justifies their best classifications rather than the others.

The city of Manaus presents the best score in the criterion with greater weight (exit width) but obtained the worst performance in the distance to the sea and distance from RJ by sea. On the other hand, the city of Belém obtained the second score in the analysis of the exit width and the best performance in the criteria state of the sea and distance from RJ by sea, besides presenting regularity in the other criteria, which corroborates with its choice.

5 Conclusion

The application of the SAPEVO-M method considered the evaluation of three different specialists and made it possible to obtain the values of the weights of the criteria taking into account the opinion of each of them, making the analysis more robust and reliable. Considering that the objective of the article is to select a headquarters for the Second Squadron, the method proved to be quite efficient, since the criteria that obtained the highest weights are of high importance for fulfilling the mission of the city to be chosen as the headquarter.

Regarding the application of the VIKOR method, it was observed that the results obtained presented a consistent basis, with easily verifiable logical chaining, since the cities with the best classifications presented the best performances in the most important criteria. Besides, the verification of acceptable advantage and stability conditions have analyzed results more reliable and safer, providing the decision-making person with extremely relevant information for the decision.

Given the above, it was clear that the hybrid modeling using SAPEVO-M and VIKOR methods can be used to solve complex problems of the most varied types, thus being a combination of methods of great utility for the contribution of decision making, considering that it takes into account the evaluation of several criteria made by multiple decision-makers, besides allowing a rich and robust analysis of the results obtained, which makes the decision-making process more transparent.

It is also emphasized that, because there are web softwares available, including free of charge, the application of the methods were greatly facilitated, since their axiomatics involve calculations often complex and long, which implements a software, which facilitates the use of methods, a determining factor for the diffusion of this modeling.

Finally, the future papers could address comparative analyses between cities where there are no pre-structured bases, including other criteria such as ease of access to coast and area available for the construction of a naval complex.

Km 21, Autopista Norte de Bogotá D.C., Chía, Cundinamarca, Colombia

Resumen. Este trabajo analiza políticas públicas relacionadas con el cubrimiento de las instalaciones de salud en el área rural de Colombia. La localización, la cobertura y el tipo de instalación de salud en muchos países emergentes no han sido factores a tener en cuenta cuando se ha diseñado la red hospitalaria. Esto ha generado que muchas regiones experimenten una baja cobertura y otras estén sobrecubiertas. En el caso de Colombia, la jerarquía de niveles de servicio de las instalaciones de salud ha generado que el área rural cuente con deficiencias en el cubrimiento espacial al tener acceso solamente a servicios primarios. Por esta razón, este trabajo evalúa la situación actual en términos de la cobertura espacial de las instalaciones de salud y propone un modelo matemático de programación lineal entera mixta (MILP) para incrementar esta cobertura, así como la de la demanda teniendo en cuenta restricciones particulares de la situación rural de Colombia. Los resultados evidencian como el cambio en la distribución geográfica de las instalaciones existentes puede mejorar la cobertura espacial al reducir las distancias que los habitantes de una vereda deben recorrer para atender las necesidades de los servicios médicos.

Palabras claves: Localización instalaciones de salud, problema de localización de instalaciones, proveedores de salud, logística hospitalaria.

1 Introducción

El acceso a los servicios de la salud está definido por diferentes factores tales como disponibilidad de la oferta, acceso físico, efectividad del servicio, barreras de utilización, etc. [1]. El bajo acceso es una de las principales causas por las que no se previenen enfermedades y las personas terminan sufriendo grandes daños en su salud [2]. El problema se incrementa en países de medio y bajos ingresos (países en desarrollo o emergentes) donde se mantienen grandes brechas en la prestación de la salud en comparación a países desarrollados en servicios como, por ejemplo, la asistencia a la infancia y la maternidad [3].

De acuerdo a Penchansky et al. [4] la accesibilidad a la salud tiene 5 dimensiones, de las cuales las dos primeras, accesibilidad y disponibilidad, hacen referencia al acceso espacial, mientras que las tres restantes tienen que ver con factores socio-económicos. Para garantizar ese acceso espacial, la planeación estratégica de la red hospitalaria es parte fundamental para minimizar costos gubernamentales y maximizar el bienestar de la población [5]. Sin embargo, el diseño de esta red es un problema que comprende múltiples restricciones según el caso específico que se esté estudiando.

Para Colombia, como en muchos países en vía de desarrollo, la cobertura de los servicios de salud, hasta el alcance de nuestra investigación, tiene pocos indicadores como por ejemplo el número de camas por cada 1000 habitantes [6]. El área rural es la que presenta mayores dificultades; dado que, allí predominan los "puestos de salud", instalaciones pequeñas que solo prestan servicios primarios; hay insuficientes "centros de salud", instalaciones secundarias que ofrecen un mayor nivel de atención; y escasos hospitales, que pueden ser de complejidad 1C, la instalación más básica, hasta 3H el más alto nivel de salas de cirugía, de cuidados intensivos, etc. Además, el servicio funciona jerárquicamente, es decir cuando un paciente en el área rural requiere atención médica pasa primero por un puesto de salud y ahí, es reasignado a un centro de salud y luego del centro de salud a un hospital [7].

Uno de los enfoques con los que se ha tratado el problema de diseño de redes hospitalarias a nivel mundial ha sido el problema de localización de instalaciones [8]. Este es un modelo de optimización ampliamente utilizado en investigación de operaciones, al cual le han dado múltiples perspectivas para mejorar la cobertura de este servicio [9]. Sin embargo, Ahmadi et al. [9] y Peng et al. [10] han identificado aún muchos retos para estudiar como la ubicación de instalación según el tipo, según el grado de complejidad y teniendo en cuenta las dificultades de la zona rural en países en vía de desarrollo.

Por todo lo anterior, este artículo inicialmente evalúa la situación actual del área de estudio en términos de cobertura espacial y de la demanda. Con esto, se propone una formulación MILP con el objetivo de maximizar la cobertura con el actual número y el mismo tipo de instalaciones teniendo en cuenta las restricciones particulares de este caso de estudio. El área utilizada para el estudio es la región del Tequendama. Está cerca de Bogotá, la capital de Colombia. Es un área rural en el departamento de Cundinamarca que cuenta con aproximadamente 140.800 habitantes.

Este artículo está organizado como se explica a continuación. La sección 2 muestra los antecedentes de este trabajo y una breve revisión de los conceptos requeridos para el desarrollo del trabajo. La sección 3 presenta la definición formal del problema y el modelo matemático asociado. La sección 4 describe el caso de estudio de la región del Tequendama y el uso del modelo propuesto. La sección 5 presenta los resultados principales de la implementación en el caso de estudio. Finalmente, la sección 6 discute las conclusiones de este trabajo y sugiere algunos trabajos futuros.

2 Antecedentes

La localización de instalaciones de salud ha sido un tema ampliamente estudiado. Ahmadi et al. [9] presentaron un resumen de todos los modelos que se han utilizado

para este fin. Ellos encontraron que las investigaciones predominantes han sido con modelos de cobertura, dado el interés por la accesibilidad geográfica al servicio de salud [2], [8]. De hecho, el más usado es el modelo de localización de máxima cobertura (MCLP, por sus siglas en inglés), dado que trata con el problema de cubrir las necesidades de salud de los pacientes teniendo un número limitado de instalaciones [10]. Este modelo ha sido estudiado por autores como Ye et al. [11] quienes combinaron el modelo con un sistema de información geográfico (GIS) para evaluar la accesibilidad a la salud y para apoyar decisiones de localización. Otro ejemplo es Dzatora et al. [12] quienes comparan el modelo p-medianas con el MCLP encontrando que este último depende de los radios de cobertura que se definan previamente. Su caso de estudio fue Mackay en Queensland, Australia.

Sin embargo, la mayoría de esos estudios se han centrado en casos de países desarrollados, como los ejemplos antes mencionados. Esto implica que la accesibilidad espacial considera características diferentes en comparación a los países en desarrollo; dado que, los primeros tienen mayor presupuesto y mejor infraestructura [13]. De los estudios que se han encontrado en países en vía de desarrollo se destacan Doerner et al. [14] quienes ubican instalaciones de salud móviles para incrementar la atención de servicios de salud primarios. Ellos resaltaron que la distancia es un factor fundamental para el cubrimiento de los servicios de salud en zonas rurales. Por otro lado, Pu et al.[2] implementaron un MCLP para mejorar la accesibilidad espacial en North Kivu, República Democrática del Congo. Ellos enfatizan que el cubrimiento espacial más bajo se da en zonas rurales por las dificultades para transportarse por la falta de vías. También hay otros estudios que analizan el cubrimiento espacial en países en desarrollo con la implementación de GIS sin uso de modelos matemáticos [15], [16].

Todos los anteriores estudios llegan a la conclusión de que el área rural es la zona crítica para mejorar la cobertura en servicios de salud en países en desarrollo; sin embargo, pocas veces se usan herramientas formarles para la toma de decisiones en estos países [17]. Adicionalmente, tanto Ahmadi et al. [9] como Hamid [10] mencionan la importancia de tomar en cuenta las restricciones asociadas al tipo de instalación de salud que se está localizando, los diferentes tipos de servicios que presta cada tipo de instalación, así como la optimización de instalaciones ya existentes. Estos vacíos en la literatura son las razones que motivaron la investigación de este artículo.

3 Propuesta

Como se mencionó anteriormente, el estudio se desarrolló considerando la falta de literatura asociada a las restricciones de los diferentes tipos de instalaciones de salud, los distintos tipos de servicios y la redistribución de instalaciones ya existentes. Estas restricciones han sido resaltadas como retos y futuras investigaciones en trabajos previos [9], [10]. El interés en la zona rural es dado los problemas que han encontrado anteriores estudios en la falta de accesibilidad que estas zonas tienen a los servicios de salud por factores de distancia y dificultad en el transporte [2], [14]. El caso de estudio colombiano se selecciona al tener estas características particulares que representan un reto; puesto que, la red hospitalaria se compone de distintos tipos de instalaciones que

prestan servicios según su grado de complejidad. Además, es una zona con más del 98% de área rural [18] en un país en desarrollo, presentando los problemas de accesibilidad geográfica antes mencionados que disminuyen la calidad de prestación de servicios de salud. La sección 4 muestra a profundidad las particularidades del caso de estudio seleccionado.

Considerando las razones por las que se desarrolló este estudio, en esta sección se presenta en primer lugar la definición formal del problema de localización de instalaciones de salud y, en segundo lugar, se muestra el modelo matemático de programación lineal entera mixta (MILP, por sus siglas en inglés) asociado a este problema.

3.1 Localización de instalaciones de proveedores de servicios de salud modelo MILP

La definición del problema se detalla a continuación:

Se consideraron en un área rural un conjunto de clientes (hogares) $H = \{1...j\}$ geográficamente distribuidos según la densidad residencial. Cada hogar $j \in H$ tenía una demanda d_{sj} de unos servicios de salud $S = \{1...s\}$ que debía ser satisfecha por algún tipo de instalación de salud $F = \{1...k\}$ de algún grado de complejidad $N = \{1...n\}$ localizada en alguna ubicación $I = \{1...i\}$. La capacidad de cada tipo de instalación $k \in F$ tuvo un límite dado por el parámetro cap_{kns} según el grado de complejidad $n \in N$ para cada servicio $s \in S$. Consideramos que cada instalación de salud ubicada en $i \in I$ tenía un radio de cobertura con respecto a cada hogar $j \in H$ dado por el parámetro a_{ijl} que es calificado según los niveles de cobertura $L = \{1...l\}$ por el parámetro γ_l en el cual $\gamma_1 > \gamma_2 > \cdots > \gamma_L$. Adicionalmente, se supuso una calificación β_{kn} de los servicios de salud prestados por un tipo de instalación $k \in F$ según el grado de complejidad $n \in N$. Finalmente, tuvimos en cuenta un número máximo N_{kn} de instalaciones tipo $k \in F$ en el grado de complejidad $n \in N$ que podía habilitarse para prestar los servicios de salud y un mínimo porcentaje α de la demanda de cada servicio a cubrir.

3.2 Formulación del modelo

La siguiente notación es usada para formular el modelo de FLP:

Conjuntos

H conjunto de hogares; $j \in H$
I conjunto de potenciales localizaciones para instalaciones médicas; $i \in I$
F conjunto de tipo de instalación de salud; $k \in F$
L conjunto de niveles de cobertura de las instalaciones de salud; $l \in L$
N conjunto de grados de niveles de complejidad de las instalaciones de salud; $n \in N$
S conjunto de servicios de salud; $s \in S$

Parámetros

d_{sj} demanda esperada del servicio s del hogar j
Q_{kns} máxima capacidad habilitada para cada tipo de instalación k en el grado de complejidad n en el servicio s

a_{ijl} parámetro binario donde es 1 si la instalación de salud i cubre al hogar j en el nivel de cobertura l y 0 en otro caso
β_{kn} calificación dada al tipo de instalación k según el grado de complejidad n
N_{kn} número máximo de instalaciones tipo k en el grado de complejidad n que pueden habilitarse
α porcentaje mínimo de la demanda a cubrir para cada servicio
γ_l calificación del nivel de cobertura l
M número muy grande para restricciones lógicas

Variables de decisión

$X_{ikn} = \begin{cases} 1 \text{ Si se abre una intalación de salud tipo } k \text{ en } i \text{ del grado de complejidad } n \\ 0 \quad \text{En otro caso} \end{cases}$

$Z_{jl} = \begin{cases} 1 \text{ Si el hogar } j \text{ está cubierto en el nivel de cobertura } l \\ 0 \quad \text{En otro caso} \end{cases}$

Y_{sjkni} = Proporción de la demanda del servicio *s* del hogar *j* cubierto por la instalación de salud tipo k en el grado de complejidad *n* localizada en i

La formulación es como sigue:

$$Max \sum_{j\in H}\sum_{i\in I}\sum_{k\in F}\sum_{l\in L}\sum_{n\in N}\sum_{s\in S}\beta_{kn}\gamma_l a_{ijl} d_{sj} Y_{sjkni} \quad (1)$$

Sujeto a:

$$\sum_{i\in I}\sum_{n\in N}\sum_{k\in F} a_{ijl} X_{ikn} \geq Z_{jl} \quad \forall j,l \; ; \; j \in H, l \in L \quad (2)$$

$$\sum_{i\in I}\sum_{n\in N}\sum_{k\in F} a_{ijl} X_{ikn} \leq M Z_{jl} \quad \forall j,l \; ; \; j \in H, l \in L \quad (3)$$

$$\sum_{i\in I}\sum_{n\in N}\sum_{k\in F} Y_{sjkni} \leq 1 \quad \forall j,s \; ; \; j \in H, s \in S \quad (4)$$

$$\sum_{j\in H}\sum_{i\in I}\sum_{k\in F}\sum_{n\in N} d_{sj} Y_{sjkni} \geq \alpha \sum_{j} d_{sj} \quad \forall s \; ; \; s \in S \quad (5)$$

$$\sum_{k\in F}\sum_{n\in N} X_{ikn} \leq 1 \quad \forall i \; ; i \in I \quad (6)$$

$$\sum_{j\in H} d_{sj} Y_{sjkni} \leq Q_{kns} X_{ikn} \quad \forall i,s,n,k \; ; \; i \in I; s \in S; n \in N; k \in F \quad (7)$$

$$\sum_{i\in I} X_{ikn} = N_{kn} \quad \forall k,n \; ; k \in F; n \in N \quad (8)$$

$$Y_{sjkni} \geq 0 \quad \forall i,s,n,k,j \; ; \; i \in I; s \in S; n \in N; k \in F; j \in H \quad (9)$$

$$X_{ikn}, Z_{jl} \in \{0,1\} \; \forall i,k,n,j,l \; ; i \in I; k \in F; n \in N; j \in H; l \in L \quad (10)$$

La función objetivo (1) maximiza la calidad de la cobertura de la demanda de salud. El conjunto de restricciones (2) y (3) establece si un hogar está cubierto en algún nivel de cobertura si este está dentro del rango de una instalación. El conjunto de restricciones

(4) asegura que la demanda de cada servicio de un hogar no se puede cubrir en más del 100%. El conjunto de restricciones (5) asegura que la proporción cubierta de la demanda de cada servicio de salud es mayor o igual que un porcentaje fijado previamente. El conjunto de restricciones (6) evita que en una misma localización se habilite más de un tipo de instalación. El conjunto de restricciones (7) garantiza que la demanda de cada servicio cubierta por una instalación no es mayor que su capacidad habilita para ese servicio. El conjunto de restricciones (8) limita el número de instalaciones de cada tipo en cada grado de complejidad que se pueden habilitar. Finalmente, el conjunto de restricciones (9) y (10) hacen referencia a la naturaleza de las variables de decisión de no-negatividad y binarias.

4 Descripción del caso de estudio

Colombia cuenta con una división política constituida por departamentos, que a su vez se dividen en municipios agrupados en provincias. Este estudio se enfoca en la provincia del Tequendama, localizada al sur occidente del departamento de Cundinamarca, conformada por 10 municipios: Anapoima, Anolaima, Apulo, Cachipay, El Colegio, Quipile, San Antonio del Tequendama, Tena, Viotá y La Mesa (lugar con mayor población). La población total es de aproximadamente 140.800 habitantes. El 98,9% es área rural y comprende aproximadamente 300 veredas [18]. Una vereda es una subdivisión administrativa de cada municipio en Colombia.

En la provincia existen actualmente 5 hospitales, 4 centros de salud y 21 puestos de salud que se clasifican por los grados de complejidad mostrados en la Tabla 1. Los puestos de salud tienen el nivel de complejidad más bajo prestando solamente servicios básicos de consulta externa y odontología. En el caso de los centros de salud, estos tienen dos tipos de grados de complejidad que se diferencian en que el grado 2B presta servicios de atención a partos adicional a los servicios que se prestan en el grado 1B.

Tabla 1. Clasificación y cantidad de instituciones actuales en la provincia del Tequendama. Fuente: (Vargas, Gomez, & Amaris, 2014)

Tipo de instalación	Grado de complejidad	Cantidad	Servicios								
			1	2	3	4	5	6	7	8	9
Puesto de salud	1A	21			X	X				X	
Centro de salud	1B	3	X	X	X	X	X			X	
	2B	1	X	X	X	X	X	X	X	X	
Hospital	1C	1	X	X	X	X	X	X	X	X	X
	2C	2	X	X	X	X	X	X	X	X	X
	3C	1	X	X	X	X	X	X	X	X	X
	3H	1	X	X	X	X	X	X	X	X	X

1=Hospitalización, 2=Observación, 3=Medicina general, 4=Consulta especializada, 5=Servicio de urgencias, 6=Obstetricia, 7=Atención de partos, 8=Odontología, 9=Cirugía general.

Por último, los hospitales prestan todos los tipos de servicio; sin embargo, según el grado de complejidad varía la capacidad de la instalación [19]. Los servicios con mayor

demanda son la consulta médica general (64% de la atención en las instituciones), la odontología (12%) y la consulta médica especializada un 8% [20]. La distribución geográfica de las instalaciones se muestra en la Fig. 1. Cabe resaltar que la institución de mayor nivel, actualmente, es el Hospital de La Mesa (localización verde 15). Sin embargo, los pacientes con enfermedades o urgencias de mayor complejidad deben ser remitidos a los Hospitales de Soacha (municipio al sur de Bogotá) o Bogotá que cuentan con mayor grado. El tiempo promedio de viaje desde la provincia hacia Bogotá es de 2 horas [21].

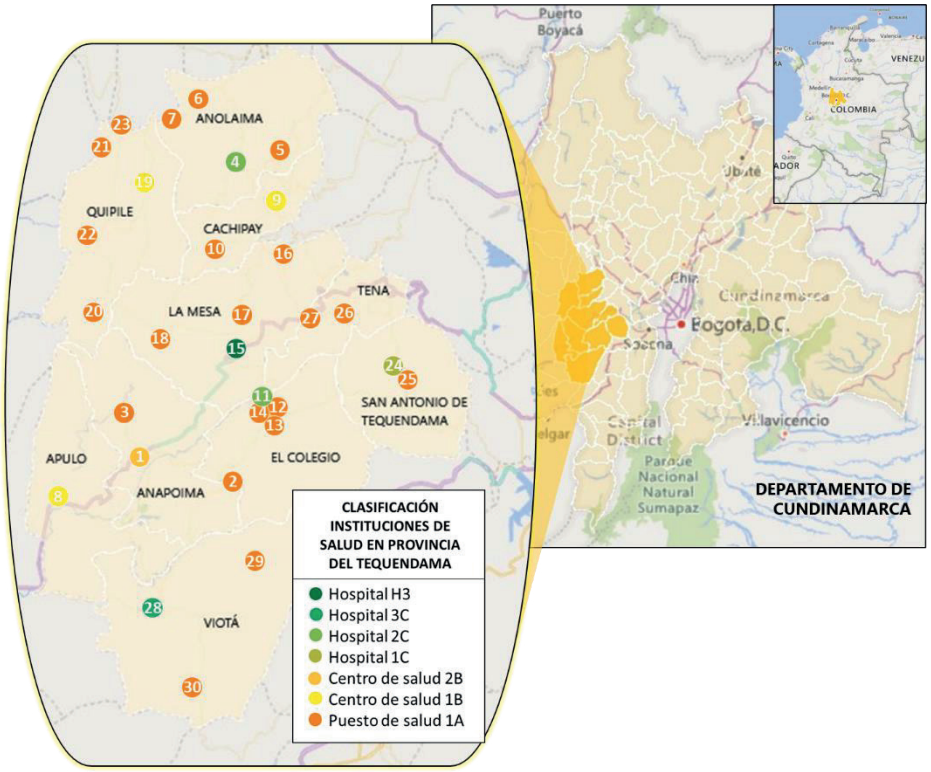

Fig. 1. Distribución geoespacial de las instalaciones de salud en la provincia del Tequendama

Actualmente, las estadísticas presentan que la capacidad instalada de las instituciones en la salud en Colombia es baja, debido a que solo hay 1,7 camas por cada 1000 habitantes, lo cual no alcanza a cumplir los estándares de la Organización Mundial de la Salud, que indica que esta razón debe estar entre 2,5 y 4 camas para poblaciones mayores a los 100.000 habitantes [21]. En Cundinamarca este indicador es de 1,04 por mil habitantes. Adicional a esto, la dispersión de la población rural ascendió en promedio a 64.6% en la provincia del Tequendama, solo el 13% de la red vial de la región se encuentra pavimentada y el 40% de esa malla vial se encuentra en mal estado, lo cual incrementa el tiempo que se necesita para llegar a la instalación más cercana. Otro factor que disminuye la calidad de la salud es la pobreza, en el Tequendama el indicador

de personas sin aseguramiento a la salud es de aproximadamente 11,1% en lo urbano y en lo rural 10,7%, por lo cual las tasas de mortalidad ascienden en las comunidades de mayor pobreza [21].

4.1 Recolección y preparación de datos

Para este estudio solo se tuvieron en cuenta las instituciones públicas; debido a que, estas aseguran cobertura médica a la totalidad de los habitantes de la región, mientras que las instituciones privadas solo ofrecen los servicios a una población parcial. Los puntos de demanda se agregaron por veredas usando un punto central para su ubicación. Para la distribución de la población por vereda se utilizó la distancia al casco urbano principal de cada municipio, usando una clasificación de 3 radios, asignando 50% de la población al primer radio (más cercano al casco urbano), 30% al siguiente y 20% al último (más alejado del casco urbano).

Todas las ubicaciones fueron establecidas por Google Maps™. La distancia fue calculada con la ecuación de Haversine [22]. Para considerar la estructura vial y otras condiciones geográficas se usó un factor multiplicador de 1.8 [23]. Los radios de cubrimiento para cada nivel de cobertura fueron estimados según el tipo de institución y el nivel de complejidad usando una función escalonada de 4 niveles similar a la empleada por Balcik et al. [24] con un máximo radio de 14 kilómetros para el hospital con grado 3H y un máximo radio de 5 kilómetros para el puesto de salud grado 1A.

Por otro lado, para el cálculo de la oferta y la demanda, se clasificaron los servicios prestados según los indicadores de salud [25], [26], [27] por cada tipo de instalación según el grado de complejidad. Estos se relacionaron con la capacidad instalada en cada instalación. La capacidad para cada servicio se obtuvo, en el caso las mesas de parto, las salas de quirófanos y las camas de hospitalización, según la distribución colombiana departamental [21],[25],[27],[28] haciendo una relación con la proporción de población de la vereda respecto al departamento. Para las camillas de observación [29], se usó una relación porcentual de información verificada de camas y camillas de los municipios de Anolaima [12], [30], [31], El Colegio , La Mesa [32], San Antonio del Tequendama [33] y Viotá [32]. La información restante se calculó con consultas directas a la administración del Hospital de la Mesa y el Hospital del Colegio. En coherencia, se asumió que todos los puestos de salud tienen un comportamiento idéntico[34].

Por otro lado, la demanda se extrajo de los indicadores anuales reportados por REPS de servicios atendidos en el departamento [35]. Para la distribución de la demanda en todos los tipos de instalaciones, se creó un porcentaje de cobertura por municipio que tenía en cuenta el número y tipo de entidades en cada uno, sin que los puestos de salud cubrieran más del 25% y que los hospitales y centros de salud cubrieran más del 50% de la demanda total por municipio. Seguido a esto, la distribución de la demanda por veredas se expandió geográficamente a cada una teniendo en cuenta el porcentaje de población que reside en ellas y su peso respecto al total de habitantes de cada municipio; no obstante, fue necesario realizar una variación de esta distribución geográfica, debido a que al recopilar los datos, se observó que los servicios como obstetricia, atención a partos y cirugías, son poco demandados y al asignarlos de esta forma, se obtenía una menor cantidad a la real, caso opuesto si se aproximaba al mayor puesto que el

comportamiento se convertía en uniforme y las cifras se desbordaban exageradamente. Por consiguiente, se usaron tres tipos de distribuciones geográficas de la demanda (DGD1, DGD2 y DGD3) donde cada una tiene una asignación aleatoria por vereda de los servicios mencionados con el fin de garantizar la exactitud de los datos y comparar su efecto frente a la solución del modelo matemático.

5 Resultados

El modelo matemático fue implementado en el software GAMS. Se probaron diferentes instancias variando el tipo de distribución geográfica de la demanda (DGD) y el porcentaje mínimo a cubrir de esta α.

En la Tabla 2 se muestran los resultados de la demanda cubierta. Observamos que para los servicios de cirugía y de hospitalización no se alcanza a cubrir más del 30% de la demanda. Esto es debido a las capacidades de ambos servicios a nivel general en la provincia, la cual no es suficiente para la demanda sin importar el tipo de DGD, evidenciando una deficiencia que afecta la rápida respuesta que se puede necesitar para estos servicios. A nivel del modelo matemático, esto ocasiona que la variación del porcentaje mínimo a cubrir α no pueda superar el 30%, dado que de no ser así el modelo pasaría a no tener una solución factible. No obstante, esto no afecta la cobertura de la demanda en los otros servicios contemplados, donde se llega a cubrir hasta el 100% de la demanda. Es decir, que para estos otros servicios el parámetro α no juega un papel importante. A nivel general, el porcentaje de cubrimiento de la demanda total oscila dentro del 97%, porcentaje que es bueno para mejorar el servicio de salud en la zona. Asimismo, se puede concluir que independientemente del caso de demanda, dicho porcentaje en el modelo no se ve afectado por el parámetro α.

Tabla 2. Porcentaje de la demanda cubierta para cada tipo de servicio y a nivel general según la variación del tipo de DGD y el porcentaje mínimo de demanda a cubrir α.

DGD	α	Porcentaje de cubrimiento de la demanda para cada servicio									
		1	2	3	4	5	6	7	8	9	General
DGD1	5%	85.1%	100%	100%	100%	100%	100%	100%	100%	28.8%	97.2%
	10%	85.1%	100%	100%	100%	100%	100%	100%	100%	28.8%	97.2%
	25%	85.1%	100%	100%	100%	100%	100%	100%	100%	28.8%	97.2%
DGD2	5%	84.8%	100%	100%	100%	100%	100%	100%	100%	29%	97.3%
	10%	84.8%	100%	100%	100%	100%	100%	100%	100%	29%	97.3%
	25%	84.8%	100%	100%	100%	100%	100%	100%	100%	29%	97.3%
DGD3	5%	84.8%	100%	100%	100%	100%	100%	100%	100%	29.1%	97.3%
	10%	84.8%	100%	100%	100%	100%	100%	100%	100%	29.1%	97.3%
	25%	84.8%	100%	100%	100%	100%	100%	100%	100%	29.1%	97.3%

1=Hospitalización, 2=Observación, 3=Medicina general, 4=Consulta especializada, 5=Servicio de urgencias, 6=Obstetricia, 7=Atención de partos, 8=Odontología, 9=Cirugía general.

Por otro lado, los resultados mostraron que el cubrimiento espacial con las instituciones reubicadas aumentó con respecto al cubrimiento actual, ya que el porcentaje de población cubierta en nivel de cobertura 1, 2 y 3 obtuvo un incremento en los 3 tipos

de DGD, siendo el mayor el tipo de DGD1 con un aumento del 4.5%, 9.81% y 1.6% respectivamente. En el caso del nivel de cobertura 4 el porcentaje de población en este nivel disminuyó en un 15.35%, lo que indica que las veredas tendrían mayor acceso geográfico al estar más cerca a las instalaciones prestadoras de servicios de salud, es decir que el tiempo de transporte de sus hogares a las instituciones es menor para la atención de sus necesidades médicas. Esto se puede evidenciar en la Fig. 2 que ilustra el porcentaje de población en cada nivel con un α del 5%.

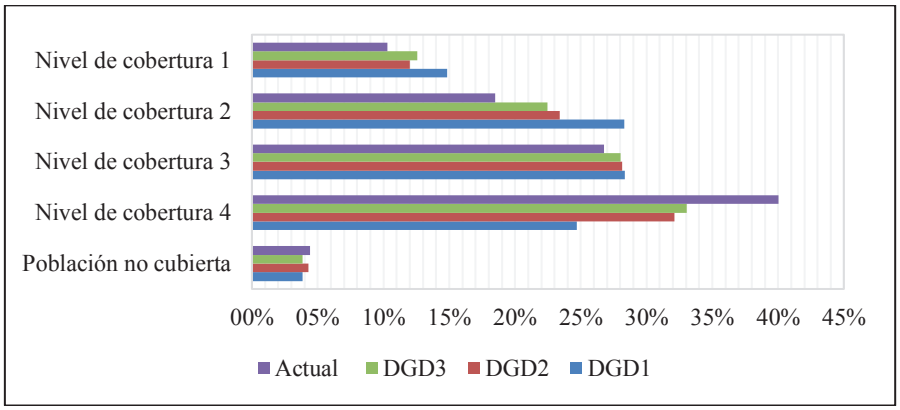

Fig. 2. Porcentaje de cubrimiento en cada nivel de cobertura según cada tipo de DGD vs. La situación actual.

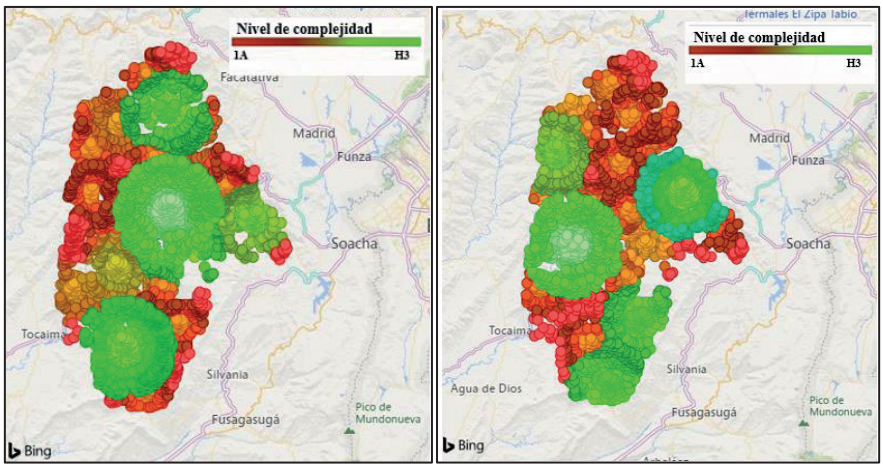

Adicional a esto, los resultados de la asignación de los diferentes tipos de instituciones evidencian cambios importantes. En la Tabla 3 se muestran estos cambios, las ubicaciones que no aparecen es porque se mantuvieron igual que las mostradas en la Fig. 1. De los cambios más significativos son los de los hospitales; dado que, se reubica el de complejidad H3 de La Mesa (localización 15) a Anapoima (localización 3) en un caso o a Quipile (localización 20), el de complejidad 3C de Viotá (localización 28) a Tena (localización 26). Por su parte, los hospitales de complejidad 2C, ubicados en Anolaima (localización 4) y El Colegio (localización 11), se reubican en Viotá (localización 29/30). La ubicación geográfica de cada localización se puede ver en la Fig. 1.

Con estos cambios se puede observar cómo esta nueva configuración (solución DGD1 con α 5%) obtiene una mejor cobertura geográfica considerando que los hospitales tienen un mayor alcance (Ver Fig. 3). Es decir, que reubicarlos tendría una incidencia positiva en el acceso espacial al disminuir las distancias entre los hogares y las instalaciones de salud como se observaba en la Fig. 2. Por otro lado, los centros y puestos de salud se distribuyen a lo largo de los municipios restantes, muchos de ellos no cambian de ubicación. La configuración de este tipo de instalaciones que atienden los servicios más básicos (consulta externa y odontología) logra que se pueda responder de manera efectiva a la demanda considerando que donde se ubican los centros y puestos de salud es donde hay una mayor demanda de estos. La distribución de esta demanda se puede ver en la Fig. 4 donde el área roja en el centro representa las áreas con mayor demanda que geográficamente coincide con las ubicaciones de los centros y puestos de

salud. Esto genera que con estas instituciones se descongestionen los hospitales para que en ellos se concentre la atención de los servicios especializados.

Tabla 3. Cambios de los tipos de instalación asignados a las localizaciones actuales en dos soluciones del modelo

Localización	Municipio	Situación actual	Solución DGD1 - α 5%	Solución DGD3 - α 5%
1	Anapoima	Centro 2B	Puesto 1A	Puesto 1A
3	Anapoima	Puesto 1A	Hospital H3	Puesto 1A
4	Anolaima	Hospital 2C	Puesto 1A	Puesto 1A

A. **B.**

Fig. 3. Mapa de calor del cubrimiento de las instalaciones de salud en A. la situación actual y B. situación propuesta con el parámetro α 5% con el tipo DGD1.

De los resultados, la configuración espacial de la DGD1 con un α de 5% es la que presenta mejores indicadores al tener un mayor porcentaje de cubrimiento de la demanda y una mejor distribución de las instituciones, al cubrir un mayor número de veredas dentro de la región en su primer nivel de cobertura. Esto se puede evidenciar en la Fig. 3 donde los puntos rojos (que son los que no se encuentran en ningún nivel de cobertura) son menores comparado con la situación actual.

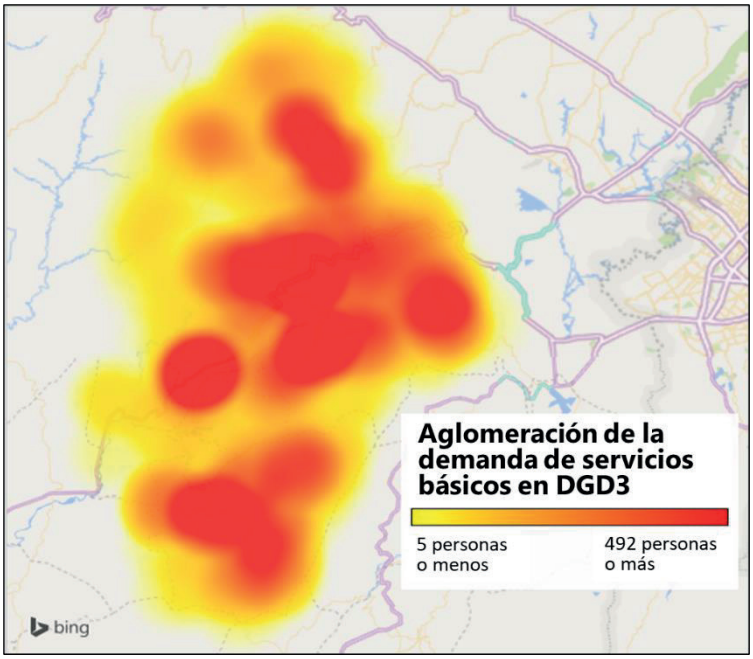

Fig. 4. Mapa de calor de la demanda aglomerada de los servicios básicos de toda la región del Tequendama según la distribución geográfica de la demanda 3 (DGD3). Las unidades de demanda son número de personas que requieren un servicio

6 Conclusiones y trabajos futuros

Esta investigación presenta una propuesta para mejorar la cobertura de los servicios de la salud con una nueva configuración de la red hospitalaria de la provincia del Tequendama. Los resultados obtenidos del modelo satisfacen las demandas de los servicios a nivel general, teniendo en cuenta que en los lugares donde se aglomera la demanda, los servicios más solicitados (servicios básicos) son cubiertos por puestos y centros de salud que se ubicaron en la zona. Esto ayuda a descongestionar los hospitales y facilitarles el cubrimiento de servicios de mayor complejidad por parte de estos últimos. Asimismo, la redistribución propuesta de las instituciones garantizaría que la accesibilidad a los prestadores de salud sea mayor, ya que hasta un 18% más de viviendas quedarían en los primeros dos niveles de cobertura, disminuyendo las distancias de las diferentes veredas a cualquier institución.

Por otro lado, se observa que con las capacidades existentes para cada instalación se puede cubrir más del 90% de la demanda de todos los servicios a excepción de cirugía y hospitalización. Estos dos servicios se resaltan como puntos críticos que obligan a los habitantes de la provincia del Tequendama a trasladarse por mínimo 2 horas de viaje a cubrir la demanda de alguno de estos servicios en municipios o ciudades cercanas, como Soacha y Bogotá, que puedan atender las deficiencias que hay en su zona al contar con hospitales de mayores grados de complejidad. A nivel del modelo matemático, esto se evidencia con el parámetro α que es la mínima demanda por cubrir de cada servicio. Este no tiene una afectación significativa, ya que siempre se busca atender lo máximo posible con la capacidad existente.

Para trabajos futuros, se puede considerar el uso de un presupuesto de inversión gubernamental para la red de instalaciones de salud, donde se consideren parámetros de costos de apertura de nuevas instalaciones, mejoramiento de estas o aumento de recursos para lograr cumplir la demanda total de la región. Esto ayudaría a fortalecer la red hospitalaria para afrontar cambios demográficos de años futuros como pandemias, emergencias sanitarias, desastres naturales, entre otras situaciones donde se requiere una óptima capacidad de respuesta (cercanía, capacidad, tiempo de espera, accesibilidad, entre otros). Adicionalmente, también se puede considerar la disponibilidad del recurso humano para el cálculo de las capacidades de las instalaciones.

Abstract. The economic development of a company is directly linked to its capacity for technological innovation and the improvement of its products and services. In this scenario, the article presents a case study related to *Banco do País*, a centenary banking organization operating in Brazil. With the technological advance present in its activities, the company identified that its massive number of services agencies gradually became irrelevant for the purpose of the company. The paper addresses a decision-making process regarding the identification of an agency that has low performance and is conducive to the closure of its activities in a county in Rio de Janeiro. In the decision analysis, the PROMETHEE-SAPEVO-M1 method is performed, enabling a transparent assessment with data of different natures. For the application of the modeling, a web platform is implemented, allowing a clear evaluation through its numerical and graphic analysis, providing the identification of the most favorable agency for closure, without loss of effectiveness and enabling the allocation of reduced costs to the improvement of services and digital channels of the company.

Keywords: Decision-making, Multiple Criteria Decision Analysis, PROMETHEE, Bank agencies.

1 Introduction

The technological advance of recent years has established new trends in the organizational world, where the technologic innovation allowed the emergence of new business models, carrying the urgency of a digital transformation into companies [1]. In this context, the Banking segment has been one of the departments that most invests in Information Technology (IT), where Alves and Galegale [2] exposed that, during 2018 in Brazil, 14% of technology expenditures made in the country, have been done by banking organizations.

According to Oliveira and Magagolli [3], technological innovation in banking services allows the client to enjoy the same services offered by agencies, in a faster, easier, and safer way. As registered by FEBRABAN (Brazilian Federation of Banks), considering 78.9 billion financial transactions made in Brazil in 2018, approximately 60% of these were executed through mobile and internet banking [4].

In this scenario, the organization *Banco do País*, an adapted name for the study purpose, is a centenary group active in Brazil, where has been identifying a relative demand reduction regarding the services made in their agencies, and an increase of transactions made through digital environments. Prospecting a scenario of greater reduction in the services of bank agencies, the need to reduce costs arose, through the closure of activities in agencies that have been registering low profitability, absence, low representativeness, etc.

Through technology investments, the banks can obtain gain in market share and reduction of marginal costs [5]. Thus, the reduction of costs in physical services in some agencies would enable the *Banco do País* to obtain an effectively increase, and improvement of services in its digital channels. In a decision-making analysis, the perception of the problem gains new dimensions, incorporating new facts from the underlying reality, leading to a better understanding of the problem [6].

For the closure of an agency to be done effectively, without harming the banking organization and its customers, it is necessary an analysis that enables to measure the efficiency level of the agencies under evaluation, not only considering the profitability of agencies, but other factors of influence [7]. Based on the methods and application from Operational Research (OR), it is possible to solve real problems in different areas [8]. In this context the Multiple Criteria Decision Analysis (MCDA) allows the understanding and structuring of a problem in complex environments, considering uncertainty and risk, transparently [9].

The MCDA methods can be understood as techniques that enable the structuring and analysis of problems, providing the establishment of preference between the alternatives under qualitative and quantitative criteria, which are usually conflicting [10]; where the importance of the criteria is defined by the decision-making agents in an interactive process with other technical-political actors[11]. It is noteworthy that these methods do not aim to present a definitive solution and solve all kinds of problems, but to support the decision-making process meeting the requested constraints, within an analyzed context [12].

1.1 Questions and Objectives

The study aims to present a decision-making analysis based in MCDA concerning the organization *Banco do Pais*, in search to identify a favorable agency, in a specific area, to end its services, providing the cost reduction to the bank. To support the analysis, the new MCDA method PROMETHEE-SAPEVO-M1 will be implemented, by the moment that its axiomatic structure is favorable to the problem in context, enabling to analyze qualitative and quantitative data. Also, a web platform based on the method will be worked, providing an effective and assertive implementation.

The article is structured into five sections. After the introduction, section 2 explores some MCDA concepts and presents the origin of the method applied. Section 3 exposes in detail the axiomatic structure of the PROMETHEE-SAPEVO-M1 method. Section 4 is dedicated to the case study, exploring all steps of the decision-making process. Section 5 concludes the research findings.

2 Multiple Criteria Decision Analysis (MCDA)

The MCDA methods have received attention among decision support tools, due to their robustness analysis, enabling the evaluation of complex cases in an effective way [13]. An MCDA methodology should enable an integrated algorithm, providing an analysis structure that allows the evaluation of qualitative and quantitative variables, making possible the representation of the subjectivity and preferences of the decision-maker in a scenario with accurate and inaccurate data[14].

Regarding a quantitative analysis, the PROMETHEE method (Preference Ranking Organization Method for Enrichment Evaluations), proposed by Brans, Vincke, and Mareschal [15], is related to a hierarchical relation model where the preferential order of the variable in each criterion evaluated is normalized by a preference function. In this method, considering cardinal data, the decision-maker should establishes the preference degree between the criteria, defining if each one is a criterion of benefit (maximization) or cost (minimization), and which preference function will be applied [16].

Providing a qualitative analysis, the SAPEVO-M method (Simple Aggregation of Preferences Expressed by Ordinal Vectors - Multi Decision Makers), an extension of the SAPEVO method, proposed by Gomes, Mury, and Gomes [17], makes possible the evaluation data by ordinal inputs, designed to problematics that aim to clarify the decision-making process by the clustering of actions in equivalents classes, ranking to the preferences of the decision-maker.

2.1 The PROMETHEE-SAPEVO-M1 method

The method was developed by the integration of two MCDA methods, they are PROMETHEE and SAPEVO-M. The algorithm procedure is based on the axiomatic structure of the PROMETHEE method integrated to ordinal evaluation presents in SAPEVO-M, enabling to evaluate both quantitative and qualitative natures, in a mono decision analysis [18].

The method provides a complete analysis composed of a criteria evaluation set by a pairwise comparison based on an ordinal scale, and three different models of results analysis in relation to the preferences obtained, along with an intra-criterion analysis by veto threshold.

3 PROMETHEE-SAPEVO-M1 procedure

The evaluation process is structured into a matrix (Criterion x Alternative) (1), composed by a set of alternatives A, where $a_i \in A$, $i = 1, \ldots, n$, evaluated under a set of qualitative criteria h, $h = 1, \ldots L$, and a set of quantitative criteria j, $j = 1, \ldots k$.

	a_1	a_2	a_3	...	a_n
h_1	a_{11}	a_{21}	a_{31}	...	a_{n1}
h_L	a_{1L}	a_{2L}	a_{3L}	...	a_{nL}
j_1	a_{11}	a_{21}	a_{31}	...	a_{n1}
j_k	a_{1k}	a_{2k}	a_{3k}	...	a_{nK}

(1)

3.1 Alternatives evaluation

Considering the presence of qualitative and quantitative criteria, first the set A is performed concerning qualitative criteria h, $h = 1, \ldots L$. The process is characterized by a pairwise comparison between the alternatives regarding each criterion from set h. The analysis is based on the preference evaluation present on an importance scale, table 1.

Table 1. Importance scale.

Absolutely worse	**-3**
Much worse	**-2**
Worst	**-1**
Equivalent	**0**
Best	**1**
Much better	**2**
Absolutely better	**3**

In each qualitative criterion evaluated, it is obtained a matrix of preference relation between the elements belonging to the set A. By the equation (2), the punctuation is normalized, obtaining an importance degree of each alternative in a specific criterion.

$$v = \frac{\sum a_{ih} - \min a_{ih}}{max\ a_{ih} - \min a_{ih}} \tag{2}$$

After the normalization process and based on PROMETHEE procedure, they alternatives are submitted to a maximization evaluation $P_h(a_1, a_2) = P(d) = f(a_1) - f(a_2)$. With a new matrix composed by the difference between each pair from A, the differ-

ences are normalized by a function with linear variation (3), then the final preference degree is obtained, representing the preference relation relationship [0,1].

$$P(d) = \begin{cases} d/1 & d \leq 1 \\ 1 & d > 1 \end{cases} \quad (3)$$

The evaluation process regarding the quantitative criteria *j*, *j* = 1, ... *k*, it is sustained the PROMETHEE procedure, where for each quantitative criterion, it is necessary to specify a general preference function (P_j: *A x A* → [0,1]).

Comparing the alternatives a_1 and a_2 from set *A*, $P_j(a_1, a_2) = P(d)$ represents the preference degree of a_1 over a_2 according to the criterion *j*. When the criterion needs to be maximized, uses $P(d) = f(a_1) - f(a_2)$ to define a preference function. If it is necessary to minimize the criterion, $P(d) = f(a_2) - f(a_1)$ is used as preference function.

As exposed in [19], six types of preference function have been proposed to normalize the values obtained from the differences between the alternatives [16], they are *Usual*, *U-shape*, *V-shape*, *Level*, *V-shape I*, and *Gaussian*. According the attribution of criterion, thresholds may be defined, for more details about which function to select, please consult [20].

3.2 Criteria weights

The weights set considers the qualitative and quantitative criteria only in one set *j, j = 1, ..., L + k*. Using the ordinal scale presented in the table 1, the preference relation between the criteria is performed. In this evaluation, two variables called *maximum sum* and *minimum sum* is considered, enable the normalization of punctuation.

The *maximum sum* is obtained by *x = (n-1). 3*, representing the highest possible preference punctuating sum of each criterion, as closer a criterion is to *maximum sum*, greater will be its dominance in the set. In other hands, *minimum sum* is obtained by *x = (n-1). -3*, representing the minimum value possible within that assessment, as lower be the value and its closer to the *minimum sum*, the criterion will represent a little importance in the set.

The values obtained in the evaluation will be normalized by equation (4). After the normalization, each degree will be submitted to equation (5), providing the weights according to their respective criteria.

$$v = \frac{\sum c_{ij} - (max\ sum)}{(max\ sum) - (min\ sum)} \quad (4)$$

$$w(c_j) = \frac{v(c_j)}{\sum v(c_j)} \quad (5)$$

In the end of procedure, a global index preference π (a_1, a_2) is obtained, indicating the preference degree of alternative a_1 over a_2, considering the weights assigned to each criterion, where (6):

$$\pi(a_1, a_2) = \sum_{j=1}^{k+l} P_j(a_1, a_2) w_j \quad (6)$$

3.3 Preference Analysis

Composed by three different formats of manipulation, the preference analysis is integrated by a Partial outranking, Complete outranking, and an outranking by intervals.

The Partial outranking is evaluated by the positive outranking flow (7) and negative outranking flow (8), representing how a_1 outranks the other alternatives and how a_1 is outranked by the other options. How higher be the positive flow and lower be the negative flow, more favorable will be the alternative, where (9) (10) (11):

$$\phi^+(a_1) = \frac{1}{n-1}\sum_{x \in A} \pi(a_1, x) \tag{7}$$

$$\phi^-(a_1) = \frac{1}{n-1}\sum_{x \in A} \pi(x, a_1) \tag{8}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\begin{cases} \phi^+(a_1) > \phi^+(a_2) \text{ and } \phi^-(a_1) < \phi^-(a_2), \text{or} \\ \phi^+(a_1) = \phi^+(a_2) \text{ and } \phi^-(a_1) < \phi^-(a_2), \text{or} \\ \phi^+(a_1) > \phi^+(a_2) \text{ and } \phi^-(a_1) = \phi^-(a_2); \end{cases}$ (9)
- a_1 is indifferent to a_2 ($a_1 I a_2$) *if* $\phi^+(a_1) = \phi^+(a_2) \text{ and } \phi^-(a_1) = \phi^-(a_2);$ (10)
- a_1 is incompatible to a_2 ($a_1 R a_2$) *if* $\begin{cases} \phi^+(a_1) > \phi^+(a_2) \text{ and } \phi^-(a_1) > \phi^-(a_2), \text{or} \\ \phi^+(a_1) < \phi^+(a_2) \text{ and } \phi^-(a_1) < \phi^-(a_2); \end{cases}$ (11)

The Complete outranking is based in the net outranking flow (12), in this case, how higher be the net flow, more favorable is the alternative, where (13) (14):

$$\phi(a_1) = \phi^+ a_1 - \phi^- a_1 \tag{12}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\phi(a_1) > \phi(a_2)$ (13)
- a_1 is indifferent to a_2 ($a_1 I a_2$) *if* $\phi(a_1) = \phi(a_2)$ (14)

The third model of evaluation, consisting in an interval procedure [$x(a_1)$, $y(a_1)$] (15), based in a standard error value, defining a complete outranking by intervals, where (16) (17):

$$\begin{cases} x_{a_1} = \phi(a_1) - \alpha\sigma_{a_1} \\ y_{a_1} = \phi(a_1) + \alpha\sigma_{a_1} \end{cases} \tag{15}$$

- a_1 is preferable to a_2 ($a_1 P a_2$) *if* $\phi(a_1) > \phi(a_2)$ (16)
- a_1 is indifferent to a_2 ($a_1 P a_2$) *if* $\phi(a_1) = \phi(a_2)$ (17)

3.4 Intra-criterion Analysis

The intra-criterion analysis by veto threshold suggests an equivalence between alternatives with low performance (a_x) and high performance (a_y) in global analysis, from the moment that a_x presents a strict preference over a_y in a specific criterion c_j.

The veto v_j does not influence the outranking flows, but the analysis works as additional information to the decision-making process, where $v_j \geq p_j \geq q_j$. For qualitative criteria $v_h = 1$, and for quantitative criteria $v_j = max(a_{ij})$. If a preference threshold (p_j) be set and it is greater than v_j, the veto becomes equivalent to preference $v_j = p_j$.

4 Case study

The organization in context is a century-old company and one of the leaders as a banking organization in Brazil with more than four thousand agencies in the country. The institution covers various types of financial services, distributed in investments, insurance, credits, payments, currency trading, etc.

The study was carried out in the state of Rio de Janeiro, analyzing five agencies presented in a specific county from the city. Although, in the last years, the company has been registering a demand reduction regarding the services provided in the region, due to the viability of services through digital platforms. Figure 1 exposes the demand reduction related to the number of services registered between the semesters 01/2018 and 01/2019.

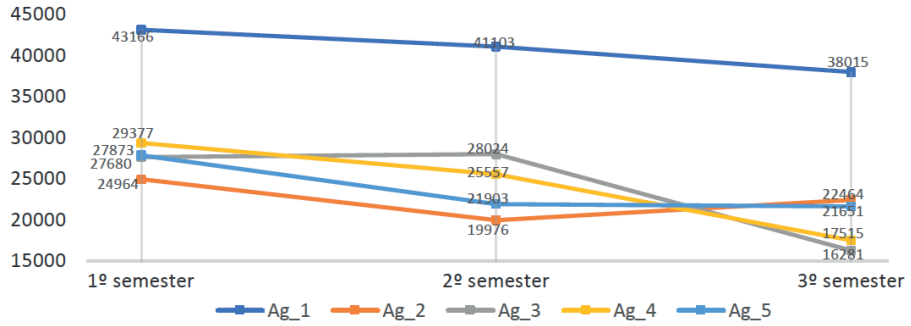

Fig. 1. Graph of number of services performed in the semesters 01/2018, 02/2018, and 01/2019.

Presenting an expressive demand reduction and handling with high fixed costs, it was considered to reduce costs by closing one of the agencies in the region, but keeping employers and customers in other agencies. In search of an effective assessment, the PROMETHEE-SAPEVO-M1 method was applied, making possible the identification of the main criteria of influence and enabling a detailed analysis.

The analysis is composed of five agencies, named: *Ag_A*, *Ag_B*, *Ag_C*, *Ag_D*, and *Ag_E*. The alternatives were evaluated under a set of seven criteria, being three qualitative and four quantitative, as presented in table 2. To enable effective implementation of the method to the case, the web platform [21] based on the method was worked, performing a friendly interaction and providing numerical and graphical results.

Table 2. Criteria for evaluation.

Criteria	Nature	Description
Coverage area	Qualitative	Criterion that considers in its assessment the distance between agencies, local competition, and region security;
Regional economic potential	Qualitative	Variable related to the proximity of commercial and business areas, public agencies, etc;
Profitability	Qualitative	Representation of the profitability of the agencies, however, by confidential, the criterion is evaluated qualitatively;
Average monthly cost	Quantitative	Criterion composed of costs with energy, water, rent, and property tax, the values are presented in thousands of reais (R$);
Number of services	Quantitative	Approximate number of services provided in the first semester of 2019, the amounts are in thousands;
Demand reduction	Quantitative	Demand reduction percentage in the semesters 01/2018 and 01/2019;
Representativeness	Quantitative	Representation of the representativeness of each agency in the county.

Identified the criteria and alternatives, the evaluation matrix for the case was built and represented in table 3, exposing numerical and qualitative data of each alternative under each criterion. Regarding the quantitative criteria, also the generalized functions and parameters for normalization were defined.

Table 3. Evaluation matrix for case study.

Criteria	*Ag_A*	*Ag_B*	*Ag_C*	*Ag_D*	*Ag_E*
Coverage area	Excellent	Poor	Poor	Excellent	Poor
Regional economic potential	High	Medium	Low	High	Low
Profitability	High	High	Low	Low	Medium
Average monthly cost (R$)	115.97	33.32	39.6	48.21	46.39
Number of services (Qty)	38	22.4	16.1	17.5	21.65
Demand reduction (%)	12	10	41	40	22
Representativeness (%)	32.8	19.4	14	15.1	18.7

4.1 Method implementation

By the web platform, it is indicated and named the alternatives and criteria. The software works in the same axiomatic structure of the method, evaluating first the alternatives under qualitative criteria. As exposed in figure 2, for the criteria *Coverage area*, *Regional economic potential*, and *Profitability*, it is realized a pairwise comparison between the alternatives in each criterion, establishing the preference relation based on the ordinal scale presented in section 3.1.

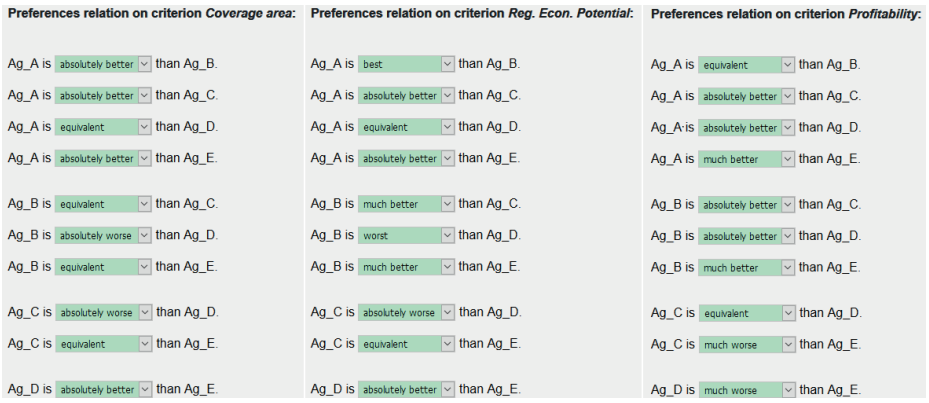

Fig. 2. Evaluation of alternatives under qualitative criteria, PROMETHEE-SAPEVO-M1 Software web.

Following the procedure, the alternatives were evaluated under the quantitative criteria. In each criterion was indicated the numerical data of each alternative, defined if it was a criterion of cost (minimization) or benefit (maximization), and established the preference function for normalization procedure. In figure 3, all data are exposed, observing that in the inferior area is set the parameters of each function selected, composed by thresholds of preference and indifference, where is established the limits for strict preference and non-preference respectively.

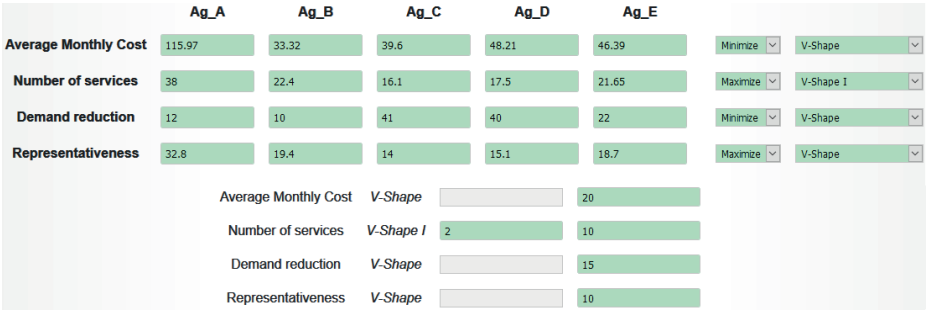

Fig. 3. Evaluation of alternatives under quantitative criteria, PROMETHEE-SAPEVO-M1 Software web.

Finished the alternatives evaluation, the procedure follows comparing the criteria in search to obtain the preference relation and the weight respective to each one. In the software, the process is similar to qualitative evaluation, just indicating the preference relation between each criterion. In table 4 is presented the punctuation of each criterion along with the final weights obtained based on the variables of *maximum sum* and *minimum sum*.

Table 4. Matrix of importance relation and weights obtained.

maximum sum = 18
minimum sum = -18

	Coverage area	*Reg. potential*	*Profitability*	*Average cost*	*Numb. services*	*Demand reduc.*	*Representati.*		*Punctuation*		*Normalized punctuation*		*Final weights*
Coverage area	0	1	-2	-2	-1	-2	0	=	-6	=	0.333	=	0.095
Regional ec. potential	-1	0	-3	-3	-2	-3	-1	=	-13	=	0.139	=	0.040
Profitability	2	3	0	0	1	0	2	=	8	=	0.722	=	0.206
Average monthly cost	2	3	0	0	1	0	2	=	8	=	0.722	=	0.206
Number of services	1	2	-1	-1	0	-1	1	=	1	=	0.528	=	0.151
Demand reduction	2	3	0	0	1	0	2	=	8	=	0.722	=	0.206
Representativeness	0	1	-2	-2	-1	-2	0	=	-6	=	0.333	=	0.095

Once obtained the weights, the preference relations expressed during the alternative evaluation are weighted. As an aggregation process, the global index preference is built, enabling to perform the positive, negative, and net outranking flows. Using these flows, it is possible to obtain the final ranking in search to identify the most favorable alternative in context. The values are exposed in figure 4.

	Ag_A	Ag_B	Ag_C	Ag_D	Ag_E	Positive Flows	Net Flows	Intervals (standard error = 0.096)	
Ag_A	0	0.051	0.113	0.094	0.089	0.347	0.227	x = 0.131	y = 0.323
Ag_B	0.033	0	0.091	0.094	0.062	0.28	0.214	x = 0.118	y = 0.31
Ag_C	0.029	0	0	0.013	0.01	0.052	-0.235	x = -0.331	y = -0.139
Ag_D	0.029	0.015	0.023	0	0.019	0.086	-0.173	x = -0.269	y = -0.077
Ag_E	0.029	0	0.06	0.058	0	0.147	-0.033	x = -0.129	y = 0.063
Negative Flows	0.12	0.066	0.287	0.259	0.18				

Fig. 4. Evaluation of alternatives under quantitative criteria, PROMETHEE-SAPEVO-M1 Software web.

4.2 Results analysis

As detailed in section 3, the PROMETHEE-SAPEVO-M1 method enables three models of results analysis, based on a partial, complete, and intervals outranking. All performances are analyzed by the graphic representation of each model of analysis in figure 5. Remembering that the partial ranking is based on the positive and negative flow, the complete ranking is based on the net flows, and the ranking by intervals is built by the lower and upper limit, with all values detailed in figure 4.

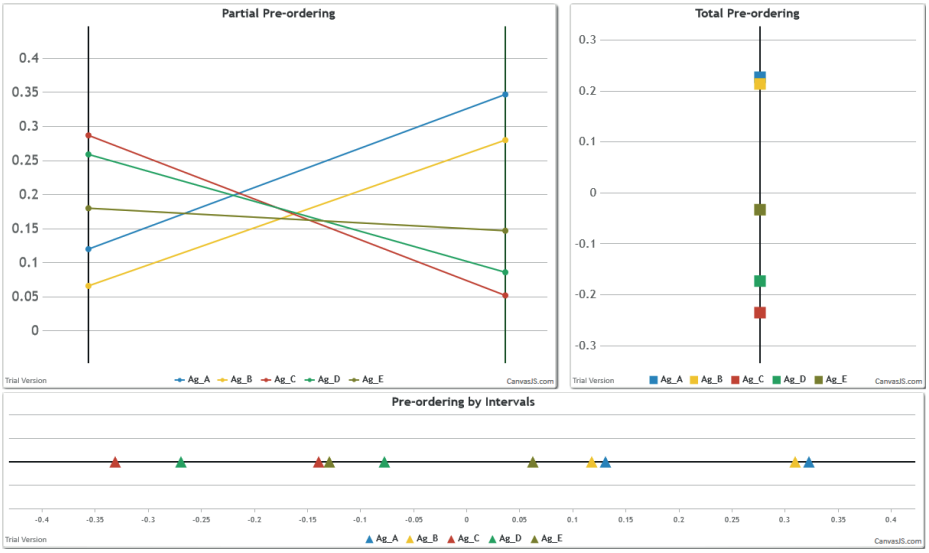

Fig. 5. Preference analysis charts, PROMETHEE-SAPEVO-M1 Software web.

In the first analysis model, the partial outranking, it was identified that the alternatives *Ag_A* and *Ag_B* obtained the best performances, both being preferable as the alternatives *Ag_C*, *Ag_D*, and *Ag_E*, but incompatible with each other, as exposed by the parallel line in figure 5. On the other hand, the alternative with the worst performance was *Ag_C*.

In the sequence, the complete outranking indicates the final ordering from the most favorable to the least favorable alternative. In this context, the best performance ranking obtained was: *Ag_A*, *Ag_B*, *Ag_E*, *Ag_D*, and *Ag_C*. Although, from the chart analysis, the proximity of the results between the alternatives *Ag_A* and *Ag_B* is noticeable.

In the third evaluation model, with the standard error value of 0.096, as exposed in figure 4, the intervals of the alternatives were generated by the lower and upper limits. In the analysis, it is noticeable that the agencies with the best performances remain *Ag_A* and *Ag_B*, indicating preference relation among the other alternatives under analysis, including, in this evaluation model, these agencies started to indicate a relationship of indifference among themselves. The agencies *Ag_C* and *Ag_D* continued to present the worst performance regarding the other alternatives from the set.

In search of efficiency regarding the analysis model, a "distillation" process of the alternatives was carried out, by the moment that the software worked enables this feature. In the procedure, the *Ag_A* agency was removed, for presenting the best result and looking to identify whether this alternative does not influence the final outranking. The new outranking flows and the interval analysis chart are exposed in figure 6.

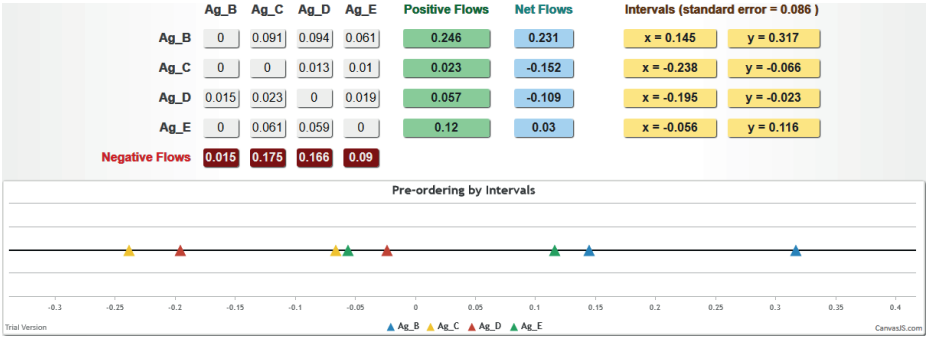

Fig. 6. New outranking flows, after distillation process along with the interval analysis charts, PROMETHEE-SAPEVO-M1 Software web.

After the distillation, it is noticeable that the preferences remain, presenting only small variations regarding the outranking flows. In this case, the agencies *Ag_C* and *Ag_D* continued to present the worst performance. In this context, the agency selected for closure was the alternative *Ag_C*, presenting the lowest performance in the three forms of analysis and prospecting a future development of the organization, and comparing to agency *Ag_D*, the *Ag_C* is not favorable for its characteristics in the qualitative criteria, as exposes the intra-criterion analysis in figure 7.

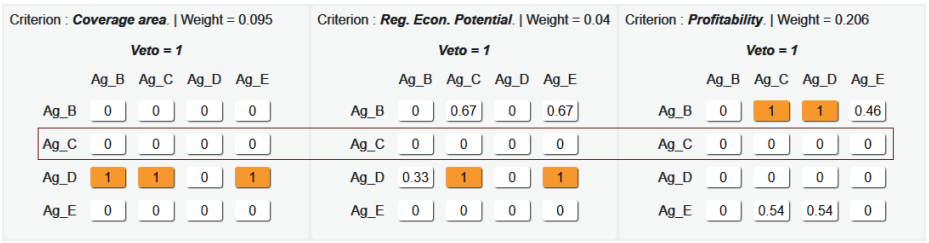

Fig. 7. Intra-criterion analysis in qualitative criteria after the distillation procedure, PROMETHEE-SAPEVO-M1 Software web.

With the analysis obtained, it is interesting to note that in the analyzed region, a cost reduction of 13.96% was acquired, with an approximate annual deduction of R$ 475 200.00. Considering that *Banco do País* has more than 4000 agencies in Brazil, the analysis is favorable to be made in other counties of the country, in search to contain costs in a macro way.

5 Conclusion

This paper purposed to present a case study based on the organization *Banco do País*, witnessing a scenario in which the closure of one of its agencies in a specific region, enabled the cost reduction through the identification of factors that allowed this action without loss of effectiveness.

In this case, a decision-making process was carried out through a MCDA methodology, listing five agencies and evaluating them under seven criteria, ranking them according to their respective performances, and identifying the most favorable for closing.

For the evaluation, the PROMETHEE-SAPEVO-M1 method was applied through a web platform, allowing the analysis of data from different natures and a structured format for obtaining weights to the criteria. The implementation proved to be efficient and effective, allowing a transparent evaluation, identifying the criteria of greatest influence, and the agencies that were most sensitive to them. In the end, the alternative that presented the lowest performance was identified, being select as the most favorable alternative for closure, where this action does not negatively influence the organization.

The selected alternative allowed a reduction of 13.9% in the costs of the company, considering the region evaluated. In this way, it is favorable for Banco do País to be carrying out a global analysis, in all its regions of operation, identifying agencies that present absence, demand reduction, and low profitability, allowing the cost reduction and providing resources to improve technologies and quality of services.

Development of a methodological proposal for the creation of strategic maps incorporating feasible futures

Abstract

This paper presents a methodology for building a strategy map of a Balanced Scorecard (BSC) that considers possible scenarios. A strategy maps is a representation of the strategy of a company and consists of strategic objectives linked by causal relationships between them. The objectives are grouped into four perspectives: financial, clients, internal processes and growth & development. One of the limitations of strategy maps is that they are built only for one future scenario. They do not take into account that the future may change. The contribution of this work is that we propose a method that allows strategy maps to change as scenarios change. It uses the Analytic Network Process (ANP) to model a strategy map. The method was implement in two manufacturing companies.
Keywords: Strategic planning, strategy map, scenarios.

1. Introduction.

The strategic planning explores and projects the possible future changes of the environment to define the strategies. The scenarios prospectively design possible futures and, consequently, the union of these two tools represents an enormous potential to improve the way of facing the future. The objective of this work is to develop a methodological proposal to create strategy maps that consider probable futures. The methodology integrates Scenarios with the Balanced Scorecard (BSC) (Kaplan & Norton, 2004), in order to relate and reflect the dynamics of environmental changes with the strategic objectives and with the strategies define d by the organizations. The methodological approach is qualitative based on the design of the case study, because it seeks to validate a methodology, the generalization of the case study does not imply that in similar industries the same results will be obtained, but it is studied how plausible is the proposed methodology to formulate strategy maps for the management and administration of strategies in organizations. Defines three Scenarios, the strategy map is constructed for each one of them, using the Analytic Network Process

(ANP) (Saaty, 2001) to determine the weight of the causal relationships in each scenario. The probabilities of occurrence of each scenario are assigned using AHP, finally achieve a "Global Scenario" that incorporates the three initially defined scenarios. Finally, the methodology is established to adjust and adapt the objectives and established strategies. This methodology was applied in two companies in Chile. The evaluation of the companies with respect to the intervention carried out coincides in that in that it is a real and valuable contribution to improve their business management.

This work is an extension of the method proposed by Gonzalez et al. (2019) who use the Analytic Hierarchy Process (Saaty, 1996) to model a strategy map under various scenarios. The limitation of that work is that it only allows hierarchical strategy maps, which are not common in real situations. Apart from that paper, the literature on the subject is scarce. The only other paper found was the one authored by Buytendijk et al. (2008), who created strategy maps for various scenarios and provides a method to combine them. It is not applied in any company.

2. The ANP model.

The strategy map is modelled using an ANP model, as shown in Figure 1.

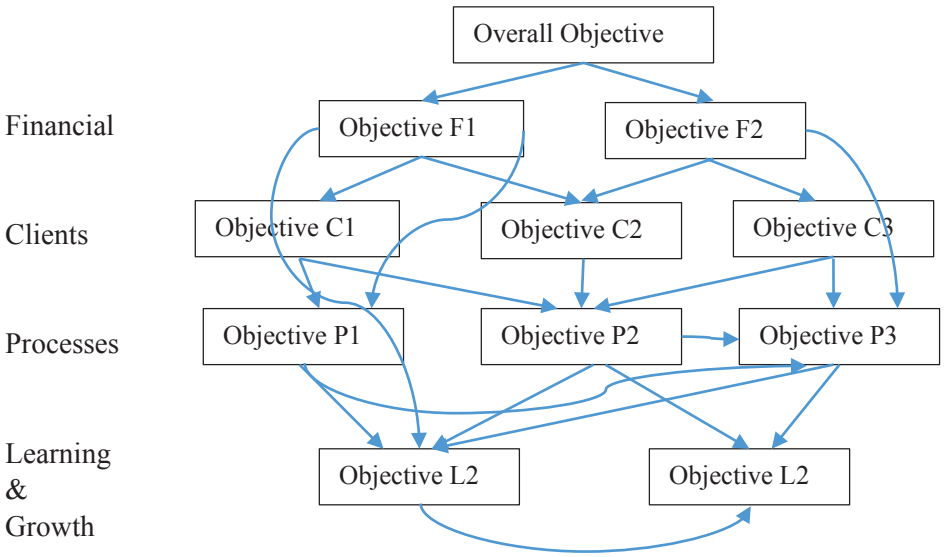

Figure 1: Representation of a strategy map.

The steps of the method are:

1. Generate scenarios
2. Build strategy map for each scenario
3. Assign weights to every relationship in the maps, using ANP.
4. Select the most important relationships in each strategy map using a threshold value.
5. Assign priorities to each scenario using AHP.
6. Combine strategy maps.

The last step is carried out by analyzing which strategic objectives are common in the scenarios and which relationships are also important in them. In this way, the company will design its strategies and their respective action plans based on this strategic map, which are valid in any of the three scenarios that appear, so that their actions represent the best option to take.

Annually, the company reviews and studies the evolution and projection of the behavior of environmental variables. Depending on the observed behavior and the estimated projection of these variables, certain objectives must be incorporated and prioritized in order to make the necessary adjustments to maintain and improve their competitive position.

3. Application

The method was applied in two companies. Company A manufactures of special glass elements used for laboratories, whereas company B Distributor and marketer of laboratory equipment mainly for the area of research and quality control and industrial processes.

After the application, managers were ask about their opinion about the proposed method. They were very happy because it allows them to look at different possible futures and be prepared for them. In the other hand, they stated that the discussion generated was very useful, because it allows considering the viewpoints from people from different areas.

4. Conclusions

The methodology developed allows companies to obtain a broad vision of their future prospects. The generation of the most probable scenarios provided the company with a vision and understanding of the relevant, sensitive variables in its environment, as well as their impact on the defined strategies.

Finally, it is concluded that the strategic maps should be based on the environmental scenarios, because the environment impacts the company in the definition of its strategic objectives and therefore impacts the strategic map that represents them and consequently their strategies and your action plans.

Toma de decisiones multicriterio para identificar los procesos de mayor impacto en la continuidad operacional en una empresa sanitaria en contexto de pandemia

claudio.macuada@usach.cl

Resumen. En la actualidad la planificación de las medidas de control para la continuidad del negocio y la resolución de imprevistos son elementos esenciales que las compañías de servicios básicos deben gestionar para disponer del buen funcionamiento de sus procesos en el caso de una interrupción. El reconocimiento de los procesos de mayor impacto para la organización es vital para el desarrollo sostenible y/o incluso para la supervivencia de cualquier organización. Un estudio de caso ha sido llevado a cabo en una empresa sanitaria de Chile priorizando los procesos de mayor impacto que podría permitir elaborar una política de prevención, lo que conlleva a un plan de inversiones. Para esto, se ha considerado cinco impactos al negocio como indispensables de ser contrastados para cada uno de los ocho procesos que posee la organización en estudio. Para la elaboración de esta priorización se aplica el Proceso de Jerarquía Analítica considerando opiniones de expertos y datos empíricos.

Palabras Claves: Proceso de Jerarquía Analítica, AHP, Impacto, Procesos, Empresa Sanitaria.

1 Introducción

Actualmente, la situación sanitaria que enfrenta el mundo y Chile deja de manifiesto la importancia de contar con medidas que apunten a salvaguardar la salud de todos quienes forman parte de la cadena productiva de la industria sanitaria.

Es por esto, que identificar los principales procesos a través de la evaluación de los impactos a los que ve expuesta la empresa sanitaria, permitirá conocer las amenazas trascendentales a la organización y fortalecer la capacidad para mitigarlas. Esto último, dará paso a que la organización genere una estrategia de mediano y largo plazo para asegurar la continuidad del servicio y tener mayor control en caso de sufrir interrupción en alguno de sus procesos.

Este documento propone un enfoque de criterios múltiples para identificar los procesos más relevantes en una empresa sanitaria, que podrían afectar la continuidad del servicio en base a su impacto legal, de imagen, financiero, medioambiental y social.

El Proceso de Jerarquía Analítica (sigla en inglés AHP) resulta adecuado para abordar este tipo de situación problema y ha sido bastante utilizado universalmente en problemas que presentan múltiples objetivos y valoraciones intangibles.

El estudio se basa en la aplicación del método a un caso real dentro de una empresa sanitaria en Chile.

2 Trabajos Anteriores

En lo que se refiere a trabajos anteriores, mencionamos los siguientes: Guan [1], que aplica el AHP al Business Impact Analysis (BIA) para orientar la aplicación de la organización del plan de gestión de continuidad de negocio a través del sistema de índice y computación científica, ya que el BIA utiliza métodos de análisis cualitativo y análisis de expertos, pero le falta apoyo teórico cuantitativo y computación científica.

Por otro lado, consideramos a Macuada [2], quien utilizó AHP para desarrollar un nuevo modelo de decisión multicriterio en base a los dictámenes de expertos para la identificación de los requisitos de dimensiones de alta prioridad para la automatización de plantas de tratamiento. El estudio proporciona una base para el establecimiento de prioridades y la toma de decisiones para la incorporación de un sistema automatizado para plantas de agua potable y aguas servidas.

Por último, se tiene en cuenta el trabajo de Yang [3], donde se propone como objetivo, extraer los aspectos y criterios para la evaluación y selección de criterios de un sitio de recuperación ante desastres en el área de las tecnologías de la información (TI) (disponibilidad del servicio, tiempo de recuperación, desempeño del servicio y otros).

3 Objetivos

El contexto de la problemática abordada comprende los procesos esenciales del negocio en una empresa sanitaria de Chile.

En la Figura 1 se muestran los principales procesos de la empresa sanitaria identificando aquellos que corresponden a la producción de agua potable, depuración de aguas servidas y relación con el cliente.

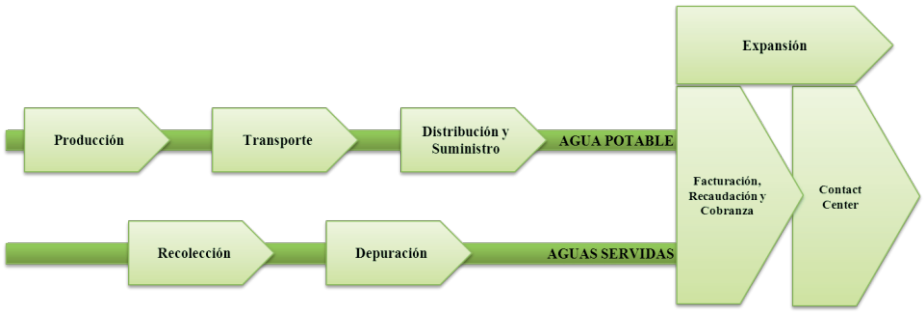

Fig. 1. Procesos Críticos de la Empresa Sanitaria.

4 Metodología de Investigación

La metodología de investigación utilizada está basada en estudio de caso aplicando el AHP [4, 5]. El planteamiento inicial comienza con la determinación de los factores más importantes (Legal, Imagen, Financiero, Medioambiental y Social) que afectan cada proceso a la empresa (Producción, Transporte, Distribución y Suministro, Recolección, Depuración, Facturación-Recaudación-Cobranza, Expansión, Contact Center. Esto permite diseñar una estructura jerárquica, donde las categorías críticas para cada nivel y sus relaciones se obtienen de la consulta a los expertos (Ingenieros de gestión de calidad, ingenieros de proyectos y miembros de la alta dirección).

5 Modelo Propuesto

El modelo de jerarquía para determinar la priorización de los criterios de impacto en los procesos del negocio está diseñado con tres niveles indicados en la Figura 2.

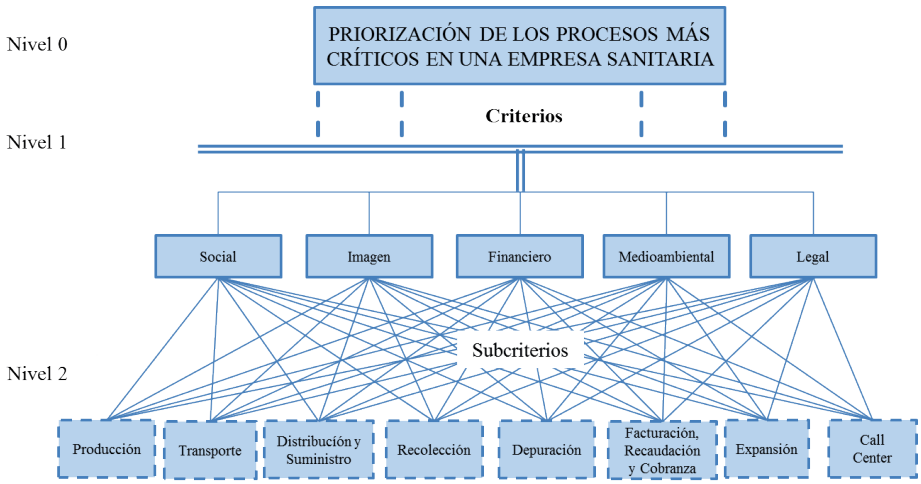

Fig. 2. Estructura Jerárquica Simplificada.

Los factores de decisión se basan en una evaluación comparativa con los procesos más críticos para la empresa, considerando todo lo relacionado a la entrega de servicio de agua potable y recolección de aguas servidas, procesos de cobranza y atención al cliente. En este punto, era posible ser testigo de ciertos tabúes existentes con relación a qué procesos impactan más en la industria bajo el contexto de pandemia. Una puntuación numérica se obtiene por el panel de expertos por referencia a una tabla con el fin de medir el estado actual de cada proceso.

6 Limitaciones

El modelo propuesto considera que no existe interrelación entre las variables. Por otra parte, los procesos críticos examinados fueron sólo los que la empresa en estudio requería evaluar.

7 Conclusiones

En el presente trabajo se ha presentado un problema real de priorización de procesos de mayor impacto en cadena productiva de la compañía, de manera de generar planes de prevención y hacer más eficiente la política de inversiones de la empresa sanitaria, utilizando el enfoque del AHP.

Dada la existencia de distintas variables de decisión para elegir qué procesos son más prioritarios, el desarrollo de un modelo de decisión utilizando AHP fue ventajoso, ya que se obtuvo un entendimiento profundo en los principales requisitos para generar una política de prevención acompañada de su respectivo plan de inversiones, y, a través del proceso de la importancia relativa, se obtuvo los procesos que deben ser considerados en primera instancia.

La priorización resultante señala que las inversiones debiesen estar abocadas en orden decreciente a: Producción, Recolección, Depuración, Distribución y Suministro, Transporte, Contact Center, Facturación – Recaudación – Cobranza y Expansión.

Los resultados de este estudio pueden ser considerados en empresas sanitarias que requieran evaluar los procesos que deben ser priorizados dentro de un plan de inversiones y mitigación de riesgos, buscando mejorar, dar continuidad a la operación y aumentar el valor de la compañía.

Agradecimientos

Un agradecimiento especial de los autores al Departamento de Investigación y Desarrollo Tecnológico (*Proyectos DICYT N ° 061817OH & 061817QL*) y al Departamento de Ingeniería Industrial de la Universidad de Santiago de Chile por el apoyo para la realización del estudio.

Resumen: La gestión del inventario tiene como objetivo determinar y controlar los niveles de inventario dentro del inventario físico, de modo que satisfacer la necesidad de disponibilidad de producto y minimizar los costos relacionados con el inventario deben estar bien equilibrados. En el sector automotriz, específicamente en la rama de autopartes, equilibrar costos y disponibilidad del producto es una ardua tarea. En esta investigación se buscan alternativas de solución a los problemas derivados de la falta de una adecuada gestión de inventarios, para una empresa de partes de repuesto automotriz en México. El objetivo de este trabajo es proponer una nueva política de inventario que permita minimizar los costos totales de inventario mientras, se satisface el nivel de servicio objetivo para los clientes de la empresa. Para llevar a cabo el objetivo, se cuenta con un análisis previo de datos de los productos seleccionados, a través de la demanda futura pronosticada mediante modelos ARIMA, para evaluar dos políticas de inventario (s, S) y (R, S). Las dos políticas permiten minimizar niveles y días de inventario, así como los costos asociados a excesos de inventario y manejo ineficiente de los mismos. Definida la mejor política de inventario se utilizó un sistema de reabastecimiento conjunto propuesto por Atkins y Iyogun en 1998, permitiendo que los artículos con baja demanda sean incluidos en los pedidos de artículos de mayor movimiento, eliminando así un costo de configuración mayor en un futuro cercano cuando el artículo de bajo movimiento alcance su punto de reorden.

Palabras clave: Gestión de inventarios; Demanda; Política de inventario; Punto de reorden; Cantidad económica de pedido.

Abstract. Inventory management aims to determine and control inventory levels within physical inventory, so that meeting the need for product availability and minimizing inventory-related costs must be well balanced. In the automotive sector, specifically in the auto parts branch, balancing costs and product availability is an arduous task. This research looks for alternative solutions to the problems derived from the lack of adequate inventory management for an automotive spare parts company in Mexico. The objective of this work is to propose a new inventory policy that allows minimizing total inventory costs while satisfying the target service level for the company's customers. To carry out the objective, there is a previous analysis of the data of the selected products, through the forecast future demand using ARIMA models, to evaluate two inventory policies (s, S) and (R,

S). The two policies allow minimizing inventory levels and days, as well as the costs associated with excess inventory and inefficient handling of the same. Once the best inventory policy was defined, a joint replenishment system proposed by Atkins and Iyogun in 1998 was used, allowing items with low demand to be included in the orders for items with greater movement, thus eliminating a higher configuration cost in the near future. When the low-moving item reaches its reorder point.

Keywords: Inventory management; Demand; Inventory policy; Reorder point; Economic order quantity

1 Introducción

La gestión y el control de inventarios representa una de las actividades más importantes en las organizaciones. Las organizaciones manejan bienes para su venta o su inclusión en la cadena de producción o suministro. El control de los costos y la determinación de políticas eficientes para el mantenimiento y la gestión de inventarios supone una disminución de los gastos derivados de su actividad logística o comercial y un crecimiento de sus beneficios [1].

La gestión del inventario tiene como objetivo determinar y controlar los niveles de inventario dentro de los sistemas de inventario físico, de modo que la necesidad de disponibilidad del producto y la necesidad de minimizar los costos relacionados con el inventario estén bien equilibrados [2]. Un objetivo es mantener los niveles de existencias lo más bajo posible para minimizar los costos y liberar capital de trabajo tanto como sea posible. Otro objetivo es proporcionar un alto nivel de servicio a los clientes para evitar el riesgo de pérdida de ventas en caso de inventarios insuficientes [1].

En general, se puede hablar de cuatro componentes fundamentales que determinan los sistemas de inventario y que dan lugar a diversas propiedades de estos. Estos componentes fundamentales son demandas, reposiciones, costos y restricciones [3].

Una cuestión importante de la gestión de inventario es encontrar una política de inventario óptima para controlar la reposición de producto en almacén y minimizar los costos relacionados con el inventario, mientras se mantiene un nivel de servicio para los clientes. Aquí, una política de inventario es un mecanismo que decide cuándo debe realizase un pedido de reposición de inventario, lo cual determina la cantidad de ordenar (cuánto) de qué producto.

En este trabajo de investigación se cuenta con información de demanda futura (previamente pronosticadas mediante modelos ARIMA (*Autoregressive Integrated Moving Average*) [4], para una empresa de repuestos de autopartes. La empresa en estudio es de origen mexicano. Comercializa autopartes de repuesto automotriz de suspensión y dirección a nivel nacional. Su marca tiene renombre en el sector como proveedor de partes de repuestos al mercado automotriz, así como importante distribuidor de autopartes automotrices en México, manejando alrededor de 1,000 productos para el mercado nacional. La empresa se considera dentro del ramo de repuestos de calidades equivalentes a la original. El problema de la empresa radica en no contar con una herramienta de gestión de inventarios eficiente en costos que le permita evaluar y controlar el sistema de inventarios de repuestos.

Con base en esta información de demandas proporcionada por la empresa en estudio, se determinaron las políticas de inventario adecuadas, de modo que se minimice el costo total de gestión del inventario. Una vez encontrada la mejor política de inventario se utiliza un sistema de reabastecimiento conjunto propuesto por Atkins y Iyogun en 1998 [5], permitiendo que los artículos con baja demanda sean incluidos en los pedidos de artículos de mayor movimiento, eliminando así un costo de configuración mayor en un futuro cercano cuando el artículo de bajo movimiento alcance su punto de reorden. Este trabajo se centra en el uso de sistemas probabilísticos de gestión de inventario, esto es, la demanda no es conocida con certeza y se aplican políticas de inventario para este tipo de demanda. Las políticas seleccionadas serán la política (s, S) (***s*-**punto de reorden, ***S*-**inventario meta) y la política (R, S) (***R*-**periodo de revisión, ***S*-**inventario meta). El objetivo es determinar la política óptima para el sistema de inventario, de modo que el costo total en todo el sistema se minimice mientras se satisface el nivel de servicio objetivo para los clientes. Los resultados obtenidos muestran que la política de inventario seleccionada mejora un 10 % en el manejo de inventario y un decremento en el costo por ordenar debido a un buen manejo de inventario.

El documento contiene cinco apartados, el siguiente a este es el apartado dos en el que se muestra la revisión de literatura necesaria para comprender la metodología a utilizar en el desarrollo del trabajo, la cual se encuentra en el apartado número tres. La descripción del caso de estudio y la aplicación de la metodología se presenta en el apartado cuatro, así como los resultados obtenidos de la aplicación de la nueva política de inventarios; finalmente en el apartado cinco se muestran las conclusiones.

2 Revisión de literatura

En la literatura el control de inventarios pretende contestar a tres preguntas fundamentales: ¿Con que frecuencia revisar el inventario?, ¿Cuándo reponer? y ¿Con qué cantidad? [6]. La primera pregunta se responde de acuerdo con la política de control de inventario que las empresas apliquen a sus inventarios. La segunda pregunta se puede responder de dos formas: i) se debe reponer el inventario cuando la cantidad de producto (*stock*) sea igual o menor a ***s*** (punto de reorden) unidades. ii) se puede reponer el inventario cada ***R*** (periodo de revisión) unidades de tiempo. Mientras que las posibles respuestas para la tercera pregunta son: i) se añaden al inventario siempre ***Q*** (cantidad fija de pedido) unidades, o bien ii) se repone una cantidad tal que, al incorporarla al inventario, el nivel de este alcanza el valor de ***S*** (inventario meta) unidades [4,5,6]. El objetivo principal de estas preguntas es brindar el nivel deseado de servicio al cliente a un costo mínimo. El primer modelo desarrollado para contestar la tercera pregunta se desarrolló hace diez décadas por Harris (1913) a este modelo lo llamo EOQ (*Economic Order Quantity*) [7].

Los modelos de inventarios se pueden clasificar en modelos determinísticos y estocásticos. Los modelos deterministas asumen una demanda y tiempo de entrega conocidos con certeza, por otro lado, los modelos estocásticos la demanda y tiempos de entrega no son conocidos con certeza [6]. El objetivo del modelo probabilístico es determinar el momento de emisión del reabastecimiento y la cantidad a pedir, sujeto a la incertidumbre de la demanda y/o cualquier otro parámetro [2].

Teniendo en cuenta lo anterior, se consideran las siguientes políticas de inventario: i) políticas de revisión continuas **(*s, Q*)** y **(*s, S*).** La política **(*s, Q*)** solicita una cantidad

fija de ***Q*** cada vez que la posición de inventario cae al punto de pedido ***s*** o inferior por otro lado la política **(*s, S*)** se produce cuando el *stock* decrece a ***s*** se ordena para elevar la posición del inventario hasta el nivel ***S***. ii) políticas de revisión periódicas **(*R, S*)** y **(*R, s, S*)**, la política **(*R, S*)** cada ***R*** unidades de tiempo, se ordena lo suficiente como para elevar la posición del inventario al nivel ***S*** [6]. Otra variable es el periodo de entrega (que se denota por ***L*** conocido como *lead time*), que representa el intervalo de tiempo que transcurre entre que se solicita un pedido hasta el instante en que dicho pedido se añade al *stock* [2].

Debido al componente aleatorio que tienen las demandas de piezas de repuesto, es necesario abordar sistemas de revisión con demanda probabilística, permitiendo el cálculo del *stock* de seguridad (***SS***), que amortigüe la demanda de repuestos; el cálculo del *stock* de seguridad será alimentado por el error que generan los pronósticos aplicados [4]. Para este caso de estudio se seleccionaron la políticas de revisión continua ***(s,S)*** y la política de revisión periódica ***(R, S)*** propuestas por [6], para control de inventarios con demandas probabilísticas.

Política (*s, S*): Este sistema de control de inventarios asume una revisión continua; y, al igual que el sistema (*s, Q*), se realiza un reabastecimiento cada vez que la posición de inventario cae al punto de pedido ***s*** o menor. Sin embargo, en contraste con el sistema (*s, Q*), se usa una cantidad de reabastecimiento variable, ordenando lo suficiente como para elevar la posición del inventario hasta el nivel ***S***. Si todas las transacciones de demanda son de tamaño unitario, los dos sistemas son idéntico porque la solicitud de reposición siempre se realizará cuando la posición del inventario esté exactamente en ***s***; es decir, ***S*** = ***s*** + ***Q*** [2]. Esta política fue abordada por [9], utilizando programación no lineal entera mixta para determinar los parámetros casi óptimos y, posteriormente utilizar programación lineal entera mixta para su comparación y mejorar el modelo.

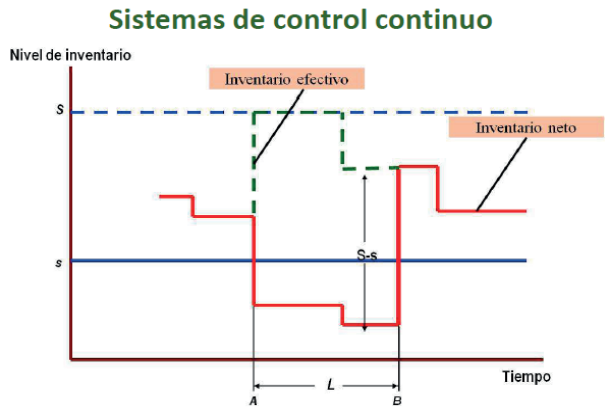

Fig. 1 Sistema de inventario (*s, S*). Fuente: Modificado de [2].

Para la aplicación de la política de gestión de inventarios de revisión continua (*s, S*) se debe hacer uso de las siguientes formulas propuestas por [2]:

Tamaño de pedido:

$$Q = EOQ = \sqrt{\frac{2AD}{vr}} \tag{1}$$

donde:

$$A = costo\ de\ configuración\ por\ ordenar$$

$$D = demanda\ anual$$

$$v = costo\ de\ producto$$

$$r = tasa\ de\ mantenimiento$$

Desviación estándar de los errores pronosticados sobre el tiempo de reposición L:

$$\sigma_L = \hat{\sigma}_1\sqrt{L} \tag{2}$$

donde:

$$\hat{\sigma_1} = desviación\ estandar\ de\ pronósticos$$

$$L = lead\ time$$

Función especial de distribución normal:

$$G_u(k) = \frac{Q}{\sigma_L}(1 - P_2) \tag{3}$$

donde:

$$P_2 = probabilidad\ o\ tasa\ de\ existencia\ del\ producto$$

Demanda esperada sobre el tiempo de reposición L:

$$\hat{x}_L = dL \tag{4}$$

donde:

$$d = demanda\ promedio\ mensual$$

Punto de reorden:

$$s = \hat{x}_L + k\sigma_L \tag{5}$$

donde:

$$k = factor\ de\ seguridad$$

Costo total relevante:

$$TRC = \frac{AD}{Q} + \left[\frac{Q}{2} + k\sigma_L\right]vr + \frac{D}{Q}(B_2 v)\sigma_L G_u(k) \tag{6}$$

donde:

$$B_2 = cargo\ fraccionado\ por\ unidad\ faltante$$

Política (*R, S*): Este sistema de control de inventarios asume una revisión periódica, también es conocido como un sistema de ciclo de reabastecimiento, es de uso común, particularmente en empresas sin control informático sofisticado. También se ve con frecuencia cuando los artículos se solicitan al mismo proveedor o requieren compartir recursos. El procedimiento de control es que cada ***R*** unidades de tiempo (es decir, en cada instante de revisión) se ordena lo suficiente como para elevar la posición del inventario al nivel ***S***. El sistema (*R, S*) ofrece una oportunidad regular (cada ***R*** unidades de tiempo) para ajustar el orden hasta el nivel ***S***, una propiedad deseable si el patrón de

demanda cambia con el tiempo. Las principales desventajas del sistema (*R, S*) son que las cantidades de reabastecimiento varían y que los costos de mantenimiento son más altos que en los sistemas de revisión continua [2].

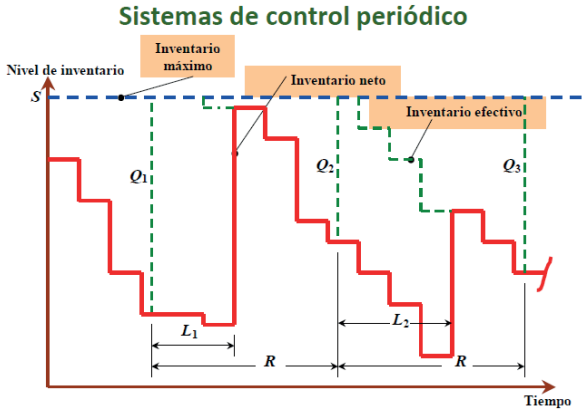

Fig. 2 Sistema de inventario (*R, S*). Fuente: Modificado de [2].

Para la aplicación de la política de gestión de inventarios de revisión periódica *(R, S)* se debe hacer uso de las siguientes formulas propuestas por [2]:

Demanda esperada sobre el tiempo de reposición L:

$$\hat{x}_{R+L} = d(R + L) \tag{7}$$

donde:

$$R = intervalo\ de\ revisión$$

Punto de reorden:

$$s = \hat{x}_{R+L} + k\sigma_{R+L} \tag{8}$$

donde:

$$\sigma_{R+L} = \sqrt{\frac{R+L}{2}} * \sigma_1\sqrt{R}$$

Costo total relevante:

$$TRC = \frac{A}{R} + \left[\frac{DR}{2} + k\sigma_{R+L}\right] vr + \frac{1}{R}(B_2 v)\sigma_{R+L} G_u(k) \tag{9}$$

Donde las variables que se integran a las ecuaciones 7, 8 y 9 tienen el mismo significado ya descrito en la política (*s, S*).

En general, se debe mantener cierta cantidad de producto en inventario para el funcionamiento eficiente de un negocio. Esa cantidad está condicionada o depende de la demanda que haya de los productos en el mercado. La demanda debe ser satisfecha con la cantidad de inventario almacenada. Los modelos clásicos de gestión de inventarios consideran que la demanda es conocida y constante. Sin embargo, esta situación en la que conocemos con precisión las demandas futuras es poco común en la práctica [3].

Estas dos políticas de inventarios propuestas para el caso de estudio han sido ampliamente estudiadas, para la gestión de diferentes tipos de inventarios, una revisión bibliográfica se realizó aplicando diferentes métodos para 2012 a 2015 para artículos perecederos [10]. Estudios para diferentes tipos de demandas se han realizado, utilizando programación no lineal entera mixta, heurísticos como *Silver-Meal* y el algoritmo de *Wagner-Whitin,* los cuales son prometedores para ciertos tipos de demandas [11].

Un sistema de reabastecimiento en conjunto se da cuando se piden varios artículos simultáneamente, en lugar de individualmente, esto con la intención de que el costo total al agregar más artículos de línea sea mucho menor que el costo total de pedir artículos individualmente, cuando los artículos son abastecidos por un mismo proveedor [9].

Un sistema de abastecimiento conjunto busca un equilibrio entre las decisiones de frecuencia de revisión del inventario y las cantidades a ordenar; logrando una coordinación de todos los productos (*ítems*), considerando que las ordenes se hacen a un solo proveedor [7]. Dentro de los sistemas de revisión para realizar el reabastecimiento conjunto, uno de ellos se adapta a las necesidades de la empresa en estudio, se trata de un sistema de revisión periódica sugerido por *Atkins y Iyogun* en 1998, quienes desarrollaron un algoritmo para realizar un reabastecimiento conjunto.

Este tipo de sistemas está orientado a generar ahorros en el costo de ordenar, permitiendo controlar los principales grupos de *ítems* que se pueden ordenar en un mismo momento, donde los productos se consumen simultáneamente, pero caen en periodos de revisión completamente diferentes. Este modelo desarrollado por *Atkins y Iyogun* permite encontrar las cantidades necesarias y los periodos de revisión adecuados a los productos [6].

El procedimiento de *Atkins e Iyogun* esencialmente asigna el mayor costo de reposición en pequeñas cantidades a los productos que se producen o compran con mayor frecuencia, manteniendo el tiempo esperado para la próxima reposición de estos productos en equilibrio [2].

Para el desarrollo de este algoritmo inicialmente se calcula el *EOQ*, usando la siguiente formula:

$$EOQ_i = \sqrt{\frac{2a_i D_i}{rv_i}} \tag{10}$$

donde:

$$a_i = costo\ menor\ de\ agregar\ un\ producto\ i$$

$$D_i = demanda\ anual\ del\ producto\ i$$

$$v_i = costo\ unitario\ del\ producto\ i$$

Al mismo tiempo, se calcula el suministro de tiempo equivalente para cada producto usando solo el menor costo de configuración a_i, asumiendo un año como 50 semanas.

$$T_i = \frac{EOQ_i(50)}{D_i}\ en\ semanas \tag{11}$$

Con esto, se obtiene un suministro de tiempo T_i para cada *ítem* dentro de una familia de productos, luego se elige el producto con el suministro de tiempo más pequeño y se

denota producto 1. Una pequeña porción $\propto_1$ del costo mayor A, se asigna a este producto. La idea es asignar eventualmente todo el costo mayor principal a varios productos de la familia. Si todo el costo estuviera distribuido en un solo producto, su *EOQ* podría incrementarse significativamente, lo mismo que su suministro de tiempo [2].

Asignar más y más $\propto_1$ al primer producto aumenta su suministro de tiempo, eventualmente hasta el punto de que coincide con el suministro de tiempo del segundo producto comprado con mayor frecuencia. Ahora asigne más del costo de instalación o reabastecimiento principal al primer producto, y algunos al producto 2, manteniendo los suministros de tiempo en equilibrio. Cuando estos dos suministros de tiempo igual aumentan al suministro de tiempo del tercer producto comprado con mayor frecuencia, comience a asignar $\propto_3$ a este tercer producto. Este proceso continúa hasta que se asigna toda la configuración principal, es decir $\sum_i \propto_i = 1$. Por lo tanto, cada vez que se ordena una familia, se contabiliza el costo total de la configuración [2].

Si se expresa el costo total para un *ítem* como $(\alpha_i A + a_i)$, es fácil resolver para un tiempo de suministro dado por:

$$\alpha_i = \frac{T_i^2 r_i v_i D_i}{2A} - \frac{a_i}{A}$$

donde:

$$A = costo\ de\ configuración\ por\ ordenar$$

3 Metodología

Para dar solución al problema de la empresa en estudio, se formula la siguiente metodología para la gestión de inventarios, la cual consta de cinco etapas para su ejecución.

1) *Identificación del sistema:* Esta identificación del sistema corresponde a la periodicidad o frecuencia con la que se realicen los inventarios en la empresa.
2) *Clasificación ABC:* Es aplicar el método de Pareto, el cual consiste en la clasificación de productos con base en su importancia para las ventas de la empresa y la cantidad de productos que estos representan para ellas. Importancia conocida como el 80% de las ventas están representadas por el 20% de los productos que se encuentran en almacén.
3) *Determinación de la demanda:* Se deben considerar los patrones de demanda: estacionaria, estacional, con tendencia o cíclica y tener en cuenta la variabilidad de la demanda.
4) *Evaluación y selección de sistemas de pronósticos:* Para calcular las demandas futuras con base en el comportamiento de la demanda de los productos, para este caso de estudio se evaluaron los modelos clásicos de pronósticos y los modelos ARIMA, resultando los modelos ARIMA con el menor error de pronóstico. Con estos modelos ARIMA se calculan los pronósticos de las demandas que serán utilizadas para aplicar la política de inventario.
5) *Evaluación y selección del sistema de control de inventarios:* En este trabajo, nos centramos en un grupo de sistemas que serán sistemas probabilísticos de

gestión de inventario, esto es, la demanda no es conocida con certeza. Las políticas seleccionadas serán la política (s, S) y la política (R, S).

6) *Sistema de abastecimiento conjunto*: En este punto se busca un equilibrio entre las decisiones de frecuencia de revisión del inventario y las cantidades a ordenar; logrando una coordinación de todos los productos, considerando que las ordenes se hacen a un solo proveedor. El sistema de revisión periódica será el algoritmo sugerido por *Atkins y Iyogun*.

4 Caso de estudio y resultados

La empresa en estudio es una empresa de origen mexicano, fundada en 1982. Comercializadora de partes de repuesto de suspensión y dirección para un mercado de autopartes. La empresa tiene renombre a nivel nacional como proveedora de refacciones al mercado automotriz, manejando alrededor de 1,000 *SKU´s* (*Stock Keeping Units*). Actualmente la empresa no cuenta con una herramienta de gestión eficiente en costos que le permita evaluar y controlar el sistema de inventarios de repuestos, como es de esperarse, se tienen bajos niveles de servicio por falta de material y un almacén con exceso de componentes y producto terminado.

La ejecución de la metodología para la gestión de inventarios es la siguiente:

1) *Identificación del sistema:* La empresa en estudio no cuenta con un sistema específico, por esta razón, como parte de la propuesta, se propone un adecuado sistema de gestión de inventarios para los productos seleccionados.

2) *Clasificación ABC:* Para la empresa en estudio se aplicó el principio de Pareto para establecer el grado de importancia de cada artículo. Con la aplicación de este principio de obtuvieron 160 artículos A de los 1,000 artículos en total. Los 15 artículos seleccionados para esta propuesta pertenecen a la clasificación A y son los que requieren mayor control, de acuerdo con información proporcionada por personal de la empresa.

3) *Determinación de la demanda:* Del análisis realizado a los artículos de clasificación A, se concluyó que presentan demanda con tendencia y, para algunos *ítems* la demanda es estacionaria, en general la demanda presenta variabilidad para los artículos A. Los 15 artículos seleccionados presentan tendencia, además de presentar variabilidad y solo uno presenta demanda estacionaria.

4) *Evaluación y selección de sistemas de pronósticos:* Para determinar los pronósticos de demanda de la empresa en estudio, se utilizaron los métodos de pronósticos cuantitativos clásicos y los modelos ARIMA, donde los modelos ARIMA presentaron el menor error porcentual absoluto medio, por lo que se utilizaron estos métodos de pronósticos para el cálculo de la demanda futura.

5) *Evaluación y selección del sistema de control de inventarios:* En esta etapa se considera un sistema de abastecimiento conjunto el cual busca un equilibrio entre las decisiones de frecuencia de revisión del inventario y las cantidades a ordenar, tomando en cuenta los datos obtenidos del caso de estudio. Un sistema de abastecimiento conjunto que se adapta a las necesidades y condiciones de la empresa, por ello se aplica un sistema de revisión periódica sugerido por *Atkins y Iyogun*.

En la Tabla I, se muestran los datos para 15 productos de la empresa de partes de repuesto, los pronósticos de la demanda se obtuvieron previamente, mediante modelos de pronósticos ARIMA, cuyos modelos arrojaron los menores errores de pronósticos comparados con los métodos de pronósticos clásicos, estos datos de demanda son utilizados para la selección de la política de inventario óptima *(s, S)* o *(R, S)*. Los datos adicionales son proporcionados por la empresa en estudios.

Aplicando las fórmulas para las políticas de inventario propuestas para la empresa en estudio, se obtuvieron los resultados que se presentan en la Tabla II.

Estos resultados de las políticas de inventario nos indican claramente, que la mejor política de inventario para aplicar a la empresa es la política de revisión continua, ya que nos ahorraría $1,515.11 (DLS) anuales para estos 15 artículos estudiados.

Siguiendo con la política de revisión periódica y aplicando el algoritmo de *Atkins y Iyogun* para un reabastecimiento en conjunto, se obtienen los resultados mostrados en la Tabla III:

TABLA III. CALCULOS *EOQ* Y *T*.

Item	Demanda (piezas)	v (DLS)	*EOQ* (piezas)	*T* (semanas)
1	5964	2.65	300	2.52
2	11280	3.72	348	1.54
3	6672	3.05	296	2.22
4	2724	3.73	171	3.14
5	4044	3.06	230	2.84
6	3108	1.77	265	4.26
7	4920	4.77	203	2.06
8	4212	5.7	172	2.04
9	3228	3.65	188	2.91
10	2508	6.79	122	2.42

Fuente: Elaboración propia con información proporcionada por personal de la empresa.

Estos nuevos periodos de revisión y *EOQ*, son los que mejor se ajustan a la empresa para generar ahorros en costos por abastecimiento en conjunto.

5 Discusiones y conclusiones

La industria de partes automotrices presenta cierta complejidad debido a las particularidades de sus productos en cuanto a variabilidad en la demanda e importancia de políticas que mantengan altos estándares de calidad. Los pronósticos son una herramienta poderosa que hace frente a este tipo de dificultades y a los cambios previstos en un futuro, contribuyendo así a la generación de beneficios económicos para las empresas.

A través de la elaboración de pronósticos de la demanda de productos, se puede desarrollar políticas de inventario adecuadas que minimicen su costo, tomando en cuenta el nivel de servicio ofrecido por la empresa. Los modelos de inventario utilizados se clasifican con base a los supuestos de demanda, periodo de revisión, faltantes, costos y tiempo de entrega (*lead time*). Adicionalmente, es importante mencionar que todos los modelos buscan optimizar sus políticas de reabastecimiento a través de la minimización de sus costos totales, los cuales en la mayoría de los modelos se utiliza un costo fijo de pedido, un costo de mantenimiento de inventario y costos por faltantes.

Con respecto a las políticas de inventario utilizadas, se recomienda priorizar los métodos probabilísticos ya que en sí la demanda para los productos de esta empresa siempre tiende a ser variable. Adicionalmente a esto una buena coordinación de productos, reducirán los costos por reabastecimiento como se observa en el caso de estudio para las empresas de piezas de repuesto automotrices.

Resumen. La gestión de los sistemas de producción configurados como *Job Shop* implica toma de decisiones en ambientes de incertidumbre relacionada con: tiempos entre pedidos, tipo de producto, cantidad pedida, tiempos de operación, múltiples rutas de producción y tiempos de operación altamente variables. A pesar de este gran desafío, no hay mucho enfoque en el desarrollo de mejores soluciones para la gestión de la producción de alta variedad, probablemente porque los *Job Shop* que son pequeños en tamaño e ingresos, no han atraído la atención de los gurús de la gestión. La simulación es un enfoque de apoyo a la gestión que ha mostrado buenos resultados en razón a que puede lidiar muy bien con la incertidumbre. Es por esto que en esta ponencia se quiere mostrar un modelo de simulación para dar soporte a dicha gestión. Inicialmente se aborda el tema de la complejidad en la gestión del *Job Shop*, seguidamente se plantea la conveniencia de emplear simulación y las bases conceptuales requisito de un posible modelo. Al final, se expone el modelo desarrollado y se hace una corrida con un *Job Shop* hipotético, planteando 2 escenarios, en cuya comparación se emplean diferentes medidas de desempeño relacionadas con la eficiencia y la efectividad.

Keywords: Job Shop, Toma de Decisiones, Simulacion.

1 Introduccion

1.1 Definiendo un *Job Shop*

No es fácil encontrar una definición universalmente aceptada de una configuración de producción del tipo *Job Shop*. Sin embargo, muchas definiciones existentes cubren algunas características importantes de estas [1, 2]. La mayoría de las instalaciones de fabricación descritas como *Job Shop* son relativamente pequeñas en tamaño e ingresos y aceptan una variedad de pedidos personalizados en pequeñas cantidades. Un *Job Shop* es más general que una línea de producción que puede fabricar una variedad de productos uno tras otro de forma secuencial.

Específicamente, los *Job Shop* [3] incluyen muchos tipos de unidades de producción como talleres de máquinas, talleres de fabricación, talleres de forja, talleres de moldes,

talleres de herramientas y matrices, unidades personalizadas de trabajo de madera, fabricantes de muebles, talleres de reparación, laboratorios, ciertas unidades de servicio, etc. El volumen de producción personalizada ha ido aumentando a lo largo de los años junto con el nivel de automatización en las industrias. Dado que la producción en masa se está subcontratando, el porcentaje de unidades de producción de alta variedad está aumentando en los países occidentales y la metodología para mejorar la gestión de la producción de alta variedad en los talleres de trabajo es cada vez más relevante.

1.2 Complejidad inherente a la gestión de un *Job Shop*

En [3] se considera que muchos *Job Shop* pequeños y medianos se ocupan principalmente de una variedad numerosa de pedidos de pequeños volúmenes sin ninguna previsibilidad de los requisitos del proceso y los tiempos de llegada de los pedidos. Este fenómeno que involucra una demanda incierta y cambios impredecibles en la mezcla de productos en la planta de producción generalmente obliga a fabricar productos solo contra pedidos realizados por los clientes. La variación en la combinación de productos puede provocar fluctuaciones rápidas en los requisitos de materiales y recursos, y las pequeñas empresas no pueden permitirse mantener inventarios de una variedad amplia de materias primas para respaldar la producción sobre pedido. Por varias razones, los *Job Shop* tienden a utilizar máquinas multifuncionales y trabajadores con múltiples habilidades de capacidad limitada para procesar los pedidos de los clientes.

Muchos expertos en fabricación sugieren la simplificación del sistema para eliminar la complejidad de la producción de gran variedad. Sin embargo, la simplificación del sistema no siempre es sencilla, fácil o económica en la práctica, especialmente para talleres pequeños. Sin la simplificación del sistema, la gestión de una producción compleja y de gran variedad es bastante difícil. La simplificación del sistema sugerida por [4, 5] la manufactura esbelta (*lean manufacturing*) y la teoría de restricciones (TOC) aún no se implementa ampliamente en sistemas de producción tipo *Job Shop*. Estas metodologías parecen carecer de algo que es esencial para una gestión eficiente de la producción en muchos *Job Shop* pequeños y medianos.

Uno de los objetivos en la gestión del *Job Shop* es maximizar primero el desempeño general del sistema (taller) mediante el uso óptimo de las capacidades de recursos disponibles y luego identificar simplificaciones rentables, así como oportunidades de mejoras que pueden producir las mayores ganancias marginales en los KPI. Un enfoque mediante el empleo de simulación puede ayudar a evaluar tanto el desempeño general del sistema, así como posibilidades de mejoramiento del mismo.

1.3 Simulación

Para [6] la simulación está referida a técnicas que, usando computadores, imitan o *simulan* la operación de varias clases de instalaciones y procesos del mundo real. En otras palabras, computadores que pueden fingir digitalmente ser una fábrica, un avión o un mercado de abarrotes. La instalación o proceso de interés usualmente es llamado sistema, y en pro de estudiarlo científicamente, a menudo se establecen un conjunto de

suposiciones de cómo opera. Estas suposiciones usualmente toman la forma de relaciones matemáticas y lógicas constituyendo lo que se denomina un *modelo* que es usado para intentar obtener algún entendimiento sobre cómo el correspondiente sistema se comporta a través del tiempo. Para [7], al imitar la operación de un sistema real, la simulación genera una historia artificial del sistema y su observación permite inferir lo concerniente a las características de operación del sistema real. Según [8] la simulación es el proceso de diseñar y desarrollar un modelo de un sistema o proceso real y conducir experimentos con el propósito de entender el comportamiento del sistema o evaluar varias estrategias (dentro de límites impuestos por un criterio o conjunto de criterios) para su operación.

Si las relaciones que componen el modelo son bastante simples, es posible usar una solución analítica (métodos matemáticos tales como algebra, calculo o teoría de probabilidad) para obtener información exacta sobre las preguntas de interés. En casi todas las soluciones analíticas, la meta es determinar soluciones óptimas. No obstante, muchos sistemas del mundo real (por ejemplo, los sistemas de producción tipo *Job Shop*) son demasiado complejos para modelarlos y evaluarlos analíticamente. Un modelo de simulación comúnmente toma la forma de hipótesis acerca del funcionamiento de un sistema, expresadas como relaciones matemáticas o lógicas entre las entidades de interés del sistema.

En [9] se plantea que, en contraste con las soluciones analíticas, el proceso de simulación incluye la ejecución del modelo a través del tiempo en una computadora, para producir muestras representativas de las mediciones del desempeño del sistema. Desde este punto de vista, se puede considerar la simulación como un experimento de muestreo sobre el comportamiento en el tiempo, del sistema real, cuyos resultados son puntos de muestra. Es claro que mientras más puntos de muestra se generen, mejor será la estimación sobre el desempeño del sistema.

Específicamente la simulación por eventos discretos (DES) se centra en representar sistemas en los que es necesario realizar una secuencia de operaciones o tareas y sus eventos asociados. Esto significa que podemos pensar en estas operaciones como un proceso e ilustrarlas con un diagrama de flujo. En DES, el estudio con simulación permite analizar las “cosas” (trabajos) que pasan por el proceso y los recursos que les ayudan a completar su flujo.

Para [10], las características de la simulación, que hacen que sea una potente herramienta de planificación y toma de decisiones, se pueden resumir en:

- Captura las interdependencias de un sistema.
- Representa la variabilidad del Sistema.
- Versatilidad para modelar casi cualquier sistema.
- Expone el comportamiento sobre el tiempo.
- Es de menor costo y consumo de tiempo simular que experimentar con el sistema real.

- Provee información sobre múltiples medidas de desempeño (KPI).
- Es visualmente atractivo e involucra el interés de los usuarios del sistema.
- Provee resultados que son fáciles de entender y comunicar.
- Provee compresión espacio-temporal.
- Fuerza al analista a pensar en los detalles operativos del sistema.

Definido lo que es un sistema de producción configurado en *Job Shop* y la complejidad asociada a su gestión y previamente haber caracterizado la simulación como herramienta apropiada de soporte en la toma de decisiones bajo incertidumbre, se identifican a continuación los requisitos que debe satisfacer el modelo mencionado en el título.

2 Aproximación conceptual al modelo de simulación de un *Job Shop*

En esta sección se planteará conceptualmente la funcionalidad del modelo que posteriormente se codificará en un software de simulación del tipo DES.

2.1 Requisitos funcionales mínimos que debe satisfacer el modelo

Al revisar la literatura [3, 9] sobre el funcionamiento de un sistema configurado en *Job Shop* se encuentran las siguientes características, tanto de componentes estructurales como operacionales:

1. Se recibe en momentos inciertos pedidos (trabajos) de una amplia variedad de productos en pequeñas cantidades con requisitos impredecibles de proceso.
2. Los productos pueden tener variaciones en cantidades, requisitos de materiales, rutas, prioridades, plazo de entrega y márgenes.
3. Un pedido puede implicar la producción de un conjunto de componentes similares o la producción de diferentes tipos de componentes y la fabricación de subconjuntos y un ensamblaje final a partir de esos componentes.
4. Varios pedidos pueden moverse simultáneamente a través del sistema a lo largo de las respectivas rutas mientras compiten por recursos compartidos.
5. El procesamiento de un pedido puede incluir algunas operaciones externas.
6. Las operaciones de fabricación de un pedido pueden ser secuenciales o pueden tener ciertas relaciones de precedencia.
7. El conjunto de operaciones y relaciones de precedencia puede variar según el producto.
8. Los tiempos de alistamiento y de proceso de cualquier operación pueden variar según el trabajo.
9. Los tiempos de alistamiento para las operaciones también pueden depender de la secuencia del trabajo

10. Una operación puede requerir un solo recurso o puede requerir simultáneamente múltiples recursos como máquinas, trabajadores, etc. La duración misma de la operación puede ser variable.
11. Los recursos pueden ser máquinas multifuncionales y trabajadores polivalentes.
12. Los recursos pueden tener calendarios individuales (horas de trabajo) y excepciones de calendario.
13. Una operación larga puede o no ser compartida por varios recursos alternativos para reducir su duración.
14. El material de un trabajo puede moverse a través del sistema como un solo lote o como pequeños lotes de transferencia.
15. Las máquinas y operarios se agrupan por proceso

2.2 Conceptualización de los componentes estructurales del sistema

Al revisar la lista anterior de requisitos funcionales encontramos que este tipo de sistemas tiene las siguientes características estructurales:

Distribución en planta: Según los requisitos funcionales 11 y 15, las necesidades espaciales pueden considerar desde cientos a miles de m2 de área que incluya además de los espacios de maquinado, espacios (vías) para el flujo de materiales, personas y equipo de transporte.

Máquinas, operarios y/o equipo de transporte: Los requisitos funcionales 3, 14 y 15 indican que el modelo debe ser capaz de representar estos componentes estructurales, tanto espacial como operacionalmente. Espacialmente mediante coordenadas tipo plano cartesiano. Operacionalmente en términos de tiempos de proceso, alistamiento, entre fallos, etc.

Materia prima, producto en proceso y producto terminado: Los requisitos funcionales 2, 3 y 14 implican que el modelo debe ser capaz de representar los 3 estados: el pedido (producto), la materia prima y el producto en proceso.

2.3 Conceptualización de los componentes operacionales del sistema

De la lista de requisitos funcionales anterior encontramos que el modelo a desarrollar debe ser capaz de representar el siguiente comportamiento operativo del sistema:

Pedidos de clientes: Según el requisito funcional 1 se debe modelar tiempos entre pedidos, tipo de producto y cantidad pedida de forma aleatoria (muestreados estos valores desde distribuciones de probabilidad).

Secuencia de fabricación de productos: Según los requisitos funcionales 2, 4, 6 y 7 se debe poder representar una ruta de procesamiento (secuencia de operaciones) para cada tipo de producto. Si se consideran m máquinas y n trabajos, una posible secuencia

de operaciones por producto se ilustra en la Fig. 1, la cual representa una configuración *Job Shop* para m=6 máquinas y n=15 productos.

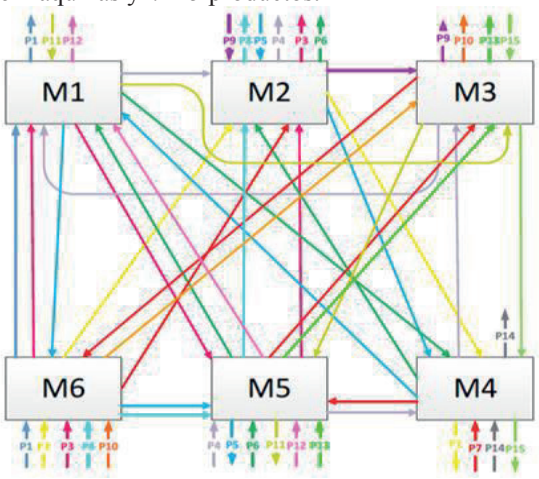

Fig. 1. Secuencia de procesamiento de 15 productos en 6 máquinas.

Tiempos de alistamiento de máquinas: Según los requisitos funcionales 8 y 9, los tiempos de alistamiento pueden depender de la secuencia de procesamiento (ver Fig. 1) y/o del tipo de producto a fabricar.

Tiempos de procesamiento de máquinas: Según el requisito funcional 8 el tiempo de proceso en cada máquina depende del tipo de producto. Además, el requisito funcional 10 establece que el tiempo de procesamiento en cada máquina no necesariamente es constante.

Uso de operarios en los procesos: Los requisitos funcionales 10, 11 y 12 indican que en el modelo debería poder representarse el trabajo de operarios, ya sea en labores de procesamiento como de manejo de materiales (su transporte).

2.4 Requisitos mínimos de entrada de parámetros que debe satisfacer el modelo

En razón a que el modelo será usado por personas (tomadores de decisiones) que no necesariamente son expertos en simulación, se hace indispensable que este tenga una interfaz usuario-modelo simple y apta para poder parametrizar la operación del mismo. Por tanto, debe cumplir con los siguientes requisitos de uso, al permitir el ingreso (algunos en formato tabular) de los siguientes parámetros de operación del sistema a simular:

1. Probabilidad (en %) de pedido de un determinado producto.
2. Cantidades mínima y máxima por tipo de producto que los clientes piden.
3. Tiempo de proceso de cada producto en cada máquina según distribución de probabilidad teórica o empírica.

4. Tiempo de alistamiento (si aplica) de cada producto en cada máquina según distribución de probabilidad teórica o empírica.
5. Ruta de procesamiento por cada tipo de producto acorde a lo ilustrado en la Fig. 1.

2.5 Requisitos mínimos de información de salida que debe satisfacer el modelo

Esta información debe proporcionarse en términos de KPI (*Key Performance Indicators*) de interés en la toma de decisiones relacionadas con la gestión de un *Job Shop*. Para un Job Shop se sugieren los siguientes KPI:

1. Relacionados con la eficiencia (uso de los recursos productivos):
    - Tasas de utlizacion de maquinas
    - Tasas de utilizacion de operarios

2. Relacionados con la efectividad (logro de los resultados):
    - Pedidos colocados y fabricados en un periodo de tiempo.
    - Productos pedidos y fabricados en un periodo tiempo.
    - Tiempos mínimos, promedio y máximo de fabricación por pedido.
    - Tiempos mínimos, promedio y máximo de fabricación de pedidos por tipo de producto.
    - Niveles de WIP.

Identificado a nivel conceptual el funcionamiento que debe tener el modelo de simulación de un sistema de producción configurado en *Job Shop* para soportar la toma de decisiones, se procede a codificar el modelo en un software de simulación tipo DES. A continuación, se expone el modelo desarrollado.

3 Resultado: Modelo de Simulación

El modelo se desarrolló en el software FlexSim v.2020. Para efectos de demostración se describe a continuación el modelo con aplicación a un sistema *Job Shop* configurado con $m = 3$ máquinas y $n = 3$ productos.

3.1 Modelamiento de la secuencia de procesamiento por producto, distribución en planta y operarios

En la Fig. 2 se muestra la secuencia de procesamiento que sigue cada producto a través de las maquinas M1, M2 y M3. Donde CM1, CM2 y CM3 son las respectivas colas de espera de la disponibilidad de cada máquina. Así, las secuencias son:

Producto A: CM1►M1►CM3►M3►CM2►M2
Producto B: CM3►M3►CM1►M1►CM2►M2

Producto C: CM2►M2►CM3►M3►CM1►M1

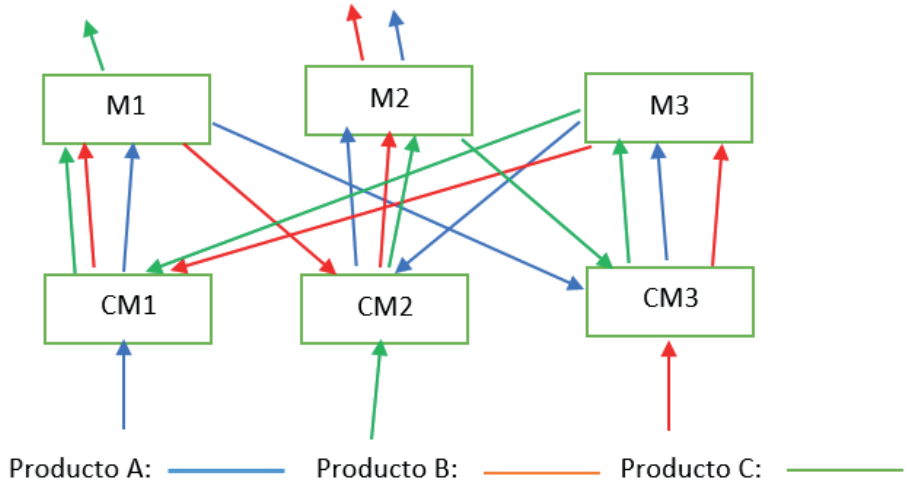

Fig. 2. Secuencia de procesamiento de 3 productos en 3 máquinas.

Para introducir una secuencia de fabricación especifica al modelo, el usuario digita esta secuencia de manera textual en una tabla en Excel, la cual es leída desde el modelo al momento de iniciar la simulación. La Fig. 3 muestra los datos correspondientes a la secuencia mostrada en la Fig. 2: secuencia de procesamiento 1. Igualmente es posible modelar otra secuencia según se muestra en la secuencia de procesamiento 2, en la cual los productos A y B son de nuevo procesados por la M1.

Secuencia procesamiento 1

	ProductoA	ProductoB	ProductoC
Espera1	CM1	CM3	CM2
Operacion1	M1	M3	M2
Espera2	CM3	CM1	CM3
Operacion2	M3	M1	M3
Espera3	CM2	CM2	CM2
Operacion3	M2	M2	M2
Espera4	Bodega	Bodega	Bodega
Operacion4			
Espera5			

Secuencia procesamiento 2

	ProductoA	ProductoB	ProductoC
Espera1	CM1	CM3	CM2
Operacion1	M1	M3	M2
Espera2	CM3	CM1	CM3
Operacion2	M3	M1	M3
Espera3	CM2	CM2	CM2
Operacion3	M2	M2	M2
Espera4	CM1	CM1	Bodega
Operacion4	M1	M1	
Espera5	Bodega	Bodega	

Fig. 3. Dos secuencias de procesamiento de 3 productos en 3 máquinas.

En la Fig. 4, se muestra una representación gráfica de la distribución en planta, la cual es un espacio rectangular (ver cuadricula) de área 24 m x 18 m (432 m2). Además de las máquinas y sus colas de espera, se incluye un punto de arribo de los pedidos, un operario por cada máquina para el transporte y procesamiento (las líneas curvas denotan las trayectorias de movimiento) de la materia prima y producto y una bodega para el almacenamiento de este último cuando esté terminado. Es conveniente resaltar que el modelo se simula con animación en 3D.

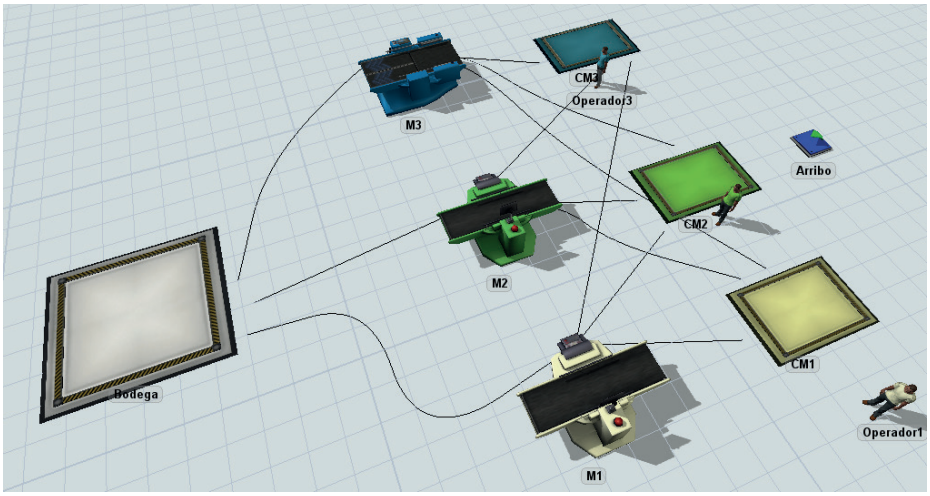

Fig. 4. Representación grafica del modelo de simulación.

En la Tabla 1 se muestra los parámetros de actuación de los operarios, los cuales son fijos, es decir el usuario del modelo no los puede cambiar. Los tiempos que emplean los operarios en las maquinas procesando los productos se describen más adelante.

Tabla 1. Parámetros fijos de operación de los operarios

Parametro	Valor
Velocidad de desplazamiento	25 m/s
Tiempo de cargue	6 s
Tiempo descargue	6 s
Capacidad de cargue	1 pedido a la vez
Descansos	Cada 2 horas 1 descanso de 10 minutos

3.2 Modelamiento de los pedidos

Se representan estos mediante 3 parámetros probabilísticos. El primero es el tiempo entre pedidos en horas, que se muestreara desde una distribución triangular. El segundo es la probabilidad que tiene cada producto de ser pedido y el tercero la cantidad pedida. En un ambiente real, estos tres parámetros se pueden estimar a partir de los datos históricos del sistema de información de pedidos. En la Fig. 5 se muestran valores específicos para los 2 últimos parámetros. Como se observa el primer parámetro se modela

con una distribución de probabilidad empírica y el segundo mediante una distribución uniforme para la cantidad pedida por tipo de producto.

Probabilidad de pedido por producto

	Probabilidad	Type
ProductoA	45	1
ProductoB	25	2
ProductoC	30	3

Cantidad a pedir por producto

	Minimo	Maximo
ProductoA	5	10
ProductoB	3	8
ProductoC	5	9

Fig. 5. Probabilidades de pedido por producto y cantidad pedida.

3.3 Modelamiento de los tiempos de proceso en las maquinas

El tiempo que demora el proceso en cada máquina se representa mediante valores probabilísticos muestreados desde distribuciones de probabilidad teóricas. El software *FlexSim* soporta más de 30 tipos de distribuciones de probabilidad. Para el caso de demostración se emplearán las distribuciones: uniforme, triangular y normal. Igualmente es posible representar tiempos de proceso constante como se muestra en la Fig. 6 (caso del tiempo de proceso del Producto B en M3).

	M1	M2	M3
ProductoA	return uniform(4,8,1);	return uniform(4,8,1);	return normal(3.5,0.4,1);
ProductoB	return uniform(5,9,2);	return triangular(2.2,7.5,6.1,3);	return 3.2;
Productoc	return triangular(2.2,6.5,4.1,3);	return uniform(4,8,1);	return normal(2.8,0.2,1);

Fig. 6. Tiempos de proceso (minutos) de cada producto en cada máquina.

3.4 Modelamiento de los tiempos de alistamiento de las maquinas

El tiempo que demora preparar cada máquina antes de manufacturar un producto determinado se representa mediante valores determinísticos. En la Fig. 7 se muestran los valores a emplear en la demostración. Igualmente es posible representar si una máquina no requiere tiempo de alistamiento para determinado producto, simplemente se representa con el valor 0.

	M1	M2	M3
ProductoA	return 30;	return 45;	return 30;
ProductoB	return 40;	return 0;	return 30;
Productoc	return 30;	return 30;	return 0;

Fig. 7. Tiempos de alistamiento (segundos) de cada producto en cada máquina.

4 Ejemplo de simulación del modelo

Se considerarán 2 escenarios de experimentación con el fin de mostrar las bondades del modelo en el apoyo a la toma de decisiones en la gestión de un sistema de producción configurado en *Job Shop*. Se muestra a continuación los resultados en términos de los KPI propuestos en la sección 2.5, simulando a una longitud de corrida de 192 horas (1 mes con jornadas de trabajo de 48 horas semana) y 10 réplicas.

4.1 Escenario 1: Simulación con parámetros de operación del sistema actual

Este escenario base de experimentación considerara tiempos entre pedidos de mínimo 0.33, máximo 0.75 y más frecuente 0.5 horas y empleara como otros parámetros de entrada los descritos en la sección 3.

KPI relacionados con la eficiencia: En las figuras 8 y 9 se muestran las tasas de utilización de máquinas y operarios.

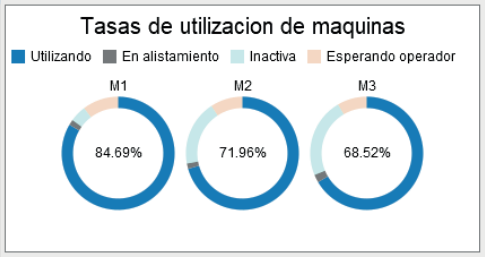

Fig. 8. Tasas de utilización de las maquinas: Escenario 1.

Se observa que la M1 es la de mayor utilización. En las M1 y M2 hay disponibilidad de utilización alrededor del 15%. En las 3 máquinas el tiempo de alistamiento es mínimo, pero el paro de las maquinas por descansos del operador puede llegar al 10%.

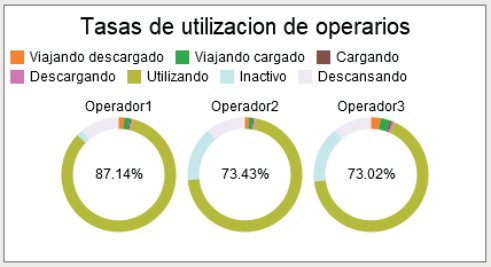

Fig. 9. Tasas de utilización de los operarios: Escenario 1.

Se observa que el Operador1 es el de mayor utilización. Los operadores 2 y 3 tienen disponibilidad de utilización adicional alrededor del 10%. Para los 3 operadores los tiempos de viaje, cargue y descargue son poco significativos.

KPI relacionados con la efectividad: En las figuras 10, 11, 12 y 13 se muestran los niveles de throughput, tiempo de proceso y WIP alcanzados.

Pedidos y cantidades de producto colocados	**Pedidos y cantidades de producto fabricados**
Numero de pedidos colocados x pdto **vPedidosA** 161 **vPedidosB** 88 **vPedidosC** 161	**Numero de pedidos fabricados x pdto** **vPedidosFabricadosA** 102 **vPedidosFabricadosB** 62 **vPedidosFabricadosC** 72
Cantidades pedidas x Pdto **vPedPdtoA** 1220 **vPedPdtoB** 476 **vPedPdtoC** 832	**Cantidades fabricadas x Pdto** **vFabPdtoA** 778 **vFabPdtoB** 338 **vFabPdtoC** 513

Fig. 10. Volumen de pedidos colocados y fabricados por producto (throughput): Escenario 1.

Se puede deducir de los resultados mostrados en la Figura 10 que el nivel de satisfacción de la demanda es muy bajo, sobre todos para los productos A y C (aproximadamente del 63% para A y 61% para C en un periodo de tiempo de 192 horas). La figura 11 muestra que a medida que el periodo de tiempo se extiende estos niveles de satisfacción de la demanda siguen bajando.

Los resultados desplegados en la figura 12 muestran que el tiempo promedio en el sistema de un pedido desde que se coloca hasta que se entrega esta alrededor de 12 horas, inclusive un pedido del producto A demoro alrededor de 66 horas (máximo = 3967 minutos). Llama la atención que en promedio un pedido de producto A demora 32 horas.

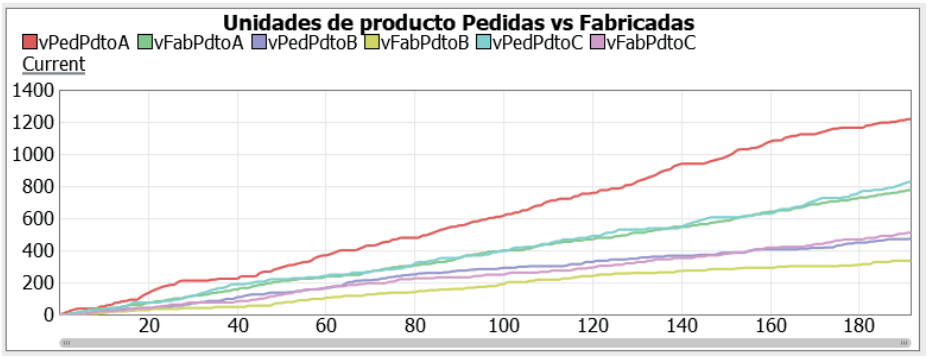

Fig. 11. Tendencia en el tiempo de productos pedidos vs fabricados: Escenario 1.

Tiempo de fabricación por pedido en minutos

Promedio	Minimo	Maximo
724.8	11.1	3967.0

Tiempo de fabricación por pedido/producto (Tipos 1, 2 y 3 corresponden con: A, B y C respectivamente)

Tiempo en el sistema pedidos por tipo de producto

Type	Promedio	Maximo	Minimo
1	1963.3	35.0	3967.0
2	63.0	11.1	231.1
3	105.5	18.5	284.7

Fig. 12. Tiempos de fabricación de pedidos: Escenario 1.

La Figura 13 muestra el estado del WIP en la planta de producción al terminar la simulación. Ha de connotarse el alto número de pedidos que quedan en proceso esperando ser procesados en M1 (122 esperando en CM1). Cada caja denota un pedido y su color el tipo de producto: rojo, verde y azul se corresponden con los tipos A, B y C.

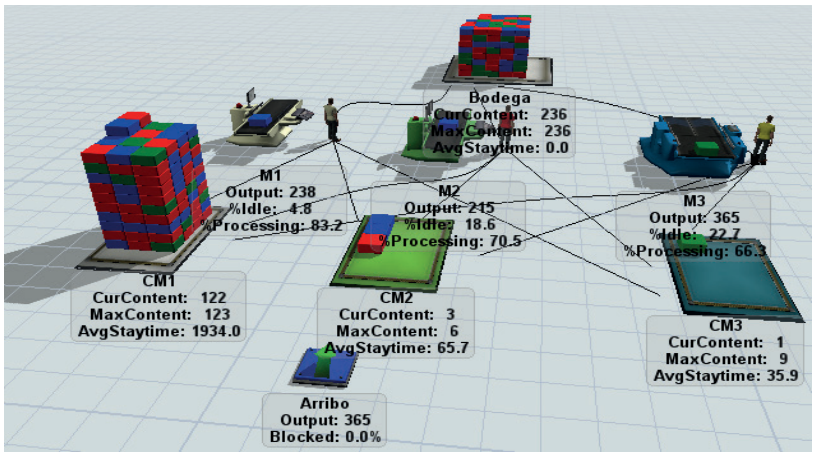

Fig. 13. Estado planta de producción al finalizar la simulación: Escenario 1.

4.2 Escenario 2: Simulación con parámetros de operación propuestos

Asumiendo el papel de un tomador de decisiones y en pro de mejorar los KPI de eficiencia y efectividad y considerando según el corto análisis hecho que la problemática se centra en la alta probabilidad de demanda de los productos A y C, además de su volumen de pedido (los piden el 75% de las veces en cantidades hasta de 10 unidades, ver Figura 5) se toma la decisión de emplear como tiempo de proceso un valor constante mínimo, bajo el supuesto que se emplearan máquinas automáticas y/o se mejorara el método de operación. En la Figura 14 se muestra el cambio propuesto. (Comparar con la Figura 6 para ver el cambio en los tiempos de operación).

	M1	M2	M3
ProductoA	return 4;	return 4;	return 3.5;
ProductoB	return uniform(5,9,2);	return triangular(2.2,7.5,6.1,3);	return 3.2;
Productoc	return 2.2;	return 4;	return 2.8;

Fig. 14. Nuevos tiempos de operación (minutos) de productos A y C en cada máquina.

KPI relacionados con la eficiencia: En la Figura 15 se muestran las nuevas tasas de utilización de máquinas y operarios. Se puede apreciar un aumento en la utilización de las máquinas M1 y M2, una disminución de M3 y aumento en la utilización del Operador3 y disminución en la utilización del Operador2.

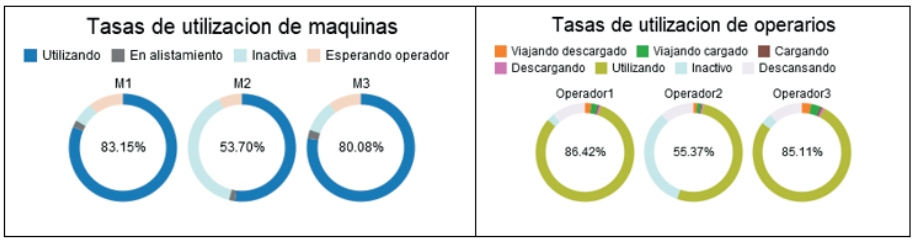

Fig. 15. Tasas de utilización de máquinas y operarios: Escenario 2.

KPI relacionados con la efectividad: En la Figura 16 se observa el throughput alcanzado en el escenario 2. Respecto al escenario 1, se pasó de 236 a 312 pedidos fabricados. Y de 1629 unidades de producto fabricadas en el escenario 1 a 2160 en el escenario 2.

Numero de pedidos fabricados x pdto		Cantidades fabricadas x Pdto	
vPedidosFabricadosA	144	vFabPdtoA	1095
vPedidosFabricadosB	81	vFabPdtoB	445
vPedidosFabricadosC	87	vFabPdtoC	620

Fig. 16. Volumen de pedidos/productos fabricados por producto (throughput): Escenario 2.

Los resultados desplegados en la Figura 17 muestran que el tiempo promedio en el sistema de un pedido desde que se coloca hasta que se entrega disminuyo de 12 a 6.4 horas. Y específicamente el tiempo de fabricación de un pedido de productos A paso de 32 a 13.2 horas.

Tiempo en el sistema pedidos en minutos

Promedio	Minimo	Maximo
382.7	12.6	1569.1

Tiempo en el sistema pedidos por tipo de producto

Type	Promedio	Minimo	Maximo
1	789.9	21.4	1569.1
2	118.9	18.4	247.3
3	33.2	12.6	75.8

Fig. 17. Tiempos de fabricación de pedidos: Escenario 2.

La Figura 18 muestra el estado del WIP en la planta de producción al terminar la simulación. Ha de connotarse que el número de pedidos que quedan esperando ser procesados en M1 paso de 122 en el escenario 1 a 47 en el escenario 2.

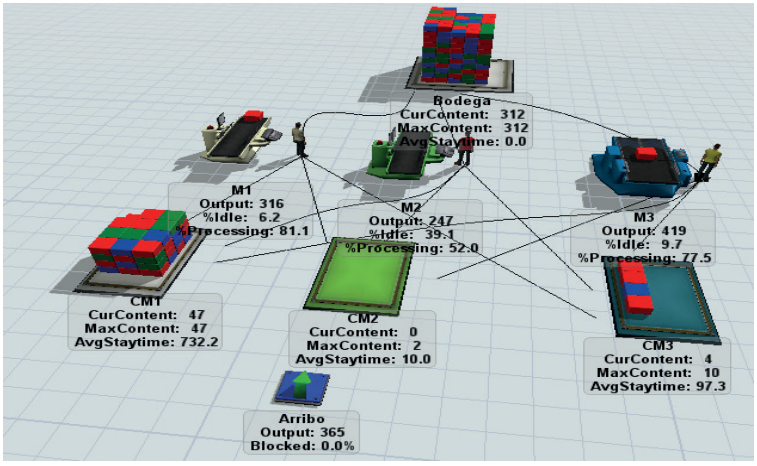

Fig. 18. Estado planta de producción al finalizar la simulación: Escenario 2.

A strategic reference model for the competitiveness of the port supply chain

Luis M. Ascencio[1], Rosa G. González-Ramirez[1] and Stefan Voss[2]

Keywords: Port competitiveness · Port supply chain · Reference Model

The logistics services industry is a fundamental pillar for foreign trade and the economic and social development of nations. Foreign trade by sea represents 90% of volume and 70% in terms of the value of world trade, according to the United Nations Conference on Trade and Development (UNCTAD, 2018). Before the COVID-19 pandemic, the UNCTAD was estimating that international maritime trade would expand at an average annual growth rate of 3.5% over the 2019-2024 period. However, the pandemic COVID-19 caused a deceleration in all the economies. Now, in the recovery phase, global supply chains need to be more efficient than ever.

Ports act as an interface between ships and shore for cargo transferring, where the evolution of global supply chains and the recent disruptive events have imposed significant challenges to their role as functional nodes in logistics networks [1,2]. To cope with this challenge, ports must evolve and adapt their operations to reduce operational costs while increasing the service levels to their users.

Port competitiveness is related to the development of different innovative alternatives and strategies with which ports can compete, as well as the efficient implementation of these strategies to attract more users and cargo to the port [3,4,5]. This should ensure a satisfactory result to all the actors that participate in the port supply chain and, therefore, the port plays a double role.

On a national level perspective, the World Bank provides logistics and competitiveness indicators. The Logistics Performance Index (LPI) measures aspects related to the efficiency of ports, Customs and logistics services for 185 countries. If we observe the results obtained by the countries in Latin America and the Caribbean, it is possible to note a structural gap as the countries have not been able to reach better positions with respect to other countries such as Germany or the Netherlands, that are always in the first positions of the ranking. This highlights the importance of trade facilitation practices as well as the need of ports being more competitive by providing better service levels in the import and export processes.

In this research, we propose a Strategic Reference Model of Management and Competitiveness of the port supply chain that aims to provide port managers guidelines and best practices so as to facilitate the development of effective port transformation programs in institutional, operational, digital and innovation matters. For this, we consider

as a case study, a set of representative ports in the Region of Latin America and the Caribbean. The research follows a grounded theory approach, in which field work such as interviews and focus group activities, as well as a literature review, provided insights of what are the areas or dimensions of competitiveness resulting in six prioritized areas that organize best practices observed and validated by the industry at a global and regional level and that, by measuring their degree of implementation in the port systems of the region, provides a qualitative and quantitative basis for ports in the region be able to implement continuous improvement programs.

Adaptation of the Balanced Scorecard to Latin American Higher Education Institutions in the Context of Strategic Management: A Systematic Review with Meta-analysis.

Mauricio F. Hinojosa V.[1][0000-0002-8962-7517]

[1] Universidad de Santiago de Chile, Santiago RM 9160000, Chile
mauricio.hinojosa@usach.cl

Abstract. The objective of this research is to examine from a scientific perspective how the use of the Balanced Scorecard has been adapted in the various types of higher education institutions in Latin America within the context of their strategic management, through a systematic review with meta-analysis, in order to contribute to the development of strategic processes in these organizations, given the relevance they have acquired, based on the new state regulations and the speed of social and cultural changes in the region. To achieve this, a statistical analysis was carried out, first to identify the most frequent implementation techniques and the type of institution in which the studies were conducted; and, secondly, to examine the underlying interrelationships between the variables involved in the strategic context through the chi-squared test. The results showed a scarcity, but incipient evidence from the year 2000, of works mostly concentrated in universities of three countries, both in public and private organizations, with greater use of the original structure of Kaplan and Norton, and of the perspective "Customer". With the meta-analysis, no relationship was found between the ownership of the organization and, on the one hand, the structure of strategic dimensions used in the comprehensive scorecard and, secondly, with the perspectives used.

Keywords: Balanced Scorecard, Strategic Management, Latin American Higher Education Institutions, Systematic Review, Meta-analysis.

1 Introduction

In the same way that it has occurred in the most developed countries of the world, the industrial sector of higher education (HE) in Latin America is now going through a time of rapid and great changes, due in large part to the transition from an industrial society to the knowledge society [1]. Now higher education institutions (HEIs) must face greater competitiveness in their markets, more empowered students, universalization of education and a new legal and regulatory framework. There is a transition, with different nuances between countries, towards expansion and then towards quality[1],

[1] In another aspect of diagnosis there is also evidence of a transition from the elite to inclusion.

phenomena that developed countries began to experience at the beginning of the 20th century [2].

With regard to expansion, in most Latin American countries there is strong growth in access to HE and enrollment, especially in the lower socioeconomic strata [3], presenting a large variance, which depends on factors such as educational spending as a percentage of gross domestic product and the nation's budget, and on the Net Enrolment Rate in secondary education[2] [1].

Because the States are not able to satisfy all the need for SE, now this service is shared by public and private institutions [2], whose difference, according to international standards[3] [4], lies in whether it is public or private the entity that has the ultimate power to make decisions about the institution's affairs[4]. Worldwide, 33% of students are enrolled in private HEIs [5], and an accelerated growth of private HE [6] is reflected in a growing Gross Enrollment Rate[5] in Latin America [7], an area that has the highest participation worldwide, with 48% of its enrollment in private HEIs[6] [2]. At one end of the spectrum are countries such as Brazil, Chile, El Salvador, Peru and the Dominican Republic, concentrating their enrollment in the private sector, and at the other end Cuba, without private registration [8]. A reflection of the above is the decrease in public investment per student in Latin America [3].

On the other hand, the transition to quality has implied the establishment of new state policies, which tend to order and try to regulate an increasingly heterogeneous and complex market, which have resulted in changes at the legislative level, in the contribution of state funds, and in the creation of evaluating and supervising bodies [9]. Opposite examples of this reality are represented by Mexico, as a case of less regulation, and Chile, as an example of greater regulation.

Within this context are the accreditation and/or quality assurance systems[7], which oblige HEIs to carry out strategic processes, execute the minimum functions required by each State, carry out performance and quality evaluations based on standardized indicators, and accountability (delivery of information, compliance with standards, transparency) [10]. For example, in Chile, the HE law [11] establishes strategic management as one of the dimensions to be accredited, and also the obligation to carry out

---

2 It is defined as the total number of students in the theoretical age group for the secondary level, enrolled at that level, expressed as a percentage of the total population in that age group [29].

3 Each country provides information on private and public HEIs to international organizations such as UNESCO [5] according to its own taxonomy. In addition, HEIs differ in terms of owner, mission, main source of income, student aid system, quality control system, institutional governance mode, and academic staff management system, with a different ideological-cultural meaning depending on the country [30].

4 Private institutions in turn are classified as "dependent" and "independent" of the government, which only refers to the degree of dependence of an institution on government financing [4].

5 In higher education, the Gross Enrolment Rate is defined as the total number of students enrolled in tertiary education, expressed as a percentage of the population in the five-year group immediately after secondary education, typically 18 to 22 years old [27].

6 In Europe in 2010 it was only 15% [31].

7 Almost every nation in the region now has an accrediting agency.

a process of institutional strategic planning, which generally it is documented in a strategic development plan.

One of the tools used by HEIs in their strategic processes is the Balanced Scorecard (BSC), which was presented by Kaplan and Norton 27 years ago [12], based on the integration and complementation of the literatures on quality, efficient management, financial economics, and stakeholder theory. It started as a tool to measure the performance of a company through financial and non-financial measures that promote the creation of long-term value for its shareholders, based on four perspectives: financial, customers, internal business, and innovation and learning ago [12]. Soon its authors realized that the priority in companies was to implement their strategy and that, therefore, the first thing was not to generate the metrics, but rather the logic is to describe the strategy through strategic objectives, based on the structure of the four perspectives, which finally leads to the selection of the ideal indicators [13]. Then, with the incorporation of the strategy map, the focus is taken away from the indicators, and put on the objectives and the relationship between them [14].

Starting in the mid-90s, the BSC began to be applied in both public institutions and non-profit organizations, so Kaplan and Norton generated an adaptation of the BSC to this type of organizations [14], which do not measure their performance with financial indicators, but through effectiveness to generate benefits to the recipients. As seen in **Fig. 1**, the financial perspective disappears from the first level, as it is not its main or final objective, being replaced by objectives related to its impact and mission; and the client perspective is broadened to donors, who provide financial resources (pay for the service), and to clients or beneficiaries, who are the recipients of the service[8].

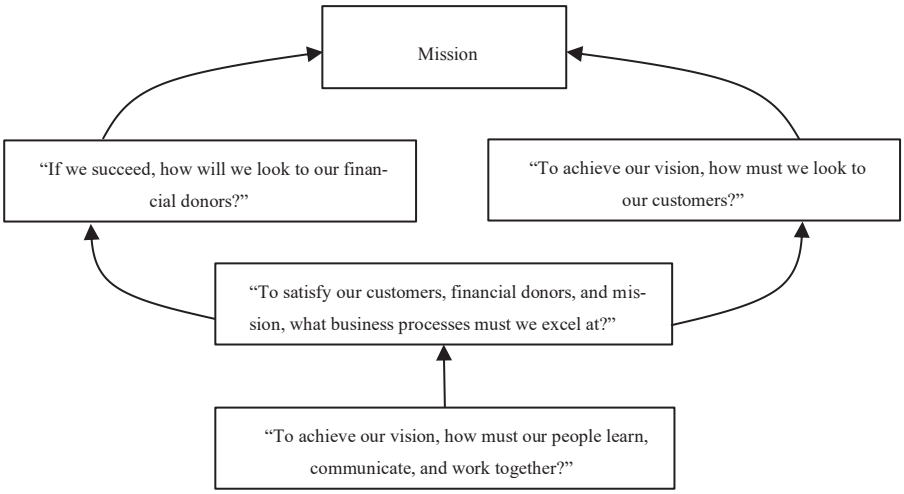

Fig. 1. Adaptation of the BSC to non-profit organizations (Source: Kaplan & Norton [14]).

[8] Faced with the question of who is the client, a cross-cutting problem for non-profit and public organizations, instead of opting for one or the other, in practice the perspectives of the donor and the recipient have been placed at the same level [14].

Then came the creation of the concept of Organization focused on strategy [14], based on 5 principles [15], and an enrichment of the methodology in 2004 [16], but it is the adaptation to other types of organizations in 2001, which should lead to a greater use of the BSC in ES.

A review of articles in ISI Web and Scopus [17] shows that in 2006 25% of the total studies found used the BSC in the context of strategic management, that only 3.8% of the total correspond to applications in educational institutions and no evidence of work was found in Latin America; there is little evidence on the application of the BSC in HEIs, compared to companies [18].

From the need to know how the BSC is being applied in HE, the idea of generating a systematic review[9] was born, whose advantage over a narrative review of the literature is that it reduces bias and error, allowing the generalization of scientific findings and supporting the decision making [19].

An Internet exploration through 8 databases (Scopus, Web of Sicence, Springer, Jstor, Science Direct, Wiley online Library, Emerald, Taylor & Francis online) and a search engine (Google Scholar), did not provide evidence of systematic or narrative reviews focused on the application of the BSC in Latin American HEIs. There are close studies, such as, for example, a narrative review on the practical application of the BSC in different industries [20], another on the application of the BSC considering environmental, social or ethical problems, called sustainability BSC [21], a systematic review of the strategies in non-profit organizations [22], and without being a review, an article from this year [23], in which the influence of the BSC on the research and innovation performance of six Latin American universities was studied. Of all the reviews found, the most related is a narrative review that focuses on the context of the BSC in IES [24], which identifies and contextualizes the perspectives.

Based on the above, this systematic review of the literature, with meta-analysis, aims to analyze how the BSC has been adapted as a tool for strategic management in Latin American HEIs, discovering what type of relationship exists between the variables of the tool and the characteristics of the organizations who have evidenced their application through publications.

This document is structured according to what Denyer and Tranfield proposed for a systematic review in the area of management [25], to which a section with the meta-analysis is added, as follows: in Chapter 2 describes the methodology used, then the results are presented and discussed, in section 4 the meta-analysis is evidenced, to end with the conclusions.

2 Methodology

The systematic review was carried out based on the methodology proposed by Denyer and Tranfield[10] [25], which consists of four steps.

[9] Although there is no single definition, it can be established that a systematic review is an academic research article that synthesizes studies through planned, explicit, transparent, and repeatable procedures to answer predefined questions.

[10] This methodology is applied since it focuses on the field of management.

2.1 Question formulation

The basic question is: In what way has the BSC been applied in strategic processes of different types of Latin American HEIs?

Reformulating the question according to the CIMO logic [25], acronym of Context, Intervention, Mechanism and Outcome, it results: Are the characteristics of an HEI (context) a determining factor (intervention) in the definition of the perspectives and objectives of the BSC (outcome)? How (mechanism) affect the design of the BSC (result)?

2.2 Location of studies

The exploration was carried out using the 9 search engines mentioned in the previous section, to which the academic platform Academia.edu was added, using keywords, Boolean operators, truncation, and special characters, to the extent that the search engine allowed it **Table 1**.

Table 1. Techniques used to search for studies.

Search identifier	*Search settings*
A	balanced scorecard higher education strategic management
B	cuadro de mando integral educación superior gestión estratégica
C	(TITLE ("balanced scorecard") AND ABS (higher AND education AND strateg* AND management) OR TITLE-ABS-KEY (strateg* AND management AND universit*))
D	"strategic management" argentina perspectives financial learning internal process customer indicators "balanced scorecard" "higher education institution"
E	strategic management argentina perspectives indicators "balanced scorecard" "higher education institution"
F	strategic management perspectives indicators argentina "higher education institution" "balanced scorecard"
G	strategic management perspectives indicators chile "higher education institution" "balanced scorecard"
H	gestión estratégica perspectiva indicador "institución de educación superior" "cuadro de mando integral"
I	gestión estratégica perspectiva indicador educación OR superior "cuadro de mando integral" -empresa -salud

An exploration was carried out with the keywords in English and Spanish, and then a more detailed search was carried out, testing different combinations, discarding the first since they were very inefficient (produced more than 500 results), using one at a time the name of different countries, until the use of the Spanish language without country restriction generated positive search results.

2.3 Study selection and evaluation

The following three selection criteria were used.

The first is that the BSC was applied in a Latin American HEI. Latin American countries are defined as: Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba,

Ecuador, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Dominican Republic, Uruguay and Venezuela [10].

It is understood "application of the BSC" according to the definition made by its creators [12], in which perspectives, objectives and indicators are identified. Therefore, if any of the first two is not present, the document is not considered.

Finally, the application must be about an organization that provides HE services, regardless of the type of degree or title that it delivers, its owner/administrator, or its teaching modality; but parts of it are not considered, that is, academic units, departments, centers, institutes, faculties, among others, nor are the institutions that train members of the armed forces.

The second criterion is that the BSC was used within the context of a strategic process. Applications that include strategic objectives are considered.

And the last criterion was that the HEI was identifiable in terms of the owner, destination of its benefits and type of institution. Are considered both public and private institutions, for-profit and non-profit institutions, and those that teach study programs levels 5 and / or 6 according to international standards [26].

2.4 Analysis and synthesis

A form was used for data extraction, with the following aspects:

- Publication: Search engine - Year - Research name - Author (s) - Type of publication (paper, thesis, conference proceeding, degree or professional seminar, monograph, working paper, or dissertation) – Country.
- Research design: Research objective - Name of the Institution - Type of organization according to its owner (public or private) - Type of HEI according to its mission (university, technical institute or professional institute) - Number of students – Institution's age - Participation of representatives of the organization in the study.
- Application of the BSC: - Map (yes / no) - Perspectives - Strategic objectives - Number of indicators.

2.5 Report and use of the results

Finally, the report is generated, in which the research is contextualized and justified, the results obtained are presented, the analysis is carried out and the research questions are answered.

To this is added a meta-analysis, in which the studies are statistically combined, which allows a more technical analysis with a greater scope.

3 Findings and discussion

Once the search was carried out through the procedure described, it yielded different results with the different search engines.

From the review of the documents applying the selection and evaluation criteria described above, positive results were obtained only through the Google Scholar search engine and the Academia.edu platform. The exploration revealed a total of 17 documents that met the established selection criteria, using H and I techniques (**Table 1**).

In publication aspect, the distribution of researches over time (**Fig. 2**) shows that it was not until 2000 that the first evidence of a study was found in which the BSC was applied to a strategic planning process in a Latin American HEI, with a slight increasing trend towards 2018.

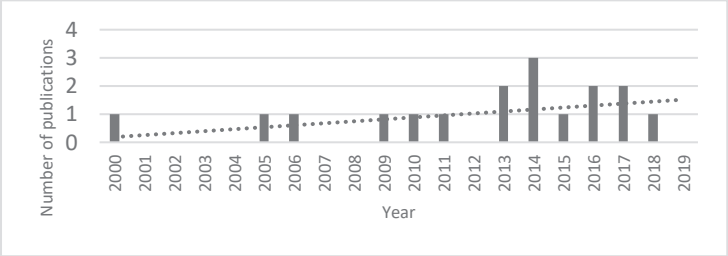

Fig. 2. Number of documents found (January 2000 - October 2019)

Regarding the country of origin of these documents, the majority came from Colombia, Ecuador and Venezuela, representing almost 80% of the publications found (**Fig. 3**).

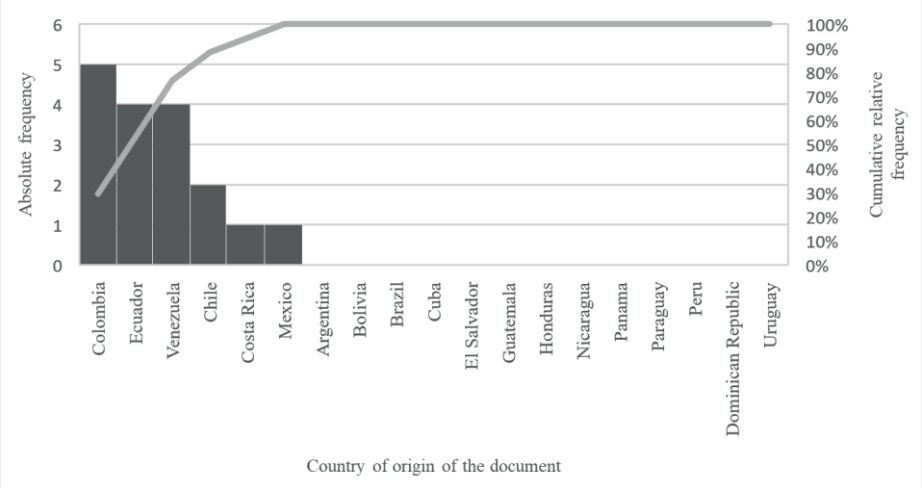

Fig. 3. Most frequent countries of origin of the 17 documents found.

The documents found are of the following classes: Degree Seminar, Paper, Thesis, Monograph, Professional Seminar, and Conference Publication. In **Fig. 4** it can be observed that most of the works (64%) correspond to degree seminars and papers.

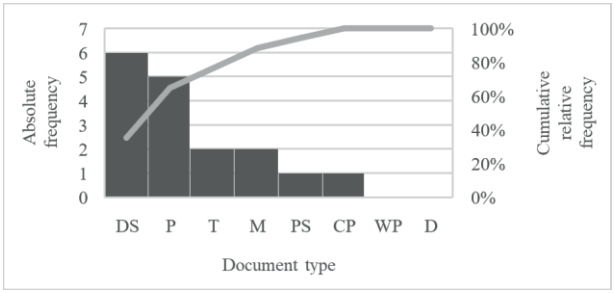

Fig. 4. Most frequent types of document (DS=degree seminar, P=paper, T=thesis, M=monograph, PS=professional seminar, CP=conference proceeding, WP=working paper, D=dissertation).

Categorizing according to the level of education of the organizations in which the research was carried out, by a large majority the researches were carried out in universities, with 70.6%, and the rest correspond to non-university HEIs. And according to the classification by type of property, 59% of the researches were carried out in public institutions and the remaining 41% in private organizations.

Within the aspects related to the research design, such as the number of students, the age of the institution and the participation of representatives of the organization in the study, they could not be considered because only partial information was found. Something similar with aspects of the application such as the strategy map or the indicators; the analysis could not be made considering that very few valid documents were found, and that 35% did not include the map, and 18% did not include indicators.

Regarding the perspectives used in each study, these are detailed in **Table 2**, and it can be inferred that in almost all the works (16 of 17) four perspectives are established, that is, the same number of dimensions as those originally proposed by Kaplan and Norton [12] [13]; there is only one study that proposes five. In addition, it is striking that only 1 of the 16 studies after 2001 considers the adaptation to non-profit organizations made by the authors of the BSC in that year [14].

Table 2. Documents found of the application of the BSC in strategic processes of Latin American HEIs.

To know which are the perspectives in which there is greater consensus to use within the institutional strategic processes of Latin American HEIs, the frequencies for each perspective were calculated.

In a first approach, the perspectives were considered as they were defined in their original studies, without applying association criteria between them. The product of this raw analysis is shown in **Fig. 5**. The most used perspectives turned out to be the 4 defined by Kaplan and Norton [12] [13], and in the following order: 1st Internal processes, 2nd Costumer, 3rd Financial, 4th Learning and growth.

Then, an adjustment was made to the perspectives found, in order to associate them according to how they were defined by their authors [12] [13] and to the approach or explanation given for each of them by the authors of the respective studies, obtaining the result of **Table 3**. From these it can be inferred that all the perspectives used in the researches can be associated with some perspective of the original Kaplan and Norton BSC. This link is summarized in **Fig. 6** and **Fig. 7**.

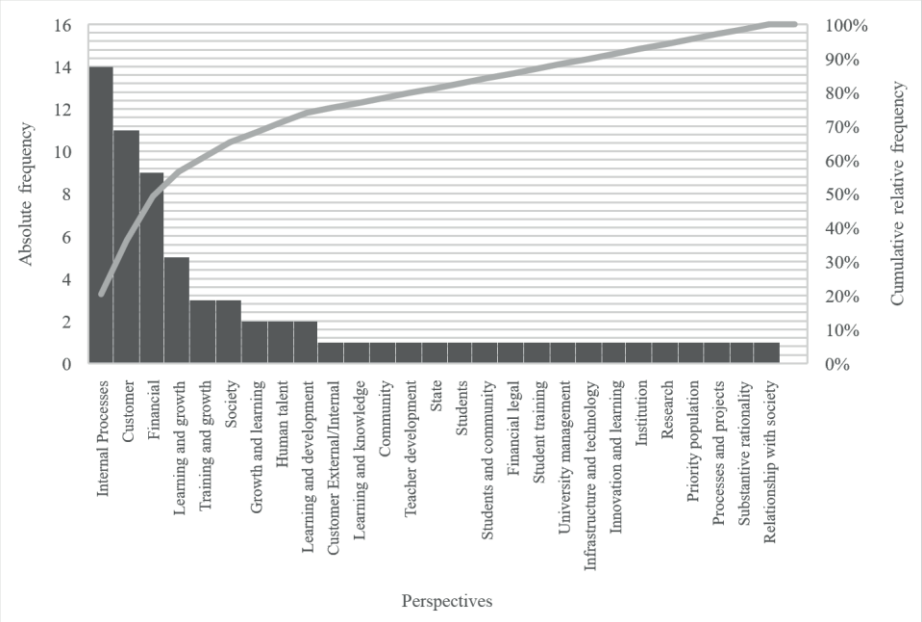

Fig. 5. Perspectives most found in documents on the application of the BSC in Latin American HEIs in the context of their strategic planning.

Table 3. Linking the perspectives established in the BSC applications found with the 4 original perspectives of Kaplan and Norton.

Kaplan and Norton perspectives	Associated perspectives of documents
Learning, development, and innovation.	Learning and knowledge Learning and growth Learning and development Growth and learning Training and growth Innovation and learning Teacher development Human talent Infrastructure and technology
Customer.	Customers Community Society Relationship with society State Students Students and community Institution Research Priority population
Financial.	Financial Financial management University management

Internal processes.	Internal processes Processes and projects Student training Substantive rationality

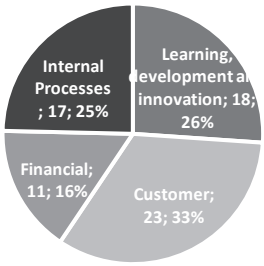

Fig. 6. Use of the original 4 perspectives of Kaplan and Norton in the documents found.

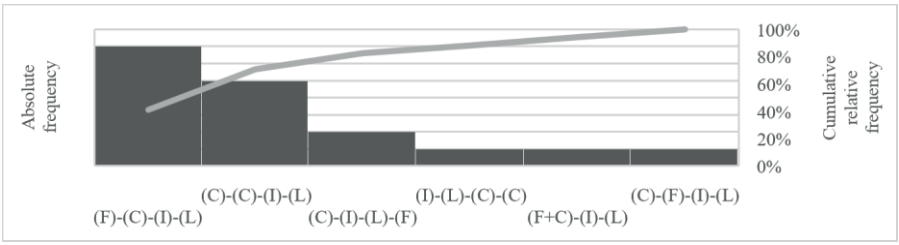

Fig. 7. Structure of perspectives most used, where: F = Financial, C = Customers, I = Internal processes, and L = Learning, development, and innovation.

It can be deduced, from these graphs, that the "Customers" dimension is the most considered of the four perspectives (33%) to generate strategic objectives, and at the same time the "Financial" perspective is the least considered (16%).

In addition, if the structure of perspectives is analyzed, that is, at what levels are located each of the strategic areas (**Fig. 7**), the most frequently used is the one originally suggested by Kaplan and Norton for the generation of the BSC in companies, this is: First level: Financial, Second level: Costumer, Third level: Internal processes, Forth level: Learning, development, and innovation.

The only case (mentioned above) that structures its perspectives according to the suggestion of Kaplan and Norton for non-profit organizations stands out within all the studies, that is: First level: Financial + Costumer, Second level: Internal processes, Third level: Learning, development, and innovation.

4 Meta-analysis

Given the need to relate nominal qualitative variables, contingency tables were developed to generate two analyzes based on the chi-square test.

4.1 Relationship between the Property of the HEI and the strategic level of the Financial perspective

The first goal was to find out if there is a relationship between two variables: the "property of the HEI" and the "level at which the Financial perspective is situated within the structure of the BSC".

For this, the following null hypothesis was raised:

H0 = The ownership of the HEI and the strategic level at which the financial perspective is situated are independent variables.

First the corresponding contingency table was designed **Table 4**, composed of the observed frequencies fij, for the financial perspective in public and private HEIs.

Table 4. Contingency table for the location of the financial perspective in public and private HEIs.

	Location of the Financial perspective			
Owner of the HEI	***Level 1***	***Level 2***	***Level 3***	***Level 4***
Public	3	2	0	0
Private	5	0	0	1

From this, the expected frequencies eij were obtained, to finally calculate the observed chi-square statistic using the expression (1):

$$\chi^2 = \sum_i \sum_j \frac{(f_{ij} - e_{ij})^2}{e_{ij}} \qquad (1)$$

The theoretical value of chi-square, 5,99, was obtained for a probability of 5%, and only 2 degrees of freedom of the original 3, since the third column was not considered, in which the expected frequencies were zero, product that the financial field in none of the applications was considered for level 3 of the BSC.

The observed result was, then, χ ^ 2 = 3,44, less than 5,99, so the null hypothesis is not rejected and, therefore, it can be stated that the variables "Property of the HEI" and the "Level at which the Financial perspective is situated within the structure of the BSC", are independent.

4.2 Relationship between the property of the HEI and the perspectives used

In a second analysis, the objective was to find out if there is a relationship between the "Property of the IES" and the "Perspectives used".

For this, the following null hypothesis was raised:

H0 = The ownership of the HEI and the perspectives used are independent variables.

Table 5 shows how the different original perspectives of Kaplan and Norton were used in private and public HEIs. From this, the corresponding contingency table was constructed (**Table 6**), composed of the observed frequencies fij for the different perspectives in public and private HEIs, which served as the basis to obtain the expected frequencies eij.

Table 5. Absolute frequencies of use of the perspectives in the different levels of the BSC according to the property of the HEI.

	Financial				*Costumers*				*Internal processes*				*Learning, development, and innovation*			
Owner of the HEI \ Level	***1***	***2***	***3***	***4***	***1***	***2***	***3***	***4***	***1***	***2***	***3***	***4***	***1***	***2***	***3***	***4***
Public	3	2	0	0	6	7	1	1	1	0	9	0	0	1	0	9
Private	5	0	0	1	3	5	0	0	0	2	5	0	0	0	2	5

Table 6. Contingency table for the use that is given to the different perspectives in public and private HEIs.

Owner of the HEI \ Perspective	***Financial***	***Customer***	***Internal processes***	***Learning, development, and innovation***
Public	5	15	10	10
Private	6	8	7	7

The chi-square statistic, calculated through (1), gave a value of 1,20.

Then, the theoretical value of chi-square 7.81 is obtained, for a probability of 5% and 3 degrees of freedom.

The result, then, is that χ ^ 2 = 1,20 is less than 7,81, so the null hypothesis is not rejected and, therefore, the variables "Property of the IES" and "Perspectives used", are independent.

5 Conclusion

There is a growing use of the BSC in support of the strategic processes of the institutions, which are key to the consolidation and sustainability of them, considering the demands posed by the new regulations in the HE systems (accountability, quality, strategic development plans, among others).

The association of the perspectives used with the original ones by Kaplan and Norton shows that the perspective that was most considered in the different strategic levels of the BSC was that of "Costumers" (in its broadest sense), evidencing the concern that HEIs have for their stakeholders[11].

HEIs tend strangely to reproduce the original structure of the Kaplan and Norton BSC model, originally aimed at companies, and not at educational services organizations, where the "Financial" perspective is established at the first strategic level. At the opposite hand, there were cases that did not consider the financial dimension, which, according to the meta-analysis, is not related to the ownership of the HEI; based on the application of the Chi-square test, there was no evidence of a relationship between ownership of Latin American HEIs (public or private) and the level at which it is situated,

[11] Internal stakeholders: students, academics, administrators, and managers. External stakeholders: employers, former students, parents and guardians, society in general, the government and its agencies, education providers, and non-governmental organizations [28].

or whether or not it represents the cornerstone of the strategy the "Financial" dimension; nor is there a specific structure of perspectives considered that reflects the differences between public and private institutions of HE.

Based on the above, it is striking that the adaptation to non-profit organizations, carried out by their authors, which recognizes the importance of mission in HEIs, has not had a great impact on the strategic planning processes of HEIs, since its appearance 19 years ago. This opens up a field of development for these processes and shows that more experience is needed in Latin America and, above all, knowledge of the results obtained from their use, in order to generate scientific conclusions about the impact that the BSC is having in this strategic and fundamental sector for the development of people and societies.

On the other hand, the systematic review and meta-analysis allowed to summarize part of the strategic planning of Latin American HEIs and, adapted to their context, they are projected as very useful and reliable tools to observe how management in higher education will continue to develop.

It is concluded, then, that the incipient use observed of the BSC in Latin America is independent of the type of HEI or the system in which it is immersed, becoming an instrument of transversal management, in a strategic process that is fundamental for an adequate management of these organizations in the current complex and challenging context.

Visão Baseada em Recursos: O uso da tecnologia *Blockchain* na Gestão do Conhecimento

Talita Frozza[1][0000-0001-8101-118X] and Andressa Maria Corrêa[1][0000-0003-0266-353X]

[1]Universidade Tecnológica Federal do Paraná, Pato Branco PR 85503-390, Brasil

Resumo. A Visão Baseada em Recursos é uma teoria que ao ser aplicada pode proporcionar vantagens competitivas para as empresas. Desta forma, o presente artigo busca analisar, por meio da lente da Visão Baseada em Recursos, dois recursos organizacionais: conhecimento e tecnologia. O conhecimento, por meio da Gestão do Conhecimento, que consiste nas atividades de criar, compartilhar e utilizar o conhecimento oferecido pelas pessoas inseridas e relacionadas à organização, e a tecnologia abordando o *Blockchain*, tecnologia por trás da criptomoeda Bitcoin. Assim, o objetivo deste artigo é identificar como a adoção da tecnologia *Blockchain* tem sido utilizada para aprimorar as capacidades dos recursos de Gestão do Conhecimento. O aspecto metodológico utilizado na pesquisa trata-se da *Fast Systematic Literature Review,* caracterizando a pesquisa como uma Revisão de Literatura. O estudo identificou como principal resultado que a tecnologia *Blockchain* tem sido aplicada na função de compartilhamento do conhecimento e tem atuado em questões como falta de confiança entre os membros das organizações, falta de transparência e segurança, permitindo uma melhor utilização desse conhecimento, gerando oportunidades de valor e promovendo vantagens competitivas para a empresa.

Palavras-chave: Visão Baseada em Recursos, *Blockchain*, Gestão do Conhecimento.

1 Introdução

No contexto em que as empresas se encontram atualmente existe uma dificuldade crescente de criar diferenciação perante seus concorrentes. A eficiência operacional já não é o suficiente, havendo um esgotamento dos modelos baseados apenas na eficiência, surgindo assim a necessidade de incorporação, por parte das empresas, de outras dimensões que complementam o quadro multidimensional do desempenho organizacional [1].

A concorrência global passou a ser "sem fronteiras", uma vez que os limites tradicionais como fronteiras nacionais têm diminuído de significância. Coordenar as atividades geograficamente dispersas para obter e manter vantagem competitiva é um dos desafios das empresas que competem globalmente. Nesta perspectiva que a economia baseada no conhecimento e o conhecimento como fator competitivo ganharam importância [2].

Além disso, para que as organizações consigam sobreviver em um ambiente tão competitivo, devem promover sua capacidade de aprender e incorporar novas práticas

e tecnologias em busca de melhorar seu desempenho e sucesso organizacional a longo prazo [3].

Neste contexto incorpora-se a teoria da Visão Baseada em Recursos. Esta teoria sugere que as empresas competem com base em seus recursos e capacidades. Estabelece que os recursos internos das organizações são responsáveis por proporcionar vantagem competitiva para as mesmas [4; 5; 6].

Assim, considerando o exposto, este artigo possui como objetivo analisar, por meio da lente da Visão Baseada em Recursos, dois recursos organizacionais: conhecimento e tecnologia. No que diz respeito ao conhecimento, este passa a ser estudado por meio da Gestão do Conhecimento, representada aqui pelas funções de identificação, aquisição, desenvolvimento, compartilhamento e distribuição, utilização e retenção do conhecimento [7].

A tecnologia estudada, por sua vez, trata-se do *Blockchain*, tecnologia por trás da criptomoeda Bitcoin, e que está tornando-se cada vez mais popular para simplificar processos de negócios e compartilhar dados, representando um sistema descentralizado, com transações transparentes e rastreáveis [8].

No que se refere à Gestão do Conhecimento, a sua execução dentro das empresas, considerando o atual cenário em que se encontram e a revolução da tecnologia, apresenta alguns desafios, dentre eles questões relacionadas ao armazenamento de conhecimento e problemas de compartilhamento de conhecimento e motivações, especialmente quanto à direitos autorais [9].

Neste sentido, a tecnologia *Blockchain* tem sido explorada como forma de solucionar alguns desses problemas, com destaque aos problemas de compartilhamento do conhecimento. Assim, com esta análise busca-se identificar como a adoção da tecnologia *Blockchain* tem sido utilizada para aprimorar as capacidades dos recursos de Gestão do Conhecimento.

2 Referencial Teórico

Nesta seção serão abordados os tópicos: (i) Visão Baseada em Recursos; (ii) Gestão do Conhecimento; e (iii) *Blockchain*, afim de compor o referencial teórico da pesquisa.

2.1 Visão Baseada em Recursos

A teoria da Visão Baseada em Recursos (*Resource Based View* – RBV) apresenta que os recursos internos da organização proporcionam vantagens competitivas para as mesmas [4; 5; 6]. Essa teoria proporciona uma visão estratégica sobre cenários nas organizações, permitindo melhor compreensão de seus recursos internos, observando em quais recursos a empresa deve basear seu crescimento e sua estratégia [4]

Quando se fala em RBV, para ter uma visão mais clara do assunto é necessária uma melhor compreensão para o termo "Recurso". Entende-se por recurso, determinada circunstância que pode ser considerada como um ponto forte ou um ponto fraco de uma organização, podendo ser, por exemplo: conhecimento interno de tecnologia, pessoal qualificado, máquinas, procedimentos eficientes, contatos comerciais, entre outros [4].

Os recursos são importantes pelas atividades e serviços que podem ser prestados através dele, pois, em geral, um único recurso, dependendo da maneira que ele é

utilizado e empregado, pode prestar um número grande de serviços, sendo assim uma vantagem a ser explorada [10].

Desta forma, a análise fundamental da RBV é determinada pelos recursos que podem ser controlados pela empresa [11]. Como os recursos não se vinculam diretamente a um uso especifico, é comum valer-se de uma classificação para defini-los. Assim, são classificados como recursos tangíveis, como recursos humanos, de infraestrutura física na forma de tecnologias de processo e de produto, recursos materiais, informacionais e financeiros, e intangíveis, que podem ser encontrados no âmbito da cultura organizacional; na forma de rotinas organizacionais; know-how entre outros. Porém, os recursos por si só não produzem valor. Assim, há necessidade de selecioná-los, combiná-los e mobilizá-los via serviços em atividades e processos [12].

Um aspecto importante a se considerar é que "os recursos constituem fonte de vantagem competitiva para as empresas na medida em que formam capacitações organizacionais e por estas são mobilizados nos processos organizacionais e de gestão" [1].

2.2 Gestão do Conhecimento

O conhecimento tem adquirido uma crescente importância na sociedade contemporânea [13], sendo visto como recurso básico para a nova sociedade que emerge da atual reorganização de valores, crenças, estruturas sociais, econômicas e dos sistemas políticos [14]. Na perspectiva da teoria da Visão Baseada em Recursos, o conhecimento é tido como um recurso fundamental para a sobrevivência, estabilidade e crescimento das organizações [15].

Esse novo papel que o conhecimento vem adquirindo exige uma mudança no pensamento quanto à inovação na organização das grandes empresas [13] e é nesta perspectiva que a gestão proativa do conhecimento adquire função central no que se refere à competitividade organizacional.

Para o desempenho da inovação, influenciado por aspetos relacionados com a rede de operações, cadeia de abastecimento e valor, bem como pelas tecnologias de informação e comunicação que coordenam o fluxo de criação de valor, a participação dos stakeholders das empresas e a gestão da informação e do conhecimento são considerados elementos fundamentais [16].

A Gestão do Conhecimento baseia-se na ideia de que o recurso mais valioso de uma organização é o conhecimento das pessoas, e reconhece que quase todos os trabalhos envolvem conhecimento em algum nível, o que significa que o trabalho depende mais do conhecimento das pessoas do que das suas habilidades manuais. Isso significa que criar, compartilhar e usar conhecimento estão entre as mais importantes atividades das pessoas em qualquer organização [17].

Ocorre que o controle, aplicação e desenvolvimento eficientes do conhecimento, afim de o gerir e utilizar com eficiência é determinado pelas capacidades da Gestão do Conhecimento [18]. Nesta perspectiva, pode-se entender capacidade como sendo a habilidade de implementar e integrar recursos para atingir objetivos corporativos, assim como os resultados obtidos através do acúmulo da interação de longo prazo entre diversos recursos [19].

A gestão do recurso conhecimento consiste das possibilidades de desenvolvimento, de transformação e de utilização de diferentes formas de conhecimento [1]. Nesta perspectiva podem ser elencadas seis funções da Gestão do Conhecimento [7]:

- Identificação do conhecimento: o conhecimento, tanto interno quanto externo, não é automaticamente visível, por isso as organizações precisam criar transparência de modo a saber onde encontrar o conhecimento de que precisam, ou seja, localizar o conhecimento, dentro e fora da empresa;
- Aquisição: as empresas podem comprar o conhecimento que não conseguem desenvolver, assim, parte substancial do conhecimento das empresas deriva de fontes externas, como por exemplo: clientes, fornecedores e concorrentes;
- Desenvolvimento: envolve todos os esforços administrativos direcionados de forma consciente para produção de novas capacidades, e seu foco está na geração de novas habilidades, novos produtos e processos mais eficientes, por exemplo;
- Compartilhamento e distribuição: são considerados como fatores vitais para transformar informações isoladas em algo que toda organização pode utilizar; a distribuição consiste em compartilhar e disseminar conhecimento que já existe na organização;
- Utilização: a organização deve assegurar a aplicação do conhecimento em seu benefício, e para isso deve tomar providências afim de garantir que as habilidades e ativos sejam totalmente utilizados;
- Retenção: consiste nos processos de selecionar, armazenar e atualizar regularmente o conhecimento, de forma a proteger a empresa contra a perda de conhecimento.

Considerando o exposto, tem-se que a gestão do recurso conhecimento não se limita a gerenciar o conhecimento em si, mas sim, possibilitar um ambiente no qual o conhecimento possa ser mobilizado e utilizado em benefício da organização [1].

2.3 *Blockchain*

Conhecida como sendo a tecnologia por trás da criptomoeda Bitcoin, a tecnologia *Blockchain*, também chamada de "razão distribuída", tem aplicações muito além das criptomoedas ou do mercado financeiro [20]. Em um sentido restrito, *Blockchain* pode ser entendido como sendo uma forma de livro razão que combina blocos de dados e informações em uma ordem cronológica e registra os blocos de forma criptografada como uma razão distribuída que não pode ser adulterada ou falsificada [21; 22].

Em sentido amplo, pode ser definida como uma metatecnologia, tendo em vista que usa, dentre outros, estruturas de dados do tipo bloco para validar e armazenar dados, algoritmos de consenso para gerar e atualizar os dados e criptografia para garantir a transmissão desses dados e para acessar a segurança [22]. Ou seja, não é apenas uma técnica, mas sim um novo modelo de aplicativo de combina tecnologias da computação como armazenamento distribuído de dados, transações ponto a ponto descentralizadas e independentes, mecanismos de consenso, algoritmos de criptografia e modelo econômico [22; 23].

Para entender de forma mais aprofundada sobre o funcionamento do *Blockchain*, pode-se analisar aspectos entendidos como principais características que sustentam o funcionamento da tecnologia, sendo: descentralização, *detrusting*, transparência, rastreabilidade e irreversibilidade de registros:

a) Descentralização: a comunicação ocorre diretamente entre os pares, sendo as informações automaticamente compartilhadas e distribuídas entre os nós, sem a necessidade de um nó central, ou seja, cada nó armazena e envia informações para todos os outros nós [22; 24];

b) *Detrusting*: como é baseada em princípios de protocolos de rede ponto a ponto e métodos puramente matemáticos, a tecnologia cria relacionamentos de confiança entre os nós da rede e as estruturas de sistema distribuídas [22; 25];

c) Transparência com pseudonimato: cada transação e seu valor associado são visíveis para qualquer pessoa com acesso ao sistema. Porém, a quantidade de informações transparentes para um observador, no entanto, pode ser diferente e nem todo participante deve, obrigatoriamente, ter o mesmo acesso a todas as informações. Ainda, os usuários podem optar por permanecer anônimos ou fornecer prova de sua identidade para os outros. As transações ocorrem entre endereços *Blockchain* [22; 24; 26];

d) Rastreabilidade: cada bloco de informações da BLC possui as informações de data e hora, que servem para identificar, registrar e validar cada transação, o que garante a sua originalidade, melhora a transparência e reduz o custo da rastreabilidade das transações [22; 27];

e) Irreversibilidade de registros: para uma transação ser validada e adicionada a um bloco, ela precisa ser revisada pela maioria dos nós do sistema. E uma vez que uma transação é inserida no banco de dados e as contas são atualizadas, os registros não podem ser alterados, porque estão vinculados a todos os registros de transação que vieram antes deles (daí o termo "cadeia") [22; 24].

A partir da definição do que é a tecnologia *Blockchain*, pode-se avançar no que se refere à sua utilização. Para tal, utiliza-se como referência o framework de driver de valor do *Blockchain* – Tabela 1 proposto por [20].

Tabela 1 - Framework de driver de valor do *Blockchain*

Qual valor é procurado?		É um opção viável adotar a tecnologia?	Por que um *Blockchain* é preferível a um ledger centralizado? Que combinação de tecnologias se alinha com o valor perseguido?
Oportunidades de valor	**Drivers de valor**	**Viabilidade**	**Tecnologias apropriadas**
Transparência	Custo de transação	Escopo	Centralizado
Imutabilidade	Serviços adicionados	Recursos para adotar e manter	Distribuído
Privacidade	Limites de organização	Compreensão de risco	
Durabilidade e confiabilidade	Tomada de decisão autônoma	Regulamento	
Tolerância ao erro		Obrigações legais	

Democratização		Desempenho	
Segurança		Interoperabilidade	
Controle de risco			
Token			

Fonte: Adaptado de [20]

Esse framework fornece insights sobre as oportunidades de valor e em que contexto e ofertas de produtos ou serviços pode-se aplicar a tecnologia. Cada etapa da estrutura fornece perguntas e recomendações acionários à adoção e uso da tecnologia [20].

3 Metodologia

Nesta seção será apresentado o instrumento de intervenção utilizado para a seleção dos artigos do portfólio bibliográfico.

3.1 *Fast Systematic Literature Review*

A Revisão Sistemática da Literatura (*Systematic Literature Review* – SLR) é composta por um conjunto de tarefas que demandam tempo, como a definição dos termos de pesquisa, análises de conteúdo e relatórios escritos [28]. Assim, para a condução desta pesquisa, foi utilizado o método *Fast Systematic Literature Review* (FASTSLR), que suporta o diagnóstico, a validação e avaliação do conteúdo da pesquisa e busca minimizar erros, tanto em relação à qualidade do trabalho quanto ao planejamento e desenho da pesquisa, assim como possibilita reduzir o tempo de execução da revisão [28].

É composto por três etapas que de maneira resumida consistem em: Etapa 1 - composta por atividades de pesquisa e busca dos artigos; Etapa 2 – consiste em um processo de refinamento dos artigos encontrados na etapa anterior, utilizando um gerenciador de referência, cálculo de amostra e leitura dos artigos, parcial e integralmente; e Etapa 3 - caracteriza-se pelo uso do software MC3R para obtenção de relatórios e matrizes bibliométrica [28]. Assim, seguindo as orientações propostas para o método, são apresentadas as etapas realizadas nesta pesquisa.

Para esta pesquisa foi selecionada apenas a base de dados *Scopus*, por ser "o maior banco de dados de resumos e citações da literatura com revisão por pares: revistas científicas, livros, processos de congressos e publicações do setor" [Elsevier, 2020]. Os termos de busca selecionados, considerando a proposta da pesquisa, foram: *"knowledge management"*, *Blockchain* e *"distributed ledger"*. Os operadores utilizados foram AND e OR, conforme Tabela 2. Ainda, em relação ao tipo de documento foram selecionados apenas *"article"* e *"conference paper"*, e em relação ao ano de publicação foram selecionados trabalhos publicados entre 2017 e 2019, a fim de obter resultados e pesquisas recentes sobre a temática. Considerando estes critérios, o primeiro conjunto de dados é composto por 36 publicações.

Considerando a baixa quantidade de artigos encontrados para a pesquisa, a técnica de cálculo de amostra não foi utilizada. Neste sentido, passou-se direto à importação do conjunto para o gerenciador de referências. Assim, o primeiro conjunto de dados foi

importado para o gerenciador de referências "Mendeley" para a realização da análise das palavras-chave, resumo e título quanto à aderência ao tema. Desta análise retornou um conjunto de dados composto por dez publicações. A tabela 2 apresenta um resumo da FASTSLR realizada:

Tabela 2 - Resumo da FASTSLR realizada

Critérios de busca	
Base de dados	Scopus
Tipo de documento	Article / Conference paper
Ano de publicação	2017 / 2018 / 2019
Termos de busca	"knowledge management" / *Blockchain* / "distributed ledger"
Operadores	AND / OR
Pesquisa na base de dados	
"knowledge management" AND *Blockchain* OR "distributed ledger"	
Resultados	
Conjunto bruto de dados	36 publicações
Conjunto final de dados	10 publicações

Fonte: Elaborado pelos autores, 2019.

Importante destacar que das dez publicações que compõem o portfólio de pesquisa, apenas oito foram encontradas na íntegra. Assim, duas das publicações não puderam ser analisadas. Por fim, destaca-se que a terceira etapa do método também não foi realizada, tendo em vista que resultaria informações que não corresponderiam ao objetivo de pesquisa.

4 *Blockchain* e Gestão do Conhecimento

A Gestão do Conhecimento, reconhecida muitas vezes pelas funções de identificação, aquisição, desenvolvimento, compartilhamento e distribuição, utilização e retenção do conhecimento [7], apresenta alguns desafios para a sua execução. Questões de armazenamento de conhecimento que, em função do aumento do conhecimento gerado nas empresas, as forçam a empregar novas estratégias de armazenamento, e problemas de compartilhamento de conhecimento e motivações, especialmente quanto a direitos autorais, uma vez que as empresas precisam garantir que seus especialistas, sobre seus direitos, compartilhem seus conhecimentos, são alguns dos exemplos de desafios enfrentados pela gestão do conhecimento [9].

Outro desafio enfrentado diz respeito à confiança. As atividades de gestão do conhecimento requerem uma cultura de confiança entre os membros de uma organização, sendo a falta de confiança uma das principais razões para o não compartilhamento do conhecimento entre os membros de uma organização [29].

A tecnologia *Blockchain* tem sido utilizada como um meio de solucionar alguns dos desafios enfrentados pela Gestão do Conhecimento. A função da Gestão do Conhecimento que tem ganhado mais atenção dos pesquisadores em relação a aplicação do *Blockchain* é o compartilhamento do conhecimento. Esta função do conhecimento, em relação à obtenção de vantagem competitiva por meio de recursos, proporciona aos

indivíduos, equipes e empresas a oportunidade de melhorar seu desempenho no trabalho, bem como criar novas ideias e inovações [30].

No que se refere a esta função, a tecnologia *Blockchain*, vista como um livro razão descentralizado e confiável, garante imutabilidade, confiabilidade e responsabilidade. Agregando a esta os contratos inteligentes, também é possível gerar melhorias na transparência e segurança nos procedimentos de compartilhamento de conhecimento [31].

Outro trabalho desenvolvido envolvendo estes dois recursos é o de [32], onde os autores buscam propor e desenvolver uma plataforma segura e confiável de compartilhamento de conhecimento em indústrias de moldes, observando que essas indústrias precisam, no que se refere ao compartilhamento, de colaboração com outras indústrias e de uma plataforma confiável. A plataforma proposta utiliza duas tecnologias avançadas: nuvem privada e *Blockchain*. Esta segunda tecnologia é implementada como uma rede distribuída para compartilhar conhecimento e registrar transações, permitindo a redução do risco do compartilhamento na plataforma.

Foi essencialmente projetada com vistas à resistência na modificação de dados, pois busca fornecer um método seguro para garantir a imutabilidade dos dados. Além disso, a verificação de associação possível a partir do *Blockchain* também possibilita garantir a validade das informações, uma vez que destaca a qualidade e responsabilidade de cada membro envolvido no compartilhamento do conhecimento [32].

Outro trabalho que busca aplicar o *Blockchain* à função do compartilhamento do conhecimento foi desenvolvido por [31], por meio do qual os autores propõem um sistema denominado *Reputation Based Knowledge Sharing* (RBKS), ou Compartilhamento de Conhecimento Baseado em Reputação, desenvolvido tendo como base o *Blockchain*. O objetivo desse sistema é explorar a proteção dos direitos autorais do dono do conhecimento por meio de esquemas de controle de acesso.

O modelo de gestão do conhecimento denominado *Block Chained Knowledge Management Model* (BCKMM), apresenta cada usuário como um nó da rede *Blockchain* e todo conhecimento acrescentado a rede é considerado uma transação. Quando uma pessoa necessitar de algum conhecimento e buscá-lo junto a rede, estarão disponíveis também todas as transações anteriores relacionadas àquele conhecimento [9].

Ainda, no modelo proposto todos os funcionários de uma empresa que façam parte da rede poderão registrar e compartilhar seus conhecimentos com todos os demais funcionários, e o seu conhecimento será retido e manterá as questões de propriedade e rastreamento, em um ambiente seguro [9].

[33] também abordam a aplicação do Blockchain direcionado ao conhecimento, mais especificamente como ferramenta de processamento rápido e seguro de ativos intelectuais e trocas de ideias, pois é capaz de fornecer um alto nível de confiança para a transferência do conhecimento.

Segundo os autores, a comunicação é o processo central na economia de conhecimento e experiência. Neste sentido, expõem que as principais preocupações de segurança da informação se concentram em tecnologias de transferência de conhecimento, cadeias ou redes de criação de valor, e de comunicação, dentro e fora das instituições. A tecnologia pode fornecer um ambiente mais seguro e confiável para as neuro-comunicações, a transferência direta de conhecimentos, experiências e sentimentos, incluindo a percepção de uma realidade [33].

[34] por sua vez, apresentam uma plataforma desenvolvida para construir um ambiente multi-nuvem a fim de compartilhar e reutilizar dados e conhecimento. Além disso, projetam um mecanismo de compartilhamento conhecimento, que usa um blockchain para registro e uso de serviços de processamento de dados, para que as entidades possam validar a integridade do histórico do processo.

Para além do compartilhamento do conhecimento, [35] expõem que o conhecimento vem sendo mal interpretado e manipulado para atender a diversos fins, sendo que informações de fontes confiáveis são muitas vezes abafadas por "fatos" de proveniência duvidosa. Explicam que não é suficiente simplesmente estabelecer a proveniência do conhecimento se esses meta-dados puderem ser alterados posteriormente. Com isso, estudam uma possível solução usando blockchain para gerenciar a proveniência do conhecimento.

O modelo implica que, como as informações na blockchain não podem ser alteradas, a proveniência do conhecimento é inerentemente mais confiável. Assim, a plataforma estudada busca ser segura para que as instituições de conhecimento publiquem fatos e forneçam a proveniência do conhecimento, assim como busca possibilitar a responsabilização dos atores sociais, como governos ou empresas. O modelo aproveita as propriedades descentralizadas do blockchain para atingir esses objetivos [35].

[36] também vão além da função de compartilhamento do conhecimento ao buscarem estudar o problema da erosão do conhecimento como resultado do crescimento explosivo de dados e informações, oferecendo um conceito baseado no sistema de objetos de aprendizagem protegido com o uso de blockchain permitido para minimizar os resultados negativos dos fenômenos de erosão do conhecimento.

A tecnologia blockchain é estudada como meio de manutenção de registros, garantindo a preservação de registros e prevenção de alterações não autorizadas neles. Segundo os autores, o núcleo do conhecimento científico geral deve ser protegido da distorção espontânea e requer uma transferência completa e garantida sem distorção. A proteção efetiva do núcleo de conhecimento deve ser combinada com um mecanismo regulatório que proporcione a possibilidade de sua edição apenas no caso de um consenso constante de especialistas [36].

A tabela 3 busca sintetizar as informações apresentadas e obtidas por meio dos artigos da revisão:

Tabela 3 – Aspectos da Gestão do Conhecimento e melhorias buscadas com o blockchain

Aspectos da Gestão do Conhecimento	**Melhorias com o blockchain**	**Autor**
Compartilhamento: oportunidade de melhorar seu desempenho no trabalho, bem como criar novas ideias e inovações.	Imutabilidade, confiabilidade e responsabilidade. Com contratos inteligentes: transparência e segurança.	[30]
Compartilhamento do conhecimento e direitos autorais.	Explorar a proteção dos direitos autorais do dono do conhecimento por meio de esquemas de controle de acesso.	[31]
Indústrias que precisam de colaboração com outras	Resistência na modificação de dados (imutabilidade dos dados), e validade	[32]

indústrias e de uma plataforma confiável para compartilhar o conhecimento.	das informações, pois destaca a qualidade e responsabilidade de cada membro.	
Explorar a proteção dos direitos autorais do dono do conhecimento por meio de esquemas de controle de acesso.	Registro das transações anteriores relacionadas a um conhecimento, e retenção do conhecimento com manutenção das questões de propriedade e rastreamento, em um ambiente seguro.	[9]
Transferência de conhecimento, cadeias ou redes de criação de valor, e de comunicação, dentro e fora das instituições	Ambiente mais seguro e confiável para as neuro-comunicações, a transferência direta de conhecimentos, experiências e sentimentos, incluindo a percepção de uma realidade	[33]
Compartilhar e reutilizar dados e conhecimento.	Registro e uso de serviços de processamento de dados, para que as entidades possam validar a integridade do histórico do processo.	[34]
Estabelecimento da proveniência dos dados.	Por meio da descentralização e imutabilidade dos dados, fornecer segurança para que as instituições de conhecimento publiquem fatos e forneçam a proveniência do conhecimento, assim como busca possibilitar a responsabilização dos atores sociais.	[35]
Erosão do conhecimento como resultado do crescimento explosivo de dados e informações.	Manutenção de registros, garantindo a preservação de registros e prevenção de alterações não autorizadas neles.	[36]

Fonte: Elaborado pelos autores, 2019.

Assim, considerando o exposto, pode-se resgatar o *framework* de driver de valor proposto por [20 ANGELIS, J.; SILVA, E. R], no qual os autores apresentam as oportunidades de valor geradas pelo *Blockchain*. Das oportunidades de valor apresentadas, é possível identificar nas aplicações de *Blockchain* no compartilhamento do conhecimento, de forma expressa, a imutabilidade do conhecimento, a sua durabilidade e confiabilidade, transparência, segurança e controle de risco. Esses valores gerados com o uso do *Blockchain* permitem uma melhor utilização do conhecimento disponível na organização.

Pode-se identificar, neste sentido, a possibilidade de aumento da capacidade da Gestão do Conhecimento com a aplicação do recurso tecnológico *Blockchain*, isso porque este recurso permite uma maior implementação e integração do recurso conhecimento dentro da organização por meio do aprimoramento da função compartilhamento. Assim como também permite, principalmente por meio da característica de imutabilidade que fornece aos dados, obter resultados por meio do acúmulo da interação de longo prazo do recurso conhecimento.

5 Gestão Estratégica de Operações utilizando a Visão Baseada em Recursos

"A melhoria contínua, o aprendizado organizacional e o desenvolvimento de competências estão sendo abordados pela estratégia de operações à medida que as organizações evoluem" [37] Neste artigo, a Gestão Estratégica de Operações foi abordada através da teoria da Visão Baseada em Recursos, ou *Resource Based View (RBV),* que apresenta que os recursos internos da organização proporcionam vantagens competitivas para as mesmas na medida em que formam capacitações organizacionais e por estas são mobilizados nos processos organizacionais e de gestão [1; 4; 5; 6].

Assim, esta seção visa ilustrar um *framework* teórico conceitual a respeito da relação teórica entre a Gestão Estratégica de Operações, por meio da teoria da Visão Baseada em Recursos, lidando com os recursos: conhecimento, por meio da Gestão do Conhecimento, e tecnologia, analisando-se a tecnologia *Blockchain.* A RBV estudada neste artigo busca interligar os recursos abordados, como exibido a Figura 1.

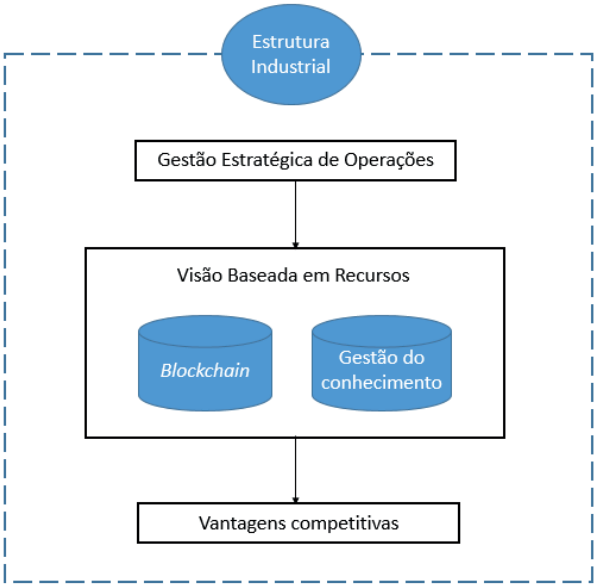

Fig. 1. Framework teórico conceitual
Fonte: Elaborado pelos autores, 2019.

Conforme ilustra a Figura 1, a Gestão Estratégica de Operações está inserida na Estrutura Industrial. Fundamentado nisso, relaciona-se a Visão Baseada em Recursos, que atua como um elo para associar a Tecnologia *Blockchain* e a Gestão do Conhecimento, buscando identificar como a combinação desses recursos podem desenvolver capacidades e reforçar seus papéis como fontes de vantagens competitivas para as organizações.

Desta forma o *framework* teórico conceitual desenvolvido, pode ser aplicado em segmentos industriais que utilizam a Visão Baseada em Recursos como uma estratégia para obter vantagem competitiva dentro da organização. A partir disso são designados os melhores recursos na organização, através dos quais a empresa poderá desenvolver suas estratégias e planejamentos. Sendo assim, determinando como recursos a tecnologia *Blockchain* e a Gestão do Conhecimento torna-se possível visualizar estratégias que podem ser empregadas na empresa, desenvolvendo uma melhoria contínua e uma boa gestão de operações.

6 Considerações Finais

O presente estudo, portanto, teve por objetivo analisar, por meio da lente da Visão Baseada em Recursos, dois recursos organizacionais: conhecimento e tecnologia. Com esta análise busca-se identificar como as capacidades dos recursos de Gestão do Conhecimento podem ser aprimorados com a adoção da tecnologia *Blockchain*. Para tal, buscou-se por meio do método *Fast Systematic Literature Review (FSLR)* artigos que abordassem ambos os recursos estudados para que fosse possível identificar de que forma estes dois recursos vem sendo relacionados.

Com a aplicação do método de revisão sistemática da literatura, FSLR, resultou-se em um portfólio composto por 10 (dez) artigos que abordavam ambos os assuntos estudados: Gestão do Conhecimento e *Blockchain*. Com esse conjunto de artigos foi possível compreender o assunto abordado e identificar de que forma a tecnologia *Blockchain* tem sido aplicada à Gestão do Conhecimento. Neste sentido, considerando a Gestão do Conhecimento a partir das funções de identificar, adquirir, desenvolver, compartilhar e distribuir, utilizar e reter o conhecimento, a tecnologia tem sido aplicada com maior foco à função de compartilhamento.

Por meio dos artigos, identificou-se que a tecnologia *Blockchain* tem possibilitado a resolução de alguns desafios que as empresas têm enfrentado na realização da Gestão do Conhecimento. Questões como falta de confiança entre os membros das organizações, falta de transparência e segurança são algumas das oportunidades de valor geradas pela tecnologia para a Gestão do Conhecimento, resultando em um melhor e maior compartilhamento de conhecimento dentro das organizações, sendo que um melhor compartilhamento de conhecimento fornece a oportunidade de melhorar o desempenho dos funcionários no trabalho, bem como criar novas ideias e inovações.

Em relação às limitações da pesquisa, devido ao fato de a tecnologia *Blockchain* estar ainda em estágios iniciais de desenvolvimento e aplicação, poucos casos foram encontrados na literatura, em especial casos que relacionassem a tecnologia ao tema Gestão do Conhecimento. Esta limitação, no entanto, pode ser vista como uma oportunidade de pesquisa.

Assim, este artigo expõe a necessidade de explorar novas aplicações da tecnologia *Blockchain* à Gestão do Conhecimento, principalmente sobre a lente da Visão Baseada em Recursos, destacando as implicações da combinação destes recursos para o desenvolvimento e potencial competitivo das organizações. Desta forma a presente pesquisa cumpre com o objetivo proposto, realizando uma revisão sistemática da literatura e acrescentando conhecimento ao tema proposto.

Abstract. Implications of Industry 4.0 and the key factors for an effective implementation is still unclear. This paper supports the understanding of what are the main success factors for implementing a new technology and what are the implications of these adoptions for the operations management. For this, cases studies were conducted regarding the implementation of new technologies in companies of the metal-mechanic and automotive sectors of the South and Southeast regions of Brazil, aiming to determine what are the key factors for a successful implementation under the analysis from a strategic and practice perspective. The results from the present research illuminates that even the financial and technology resources being relevant factors for a successful implementation, the main factors for an effective implementation are not related to the resources available but the way that they are being managed and integrated.

Keywords: management of operations, strategic dimensions, dimensions of practice.

1 Introduction

The term "Industry 4.0" became publicly known in 2011 through a German government initiative called "Industrie 4.0" and are being used to denote the fourth industrial revolution [1–3]. This revolution aims at a fusion of the physical and virtual word into cyber-physical systems (CPS) and was preceded by three other industrial revolutions that have driven dramatic increases in industrial productivity, being these related to the steam engine, mass production systems and automation technologies [4–9].

In the past few years, this topic became one of the most discussed topics in manufacturing conferences, forums and exhibitors and attracted interest of governments and industries worldwide regarding the benefits that this revolution could provide [10]. However, even with the increasing research attention on this topic, the implications of these technologies to the production systems is still unclear, being the academic papers

focusing excessively on the technologies, such as the Internet of Things (IoT) and technologies associated with large volumes of data (Big Data Analytics), without approaching their impact on management systems and the key factors for an effective implementation [10].

Based on this scenario, the present paper aims to support the understanding of what are the main success factors for implementing a new technology and what are the implications of these adoptions for the operations management. For this, nine cases studies were conducted regarding the implementation of new technologies in companies of the metal-mechanic and automotive sectors of the South and Southeast regions of Brazil, aiming to determine what are the key factors for a successful implementation under the analysis from a strategic [11] and practice perspective [12]. The case studies were developed using the case study protocol proposed by Brunheroto et al. [13], which emphasizes the strategic perspective of the change, using the strategic dimensions proposed by Pettigrew [11] as basis for its construction. For the analysis under a practice perspective, the protocol was reviewed using the dimensions of practice proposed by Nicolini [12] through a comparison between both approaches using a Quality Function Deployment (QFD) matrix, aiming to determine the most relevant aspects of the protocol under a more practical-based approach.

Therefore, the present paper is organized in five sections, besides this introduction. In the following section, concepts regarding the strategic dimensions proposed by Pettigrew [11] and the dimensions of practice proposed by Nicolini [12] are presented. Next, the case study protocol is presented. After that, the case studies conducted related to the implementation of new technologies are shown. Then, an analysis of the used case study protocol according to the Nicolini's [12] dimensions of practice is made. Finally, in the last section, conclusions obtained with the present research are drawn.

2 Theoretical background

2.1 Strategic dimensions

Strategic change can be defined as a radical alteration or substantial overhaul of previous organizational strategies, structures, and activities [14]. The starting point for the analysis of strategic change is the notion that formulating the *content* of any new strategy inevitably entails managing its *context* and *process* [11]. Based on that scenario, the present paper aims at the analysis of several case studies through a protocol based on the Pettigrew's strategic dimensions of *context*, *process* and *content*, which has been used as basis for several studies related to enterprise engineering [11, 13, 15–17].

First, in relation to the *context*, it can be defined as the circumstances under which process and content occur [18]. In other words, it is related to the *why* of the change and refers to the environmental forces and internal aspects that constrain and enable strategic changes at the firm level. This dimension can be subdivided into two main contexts: outer context, related to the aspects in which the firm operates (macro environment, sector, etc.), and inner context, related to the aspects of the firm itself (corporate culture, strategies, etc.) [11, 13, 19].

The *process* dimension is related to the *how* of change and is related to the actions, reactions, and interactions from the various stakeholders as they seek to move the firm from its present to its future state [11, 19]. This dimension can be subdivided in two main aspects: project, related to the methodologies and consequences of the process, and resources, which englobes the resources necessary for the process (financial, human, technological, etc.) [13].

Finally, the *content* dimension refers to what has changed in the organization or the product obtained by the implementation of the strategies [18]. This dimension is related to the *what* of the change and can be subdivided in the improvements regarding the performance objectives (dependability, cost, flexibility, etc.) and other improvements (sustainability, opportunities, etc.) [11, 13, 19, 20].

2.2 Dimensions of practice

Besides the strategic domain, practice-based approaches are also being used to study many complex settings, such as healthcare, biomedical engineering, government, and construction projects [21–24]. Based on that scenario, the present paper also intends to support the understanding of the similarities between both approaches. For this, the five dimensions of practice proposed by Nicolini [12] were also taken as basis, which are considered as a toolkit approach that allows a rich investigation of social reality [12, 25].

Regarding these dimensions of practice, the first one is related to the *work and efforts* and it is related to the work and efforts made to achieve its objective and helps the overcome the illusion that "rational" decision, plans or organization leads automatically to the effective project implementation. In other words, this dimension supports the enlightenment of the difficulties involved in a diversity of project activities from building a project concept to making consensus and cultivating relations between participants [25].

The second dimension is related to the *materially* and aims at the understanding of why some difficulties and unforeseen events are so frequently present in the projects. In other words, it helps to identify why projects are surprised by unforeseen events, why planning and sharing spaces on project sites is so difficult, why so many failures occur when projects start operation, among others [25, 26].

The *agency and creativity* dimension is related to reasons for the necessity of capabilities for the project development, planning, etc. [27]. In other words, it helps to understand why projects need competent, creative and active clients or sponsors to steer them in the right direction, why inertia takes hold of project organization during implementation, and so on [25].

The fourth dimension, *knowledge*, is related to the distribution of expertise and support the understand of how the knowledge is created, maintained, and used by the project participants. In other words, it helps to identify how the knowledge fails to transfer and mobilize from past projects or, conversely, how the project participants fail by over-relying on past knowledge [25, 28].

Finally, the dimension of *interests and power* illuminate shifts of authority and dependence patterns in temporary organizations, the conflicts, tensions, and aberrant

response to unexpected events that affect so many projects. In other words, it supports the understanding of the difficulties regarding organizational aspects, such as culture, leadership, internal conflicts and disputes [25, 29].

3 Research Design

For the present research, 9 case studies, including the pilot case, were conducted with companies from the metal-mechanic and automotive sectors of the South and Southeast regions of Brazil in relation to the implementation of new technologies. For the data collection, the protocol proposed by Brunheroto et al. [13] was used, which was based on the methodology proposed by Yin [30] for case studies and the strategic dimensions proposed by Pettigrew [11].

Regarding the case study conduction, it consisted in three main phases: data collection, data structuring and data analysis, similar to the methodology proposed by Cestari et al. [31]. In relation to these phases, an overview can be seen in Figure 1.

The first phase, data collection, happened in two main parts: the main collection and the additional collections. Regarding the main collection, it consisted of semi structured interviews with the responsible for the projects, aiming to collect general information regarding the case. In relation to these interviews, they were initially person to person, mainly through visit to the companies, and later by video conferences, due to pandemic scenario, being these interviews recorded with the interviewee permission for future analysis. The additional collections were made through questionnaires, documents, and structured interviews, and aimed at the collection of missing information that could not be collected in the semi structured interviews.

The second phase, data structuring, also happened in two main parts: transcription and organization. Regarding the transcription, it was made using a speech recognition program to automatically transcript the interviews, being later reviewed by the researchers aiming to identify any mistakes. After the transcription, the data obtained were organized according to the information requirements of the protocol, aiming to identify the need of any additional collection.

Finally, after the data collection and structuring, the third phase took part, where all the information was synthesized in keywords or key phrases for a better understanding of the case, being this information later analyzed for the conclusions making.

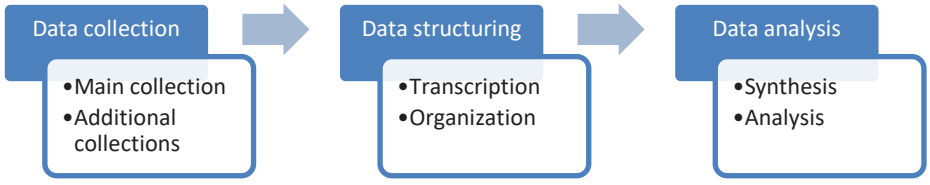

Fig. 1. Case study conduction overview

4 Results

As stated early, 9 case studies were conducted regarding the implementation of new technologies, which can be observed in Table 1. In relation to the synthesis of the results obtained for each case study for the Pettigrew's [11] strategic dimensions of context, process and content, they can be seen, respectively, in Tables 2, 3 and 4.

Table 1. Case studies overview

Case	Technology	Department
1	Machine vision system	Process engineering
2	Predictive maintenance	Maintenance
3	Data Matrix	Process engineering
4	Advanced Planning and Scheduling (APS)	Production Planning and Control
5	Data Matrix	Process engineering
6	Enterprise Resource Planning (ERP)	Production Planning and Control
7	Indoor geolocation	Process engineering
8	Business Intelligence (BI)	Quality
9	Photogrammetry	Quality

As observed in Table 1, nine case studies were conducted, being great part of them related to the adoption of technologies in the process engineering department. In addition, except for the case regarding the ERP adoption, all companies are classified as large companies according to the SEBRAE (*Serviço de Apoio às Micro e Pequenas Empresas*) classification [32].

The results obtained with the case studies, more specifically for the strategic dimension of *context* (Table 2), shows that great part of the demand for the technologies were related to legal aspects (3 cases), dependability (2 cases) and quality (2 cases). Regarding this legal demand for these cases, it is related to the demanded traceability of the process in order to obtain the ISO 9001 certification [33], being the cases 3 and 5 related to the maintenance of the certification by implementing traceability systems in their processes and the case 6 related to a small-sized company which are adopting an ERP system to further obtain the certification. Therefore, the demand for these cases could be also related to the quality and dependability since the ISO 9001 is a quality standardization and the traceability is related to the dependability of the process.

As for the context of the implementations, it can be observed that, except for the case 8, which were a personal initiative to implement a BI system, all the cases had an investment model based on a strategic management. However, even with this strategic management, it is also possible to observed that only the case 7 used a tax initiative existent in Brazil to promote innovation [34] in their strategic management and none of them informed about the uses of credit lines. In addition, it also can be noted that only few companies had a partnership in their development process, being only the cases 1, 2 and 7 supported by the academy. Therefore, even the companies having an innovation strategy, some initiatives that could also support the process are being misused.

Table 2. Case studies overview (Context)

Case	Outer context					Inner context		
	Macro environment	Sector	Suppliers	Demand criteria	Solutions	Technology access	Culture (Partners)	Investment model	Department (Leadership)
1	N/A	N/A	External (Partial)	Quality	3	Academy	Academy/ suppliers	Strategic management	Process
2	N/A	N/A	External (All process)	Dependability	1	Academy	Academy	Strategic management	Maintenance/ IT
3	Regulatory aspects	ISO / ABNT	External (Partial)	Legal	1	Partnership	None	Strategic management	Process
4	N/A	ISO / ABNT	External (All process)	Dependability	3	Supplier	None	Strategic management	PPC / IT

Table 4. Case studies overview (Content)

	Performance objectives (Influence)						Other (Influence)	
Case	Dependability	Cost	Flexibility	Quality	Speed	Ergonomics	Sustainability	Opportunities
1	Positive	Negative	-	Positive	Positive	Positive	-	Positive
2	Positive	Positive	Positive	-	Positive	Positive	Positive	Positive
3	Positive	Negative	-	-	Negative	Negative	-	-
4	Positive	Positive	Positive	-	Positive	Negative	Positive	Positive
5	Positive	Negative	-	-	Negative	Negative	-	-
6	Positive	Negative	-	-	Negative	Negative	Positive	Positive
7	Positive	Positive	Positive	-	Positive	Positive	Positive	Positive
8	Positive	-	-	Positive	-	-	Positive	Positive
9	Positive	Positive	Positive	Positive	Positive	Positive	Positive	Positive

Regarding the *process* of the implementations (Table 3), it can be observed that great part of the companies used different models of methodologies related to the project management, which were a significant factor for the success of the initiatives, since cases that do not used a formalized methodology, such as cases 1 and 8, did not had results as good as the other companies. However, even with the use of traditional methodologies, it is possible to observe that the use of agile methodologies, such as the Scrum [35], which could increase the speed of the process and, therefore, the returns of the technologies, are not being used.

In relation to the resources, as will be evidenced further with the analysis under Nicolini's [12] perspective, it is also possible to observe that other factors related to the success of the implementations are the human resources management and the budged forecast, since the cases 1 and 8, that did not used a formalized methodology or a formalized team for the implementation, had an impact on the effectiveness of the project. In addition, another aspect showed relevant to the success of the implementations were the knowledge management, since companies that adopted for informal trainings or that did not transferred the knowledge properly between the participants can have negative impacts after the implementations. This scenario was observed specifically in the case 1, where one of the teams responsible for the development of the solutions exit during the implementation process, and case 4, where the exit of the responsible for the process after the implementation resulted in a 6 month gap without the use of the system. However, as the case 4 had a formalized methodology, the knowledge could be reobtained and the system returned to operate normally, while in case 1, due to the lack of a formalized methodology and mainly the lack of financial resources and human management that made the team exit, resulted in a loss of knowledge. Therefore, a formalized methodology associated with a good resource's management is one of the main factors to the success of an implementation.

Regarding the *content* (Table 4), or the results obtained with the implementation, all the adoptions had a positive influence on the dependability of their process, which was already presented as one of the most influenced aspects by the implementation of new technologies by some studies [36, 37]. Conversely, cost and speed presented negative influences for several case studies. However, as can be observed in Table 4, the cases with these negative influences (1, 3, 5 and 6) are all related to legal and safety aspects of their products, being cases 3, 5 and 6 related to adoptions necessary for the ISO 9001 certification and case 1 related to the use of a machine vision system from improve product quality. Therefore, even these technologies having negative impacts in some performance objectives, they are still important for the companies to ensure the quality and safety of their products.

Finally, in relation to the other improvements, besides some negative influences in the ergonomic of some cases due to the reasons mentioned early, great part of the cases presented positive influences in the sustainability and opportunities. As for the ergonomics, the positive influences of the cases 1, 2, 7 and 9 are related to the automation of the process, reducing the activities necessary by the operators, while the negative influences, as stated early, are related to the increase of activities necessary by the operators in order to satisfy some legal objectives or to the implemented systems work properly. Regarding the sustainability, which is one of the main topics nowadays and

has been focus of several studies [38–43], 6 cases presented positive influences in this aspect, being them mainly related to the use of resources for operation (cases 2, 7 and 9), while the others were influenced for aspects such as the reduction of papers in the factory and of analysis systems (cases 4, 6 and 8). Finally, in relation to the opportunities, besides the cases related to the maintenance of the ISO 9001 certification, all cases presented a positive influence in this aspect, being great part of them related to the possibility to perform different analysis through the data collected and the possibility to adopt new systems and achieve new markets.

5 Protocol review

As stated early, another approach to evaluate the adoption of the new technologies are the five dimensions of practice proposed by Nicolini [12], which are considered as a more practical-based approach [12, 25]. Based on that scenario, this section aims at the understanding of the similarities and differences between both approaches: the strategic dimensions proposed by Pettigrew [11], which was the basis for present research and the construction of the case study protocol, and the dimensions of practice proposed by Nicolini [12].

For this comparison, a Quality Function Deployment (QFD) matrix was elaborated, where the information requirements of the used protocol were considered as being the quality characteristics and the dimensions of practiced proposed by Nicolini [12] as the demanded quality, aiming to understand which information requirements of the used protocol are considered the most relevant for the Nicolini's [12] approach [44]. In addition, it also should be noted that the QFD used for the present research was adapted for the present analysis, being all dimensions of practice considered equally relevant (same weight / importance) and without any correlation between the information requirements. Besides that, it also should be noted that, as the Nicolini's [12] approach involves only the understanding of the projects and the factors for its success, the information requirements regarding the strategic dimension of content were not included in the present analysis, since, as stated early, this dimension focuses in what were achieved by the implementation, which was not the focus of Nicolini's [12] five dimensions of practice and, therefore, the results for this strategic dimension would be considered as irrelevant for this approach. In relation to the results obtained with the QFD matrix, it can be observed in Table 5.

Table 5. Quality Function Deployment (Pettigrew x Nicolini)

	Context					Process					
	Outer context			Inner context		Project		Resources			
	Macro environment	Sector	Suppliers	Culture	Innovation strategy	Methodology	Consequences	Financial	Human	Technological	Knowledge transference
Work and efforts	O	O	Θ	Θ	Θ	Θ		Θ	Θ	Δ	Θ
Materially	Θ	Θ	Θ	Θ	Θ	Θ		O	O		O
Agency and creativity	O	O	O	Θ	Θ	O	Δ	Δ	O	O	O
Knowledge				Δ	Δ	O		Δ	O	Δ	Θ
Interests and power			Δ	Θ	O	O			O		Θ
Max relationship value	9	9	9	9	9	9	1	9	9	3	9
Weight / Importance	300	300	440	740	620	540	20	280	420	100	480
Relative Weight	7,1	7,1	10,4	17,4	14,6	12,7	0,5	6,6	9,9	2,4	11,3

Θ – Strong relationship (9) O – Moderate relationship (3) Δ – Weak relationship (1)

As observed in Table 5, the most relevant information requirements for the understanding of the projects under Nicolini's [12] approach were Culture, Innovation Strategy, and Methodology, which is also observed in related studies [45]. Conversely, the least relevant information requirements for the five dimensions perspective were Consequences and Technological resources.

Regarding the least relevant information requirements under Nicolini's [12] perspective, it can be observed that they were mainly associated with the goals of the projects and resources that do not directly involves communication and relations between the project participants for its management. Conversely, resources that demands the interaction between the participants to its management, such as Human resources and Knowledge resources, presented great relevance under a Nicolini's [12] perspective, which is also considered as relevant aspects for different models [46].

In relation to the most relevant information requirements under Nicolini's [12] perspective, it mainly involves the context of the company (inner context) and the methodology used to achieve their objective. Analyzing these results from a similar point of view as used for the resources, it can be observed that these three main information requirements under Nicolini's [12] perspective are also related to the communication and human resources management, since these aspects involves the relationship between the project participants and the people from outside of the organization, such as

suppliers, partners, stakeholders, academy, headquarters, etc. In addition, as observed in the case studies, a great strategy and the use of a proper methodology is also relevant for the effectiveness of the change, being the projects with a more consolidated innovation strategy and formalized project managements methodologies with the highest success rates [46].

Therefore, it is possible to observe that even the financial and technological resources being important for an implementation, the key factors for a more effective change is the integration and relationship between all the people involved in the project (employees, companies, suppliers, stakeholders, etc.). This scenario was observed in the case studies of the present research, since projects that did not had a formalized human resources management or a project management that included these integrations between the companies and the third parties involved in an early stage of the process, did not have the same level of success as the other companies who have done these predictions in the early stages of the process. In addition, consolidated innovation strategies and formalized project management methodologies are also key factors to increase the success rate of an implementation, being the highest successful implementations associated with projects that had formalized methodologies and a consolidated innovation strategy.

Finally, the analysis of the protocol under a Nicolini's [12] perspective allowed to identify that great part of the information collected using the Pettigrew's [11] strategic dimensions of *context*, *process* and *content* are also related to the Nicolini's [12] dimensions of practices, but analyzed from a different perspective, being the Pettigrew's [11] method associated to a more strategic point of view, englobing aspects that are not included in the other theories, such as the benefits and goals of the implementation, and the Nicolini's [12] framework associated to a more practical point of view, englobing aspects related to the key factors for a successful implementation, without approaching what was the objectives of the implementations.

6 Conclusion

Through the presented method, it can be said that the objective of support the understanding of what are the main success factors for implementing a new technology and what are the implications of these adoptions for the operations management was achieved, since several case studies regarding the implementation of new technologies could be performed and analyzed throughout different perspectives. it should be noted that the results presented in the case studies refer only to the scenario of the South and Southwest of Brazil, more specifically of the companies of the metal-mechanic and automotive sector, and may differ from other sectors or regions studied. Besides that, due to the pandemic scenario, some cases presented difficulties in the data collection, not being able to perform company visits or personal interviews.

In relation to the results obtained with the case studies, it was possible to identify that a good strategic plan and the use of a formalized methodology associated with a proper resources management are key factors for the effectiveness of an implementation. However, even with great part of the case studies having satisfactory results, some

other measures are still necessary to improve even more the performance of the implementations, being mainly related to the study of the macro environment of the company, since great opportunities as tax incentives and credit lines are not being used, and the development of agile methodologies for the implementation, since it was not observed for any of the companies and could help to improve the speed of the implementation processes and the benefits.

Regarding the analysis of the protocol under a Nicolini's [12] perspective, it allowed to identify that great part of the information collected using the Pettigrew's [11] strategic dimensions of *context*, *process* and *content* are also related to the Nicolini's [12] dimensions of practices. In relation to these similarities, they are mainly related to the understanding of the context of the organization and the used methodology, which were also observed in the case studies along with the human resources management as key factors for an effective implementation.

Therefore, using the information obtained with the case studies and the most relevant aspects under Nicolini's [12] perspective, it can be concluded that even the financial and technology resources being relevant factors for a successful implementation, the main factors for an effective implementation are not related to the resources available but the way that they are being managed and integrated. In relation to this scenario, it was also observed in the studies, where the companies that had a better strategy, using formalized methodologies, and a great relationship between the project participants and the third parties involved in the project presented the better results.

Finally, for future works, it is suggested to apply the proposed methodology to other regions and sectors related to the implementation of new technologies to analyze the differences between the applications in different scenarios. In addition, an analysis under other aspects, such as the batteries of change proposed by Prins et al [46] is also suggested.

Abstract. Implications of Industry 4.0 for enterprises in general are still unclear. This paper examines how key technologies of Industry 4.0 impact production systems, more specifically performance objectives. The research method is based on a quantitative study carried out in Curitiba and Metropolitan Region with a focus on the metal-mechanic and automotive sectors. The results show which Industry 4.0 technologies have the highest implementation level and which technologies have the most impact on performance objectives. Furthermore, the presented survey provides not only a scenario of what the technologies being adopted are, but also a starting point for companies that are willing to invest in new technologies of what the possible benefits that they can possibly achieve are, based on what has already been adopted.

Keywords: Industry 4.0, production management, performance objectives.

1 Introduction

The fourth industrial revolution has been one of the most frequently discussed topics in the past few years [1]. This new technological revolution, also known as "Industry 4.0", has become publicly known in 2011 through a German government initiative called "Industrie 4.0" and was preceded by three other industrial revolutions that have driven dramatic increases in industrial productivity [2–6].

This revolution is based on new and radically changed technologies that aim at a fusion of the physical and the virtual world into cyber-physical systems (CPS) and attracted the interest of several studies, many related to the technologies being used, such as the Internet of Things (IoT) and computational techniques associated with large

volumes of data (Big Data Analytics) [1, 7–9]. However, the implications of these technologies to production systems is still unclear, since studies that formally discuss these implications are lacking, focusing excessively on the technologies without approaching their impact on management systems.

Based on this context, the present paper aims to support the understanding of how key technologies of Industry 4.0 are impacting production systems, more specifically performance objectives. For this, a survey was made with companies of the metal-mechanic and automotive industry of Curitiba Metropolitan Region, aiming to determine the overall implementation level of these technologies and their respective impacts on performance objectives [10, 11].

Therefore, the present paper is organized in four sections. In the following section, some concepts regarding the information used to the questionnaire construction are presented. After that, the research method used for the survey conduction and data processing is shown. Then, results and discussions regarding the implementation and improvement level results are presented. Finally, in the last section, conclusions obtained with the present research are drawn.

2 Theoretical Background

2.1 Industry 4.0 technologies

For the present research, six technologies associated with Industry 4.0 were selected based on their relevance in consulting reports and their use by companies of the target group (Curitiba Metropolitan Region) [4, 7, 12–15]. Regarding this selection, it was made taking the 27 technologies proposed by Brunheroto *et al*. [12] as a starting point and filtering them based on their number of appearances on five consulting reports (>3) and their number of uses by the companies of the target group (>10) on Brunheroto *et al.´*s [12] research.

After the filtering process, five technologies were obtained: Internet of Things, Cloud, Cybersecurity, Big Data Analytics and 3D Printing. However, due to the relevance of the Virtually Guided Self-Services on Brunheroto *et al.´*s [12] research, it was also included on the final set, even not being as cited as many times as the others in the consulting reports. Therefore, six technologies were selected to be used in the analysis of the impacts of their adoption on performance objectives: Internet of Things, Cloud, Cybersecurity, Big Data Analytics, Virtually Guided Self-Services and 3D Printing.

2.2 Performance objectives

Performance objectives describe what the manufacturing function should achieve in order to satisfy market requirements [10, 16–18]. About the definition of this set, many authors on operations strategy have their own set of performance objectives, and, therefore, no overall agreement exists on the terminology [10, 18]. Therefore, for the present research, the model proposed by Slack and Lewis [10] and Corrêa and Corrêa [11] was chosen, where five performance objectives are considered: dependability, cost,

flexibility, quality and speed. Regarding the definition of each topic, they can be observed in the following topics.

- **Dependability:** carrying out the work in a timely manner, abiding by the delivery commitments promised to the customers [19].
- **Cost:** carrying out the work in an inexpensive manner, producing goods and rendering services with a cost that enables them to properly perform, pricing for the market in a way that the organization revenue is also allowed for [19].
- **Flexibility:** changing what you do or the way the work is done, the ability to change or match the activities of operations to overcome unexpected circumstances or gain customers' unique behavior or introducing new products or services [19].
- **Quality:** performing tasks properly, procuring goods and services without error and in accordance with the previously-determined goals [19].
- **Speed:** performing tasks rapidly, minimizing the time between the customers' request for goods or services and the delivery [19].

3 Method

3.1 Study design

For the analysis of the main impacts of the adoption of Industry 4.0 technologies to production systems, more specifically the performance objectives, a survey was conducted with companies of the metal-mechanic and automotive sectors of Curitiba Metropolitan Region.

For this, the production system management model proposed by Slack and Lewis [10] and Corrêa and Corrêa [11] was taken as basis, which emphasize the strategic aspects of production systems management, since some companies' initiatives are being conducted in a strategic domain [20]. For the assessment of the Industry 4.0 technologies, as presented earlier, results from Brunheroto *et al.* [12] and five consulting reports were taken as basis [4, 7, 12–15]. Regarding the specific method for the present research, including the questionnaire construction and survey conduction, they will be further explained in the following topics.

3.2 Target group

As stated earlier, the target group for the present research was the Curitiba Metropolitan Region, more specifically from the metal-mechanic and automotive sectors. This target group was chosen due to the location of the university, which is sited in this region, and the economic relevance of this sector for the studied region [21].

Regarding the universe definition, it was made using a database, made available by FIEP (*Federação das Indústrias do Estado do Paraná*) [22], a civil society organization that serves as a hub for industry initiatives and partnerships in the selected area. In this database, filters were made based on the desired location and sectors, and 762 companies were found as the universe of companies for the present research.

3.3 Questionnaire construction

Once the universe of companies was defined, an online questionnaire was developed based on the information gathered in the theoretical background. Regarding the questionnaire, it consisted of a presentation section, four main sections and a last section referring to the feedback.

In relation to the four main sections, it aimed to present some concepts regarding the technologies and the performance objectives and to collect the data referring to the respondents, the implementation level of the six technologies and their respective improvement levels for all five performance objectives. For the implementation level questions, the respondent was asked to inform, in a level from 1 (we do not have) to 5 (we have advanced implementation), the implementation level of each one of the six technologies by their companies, similar to the model proposed by Frank *et al.* [23]. As for the improvement level questions, the respondent was asked to inform, in a level from 1 (none) to 5 (excellent), the improvement level provided by the used technologies in each one of the performance objectives, based on the responses of the previous sections.

3.4 Collection of responses

Once the questionnaire was constructed, they were sent mainly by e-mail to the whole universe previously mentioned and later resent to the companies with wrong contact information. After the questionnaire was sent to the entire universe, some other measures were made regarding possible restrictions on internet access by the companies, being the first one the rewrite of the questionnaire in document formats and the second one related to a warning e-mail, without any link or attachment, informing about the previous emails and the deadline for the responses.

3.5 Data processing

For the data processing, the responses were exported, briefly organized and sent to a BI (Business Intelligence) platform for the final processing and report generation. Regarding this report, it was divided in 3 main sections: Sample data, Implementation and Improvement and are explained below.

- **Sample data:** For the sample data section, pie charts regarding the companies' size and sector were constructed, as well as a map indicating the cities of the participant companies and graphs presenting the participation status, including the incomplete and complete responses, number of respondents and number of respondent companies.
- **Implementation:** The implementation section aims to analyze the implementation level of each technology. For this, pie and bar charts were respectively created to present the implementation level responses and the number of uses of each technology. Besides that, a table and a dispersion graph were also generated, aiming to

analyze the average implementation level and standard deviation for each technology across different sizes of companies.

- **Improvement:** For the improvement section, spider and boxplot graphs were constructed, as well as a table with the average improvement level and the standard deviation for each technology in each performance objective. In relation to the spider graph, it was created aiming to facilitate the visualization of which performance objective was more impacted by the adoption of each technology. Finally, regarding the boxplots and the table, they were generated to analyze the responses distribution and identify if the improvements are generally the same or if they have discrepancies according to different contexts of applications.

4 Results and discussion

For a better understanding of the present research, results are divided according to the report sequence presented previously, being presented first the sample data, followed by the implementation level and the improvement level results. In addition, an overview of the results regarding the implementation and improvement levels can be seen after the results in Figure 2.

4.1 Sample data

Using the method described previously, 76 responses from 63 companies were obtained, including 7 incomplete responses that could be used for the analysis. The size of the respondent companies according to SEBRAE (*Serviço Brasileiro de Apoio às Micro e Pequenas Empresas*) classification [24] can be seen on Figure 1.

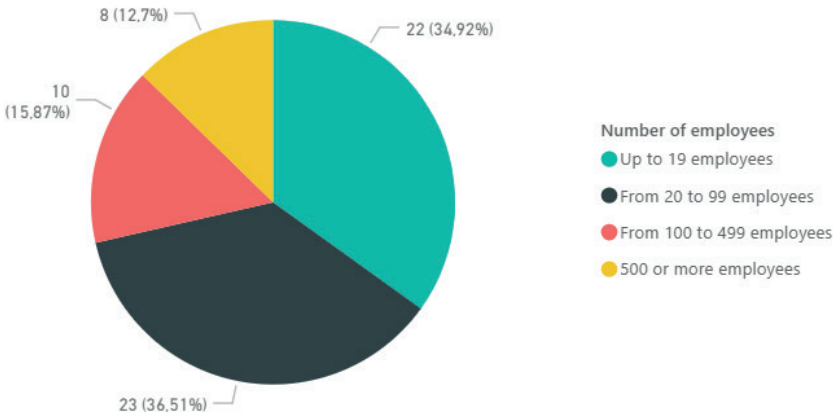

Fig. 1. Companies size (Curitiba Metropolitan Region)

As seen in Figure 1, great part of the respondents were from micro and small-sized companies, which represent more than 80% of the universe of companies in Curitiba Metropolitan Region. However, it also should be noted the number of responses from

large companies, which represent less than 5% of the universe and had a considerable response rate on this study [22]. Regarding to the reasons for this great diversity of sizes, it can be related to the interest regarding the subject (Industry 4.0), since it usually attracts more interest from companies that are trying to implement those technologies, which are usually the larger companies, and the easier access to larger companies throughout internal contacts and by the number of employees itself, since it has more possibilities of contacts inside the company.

4.2 Implementation levels

In relation to the implementation levels (Table 1), besides Cybersecurity, all technologies obtained an overall implementation level lower than 3, representing that great part of the companies from Curitiba and Metropolitan Region do not have any of the technologies presented in this study. These low overall implementation levels can be related to the sample, since, as stated earlier, a large number of responses were from micro (34,92%) and small (36,51%) companies (Figure 1), which can directly reflect on the overall results, since higher adoption levels are usually associated with larger companies, hypothesis that will be further evaluated through a Pearson correlation test. As for the overall implementation levels and their respective standard deviation obtained for each technology, they can be observed in Table 1.

Table 1. Average implementation levels

Pos.	Technology	Avg. Implem. level	St. dev.
1º	Cybersecurity	3,04	1,72
2º	Virtually Guided Self-Services	2,44	1,55
3º	Cloud	2,41	1,55
4º	3D Printing	2,14	1,47
5º	Big Data Analytics	2,06	1,26
6º	Internet of Things (IoT)	1,96	1,20

As observed in Table 1, the highest overall implementation level was associated with Cybersecurity (3,04), while the lowest levels were associated with Internet of Things (1,96) and Big Data Analytics (2,06). This is due to two main reasons: necessity and complexity, since technologies such as Cybersecurity are usually necessary to increase the security and reliability of the company and, therefore, can be considered a necessity for those companies that are willing to adopt digital technologies to prevent them from cyberattacks. Conversely, Big Data Analytics and Internet of Things are not a necessity for companies of all sizes, since they usually aim to improve the process and do not have a direct demand in terms of security and legislation, and are usually more complex to implement than other technologies, since they usually need the support from other technologies for their correct operation.

Table 2 shows the results obtained for each technology by the companies' size, as well as their respective correlation level between the average implementation levels and

companies' size. Regarding the correlation level results, the coefficients were calculated considering the implementation levels responses for each size of company and the companies' size in a level from 1 to 4, being level 1 associated with the micro-sized companies and level 5 with large companies.

Table 2. Average implementation levels per size and correlation

Pos.	Technology	Micro	Small	Medium	Large	r (corr.)
1º	Cybersecurity	1,80	2,96	3,27	4,79	0,60
2º	Virtually Guided Self-Services	1,52	2,35	2,82	3,77	0,51
3º	Cloud	1,48	2,29	2,73	3,85	0,53
4º	3D Printing	1,47	1,64	2,00	3,85	0,57
5º	Big Data Analytics	1,57	1,83	2,00	3,31	0,45
6º	Internet of Things (IoT)	1,43	1,64	2,09	3,31	0,54

As observed in Table 2, there is a positive correlation between companies' size and the implementation, since all technologies presented a positive Pearson correlation coefficient between their implementation levels and the companies' size, being 0,45 the lowest coefficient. Therefore, the low overall implementation levels presented in Table 1 are indeed related to the sample, as stated earlier, and not a reality for all sizes of companies, being the results for the large companies higher in comparison to companies of other sizes, as can be observed in Table 2.

Regarding the results by companies' size (Table 2), the overall implementation level of the technologies for large companies is high, being all levels higher than 3, representing that most of the companies have at least an implementation project under development. In relation to the highest implementation level for large companies, it is associated with Cybersecurity (4,79), which has an advanced implementation in most part of the companies. Conversely, Big Data Analytics (3,31) and Internet of Things (3,31) presented the lowest levels for large companies, which can be related to the complexity issues mentioned earlier.

As for SMEs, Cybersecurity also presented the highest implementation level among all technologies for micro (1,80), small (2,96) and medium-sized companies (3,27). As for the lowest implementation levels, it is associated with the Internet of Things for micro-sized companies (1,43), 3D Printing and Internet of Things for small-sized companies (1,64) and Big Data Analytics and 3D Printing for medium-sized companies. In addition, it should be noted that, even these technologies presenting the lowest average implementation levels, some of these averages can be considered statistically equal to other technologies, which can be observed mainly for the micro-sized companies, and, therefore, there is no clear definition regarding the lowest implementation levels.

4.3 Improvement levels

In relation to the improvement levels (Table 3), the overall improvement levels were, in general, higher than 3, representing that the companies had at least a good overall improvement by adopting the studied technologies. Regarding these overall implementation levels, they were calculated as the average of the implementation levels for all performance objectives (dependability, cost, flexibility, quality and speed) and, therefore, technologies that have a higher overall implementation level also tend to have a high average improvement level for all performance objectives.

Table 3. Average improvement levels (General)

Position	Technology	Avg. Improv. level	St. dev.
1º	3D Printing	3,50	0,97
2º	Internet of Things (IoT)	3,35	0,82
3º	Cybersecurity	3,34	1,12
4º	Cloud	3,18	0,91
5º	Virtually Guided Self-Services	3,17	1,04
6º	Big Data Analytics	3,06	0,90

As observed in the general ranking of technologies (Table 3), the 3D Printing presented the highest overall improvement level (3,50), while the lowest was associated to the Big Data Analytics (3,06). However, as will be discussed further, the overall improvement level does not necessarily represent what the best technology is in terms of improvement, since it can vary according to the context of application. Therefore, the results presented in this section aim to support the understanding of what improvements can be achieved by adopting these technologies, and what technology has a better improvement potential for each of the performance objectives.

In addition, it also should be noted that, even the Big Data Analytics having presented the lowest overall improvement level, some technologies, such as the Internet of Things, are still necessary to enable its full potential and, therefore, its performance may have been influenced by the low adoption rate of the Internet of Things.

In relation to the technology rankings for each of the performance objectives (dependability, cost, flexibility, quality and speed), they can be observed, respectively in Tables 4, 5, 6, 7 and 8.

Table 4. Average improvement levels (dependability)

Position	Technology	Avg. Improv. level	St. dev.
1º	Cybersecurity	3,81	1,05
2º	Internet of Things (IoT)	3,64	0,67
3º	3D Printing	3,50	0,65
4º	Virtually Guided Self-Services	3,39	1,16
5º	Cloud	3,38	1,01
6º	Big Data Analytics	3,07	0,83

As observed in Table 4, the Cybersecurity presented the highest average improvement level for dependability (3,81), while the lowest level was associated with Big Data Analytics (3,07). Regarding the reason for this ranking, as stated earlier, the low improvement level of Big Data Analytics could be related to the low adoption rate of the Internet of Things, since this technology is used to collect the data for the analysis and, therefore, a lack of an automatic gathering system can result in a bad input for the Big Data Analytics and, consequently, a bad analysis (output).

In relation to cybersecurity, as expected, it presented the main improvements in the dependability of the process, since, as stated earlier, it is a technology that usually aims at this objective by improving the security of the company. However, it also should be noted that the Internet of Things and 3D Printing also had good results in terms of average improvement levels for Dependability and mainly in terms of standard deviations, which were the lowest for this ranking, representing that they had a good performance for different contexts of applications.

Table 5. Average improvement levels (cost)

Position	Technology	Avg. Improv. level	St. dev.
1º	3D Printing	3,29	1,38
2º	Internet of Things (IoT)	3,18	0,87
3º	Big Data Analytics	3,07	0,83
4º	Virtually Guided Self-Services	3,00	1,04
5º	Cybersecurity	2,95	1,08
6º	Cloud	2,83	0,82

As observed in Table 5, 3D Printing presented the highest average improvement level for cost (3,29), while the lowest level was associated with Cloud (2,83), which is also the lowest score among all performance objectives and technologies. However, it should be noted that, even this technology having presented the highest average improvement level for cost (3D Printing), it did not present an improvement level as high as observed in other rankings, being the only ranking where all technologies presented an average improvement level under 3,5, representing that cost is not the main goal of the studied technologies.

In addition, it should also be noted that, even the 3D Printing having the highest average improvement level, it also presented the highest standard deviation of all rankings, representing that even the technology with the most improvement in terms of cost can perform differently according to its context of application.

Table 6. Average improvement levels (flexibility)

Position	Technology	Avg. Improv. level	St. dev.
1º	3D Printing	3,86	0,86
2º	Cloud	3,29	1,00
3º	Internet of Things (IoT)	3,09	0,94
4º	Virtually Guided Self-Services	3,09	1,08
5º	Cybersecurity	2,97	1,01
6º	Big Data Analytics	2,86	0,86

As observed in Table 6, the 3D Printing presented the highest average improvement level for flexibility (3,86), which is also the highest score among all performance objectives and technologies, while the lowest level was associated with Big Data Analytics (2,86). Regarding this result, the goal of the technologies can explain this ranking, since 3D Printing is usually used to improve the flexibility of the manufacturing process or to support the development process, which intrinsically demands high flexibility. Conversely, Big Data Analytics and Cybersecurity usually aim to improve other aspects of the production system and, therefore, are understandable to have lower levels compared with the other technologies, besides the fact already explained regarding the additional technologies necessary to enable the full potential of Big Data Analytics.

In addition, it should also be noted that 3D Printing, besides the highest improvement level, also has the lowest standard deviation, representing that its great performance was not exclusive for some context of applications.

Table 7. Average improvement levels (quality)

Position	Technology	Avg. Improv. level	St. dev.
1º	Cybersecurity	3,62	1,11
2º	Internet of Things (IoT)	3,55	0,82
3º	3D Printing	3,36	0,74
4º	Cloud	3,29	0,81
5º	Virtually Guided Self-Services	3,26	1,01
6º	Big Data Analytics	3,14	1,03

As observed in Table 7, the Cybersecurity presented the highest average improvement level for Quality (3,62), while the lowest level was associated with Big Data Analytics (3,14). Regarding this ranking, the high position of Cybersecurity can be explained by the association that people usually make with security, reliability,

dependability and quality, since both rankings (Tables 4 and 7) presented similar results. Therefore, as the results were very similar, the comments made for the dependability ranking are also applied for the present ranking, where the Internet of Things and 3D Printing presented the lowest standard deviations and, therefore, presented a great performance throughout different contexts and the low performance of Big Data Analytics can be associated with the low adoption of its supporting technologies.

Table 8. Average improvement levels (speed)

Position	Technology	Avg. Improv. level	St. dev.
1º	3D Printing	3,50	1,09
2º	Cybersecurity	3,32	1,11
3º	Internet of Things (IoT)	3,27	0,79
4º	Big Data Analytics	3,14	1,03
5º	Virtually Guided Self-Services	3,13	0,92
6º	Cloud	3,08	0,88

As observed in Table 8, 3D Printing presented the highest average improvement level for speed (3,50), while the lowest level was associated with Cloud (3,08). However, even with the high improvement level of speed for 3D Printing, it also presented a high standard deviation, representing that its application can perform differently according to the context. Regarding the reason for this high standard deviation, it can be associated with the two main applications of this technology: manufacture and development, since the manufacture process usually demands a higher speed than in a prototyping process and, therefore, the adoption of the technology in this context could not provide an improvement as good as in a development context.

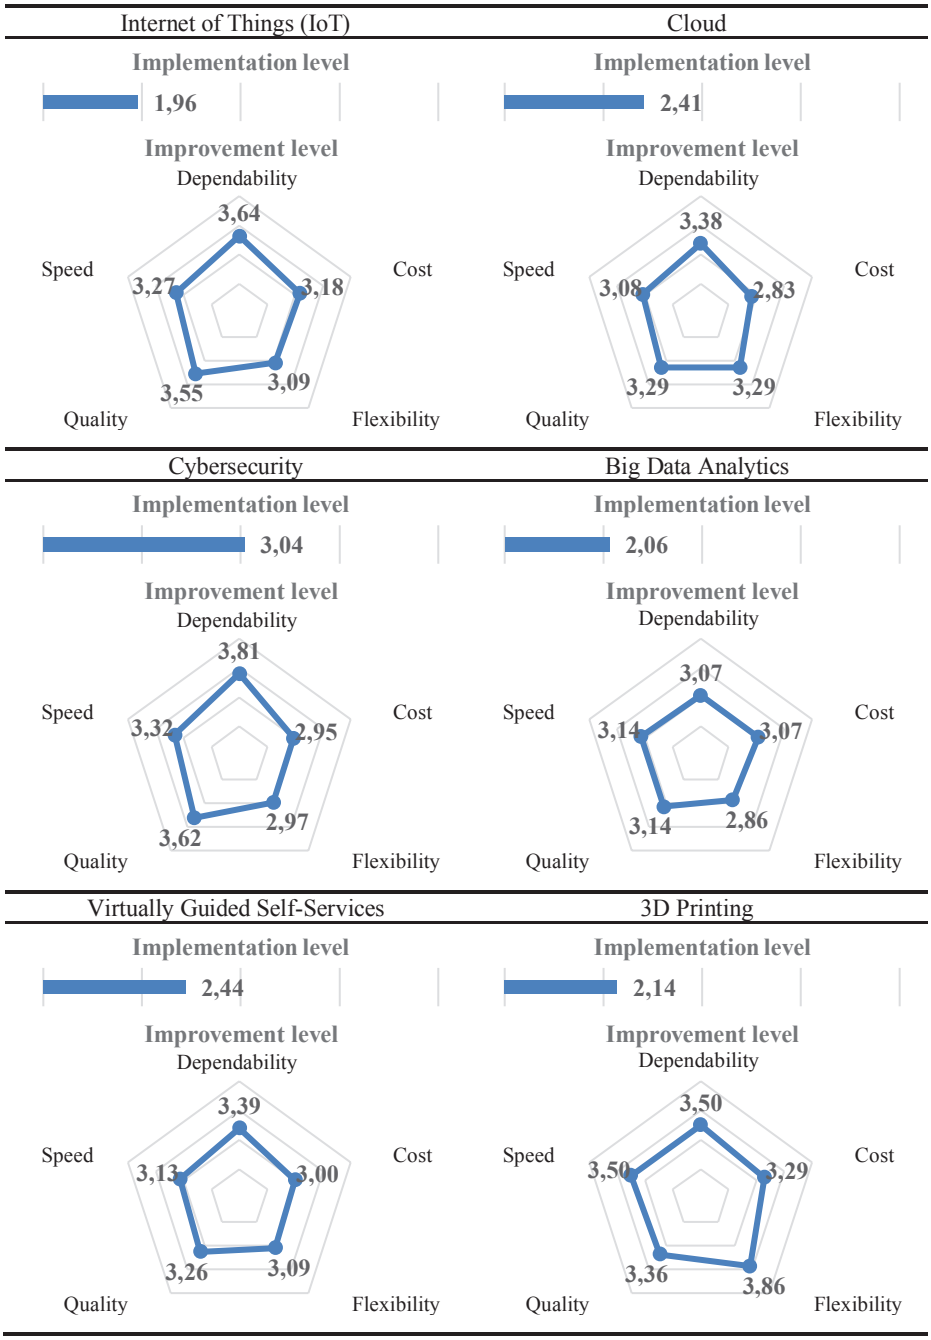

Fig. 2. Results overview

5 Conclusion

Through the presented method, it can be said that the objective of analyzing the main impacts of the Industry 4.0 technologies to the production systems was achieved, since a survey of companies of Curitiba and Metropolitan Region regarding the overall implementation level and their implication to the performance objectives could be performed. However, it should be noted that the results presented refer only to the scenario of the Curitiba Metropolitan Region, more specifically of the companies of the metal-mechanic and automotive sector and may differ from other sectors or studied regions.

As presented in the topic of results and discussion, the overall implementation level of the Industry 4.0 technologies of companies in Curitiba and Metropolitan region is low, representing that great part of the companies do not have any of the studied technologies. In addition, it also should be noted that an increase of the implementation levels according to the companies' size was observed, being the results for the large companies significantly higher comparing to other sizes of companies, representing that great part of the technologies adopted in the studied region are located in large companies. Regarding the adoption patterns, throughout the ranking presented in Table 1, was possible to identify that the technologies are being adopted mainly in terms of its necessity and complexity, being fundamental technologies for security, such as Cybersecurity, the most implemented, while more complex technologies, such as Internet of Things and Big Data Analytics, the least implemented technologies.

In relation to the improvement levels, the dependability and quality were the most improved aspects by the implementation of the technologies, which is congruent with the results obtained in previous researches related to the most considered performance objectives for technologies adoption [12]. Regarding the technologies, the 3D Printing (3,50) and the Internet of Things (3,35) presented the highest overall improvement levels, being both in the top 3 of improvements for all performance objectives. However, it should be noted that the overall improvement level results do not necessarily represent what are the best technology in terms of improvement, since the results can vary according to the context of application, which was observed with 3D Printing, that presented the highest average improvement level for cost and speed, but also one of the highest standard deviations, representing that its performance strongly depend on the context of application. Therefore, the results regarding the improvement levels, aims to support the understanding of what improvements can be achieved by adopting these technologies and what technology has a better improvement potential for each of the performance objectives based on what has been adopted by the companies of the present study.

Furthermore, it can be concluded that even with the constant adoption of Industry 4.0 technologies, the implementation levels are still low, being great part of the technologies still concentrated in the larger companies. Regarding the improvement levels, it could be observed that not all technologies have the potential to improve all the performance objectives like the Internet of Things and, if they have, the results can vary according to the context of the application, as observed with 3D Printing.

Finally, for future works, it is suggested to apply the proposed method to other regions and sectors to analyze the differences between the applications in different

scenarios. In addition, case studies are also suggested related to these adoptions, aiming to understand how that adoption occurred and the reasons for differences between regions, since there is other factors to be considered (management, internal capacities, human resources, infrastructure, interoperability, etc.) that could impact on the technologies implementation and performance, as observed in other studies [25–30].

Resumo. O presente artigo tem como objetivo mapear as tecnologias, em especial as relacionadas à transformação digital e por consequência à Indústria 4.0, que têm sido implementadas nas operações de serviços. A análise buscou identificar, além de qual tecnologia era utilizada/estudada, questões como qual o contexto em que foi aplicada, qual problema ela pretende solucionar e qual o tipo de serviço em que é aplicada. Para atender ao objetivo supramencionado, foi realizada uma revisão sistemática da literatura, composta pelas etapas de definição das bases de dados e termos e critérios de busca, busca dos estudos, eliminação de duplicados e seleção dos estudos. Assim, no portfólio de 10 artigos selecionados por meio da revisão, foram encontradas aplicações de tecnologias mais básicas, como sistemas de gerenciamento, até tecnologias mais complexas e que integram a chamada Indústria 4.0, como *Cloud Computing*, Internet das Coisas e *Blockchain*. Infere-se, através dos estudos, que as aplicações das tecnologias são realizadas com maior foco em serviços que possuem alta quantidade de informações, o que dificulta sua análise e armazenamento, e em serviços que requerem mais informações do que as disponíveis pela organização. Como contribuição da pesquisa tem-se a demonstração da possibilidade da aplicação de diversas tecnologias nas operações de serviços, com finalidades individuais diferentes e que têm sido aplicadas com frequência na indústria, e que podem trazer diversos benefícios para a prestação de serviço.

Palavras-chave: Tecnologia, Transformação Digital, Operações de serviços.

1 Introdução

A moderna indústria de serviço tornou-se uma das principais fontes de crescimento econômico mundial na maioria dos países. Uma convergência de circunstâncias tem levado as funções de Tecnologia da Informação a se tornarem mais orientadas a serviços para um melhor alinhamento com os objetivos das organizações. Exemplo disso é que as operações de serviço passaram a abranger questões como comércio eletrônico B2B, educação digital e medicina digital [1, 2].

Essas tendências geram para os setores responsáveis pela TI, tanto por parte do setor público quanto do privado, uma crescente pressão para que operem com uma base mais econômica. Também geram uma crescente dependência de informações quase em

tempo real para apoiar atividades de caráter crítico, uma necessidade de integridade de relatórios para fins de atender requisitos regulatórios mais rigorosos, e demandas mais exigentes para redução no nível de tolerância e falha na infraestrutura de TI [2].

Considetando que a engenharia empresarial é um campo de estudo multidisciplinar, que envolve conhecimento de diversas áreas, a exemplo de ciência organizacionais e tecnologia da informação [3], e tendo em vista as questões apresentadas, este artigo tem como objetivo mapear as tecnologias digitais que têm sido implementadas nas operações de serviços, com foco em identificar questões como: qual o contexto em que a tecnologia foi aplicada, qual problema ela pretende solucionar, e qual o tipo de serviço em que é aplicada.

Além desta seção introdutória, este artigo está estruturado com seções que abordam o referencial teórico necessário para o alcance do objetivo, com uma seção que aborda os aspectos metodológicos utilizados na elaboração deste estudo, e com as seções que apresentam os resultados alcançados. Finalmente, a última seção apresenta as considerações finais, sugestões de pesquisa e contribuições deste estudo.

2 Transformação digital

As tecnologias digitais têm se mostrado como um novo núcleo vital das economias modernas. Países líderes têm se posicionado de forma estratégica em relação ao tema, perante o qual governos, academia e indústrias têm se esforçado para antecipar o ritmo e a escala com que esses avanços mudarão a maneira como o mundo funciona, assim como para identificar e alavancar as oportunidades e enfrentar os desafios que esses avanços trarão [4, 5].

De forma holística, a transformação digital pode ser entendida como “as mudanças que a tecnologia digital causa ou influencia em todos os aspectos da vida humana” [6, p. 689]. No âmbito organizacional, pode ser definida como “o uso de tecnologia para melhorar radicalmente o desempenho ou o alcance das empresas” [7, p. 1]. Em suma, pode ser entendida como os efeitos combinados de várias inovações digitais que produzem novos atores, estruturas, práticas, valores e crenças, os quais mudam as regras existentes no contexto das organizações, ecossistemas e indústrias [8].

Algumas das principais tendências da transformação digital das empresas possuem relação com a digitalização de produtos e serviços, por meio da qual os produtos e serviços são enriquecidos com serviços de valor agregado ou completamente digitalizados; com a digitalização do trabalho, o que facilita o trabalho em conjunto a grandes distâncias; e com a digitalização de modelos de negócios, uma vez que as empresas precisam repensar em seus negócios para desenvolver modelos inovadores de acordo com as habilidades e competências dos funcionários [9].

A manufatura digital, conjunto de tecnoloigas utilizadas para o gerenciamento de informação que auxiliam na tomada de decisão em todo o ciclio de vida de um produto, vem ganhando cada vez mais importância no cenário de base tecnológica como uma área de conhecimento da chamada Indústria 4.0 [10].

Esse termo foi apresentado pela primeira vez em 2011, por meio de um artigo do governo da Alemanha para designar um conjunto de estratégias de alta tecnologia para 2020. Atualmente, o termo Indústria 4.0 tem sido utilizado para descrever uma nova revolução industrial, que se baseia na integração de tecnologias da informação e

comunicação e da tecnologia industrial, bem como na construção de sistemas cyber-físicos com o objetivo de tornar as fábricas digitais e inteligentes [11].

Alguns dos principais recursos relacionados à Indústria 4.0 dizem respeito à capacidade em tempo real, interoperabilidade, e integração horizontal e vertical de sistemas de produção através de tecnologias de informação e comunicação [12]. Envolve tecnologias como Internet das Coisas (IoT), serviços em nuvem, *Big Data* e *analytics*, que, dentre outros, permitem a coleta e análise de dados em tempo real, fornecendo informações úteis ao sistema de fabricação, e que compõem o chamado sistema cyber-físico [13]. Além dessas, pode-se citar ainda tecnologias como *Blockchain* e realidade aumentada [5].

3 Serviços

Gerenciar serviços é uma tarefa diferente de gerenciar a produção de bens, isso porque os serviços possuem características especiais em comparação à gestão da manufatura. A classificação tradicional de bens e serviços determina quatro principais diferenças: perecibilidade, sendo os serviços perecíveis e os produtos, por durarem um período de tempo, menos perecíveis; intangibilidade, sendo os serviços intangíveis e os produtos tangíveis; heterogeneidade, característica pertencente aos serviços, tendo em vista que cada serviço é prestado de forma diferente para cada cliente, enquanto os bens físicos são mais homogêneos, e inseparabilidade entre produção e consumo, sendo que os serviços são produzidos e consumidos simultaneamente, enquanto os bens físicos são produzidos para posteriormente serem consumidos [14].

No entanto, a importância dos serviços para as organizações varia de acordo com alguns fatores, sendo muito difícil que uma empresa não possua atividades de serviços, seja como atividade-fim principal ou complementar, ou como atividade de apoio interno. Os serviços podem desempenhar quatro diferentes papéis dentro de uma organização: 1) serviço como atividade principal da empresa, prestado diretamente ao cliente; 2) como diferencial competitivo em empresas de manufatura, os quais complementam os produtos criados pela empresa e agregam valor ao cliente, mas que não geram receitas significativas; 3) como centro de lucro para empresas de manufatura, os quais complementam os produtos, agregam valor ao cliente assim como geram receitas e lucro para a empresa; e 4) serviços como atividade interna da empresa, prestados aos clientes internos [14].

4 Metodologia da pesquisa

Para o alcance do objetivo do estudo – mapear as tecnologias que têm sido implementadas nas operações de serviço, em especial as tecnologias que caracterizam a chamada transformação digital, optou-se pela realização de uma revisão de literatura, isso porque, fundamentalmente, o avanço do conhecimento deve ser construído com base em trabalhos anteriores existentes. A revisão deve ser válida, confiável e repetível [15].

Assim, a fim de atender a esses critérios, a revisão de literatura desta pesquisa consistiu em: 1 – definição das bases de dados e termos e critérios de busca; 2 – busca

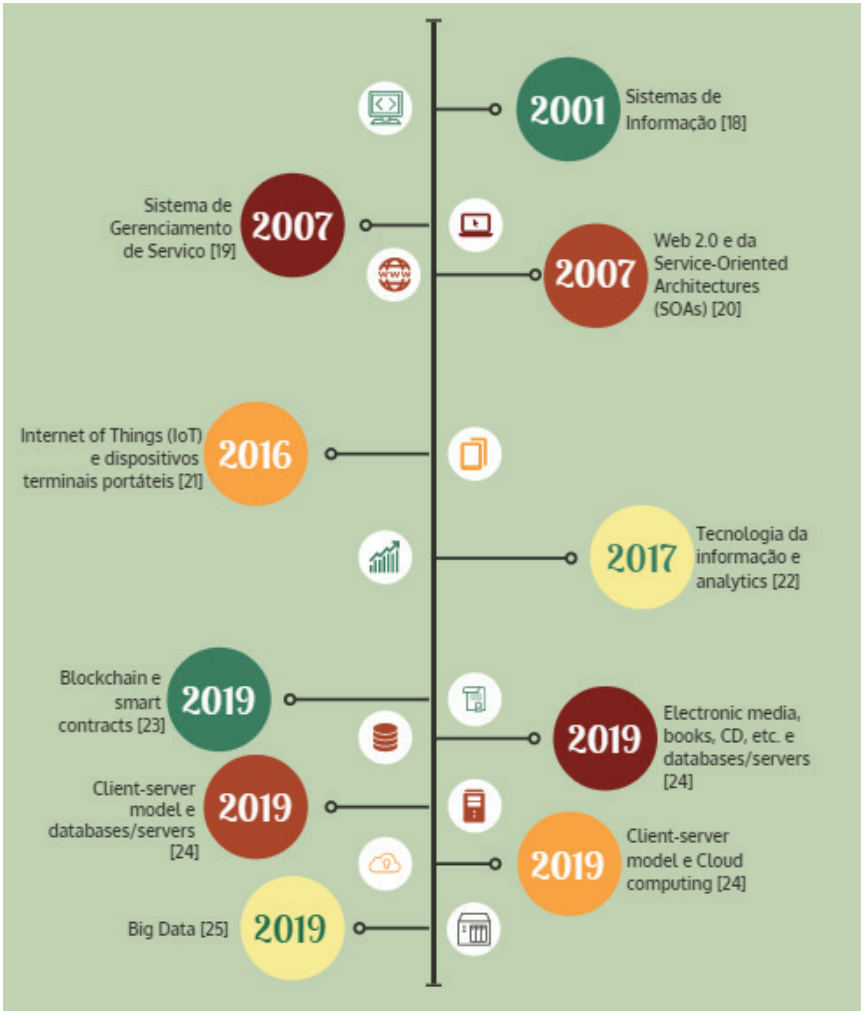
dos estudos; 3 – eliminação de duplicados e 4 – seleção dos estudos, composta por três sub-etapas: leitura do título, leitura do resumo e por fim, leitura do documento na íntegra. Em relação à primeira etapa do método, foram definidos os critérios de busca conforme apresentado na Quadro 01:

Quadro 01 – Critérios de busca

Critérios de busca		
Base de dados	*Scopus*	*Web of Science*
Tipo de documentos	Não limitado	
Ano	Não limitado	
Termos de busca (em título, resumo, palavras-chave e tópico)	*"service management" / technolog* / digital*	
Operadores	*AND*	
Idioma	Não limitado	
Pesquisa no banco de dados		
"service management" AND technolog AND digital*		
Resultados		
Portfólio inicial	127	37
Sem duplicados	137	
Portfólio final	09	

Fonte: Elaborado pelos autores (2020).

Para a busca dos artigos, realizada em meados de dezembro de 2019, foram selecionadas as bases de dados Scopus, por ser considerada o maior banco de dados de resumos e citações da literatura com revisão por pares: revistas científicas, livros, processos de congressos e publicações do setor [16], e a base Web of Science, por justificativa semelhante, considerando a abrangência desta base ao fornecer acesso a cerca de 12 mil períodos, de todas as áreas do conhecimento [17].



O Quadro 01 também apresenta os resultados das buscas. De um portfólio de 137 artigos não duplicados, foi possível obter, após a filtragem pela leitura dos títulos, pela leitura do resumo e por fim, pela leitura integral dos estudos que passaram pelos filtros anteriores, um portfólio de 09 artigos. Para a seleção dos artigos, seguindo os passos descritos, foram levados em consideração artigos que continham em seu conteúdo o estudo da aplicação de uma tecnologia de informação e comunicação com fins a proporcionar solução a problemas ou melhorias na prestação de algum serviço.

Os artigos que compõem o portfólio obtido com a aplicação do método foram analisados, por meio de análise de conteúdo, com vistas a identificar questões como: qual a tecnologia utilizada/estudada; qual o contexto em que foi aplicada, qual problema ela pretende solucionar, quais problemas ainda precisam ser solucionados, e qual o tipo de serviço em que é aplicada. Porém, nem todos os artigos disponibilizavam todas as informações desejadas, e as informações disponíveis são expostas na seção a seguir.

5 Resultados e discussões

O relacionamento entre TI e operações de serviços não é recente, e embora tenha se intensificado com o advento da chamada Transformação Digital, sistemas de gestão de serviços baseados em tecnologia da informação já vinham sendo usados há algum tempo. A Figura 01 busca apresentar um histórico do estudo de tecnologias aplicadas aos serviços. Os dados que compõem a figura foram extraídos dos artigos do portfólio, sendo a representação temporal baseada no ano de publicação do artigo, e as tecnologias, o que o respectivo artigo estuda ou apresenta como tecnologia.

Figura 01: Tecnologias estudadas para aplicação nas operações de serviços com base no ano do estudo

Fonte: Elaborado pelos autores (2020).

Com isso é possível verificar que no início dos anos 2000 a área de tecnologia da informação já era estudada como forma de auxiliar, por meio de sistemas, o gerenciamento de serviços, evoluindo para a aplicação de tecnologias mais complexas ao final da segunda década, a exemplo do *Blockchain* e *Cloud Computing*. Assim, conforme apresentado na Figura 01, a primeira tecnologia identificada no portfólio foi o Sistema de Informação no contexto da enfermagem. Neste, [18] descrevem o desenvolvimento e a avaliação de um Sistema de Informação para a Administração de Serviços de Enfermagem que classifica todas as informações relacionadas ao pessoal de enfermagem e ajuda a administração a lidar com os dados de enfermagem apropriados [18].

A segunda tecnologia apresentada refere-se à um Sistema de Gerenciamento de Serviços. Em 2007, com o objetivo de atender a todos os requisitos necessários para criar um sistema de governo eletrônico em torno dos cidadãos e alcançar a população o máximo possível para superar o fosso digital em territórios e comunidades em desvantagem, [19] apresentam um Sistema de Gerenciamento de Serviços.

Os principais problemas enfrentados por comunidades desfavorecidas (na Itália) frente à necessidade de interação com as administrações públicas e os governos, eram questões relacionadas à burocracia, procedimentos ambíguos, desintegração funcional, estruturas de autoridades vagas e/ou sobrepostas, e fragmentação de informações [19].

Porém, no que tange a prestação de serviços eletrônicos pelo governo italiano, onde a pesquisa teve seu foco, e o desenvolvimento de ofertas integradas de serviços administrativos, a Itália promovia um processo para renovar o setor de Administração Pública (AP) usando tecnologias de TIC para reduzir custos e melhorar a satisfação dos cidadãos e das empresas, e embora, em alguns casos, tenham sido introduzidas soluções interessantes e inovação tecnológica, vários problemas ainda estavam em aberto, a exemplo da padronização das tecnologias envolvidas, à interoperabilidade entre diferentes administrações públicas, e a introdução de soluções econômicas [19].

Para amenizar alguns desses problemas, os autores apresentam uma arquitetura composta por um repositório, o qual contém o catálogo de serviços e centraliza as informações. Cada Services Management System, como por exemplo, o sistema do governo eletrônico federal, estadual e municipal, operam de forma independente, mas exploram o mesmo catálogo e, em seguida, usam os mesmos serviços [19].

Também em 2007, [20] busca por meio de seu estudo contrastar a internet da época com a internet de serviços prevista, sob a perspectiva de três categorias: partes interessadas, aplicativos e tecnologia. Por meio do artigo, o autor elabora como os princípios e tecnologias da Web 2.0 e da Service-Oriented Architectures (SOAs), podem ser usados para facilitar o surgimento de uma "SOA global". O autor propõe uma arquitetura de referência da Internet dos Serviços (IoS), que considera a Internet como uma plataforma global para a recuperação, combinação e utilização de recursos interoperáveis. Essa Internet de última geração permitirá que usuários e empresas privadas colaborem sem problemas através do uso de serviços eletrônicos interoperáveis e, assim, impulsionar a industrialização de serviços intensivos em informações [20].

Em 2016, a temática de aplicação de tecnologias digitais e prestação de serviços foi abordada por [21]. Neste, os autores apontam que o turismo rural desempenha um papel cada vez mais importante na proteção cultural, desenvolvimento econômico, aumento da renda dos agricultores e desenvolvimento rural sustentável. Porém, apresenta alguns

problemas como pontos cegos no canal de serviço, conteúdo de serviço unilateral simples e prestação de serviços passiva, assim como as aplicações de tecnologia nesse tipo de serviço são muito restritas e apresentam problemas nos seguintes aspectos:

- os canais de serviço não são suficientes: como as fazendas geralmente são muito grandes, é difícil e demorado fornecer serviços pelos métodos tradicionais, gerando possíveis pontos cegos;
- é difícil obter o conteúdo do serviço: há muitos tipos de informações em uma fazenda, como nomes de vegetais, métodos de plantio, métodos comestíveis, ambiente de crescimento e assim por diante. Mesmo perguntando às equipes de serviço, a resposta geralmente é simples, unilateral e falta de confiabilidade científica razoável;
- os serviços são fornecidos apenas nos métodos passivos: o serviço vem das demandas dos consumidores, como informações, compras e entretenimento. Isso significa que se não há demandas, não há serviço. Esse tipo de método de serviço é passivo, único e falta de individualidade e serviço de iniciativa.

Para auxiliar na resolução dessas questões, os autores [21]. propõem um sistema chamado Intelligent Entertaining Farm Management System (IEFMS), que tem como base a *Internet of Things* (IoT) e dispositivos terminais portáteis.

Em suma o sistema possibilita:

- (1) Gerenciamento dinâmico digital: onde, com base em uma variedade de aplicações da tecnologia IoT, é possível atingir o monitoramento em tempo real do ambiente das fazendas, promovendo gerenciamento de inovação em tecnologia agrícola, e permitindo analisar as preferências dos passeios de acordo com os dados coletados das ações dos turistas;
- (2) Serviços ativos e personalizados: atendendo às necessidades de usuários individuais, é possível alcançar experiências, processos e monitoramento personalizados, usando a tecnologia de identificação pessoal e a política de acesso. Para isso, serviços de exibição de recursos de informação, mensagens de texto e serviços de envio ativo de jornais móveis foram fornecidos de acordo com o processo de personalização do usuário, usando dispositivos de IoT;
- (3) Modo Experiência Multidimensional: com base no serviço de informações multimídia e nos traços do serviço de localização, é proposto um modo de experiência multidimensional desenvolvido com base em uma grande quantidade de recursos de informação, como vídeo, áudio, imagens, texto, localização turística, pista de turismo e assim por diante [21].

Em 2017 um exemplo de estudo que aborda as temáticas aqui estudadas foi desenvolvido por [22]. Tendo em vista a crescente população de pacientes em todo o mundo e a crescente demanda por serviços de saúde de alta qualidade, o que tem imposto severas restrições de capital, recursos e capacidade humana aos hospitais, a adoção de serviços de internação que visam melhorar o planejamento de fluxos de trabalho em todo o hospital usando técnicas de tecnologia da informação (TI), gerenciamento de operações (OM) e análise avançada de dados (DA) tem sido identifica com frequência na prestação de serviços de saúde.

Considerando este contexto, [22] propõem uma bancada digital unificada para ajudar várias partes interessadas a melhorar o planejamento e a alocação de escassos recursos hospitalares, a fim de melhorar a transparência e a eficiência dos serviços de internação. A plataforma utiliza tecnologia da informação, gerenciamento de operações e análise de dados para apoiar não apenas os tomadores de decisão da área de saúde, mas também

especialistas em análise e sistemas de informação da área de saúde, bem como educadores desses tópicos.

Em 2019, tendo em vista o fato de que o banco digital, como um serviço essencial, pode ser difícil de acessar em regiões rurais remotas, onde a conectividade de rede está indisponível ou intermitente, [23] propõem um esquema de pagamento digital baseado em *Blockchain* que pode fornecer serviços confiáveis sobre redes não confiáveis em regiões remotas, considerando um cenário em que exista uma estação base administrada pela comunidade e que fornece conectividade de rede local confiável, enquanto se conecta intermitentemente à Internet mais ampla.

Os autores [23] propõem implementar cadeias de blocos para processamento de transações, tendo em vista que elas podem ser operadas por indivíduos sem nenhuma autoridade centralizada. Ainda, o cenário proposto se encaixa nas condições de uma *Blockchain* com permissão pública. Para rastrear e gerenciar a operação do sistema, os operadores de pagamento criam um Contrato Inteligente para registrar tipos de contas, saldos de usuários tanto na moeda fiduciária quanto na moeda Token, além de distribuir recompensas de mineração.

Ou seja, por meio da proposição dos autores, aproveitam-se as garantias de verificação distribuída da tecnologia *Blockchain* para verificação de transações financeiras e alavanca-se contratos inteligentes para gerenciamento seguro de serviços [23].

Também em 2019, [24] apresentam que a mudança no papel do setor de tecnologia da informação dentro das organizações, de um setor responsável por "dominar e dar suporte à tecnologia" para um setor responsável por "melhorar e apoiar continuamente os processos de negócios dos clientes da empresa" possibilitou a redução de problemas como mal-entendidos e insatisfação de funcionários.

Com base nisso, [24] revisam e comparam a literatura sobre práticas de Information Technology Service Management (ITSM) em organizações da administração pública, do setor privado e em bibliotecas, a fim de identificar, dentre outros, até que ponto as práticas de ITSM são diferentes nos setores estudados.

Assim, a partir da revisão da literatura, os autores [24] apresentam algumas características relativas ao ITSM de cada organização. No comércio (setor privado), as propriedades subjacentes ou estrutura dos componentes digitais utilizadas são Client-server model e *Cloud Computing*, e os fatores que influenciam a implementação das diretrizes de ITSM dentro desse tipo de organização são: funcionários (motivação), estratégia corporativa (treinamento da equipe, conhecimento específico do departamento, etc.), os processos, clientes, organização e sua cultura (objetivo da organização, mentalidade e cultura de funcionários individuais) e meio ambiente e infraestrutura.

No setor público, as propriedades de estrutura utilizadas são Client-server model e Databases/servers, e os fatores que influenciam o ITSM são: o ambiente regulatório (leis e regulamentos), a dinâmica do portfólio de serviços (governo eletrônico, por exemplo), o controlador, a orientação ao serviço (por exemplo, entendimento do cliente), a proteção e segurança de dados e o desenvolvimento de pessoal (por exemplo, negociação coletiva e lei da função pública). No caso das bibliotecas, por sua vez, as propriedades de estrutura utilizadas consistem em electronic media, books, CD, etc. e databases/servers, e os fatores de influência são, por exemplo, leis e regulamentos, usuários (estudantes, professores etc), a dinâmica do portfólio de desempenho (por

exemplo, governo eletrônico), os funcionários, a proteção e segurança de dados e o licenciamento [24].

Em 2019 também, [25] apresentam um estudo com o objetivo de avaliar aplicações de Smart Cities sob a ótica da incorporação do *Big Data* na gestão de serviços e na tomada de decisões. Os autores apresentam o *Big Data* como uma resposta aos governos, afim de que estes consigam entender, classificar e utilizar grandes conjuntos de informações gerados pela digitalização da vida social.

A aplicação do conceito de *Smart City*, ou seja, estabelecer uma Cidade Digital Estratégica, carrega consigo o problema do aumento exponencial de dados. Esses dados, consequentemente são o cerne dos serviços prestados por todos. Assim, as informações são essenciais nas Smart Cities para gerir os recursos de uma cidade. E é nesta perspectiva que os autores apresentam a tecnologia *Big Data*, como uma ferramenta para manipular esse volume e variedade de dados no menor tempo possível [25].

Com todo o exposto e considerando que os artigos foram analisados com vistas a identificar questões como qual a tecnologia utilizada/estudada e qual problema ela pretende solucionar, a Quadro 02 apresenta as principais informações encontradas.

Quadro 02: Tecnologias e características de aplicação

TECNOLOGIA	**CONTEXTO**	**PROBLEMA A SER SOLUCIONADO**	**TIPO DE SERVIÇO**	**AUTOR**
Sistema de Informação	Serviços de enfermagem	Disponibilidade de informações confiáveis, válidas e qualitativas.	Atividade interna	[18]
Sistema de gerenciamento de serviços	Governo eletrônico	Burocracia, procedimentos ambíguos, desintegração funcional, estruturas de autoridades vagas e/ou sobrepostas, fragmentação de informações, padronização das tecnologias envolvidas, interoperabilidade entre diferentes administrações públicas, e a introdução de soluções econômicas	Atividade principal	[19]
Web 2.0 e Service-Oriented Architectures (SOAs)	Serviços intensivos em informação	Alta variabilidade, quantificação difícil e terminologia informal	-	[20]
Internet of Things (IoT) e dispositivos terminais portáteis	Turismo	Pontos cegos no canal de serviço, conteúdo de serviço unilateral simples e prestação de serviços passiva	Atividade principal	[21]
Tecnologia da informação (TI) e análise avançada de dados – *analytics*	Hospital	Transparência, eficiência dos serviços e tomada de decisão	Atividade interna	[22]

Blockchain e smart contracts	Banco digital em regiões rurais remotas	Serviços confiáveis sobre redes não confiáveis em regiões remotas	Atividade principal	[23]
Client-server model e *Cloud Computing*	Comércio	Não especificado	-	[24]
Client-server model e Databases/server	Setor público	Necessidade da manutenção de registros e eficiência econômica	Atividade interna	[24]
Electronic media, books, CD, etc. e *databases/servers*	Bibliotecas	Garantir bom atendimento ao cliente	Atividade principal	[24]
Big Data	Setor público	Aumento exponencial de dados no estabelecimento de *Smart City* (Cidade Digital Estratégica)	Atividade principal	[25]

Fonte: Elaborado pelos autores (2020).

Em análise ao Quadro 02, é possível inferir que o setor da saúde, por meio de hospitais e serviços de enfermagem e o setor público, por meio de portais de governo e estabelecimento de estratégias digitais receberam considerável atenção no que se refere à aplicação de tecnologias digitais para solução de problemas. E embora não se tenha encontrado citações das técnologias em duplicidade nos artigos, pode-se verificar tendências de questões nas operações de serviços que carecem de apoio e que podem ser aprimoradas por meio das tecnologias digitais, em especial as tecnologias que tem gerado a chamada Indústria 4.0, como *Blockchain* e *Internet of Things*.

Uma dessas tendências é a aplicação das tecnologias em serviços que possuem pouca informação, e que a falta dessa informação pode gerar ineficiência no serviço e, no caso do setor privado, perda de competitividade e redução de lucros, a exemplo da aplicação de IoT no serviço de turismo. Outra verificação que pode ser feita é o uso de tecnologias onde o excesso de informação traz dificuldades para as organizações, o que vai desde a perda de informações à dificuldade no processo de tomada de decisão. Esse excesso de informações é identificado por meio da aplicação de tecnologias de armazenamento como servidores e repositórios, assim como *Cloud Computing* e tecnologias de manipulação de dados, como o *Big Data*.

Também pode-se inferir que o uso da tecnologia *Blockchain*, tal como sua primeira aplicação, a qual foi realizada para na criptomoeda Bitcoin, também foi estudada para ser aplicada em serviços financeiros, embora possa ser aplicada a qualquer transação de ativos digitais realizada online, tendo o potencial de se tornar uma fonte significativa de inovações disruptivas na área de negócios e gestão [26, 27].

6 Considerações finais

Este estudo teve como objetivo mapear as tecnologias, em especial as relacionadas à transformação digital e por consequência à Indústria 4.0, que têm sido implementadas nas operações de serviços. Como objetivo complementar, buscou-se identificar, além de quais as tecnologias utilizadas, questões como: qual problema essa tecnologia pretende solucionar e em que tipo de serviço ela é aplicada. Embora parte das

informações buscadas não tenham sido encontradas nos artigos do portfólio, ainda foi possível identificar em que setor as tecnologias têm sido aplicadas e quais questões elas têm visado solucionar.

Na Indústria 4.0, devido às mudanças tecnológicas, a maneira como a manufatura digital é usada mudou drasticamente. Muitas das tecnologias utilizadas não são novas, mas as formas de integração, melhorias no uso e uso conjunto mudaram o campo da manufatura digital, abrindo novos desafios e oportunidades [28].

Assim, com base em estudos disponíveis na literatura, foi possível relacionar a aplicação de tecnologias digitais que visam solucionar questões que abrangem tanto o excesso de informações, quanto a baixa quantidade de informações. Isso é verificado por meio das tecnologias que são aplicadas, como no caso de repositórios e serviços em nuvem, a exemplo do *Cloud Computing*, utilizados para armazenamento de informações, e do uso de *analytics* para apoio na análise de informações e tomada de decisão, assim como pela aplicação de tecnologias como o IoT, capazes de fornecer novas informações.

Conforme apresentado na Figura 01, pode-se inferir que a aplicação das tecnologias de informação e comunicação no âmbito da prestação de serviços evoluiu da aplicação de sistemas de gerenciamento a tecnologias que têm sido aplicadas com intensidade na chamada Indústria 4.0, como computação em nuvem e *Blockchain*, o que possibilita entender que o campo das operações de serviços pode ser aprimorado utilizando-se as tecnologias atuais, ainda com aplicações predominantes na manufatura. A partir da Quadro 02 algumas questões podem ser identificadas, conforme descrito na seção de Resultados e Discussões, a exemplo das tendências de aplicação das tecnologias, e que os estudos têm sido direcionados com mais frequência aos setores da saúde e público, por meio de práticas de governos.

Considerando o exposto, entende-se que a principal contribuição desta pesquisa reside na demonstração da possibilidade da aplicação de diversas tecnologias, com finalidades individuais diferentes e que têm sido aplicadas com frequência na indústria, que podem ser aplicadas e trazer benefícios para as operações de serviço. Porém, embora a pesquisa tenha apresentado contribuições, considera-se válida a hipótese de realização de outros tipos de estudo, como empírico ou qualitativo em profundidade, a fim de entender as razões pelas quais as tecnologias têm sido adotadas ou não, percepções, dificuldades, dentre outros, assim como obter mais exemplos de uso de tecnologias digitais em serviço, permitindo mapear de forma mais ampla as tecnologias que têm sido aplicadas, e validando as informações aqui apresentadas.

Resumo: Esse estudo tem objetivo de analisar a produção científica sobre modelos de maturidade aplicáveis para a cadeia de suprimentos inteligente – Smart Supply Chain, publicada em artigos internacionais entre 2016 e 2020. Realizou-se uma revisão sistemática da literatura a respeito desse tema, com os artigos sendo pesquisados nas bases de dados: Scopus, Science Direct e Web of Science a partir das descrições: Maturity Model, Smart Supply, Connected Supply, Digital Enterprise, Industry 4.0.. As publicações analisadas descrevem sobre modelos de maturidade para logística 4.0, a necessidade de maturidade do gerenciamento da cadeia de suprimentos, impacto da indústria 4.0 e da transformação digital no compartilhamento de informações e na tomada de decisões em toda a cadeia de suprimentos, estado da arte da literatura existente da cadeia de suprimentos digital em detalhes e por fim estudam e exploram o status das correntes e as questões para conceituar e discutir as características da cadeia de suprimentos inteligente. Assim, a partir desses achados, observou-se uma lacuna para dirigir estudos visando a mensuração do modelo de maturidade a ser concebido, considerando como atributos recomendações de uso de tecnologias emergentes, sob a ótica da cadeia de suprimentos inteligente.

Palavras-chave: Maturity Model, Smart Supply, Connected Supply, Digital Enterprise, Industry 4.0.

1 Introdução

Os autores [12] apontaram em seus estudos, que na medida em que as cadeias de suprimentos tradicionais estão passando por um processo de transformação, em função da inserção de ferramentas tecnológicas para a tomada de decisão, a cadeia de suprimentos inteligente apresenta oportunidades para gerar: (i) redução de custos e (ii) melhorar a eficiência.

(i) A redução de custos é fator primordial para manter a competitividade das empresas, pois apenas a eficiência dos custos de produção não é por si só, um fator de vantagem competitiva [13].

(ii) A melhoria da eficiência pode ser mensurada através de níveis de modelos de maturidade, que é transferir a filosofia da melhoria de processos do nível do processo para o nível da empresa e, além disso, para o nível da cadeia de suprimentos [4].

O conceito de maturidade pode ser explicado, de acordo com [15], como sendo uma forma de organização de evolução de processos, através de patamares, que são estágios de desenvolvimento. Na medida em que há uma evolução no processo, através de padrões de comportamento e de desempenho robustos quanto à forma e seu conteúdo, o modelo de maturidade se torna aplicável para o desenvolvimento e a melhoria contínua dos negócios [17] com o potencial de ser replicável para vários propósitos distintos. Assim, os modelos de maturidade são ferramentas adequadas para: (i) documentar o status quo atual e futuro; (ii) desenvolver uma visão corporativa para a excelência do processo e (iii) fornecer orientação sobre esse caminho de desenvolvimento [1].

Cadeia de suprimentos inteligente (Smart Supply Chain), é uma cadeia instrumentada, interconectada, inteligente [18], [12] e também automatizada, integrada e inovadora [12]. O uso de sensores, etiquetas RFID e medidores com entidades e ativos de negócios, sistemas de TI, produtos e outros objetos que estão todos conectados e; inteligente: tomam decisões ideais em larga escala para aperfeiçoar o desempenho, através de ferramentas de business intelligence, de acordo com [12], [18] e [7].

Outra característica da cadeia de suprimentos inteligente é a forma ágil e sustentável no seu fluxo de comunicação [19], através da absorção de inteligência incorporada, acompanhando a evolução da Indústria 4.0 para a cadeia de suprimentos, com suas ferramentas de digitalização, automatização, transparência, mobilidade, modularização, redes de colaboração e socialização [20].

A autora [19] explica que isso ocorre devido à redução de custos e o avanço tecnológico e de confiabilidade das tecnologias de sensores, por exemplo, o que faz com que cada processo ou atividade possa ser mensurável. Dessa forma, podem-se criar redes de sistemas interconectados não somente em cadeias de fornecimento com outros fornecimentos, mas também com sistemas de transporte, financeiros, redes de distribuição de energia elétrica. Ainda para [19], com essa incorporação, a gestão da cadeia de suprimentos pode progredir de apoiar as decisões de delegação e de previsão para quais decisões devem ser realizadas, de forma inteligente.

Abaixo, apresentamos a figura 1, onde sintetizamos o conceito de cadeia de suprimentos inteligente – smart supply chain, conforme [18], [12], [19] e [20] e o entendimento dos artigos estudados sob esse tema.

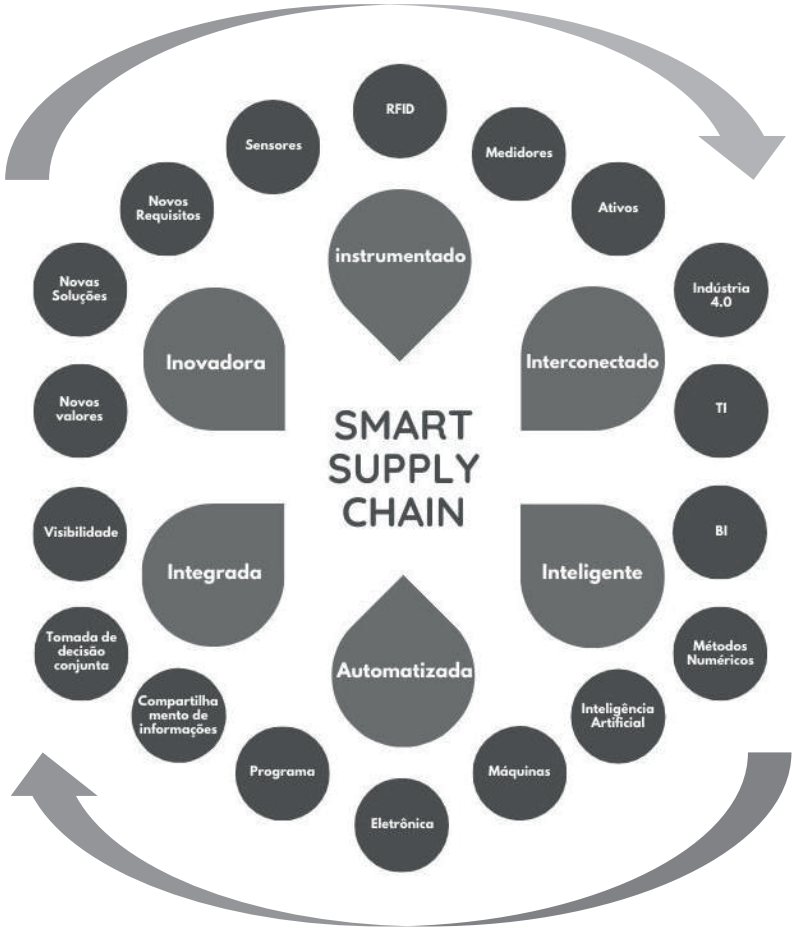

Figura 1 – Conceito de Smart Supply Chain.

Fonte: Autores (2020), adaptado de [18], [12], [19] e [20]

O objetivo deste artigo é fazer uma pesquisa sobre os estudos feitos e os principais tópicos que compõem modelos de maturidade associados à cadeia de suprimentos inteligente publicados nos principais jornais e periódicos acadêmicos no período de 2016 a 2020. Como consequência, uma das contribuições deste trabalho é apresentar tópicos de pesquisa na área que ainda precisam ser explorados e elencar os principais resultados encontrados nas pesquisas desenvolvidas até então.

2 Revisão de Literatura sobre Modelos de Maturidade na Cadeia de Suprimentos Inteligente

Nesse tópico, apresentaremos os trabalhos existentes na literatura nos últimos cinco anos, assim como serão exibidos os modelos de maturidade da literatura. Três pontos serão apresentados: (i): método de estudo; (ii) literatura acadêmica e (iii) principais pontos de contribuição para o tema, explicados conforme afigura da trilha de estudos abaixo:

Figura 2 – Trilha do estudo.

2.1 Método do estudo

Duas dimensões foram utilizadas para classificar os artigos analisados:

i) Dimensão do período da busca dos últimos cinco anos. As bases de dados consultadas foram: Scopus, Web of Science e Science Direct; utilizando as seguintes palavras chave: Maturity Model, Smart Supply, Connected Supply, Digital Enterprise, Industry 4.0. Essas palavras chave foram combinadas aleatoriamente, para gerar combinações diferentes. O sufixo

de referência utilizado foi o operador AND em todas as combinações. Dessa forma, obtemos a busca com as duas palavras-chave simultâneas na relação de artigos a serem buscados nas bases pesquisadas.

Tabela 1. Relação de artigos localizados nas bases de dados

Base	Keywords	2020	2019	2018	2017	2016	∑
Scopus	Smart Supply AND Industry 4.0	11	71	63	28	17	190
Scopus	Supply 4.0 AND Connected Supply	02	23	14	14	11	64
Scopus	Digital Enterprise AND Smart Supply	0	14	16	8	7	45
Scopus	Maturity Model AND Supply Chain 4.0	0	1	8	2	0	11

ii) Dimensão da metodologia empregada para detecção do nicho da pesquisa: o uso da metodologia CARS – Creating a Resource Space – de [6]. Esse método consiste detectar a pesquisa em três blocos:

(a) **Estabelecimento do território da pesquisa**: Emprego de palavras-chave de acordo com os assuntos sobre cadeia de suprimentos inteligente em suas bases de dados, como já citado anteriormente. Além disso, criamos um espaço de busca entre 2016 a 2020, por ser um tema recente.

(b) **Estabelecimento do nicho da pesquisa**: conforme a **Tabela 1**, 594 artigos foi localizada. Foram criados critérios de inclusão e exclusão para determinar os artigos que seriam selecionados para o estudo. A exclusão de publicações não relevantes de acordo com o JCR – Journal Citation Report < 1 e análise da leitura de 51 resumos dos artigos completos. Após esse processo, foram selecionados artigos, de acordo com a aderência ao tema da pesquisa. Assim, estes artigos que tratavam do tema cadeia de suprimentos inteligente e modelos de maturidade na cadeia de suprimentos, foram estudados 10 artigos na íntegra, mas de forma isolada.

(c) **Ocupando o nicho da pesquisa:** dessa forma, ao associar os estudos de métodos para mensurar o modelo de maturidade, somados aos estudos de cadeia de suprimentos inteligente, ocupamos o nicho da pesquisa, que será apresentado mais adiante.

2.2 Literatura acadêmica sobre o tema

2.2.1 Conceito de Modelos de Maturidade

Os primeiros estudos envolvendo modelos de maturidade ocorreram na área de Engenharia de Software [8] e na área de Qualidade, com o grid de maturidade de Crosby [9]. Os modelos de maturidade servem para avaliar o nível de desenvolvimento das capacidades de uma organização em relação a um domínio [10], através da evolução de patamares, que são estágios de desenvolvimento [15]. Assim, é uma metodologia que possui por objetivo uma linha de crescimento para atingimento da excelência na organização.

Na medida em que há uma evolução no processo, através da avaliação do padrão de desempenho da organização, modelos de maturidade são ferramentas para promover o desenvolvimento e a melhoria continua dos negócios [17], sendo o Capability Maturity Model (CMM) desenvolvido no início dos anos 1990 e que evoluiu para Capability Maturity Model Integration [17], o que foi para os autores [11], um estudo disseminador do uso da ferramenta para várias áreas do conhecimento.

A estrutura do CMMI é baseada em cinco níveis de maturidade e incluem ainda em suas categorias atributos comuns (tipos de atividades) e qualificadores (atividades) [11]. Dessa forma, pela sua natureza genérica de apresentação, várias áreas do conhecimento passaram a utilizar o modelo de maturidade para avaliar a evolução de processos.

Posteriormente, outros modelos foram criados outros modelos de maturidade, como CSC Framework, Business Process Orientation Maturity Model (BPOMM) e Supply Chain Management Maturity Model (SCMMM) [21]. Esses modelos possuem cinco níveis também, que se equivalem aos apresentados na **Tabela 2 –** Níveis de Maturidade.

Tabela 2. Níveis de Maturidade – CMMI

Níveis	Qualificadores
Inicial	Poucos processos são definidos
Gerenciado	Processos básicos são definidos
Definido	Processos documentados e padronizados
Nº Gerenciado	Processos numericamente controlados
Otimização	Processos em melhoria contínua

Fonte: Adaptado de [11]

Tratando de maturidade na cadeia de suprimentos, o conceito de maturidade tem sido aplicado na cadeia de suprimentos como um método de avaliação e um modelo de melhoria contínua no atingimento dos objetivos do negócio [21]. Portanto, da mesma forma que os demais modelos de maturidade apresentam um modo genérico de estrutura, mas a sua estrutura de atributos muda conforme a necessidade de determinar o nível daquilo que está sendo avaliado.

2.2.2 Apresentação dos Modelos de Maturidade da Cadeia de Suprimentos na Literatura

Apresentamos na Tabela 3, uma amostra dos modelos de maturidade estudados. Preliminarmente, interessante observar que 80% da amostra analisada, há presença de cinco níveis de maturidade, assim como os atributos possuem sua proposta de forma semelhante, que denominamos como genéricos sobre os modelos.

Tabela 3. Amostra dos artigos que tratam sobre modelos de maturidade, conforme os critérios de busca desse estudo

Autor / Ano	Níveis	Atributos Genéricos
[2]	7	1 - agregação de valor; 2 – encanto; 3 – relações com fornecedores; 4: envolvimento; 5 – gerenciar custos; 6 – melhoria contínua e 7 – desenvolver pessoas
[5] [22] [21] [1] [12] [11]	5	1 – inicial; 2 – padronização; 3 – definindo; 4 – gerenciado; 5 – melhoria contínua.
[23] [24]	3	1 – custos e estrutura; 2 - gestão dados e tática; 3 – alta liderança e analytics

Fonte: Autores (2020)

Para [2], os sete princípios descritos apresentam processos fundamentais para a implantação eficiente de uma gestão da cadeia de suprimentos. A estes sete princípios, o autor denominou de níveis, no qual a partir de cada nível superado, a organização tende a obter um funcionamento equilibrado ou "maduro" como próprio autor citou dentro de uma cadeia de suprimentos interdependente. Assim, [2] apresenta os níveis e atributos: primeiro nível: competir através de valores superiores em termos de lucro e de volume de negócios, visando atividades de agregação de valor financeiro e combate a desperdício, passando por estreitar relações com fornecedores, gerenciar os custos e os riscos associados e desenvolver a melhoria contínua, para que por fim, em seu último dos sete níveis apresentados, o autor cita em desenvolver, treinar pessoas dentro da cadeia de suprimentos.

Para o nível de maior incidência da pesquisa, os cinco níveis de maturidade foram definidos na etapa inicial como um entendimento do status quo atual em relação as práticas realizadas internamente na organização para obter um mapeamento da

integração entre as áreas da cadeia de suprimentos e de seus clientes, para posteriormente desenvolver um plano escalonado para aumentar suas competências internas para reposicionamento do fluxo de comunicação e de relacionamento entre as áreas envolvidas, conforme [21], [1], [12] e [11]. Na medida que apresenta uma evolução palitativa para as demais etapas, visa a padronização de rotinas e de processos de comunicação e de estreitamento de relações já num patamar intermediário de maturidade [22] de forma a controlar a flexibilidade entre empresas junto com seus sistemas de TI, de forma a permitir a troca de informações e eventualmente o replanejamento conjunto entre clientes e fornecedores, integrando com dados internos (por exemplo, capacidades, pedidos, vendas, previsões) [22]. Uma vez essas práticas e processos definidos, são sistematicamente gerenciados através da continuidade de otimização dos processos de modo a garantir a melhoria contínua [5] da cadeia de suprimentos.

Importante salientar, conforme [12], que a cadeia de suprimentos inteligente como o novo sistema de negócios interconectado que se estende desde aplicações isoladas, locais e únicas empresas até implementações inteligentes sistemáticas de toda a cadeia de suprimentos. Para [12] ainda comentam que a cadeia de suprimentos inteligente deve possui a maioria dos recursos discutidos acima, incluindo a suas respectivas tecnologias como IoT, máquinas e infraestrutura inteligente, e recursos como interconectividade, permitindo totalmente a coleta de dados e a comunicação em tempo real em todas as etapas da cadeia de suprimentos, tomada de decisão inteligente e processos eficientes e responsivos para melhor atender os clientes. Dessa forma, as atividades apresentadas aqui até então, de acordo com o escopo do estudo, deverão ser compreendidas na forma "o que fazer" para determinar os níveis de maturidade, no entanto, "o como fazer" as atividades, ou seja a operacionalização delas, remetem aos sistemas provenientes do smart supply chain.

Os autores [23] e [24] citam três níveis de maturidade – inicial, intermediário e final, remetendo-os aos mesmos pontos dos modelos de cinco níveis, onde há um agrupamento de níveis intermediários (dois, três e quatro) numa única etapa, porém há uma alteração de foco em gestão de dados e do maior envolvimento do nível tático e operacional nos processos, onde o nível de melhoria contínua, mais comumente apresentados nos outros modelos de maturidade, entra em evidência a visão de analytics [24]. Assim, compreendemos que essa proposta de modelo é voltada para a apresentação níveis de maturidade analíticos diversos, como o Business Intelligence Maturity Model (BIMM) [25]. A natureza genérica de apresentação dos modelos de maturidade pode permitir que outras áreas do conhecimento usar o modelo de maturidade para evolução de processos. Como trata de smart supply chain a pesquisa, esse modelo também pode ser utilizado no processo na etapa inteligente do conceito cadeia de suprimentos inteligente.

2.2.3 Principais pontos de contribuição da literatura acadêmica sobre o tema

A análise dos modelos de maturidade estudados na literatura foi realizada de acordo com os itens que conceituam a cadeia de suprimentos inteligente, como um

sistema de negócios interconectado [12]. É uma cadeia instrumentada, interconectada, inteligente [18] e também automatizada, integrada e inovadora [18] e [12]. Assim, na análise desses itens, procurou-se estabelecer uma relação de nexo causal entre o conceito de smart supply chain e os elementos necessários para a concepção de um modelo de maturidade, analisando não somente os artigos que tratam sobre cadeia de suprimentos inteligente, mas também artigos que permeiam o tema, com assuntos periféricos sobre smart supply chain, através do entendimento dos conceitos de supply chain management e de que forma esses conceitos abordados poderiam de alguma forma enriquecer o estudo com constructos teóricos.

Através desse entendimento, concebemos o Quadro 1, com o intuito de apresentar uma relação de artigos selecionados na literatura que contribuem para os estudos de modelos de maturidade de smart supply chain, conforme os critérios estabelecidos e explicados acima. Esse quadro foi dividido através dos seguintes itens: (i) extração autor e título; (ii) interpretação do artigo e; (iii) relação de achados quanto estrutura de atributos e níveis.

Quanto ao item estrutura de atributos e níveis, segue os princípios apresentados por [16], através de suas definições sobre Business Process Orientation – BPO, pois esses autores apresentam em seus trabalhos que a BPO é fundamental para gerar subsídios para obter maior conexão dentro de uma organização, enquanto melhora a performance dos negócios. BPO para [16] apresenta princpalmente os seguintes elementos-chave: gerenciamento, medição, e aspectos do processo. Assim, a compreensão da estrutura de atributos e níveis são aspectos importantes, não apenas para a concepção do modelo de maturidade, mas para serem direcionadores para o processo de evolução da melhoria contínua nesse ambiente de smart supply chain.

Quadro 1. Relação de artigos selecionados que contribuem para os estudos de modelos de maturidade de smart supply chain

Contribuição	Detalhe dos níveis e atributos
Esta pesquisa enfoca o impacto do "Industry 4.0" e "Digital Transformation" no compartilhamento de informações e na tomada de decisões em toda a cadeia de suprimentos. Seguindo uma abordagem qualitativa demonstram que uma avaliação e integração da cadeia de suprimentos baseada em novas tecnologias ainda estão distantes.	Avaliação da cadeia de suprimentos digital (sinônimo de inteligente) através dos 5 atributos listados: 1) Hardware, 2) Software, 3) Pessoas, 4) Processos e 5) Dados; nessa ordem.
Apresenta metodologias de gerenciamento da cadeia de suprimentos que, baseadas nos princípios do pensamento enxuto integrados aos conceitos da indústria 4.0. e uma política de compartilhamento de dados em tempo real.	5 níveis: 1) Identificação 2) Planejamento de alternativas; 3) Implementação das propostas; 4) Avaliação da implementação e, 5) especificação do aprendizado.

Este estudo propõe uma nova estrutura para identificar o SCMP (Supply Chain Management Practices) inteligente-sustentável como critério de seleção de fornecedores para uma cadeia de fornecimento inteligente para uma seleção sustentável de fornecedores para uma cadeia de fornecimento inteligente..	4 atributos identificados na leitura foram: Redução de custos usando tecnologias inteligentes (EC1); Melhoria da qualidade do produto (EC2); Entrega inteligente ao cliente (EC3) e Melhoria da flexibilidade de fornecimento (EC4).
Este artigo tem como objetivo conectar cada uma das principais tecnologias qualificadoras da I 4.0 com os paradigmas mais significativos da cadeia de suprimentos: Lean, Agile, Resilience	5 níveis 1) Econômicos, 2) Energéticos e 3) Ambientais através da implementação das seguintes qualificadores – tecnologias: Robôs Autônomos, Fabricação de Aditivos, Computação em Nuvem, Robôs Autônomos, Cyberse- curity e Realidade Aumentada. Uma segunda fase onde convergem os atributos 4) Funcionais e 5) Sociais através da implementação das seguintes qualificadores – tecnologias de Integração Horizontal e Vertical, Grandes Dados, Blockchain, Simulação, Internet das Coisas e Inteligência Artificial,.
Assim, as principais contribuições do estudo são (1) o desenho de artefatos prescritivos que descrevem as relações no SSCM, (2) oferecer funcionalidades direcionadas e avaliadas de apoio à decisão para cadeias de abastecimento sustentáveis, e (3) fornecer um terreno fértil para futuras pesquisas.	5 níveis que os autores apresentam com enfoque em sustentabilidade da cadeia de suprimentos, 1) não é ciente e não cumpre nada sustetnável; 2) medidas ainda tímidas e desconectadas com a alta direção; 3) As metas/normas de sustentabilidade definidas e seus KPIs.; 4) de conformidade para sistema de medição de desempenho; 5) **C**onceito totalmente integrado com propagação de conceitos estratégicos e Melhoria Contínua.
Modelo de maturidade para logística 4.0. Além disso, os resultados mostram que o amplamente utilizado modelo de referência de operações da cadeia de suprimentos pode servir como base para modelos adicionais de maturidade do processo.	São 5 níveis de maturidade com os seguintes atributos: 1) digitalização básica: muitos processos manuais 2) digitalização entre áreas departamentais; 3) digitalização horizontal e vertical: integração em toda a empresa no sistema operacional IoT baseado em nuvem; 4)

	digitalização completa em tempo real IoT e 5) digitalização total otimizada IoT
O modelo de maturidade de cadeia de suprimentos apresenta um estrutura de melhoria aplicável para a implementação bem-sucedida da gestão da cadeia de suprimentos.	7 níveis: Princípio 1: valor lucro/volume de negócios Princípio 2: definir os valores do cliente Princípio 3: estabelecer relações com fornecedores. Princípio 4: integrar as atividades do projeto. Princípio 5: gerenciar os custos de forma colaborativa. Gerenciamento de risco Princípio 6: desenvolver a melhoria contínua Princípio 7: mobilizar e desenvolver as pessoas
Demonstra a necessidade de maturidade do gerenciamento da cadeia de suprimentos na implementação das melhores práticas	Os autores definiram três níveis de maturidade, primeiro inicial onde não há práticas definidas, o segundo e o terceiro, mostrando que Fornecedores e inventário, Recursos Humanos, Estratégia e planejamento, Processos e Tecnologia da Informação estão no segundo nível de maturidade, enquanto que Liderança e cultura, Desempenho e Clientes estão no terceiro nível.

Fonte: Autores (2020)

3 Resultados e análises – níveis e atributos

Os autores [14] apontaram em seus estudos, uma classificação de atributos de modelos de maturidade, que são usados para conceber uma visão geral do modelo. Ainda segundo esse autor, os atributos são divididos em três categorias: gerais, design e uso do modelo. Vamos adotar essa estrutura para apresentar os principais achados dos níveis e atributos dos modelos de maturidade analisados até então.

Durante os estudos, observamos a importância de possuir uma métrica para mensurar não apenas de maturidade, mas sim o seu grau de evolução, pois também desenvolveremos ao longo do estudo, indicadores para cada um dos atributos, de forma a obter subsídios para avaliar o grau de evolução de cada nível, conforme [21].

Esse conceito aqui apresentado é crucial para a pesquisa, pois no decorrer dos estudos, em planos futuros na etapa decisional e prognóstica sobre a recomendação do uso de tecnologias 4.0 no ambiente smart, serão as bases para a formulação de critérios visando à concepção do modelo de maturidade, utilizando como base a estrutura apresentada nos estudos de [14], apresentando a sua estrutura de atributos, de acordo com a leitura dos artigos citados no tópico anterior.

Os autores [3] em seus estudos mostraram que a Indústria 4.0 e a Transformação Digital têm o potencial de alcançar uma integração total do SC digital em termos de maior transparência, por exemplo, através de plataformas centralizadas. Para esses autores, um problema central da digitalização dos processos em todo o SC em termos de troca de informações entre parceiros comerciais é a falta de padrões para o processo de compartilhamento de informações de um ponto de vista tecnológico. Nos seus estudos, ele apresenta 5 níveis de avaliação da cadeia de fornecimento. Esses 5 níveis podem ser interpretados também, como níveis de maturidade para a transformação digital, pois de acordo com [14], a maturidade implica um progresso evolutivo na demonstração de uma habilidade específica ou na realização de um alvo desde uma inicial até um desejado ou normalmente ocorrendo no estágio final.

Através desse conceito, extraímos esses pontos de avaliação dos estudos de [3] para serem itens de aprofundamento de estudos para propor um método de avaliação para em nível de avaliação da cadeia de suprimentos inteligente. Para isso, os atributos desse modelo permeiam os pontos: Hardware, Software (visando a padronização no compartilhamento de informações), com Pessoas, Processos e Dados.

Os autores [1] apontaram em seus estudos, uma estrutura de níveis e atributos relacionados as ferramentas de transformação digital para tornar um processo de supply chain management inteligente, o processo fim da cadeia, a etapa de entrega. Nessa proposta, os autores propõem um modelo genérico de maturidade com 5 níveis:

(i) Digitalização básica; (ii) Digitalização entre os departamentos; (iii) Digitalização horizontal e vertical; (iv) Digitalização completa e (v) Digitalização completa otimizada.

Os seus atributos de cada um dos níveis apresentados são (i): fluxos de informações são recebidos de forma manual. Não são sistemas que os concebem. O input é feito no sistema a partir de uma informação manual.

No atributo seguinte (ii): recebe-se de forma eletrônica dados de consultas de clientes e solicitação de cotações via interface padronizada e com resposta eletrônica às consultas do cliente e solicitação de cotações via interface padronizada.

O atributo (iii) apresenta o recebimento automático de consultas de clientes e solicitação de cotações através de interface padronizada e acesso às informações de processamento de pedidos através de dispositivos móveis.

Os atributos seguintes (iv) já deixam de ser um padrão intermediário de maturidade e migram para uma dimensão avançada, pois ocorre a digitalização completa em ambiente IoT, com recebimento automatizado em tempo real de consultas e solicitações de orçamentos por parte dos clientes, recurso a dados específicos do cliente, e resposta automatizada em tempo real a consultas e solicitações de cotações de clientes.

A etapa (v) digitalização completa otimizada conta com recursos de simulação em tempo real para tomada de decisão; análise automatizada de consultas de clientes, solicitação de cotações ou transmissão de dados em caso de falha; e habilidades de autoaprendizagem a partir de casos de falha resolvidos – entrando na questão da inteligência artificial.

4 Conclusões

Os autores [1] apontaram em seus estudos, uma lacuna para continuidade de pesquisas para a cadeia de suprimentos inteligente, pois esse estudo focou em apenas o processo de entrega. E esse gap foi detectado na revisão literária sistemática, assim, vamos dar continuidade nos estudos desse modelo, extrapolando além do processo de entregar propôs em seus trabalhos, mas para fazer uma análise da cadeia de suprimentos como um todo, focado no conceito smart supply chain.

Para [12], desenvolver o sistema de informações para uma cadeia de suprimentos inteligente, provavelmente deve-se começar com perguntas sobre quais informações a empresa e outros parceiros da cadeia de suprimentos precisam e responder perguntas sobre quais informações eles podem fornecer para beneficiar a si mesmos e a outros parceiros. Dessa forma entendemos que o ponto chave para criação dos níveis e atributos para avaliar a cadeia de suprimentos inteligente é, conforme [14], uma descrição de cada elemento ou atividade e como ela pode ser realizada em cada nível de maturidade.

Assim, um dos achados importantes dessa pesquisa foi compreender que os níveis de maturidade apresentados de forma genérica quanto a sua classificação, mas ao conceber os atributos que qualificam a evolução do modelo proposto deverão permear as inovações e as ferramentas da indústria 4.0 para avaliar a cadeia de suprimentos inteligente, de acordo com sua definição smart.

A partir desse resultado, vamos dar continuidade na pesquisa focando métodos de avaliação do grau de maturidade em outras áreas de estudo, e verificar a possibilidade de incorporar métodos de diferentes áreas do conhecimento para a replicação de outros métodos de avaliação do nível de maturidade da cadeia de suprimentos inteligente.

Abstract. Logistics service providers have to offer their clients highly reliable and high-quality services at competitive prices while ensuring constant technological updates in equipment, and looking after their profits. To face this challenge, transportation service companies have chosen to consolidate goods that share a vehicle to be delivered. However, the design of these services involves taking decisions about the frequency, the type of vehicle, and the route of the service. This problem is typified in the literature as a Service Network Design Problem, which may include stochastic elements in the formulation of the problem, the objective of which is to determine the vehicle departure schedule, and the delivery sequence merchandise for companies dedicated to offering cargo transportation services in Mexico. In this review, it is showed a state-of-the-art review of the Service Network Design Problem and its current challenges.

Keywords: Service networks, LTL service, freight transportation, transportation optimization, service network design problem.

1 Introduction

Freight transportation is a highly competitive sector, where carriers have to offer reliable, high-quality services at competitive costs, given a set of potential resources and a demand to satisfy. A freight transportation plan must be designed that meets both parameters to guarantee customer satisfaction considering minimizing the total costs incurred when providing a service. To achieve the balance of customer-supplier profits, the Design of Service Networks problem has been formulated, which include strategic decisions such as the size and allocation of the fleet, the acquisition or subcontracting of third parties, the tactical decisions that define a plan, and a repeatable transportation schedule. Early research indicated that in realistic instances of such planning-level

problems were hard to solve. However, with progress in scientific research, some of these practical problems have been modeled and solved using more sophisticated mathematical programming techniques.

The less-than-truckload (LTL) trucking industry uses consolidation as a means to increase service frequencies while keeping costs under control. This is performed by transporting various products, established for different destinations, from one terminal to a distribution center. There they are consolidated with other products that come from other terminals before being sent out of the center. Products can be loaded and unloaded at various hubs/breakbulk before reaching their final destinations. This use of consolidation provides a lower cost compared to not consolidating the freight [1].

Typically, Service Network Design is a part of planning activities, although it is often referred to as strategic/tactical or tactical/operational following planning traditions and company horizons. The objective is to operate efficiently to respond to demand and guarantee the profitability of the company. The supply side of this equation involves a view of network operations throughout the system, integrating consolidation activities at terminals, and selection, routing, and scheduling of services. On the demand side, the route of the cargo through the network must be planned to ensure timely and reliable delivery to meet customer's specifications and the carrier's objectives [2].

2 Problem Statement

Network flow planning relates to flow planning decisions that address the movement of orders (commodities) throughout the network. The input parameters include a hub-and-spoke network, where the merchandise will be consolidated, with a set of nodes N and a set of arcs A

In addition, values are given for fixed and variable network costs. Fixed costs cover costs $c_{a\ ,ij}$ or services in a single network arc. The variable costs $c_{c\ ,ij}$ represent the costs of each unit of merchandise flow between the pairs of nodes $_{,ij}\in$ N. As demand parameters, a transport demand d_{ij} s given for each pair of nodes $_{,ij}\in$ N, which must be satisfied by the network. In [3] the author defines a difference between dynamic and non-dynamic service network design problems, so the latter incorporates the dimension of time in the model. In this case, the transportation times t_{ij} between the pairs of nodes $i, j \in$ N as well as the transshipment times t_h for each central node h is added [4].

Continuing the classification elaborated by [3], we highlight the introduction of decision variables in service networks, and these networks respond to dynamic or non-dynamic services either with a given network structure or a variable network structure. The attributes of these dimensions are listed below.

I. Dynamic service network with variable network structure. The capacity of the service is calculated through the frequency or by the number of services

within a certain schedule, or also, by defining the number of services in the network within a certain planning period.

II. Dynamic service network with a given network structure. In this network, transportation schedules are provided, and services are chosen from a pre-defined set of orders.

III. Non-dynamic service network with variable network structure. In this type of network, it is determined a subset of open arcs without considering transportation schedules.

IV. Non-dynamic service network with a given network structure. Similar to a network flow problem.

In Fig. 2 it is presented a classification of the problem.

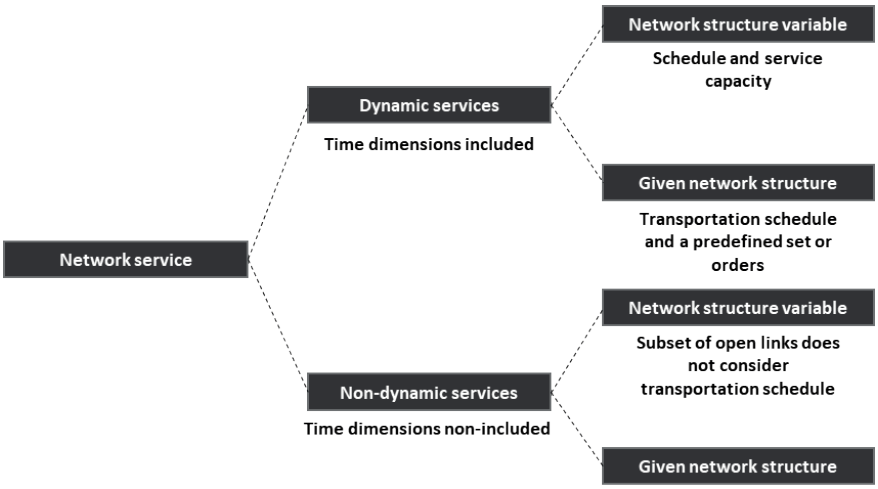

Fig. 1. Service Network Design Problem classification, based on [3].

The variable transportation costs within a network are closely related to the flow of freight so that a change in the choice of transport service offered can reduce the costs of the flow of goods or the overall costs of the operation can be reduced by balancing fixed and variable costs. However, the design of a service network not only seeks to reduce them, depending on the focus of the company, the maximization of benefits is also sought. In this sense, the benefits will be given by the willingness that the client has for paying high prices for the services offered even if, for the company, it does not contribute to efficiency.

3 Methodology

The development of this research was carried out through the implementation of the hypothetical deductive method where, from the statement of a hypothesis, the search for information that would support said approach began. In the Network Service Design

Problem, the optimization of the vehicle travel times could be achieved by building a network of services to consolidate freights and establishing vehicle departure times based on quantitative methods.

Based on this premise, a work plan was determined to carry out the study that includes three stages as follows. The first stage consisted of a preliminary review of the literature, without being exhaustive regarding the Design of Service Networks to have a general concept. In the second stage, the research guideline was established, setting key concepts that delimited the research. Due to the magnitude of information for Network Design and according to the main focus of the study, the search was limited to concepts such as "Freight Transportation", "Consolidation", "LTL", and "Design of Stochastic Service Networks". Under this approach, the search was conducted in Science Direct databases. With this information, in the third stage, a referential framework was built regarding our initial premise; there were identified retrospective articles that contain the key concepts and various variations in the formulation of the Service Network Design. Finally, it was made a comparison between the performance measures, parameters, and approaches of the models used.

4 Literature review results

The objective of the design of a freight service network is to determine how the freight transportation service has to be performed, to satisfy the current demand and meet the economic objectives of the transportations companies and their customers' level of service through the approach of mathematical models and the algorithmic approach needed. However, the scope of the mathematical models formulated and their corresponding algorithms had been somewhat limited because of the computational complexity involved. [2] and [3] show the formulation of the Service Network Design Problem for long-distance land transportation. The results are impressive concerning the impact of the system both in the context of cargo planning operations and for strategic studies of possible terminal locations.

The specialization in the design of service networks, now dynamic (SNDPD), is presented by [5] who make a formulation with stochastic values that depend on time, aims to optimize the problem in a given planning horizon and propose a solution approach based on dynamic programming principles from a single terminal that dispatches services to several Clients and other terminals, coupled with this model, propose a static, single-period formulation of the single node problem that appears as a subproblem when addressing the time-dependent version and general service network design cases.

In [1] the authors introduce the correlations between the random demands in a service network design problem affect the optimal routes of trucks, as well as the flexibility in the shipment of basic products. demonstrate that a design can be flawed if it is based on incorrect correlations. The consolidation of merchandise that takes the role of

shipping small loads together over long distances and in turn coverage is also considered for the approach of this model; When random demands travel the same paths, particularly if they are negatively correlated, consolidation implies hedging. The solution is carried out through simulation techniques that included generation of scenarios, and indicating that if a procedure for such generation produced random or biased correlations.

With an application in a transportation network in Europe, in [6] different formulations of problems published in the literature were evaluated. It was conducted analyzes and comparisons of the specific solution, showing that good solution approaches have been developed for the SNDPs. Generally, all problems are focused on a particular part of the entire tactical planning problem. On the other hand, [7] presents a model attached to the needs of the design of a service network for a company providing a viable weekly-use planning tool. This situation enables LTL companies to regenerate load plans every week based on the most up-to-date and accurate load forecast with the latest load trends.

Uncertainty in the demand of services or products plays an important role in the construction of schedules in the design of service networks, solutions based on uncertain demand have characteristics that provide value in terms of operational flexibility with robust schedules. Structural differences prevail that differ from deterministic solutions. Among the main differences is in the number of routes between the origin and destinations, as well as the use of vehicles resulting from the consolidation of goods, which represents the main correlation problem, the correlation between merchandise and it is here where the work carried out in [1] and in [8] makes contributions to the primary model.

Once stochastic elements and time dependence are considered in the design of the service network, in [9] it was represented fluctuating demand through scenarios and integrating a model that has a balance of empty vehicles, cost of loading in intermediate terminals, costs associated with the movement of cargo using the selected services and the penalty costs for not being able to deliver the load. That is, it is the first approach to real network design problems with a metaheuristic algorithm and is closely related to the work of [1]. Another metaheuristic algorithmic contribution was introduced by [10] through a hybrid Taboo Search model, which reduced the calculation time by more than a third.

In [11] continues with an extension of a stochastic programming model from [8] and proposed a network design model with vehicles re-routing, as well as the outsourcing of services to handle the uncertainty of demand. A set of integer variables for modeling the detour of vehicles is introduced in the second stage of the stochastic program. The results offer various redirection options and flexibility to handle uncertainty. Although the model seems to adapt to a real case, the contribution is focused on study cases taken from the literature.

In [12], the authors developed an algorithm to solve service network design problems that use expanded networks in time, which avoids having to introduce model approximations, which improves the quality of the solution, to maintain the size of the expanded time. The results through Solve-CTSNDP is quite effective. However, there are improvements that will increase its efficiency. One of them is in the initial iterations, which suggest solving through the relaxation of linear programming or solving the problem within a proven percentage of optimization.

In [13] highlights the impact on the quality of the solution to the approach to the design of service networks where networks expanded in time are common to model transport problems, however, their use requires that a discretization scheme is chosen. Empirical results show that this is an important choice since the main loss in solution quality is due to the loss of viable low-cost routes over time and the loss of potential consolidations. Instances with high flexibility are less affected by coarse discretization but can be hard to solve, with high-cost rates, as high flexibility allows greater consolidation possibilities, and a high-cost rate emphasizes consolidations over routes.

The contributions of [14] are brought together for them by developing a scheduled service network design model that addresses strategic decisions regarding fleet size and allocation, including procurement and subcontracting, as well as tactical decisions regarding scheduled repeatable transportation plans. Given the computational difficulties associated with the exact resolution of stochastic programs, they propose two ways based on the generation of columns to approach the model. They proposed a heuristic model based on the column generation technique, which decomposes the optimization problem into multiple dimensions and evaluates a neighboring solution in all scenarios; also by applying the knowledge in two instances of an LTL carrier. The second is based on the network of a European postal carrier. The results of the effectiveness of the proposed heuristic methods suggest a study of the impact of the operating environment on managerial decision-making, both at the strategic and tactical levels.

The problem of routing and design of service networks that integrates local and long-distance transport planning decisions is important for consolidated service carriers that need to provide efficient services that involve the synchronization of their movements. [15] present two formulations to this problem, the first is based on a set of rules for local deliveries which has greater ease of modeling compared to the second approach with faster time resolution but more limited modeling.

[16] propose deterministic robust optimization formulations and two-stage use a set of uncertainties without probability to face the uncertainty of the demand in the proposed robust model. Where the Bender decomposition method is lessened in contrast to the column generation approach and restrictions used. They also analyze the impact of considering multiple types of services in the transportation system, confirming that diversifying the types of services helps to reduce the total cost and the optimal total number of vehicles used in the network. The quality of deterministic solutions in sto-

chastic service networks is studied by analyzing time-dependent formulations (scheduled services), they propose a measurement scheme to evaluate the level of potentially beneficial structural properties (use of multiple routes and route sharing) in different solutions. The results show that the structural properties have high impact and are correlated with the performance of a solution in the stochastic environment [17]. In [18] the authors work on the stochastic problem of programmed service network design, but now it includes the uncertainty in travel times, as well as the quality of deliveries referred to the punctual operation, the solution of this approach is generated through of a metaheuristic based on progressive coverage. Finally, [4] summarize the current state of the different modes of transport as of 2008 and categorize in terms of problem characteristics, model formulations and solution approaches, including uncertain demand, transport times, costs and capacities, this was our reference in the realization of this work.

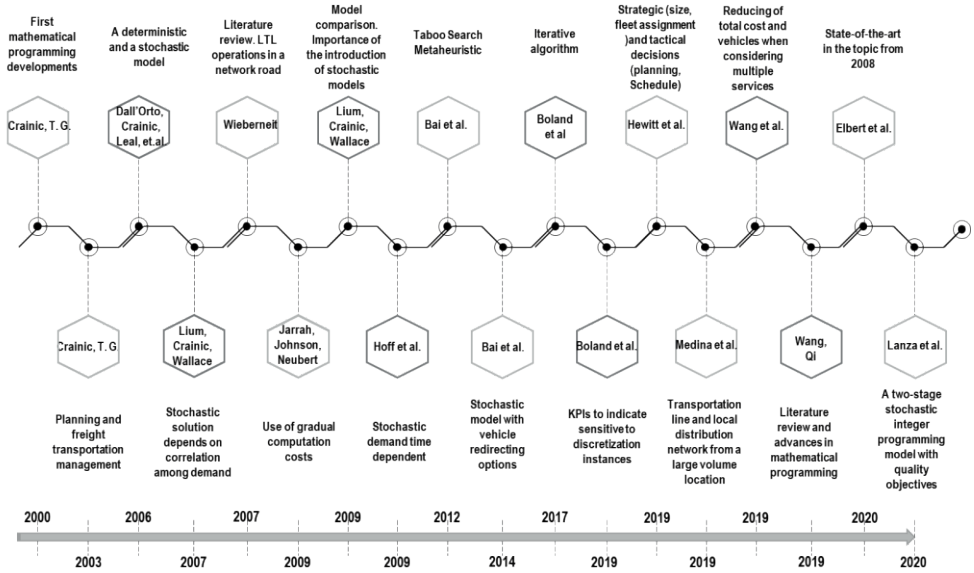

Fig. 2. Timeline of the main findings in the Service Network Design Problem.

5 Conclusions

The present state-of-the-art allows correctly dimensioning the importance of the Service Network Design Problem topic. It is possible to recognize that the incorporation of stochastic considerations is necessary, especially in those related to the demand side. From the perspective of those who offer the transport service between links in the supply chain, the ultimate goal would be to achieve a scheme that helps to determine pre-positioning strategies of the vehicle fleet in strategic locations. Hence, it is expected to use the elements listed in this review to define the state variables, the performance measures, and the elements that allow modeling for a customized study case.

Abstract. Within the data science and artificial intelligence fields of study, machine learning have supported performance improvement in medicine, manufacturing, law and even sport environments. The purpose of this paper is to investigate how machine learning has been used as a tool to improve the assertiveness of decision- making, providing competitive advantages in the wide field of operations management. This exploratory research analyzes the content of five machine-learning studies, relating each of them to Slack's strategy pillars: cost, speed, quality, flexibility and dependability. Research design was limited to Scopus' papers published exclusively in high impact journals. Results emphasize the important role of machine learning in organizational competitive advantages and limitations are used to address further research suggestions, extending the present investigation with a more extensive bibliographic portfolio analysis. The contribution of this paper is a matrix analysis of how machine-learning projects indirectly contribute to at least three strategy dimensions simultaneously. Complementarily, an illustration was built for a better comprehension of the interrelationships among the strategic pillars reinforced by the analyzed studies.

Keywords: Slack, machine learning, operations strategy, strategy, operations.

1 Introduction

Strategy has a variety of different concepts, with multiple perspectives and definitions, which are considered important for academic research, since this diversity can offer distinct horizons and guidelines (Mintzberg, 1987, Skinner, 1969). Porter (1996) reinforced this point of view and tried to differ strategy from operational effective-

ness, since its importance is not enough to achieve competitive advantages. With Industry 4.0 and artificial intelligence scenario, organizational environment became even more aggressive among competitors, and Porter's analysis demonstrated that the essence of strategy is the choice to perform activities differently from the others. Therefore, the need of solutions to improve performance in various levels combined with technologies is a key factor for success.

In this context, the purpose of the present paper is to investigate how machine learning has supported operations strategy in organizations focusing on Slack's (2009) performance objectives: cost, speed, quality, flexibility and dependability. Among Slack's performance dimensions (2009), cost is the direct competition on rates while speed is the turnaround time between customers ordering a product or service and the point at which they receive it. Quality is the visual aspect of how well an operation does what it does. Dependability means that customers can rely on organization to receive their goods exactly when expected and finally, flexibility is the ability to change an operation to match customers' requirements. Since the dimensions influence positively or negatively on each other, the present study also analyzes an integration of performance objectives, comparing and relating their multiple gains, despite the tradeoffs.

Regarding the paper structure, Section 2 introduces a brief theoretical background of operations strategy and machine learning. Section 3 details the research design, which consists on the search terms for the paper selection on Scopus database. Sequentially, Section 4 brings the results, which are segmented by two subchapters, the selected papers with their content analysis and a following operations strategy matrix to allocate them in Slack's competitive advantage pillars. Finally, Section 5 presents the conclusions, addressing limitations and further research.

2 Literature review

This literature review presents firstly a brief theoretical background of operations strategy along with a following machine learning overview.

2.1 Operations strategy

In a decade of high manufacturing processes, the companies need to stand up for their competitors. Porter (1996) once said the only way to outperform is by preserving competitive advantages. These advantages are grounded by the costumers needs and are related to the continuous improvement methods applied on quality, flexibility, cost, time and productivity (Slack *et al.*, 2009). Focused on the core business, costumers and the companies' competitive advantages meet to perform strategically trying to achieve every aspect of improvement in order to reach exceptional performance. Strategy is essential for the competitiveness and according to Porter (1996), the competitive positioning is a matter of choosing the right factors to focus on, applying trade-offs.

Strategy is related to the company's plans, ploy, patterns, position and perspective (Mintzberg, 1987). Operations strategy develops internal guidelines to deal with the competition and the market threats, creating patterns to establish the intended company's behavior. Traditional strategy management has been challenged due to organizational competitiveness, demanding new frameworks and models considering the relationship between roles, capabilities and design theoretical recommendations for a performance measurement system (Pinheiro de Lima *et al.*, 2008).

Strategy purpose is to demonstrate how well grounded is the management process, its influence on the organization position on a specific market and the perspective sets of the internal characteristics of the company (Bititci *et al.*, 2011).

All these definitions guide the organization to achieve its unique strategy, which provides the necessary differences to reach competitive advantages with faster results (Bititci *et al.*, 2011). However, defining a strategic process plan is not an easy task and cannot be static (Hayes, 1985). Once the company's strategy is created, it has to be continually analyzed to identify its efficiency and evolution. Nelly (2006) shows the relationship between strategy and performance gains, concluding that the strategy objectives in action can bring not only unique performance results, but also a combination of categories, like cost and quality. As the competition arises, the competitors tend to find new ways to compete and the managers need to choose new trade-offs to shape the strategy plan. Hayes (1985) highlighted that the company has to establish its corporate goals, find alternative paths to achieve these targets and marshal what is necessary in capabilities to implement and follow defined strategies. Even so, easy-ways-means method itself does not guarantee organizational performance, since the strategy happens in the long-term with all employees playing a respective role in its work execution and developing their proper capabilities strengthen the competitive strategy (Skinner, 1969). Okoshi *et al*. (2019) have recently found performance results depend on policies and capabilities that are addressed and managed by companies' decision areas.

Personal capabilities and competitive technologies are some key recourses for outstanding performance, once they can possibly be unique and not easily copied by competitors (Hayes and Upton, 1998). This approach focusses on innovative operation tools and it has been enhanced by this new technological era. Within Industry 4.0 context, artificial intelligence reinforces operational advantages with a faster and more reliable work execution. However, the benefits are not exclusively limited to shop-floor and operational activities, since data science is an inter-disciplinary field that uses not only scientific methods and processes, but also algorithms and systems to extract knowledge and insights from structured and unstructured data (Moorthy and Gandhi, 2017). Therefore, competitive indicators together with consistent advanced knowledge are also provided by artificial intelligence, bringing important relevance for strategy definitions. In this context, the present study links machine learning to organizational strategic goals.

2.2 Machine learning

Performance fulfillment has a high value service that goes beyond management and control, enabling communication, roles and informational skills to translate the strategy and challenge predefined concepts by senior leadership (Neely and Alnajjar, 2006; Pinheiro de Lima *et al*., 2008). Machine learning has been used as a tool to provide this meaningful knowledge. However, most of the frameworks postulating the best practices, which should be adopted in performance analytics projects, do not involve the respected data complexity. In this context, Dutta and Bose (2015) developed a new framework with the purpose to provide organizations a holistic roadmap in conceptualizing, planning and successfully implementing Big Data projects. The procedural steps involve a step-by-step project map with a cross functional project team, adoption of innovative visualization techniques, and a consistent top management commitment to data driven decision making.

Machine learning is an interdisciplinary research area, which combines ideas from several branches of science namely, artificial intelligence, statistics, information science, mathematics and many others. The main purpose of machine learning approach is on the development of fast and efficient learning algorithms that can make predictions on data (Moorthy and Gandhi, 2017). Therefore, machine learning is also known as predictive analytics, which aims to determine what is likely to happen in the future. The predictions are based on statistical techniques that fall under the general category of data mining (Ouahilal *et al.*, 2016). This quantitative accuracy for predictions is extremely important for an assertiveness in decision-making processes, although the computational time of the algorithms are critical in terms of cost and project viability (Moorthy and Gandhi, 2017). In this digital era context, a recent study revealed real-time data, connectivity and interoperability are some of the most important key factors for a successful digital manufacturing adoption (Da Silva *et al*., 2019)

Machine learning projects have been increasingly managed by healthcare environment, providing accurate diagnosis, helping to predict cancer, chronic kidney disease (Charleonnan *et al.*, 2016) and even the effectiveness of music therapy (Raglio *et al.*, 2020). However, its multidisciplinary has also reached sport analysis, quantifying the relation between performance and success in soccer (Pappalardo and Cintia, 2018) and the educational setting, predicting academic performance with matriculate score and previously semester and pre-university exams as predictors' variables (Halde *et al.*, 2017). Organizational field was not left behind. Some companies have applied artificial intelligence for customer retention (Sabbeh, 2018), identify potential customers based on purchase behavior (Choudhury and Kur, 2019) and even employee performance prediction through historical datasets (Jayadi *et al.*, 2019) This study consists on analyzing how machine learning has contributed to operations strategy pillars defined by Slack *et al.* (2009).

3 Research Design

The research design consisted on a Scopus' search following the initial ProKnow-C steps for axes' definition, although our portfolio composition consists of exclusively five papers in a first iteration (Ensslin *et al*., 2010). Machine learning and operations strategy themes were searched with the reunion of 1st and 2nd axes linked by Boolean Operator "AND", as presented by Figure 1.

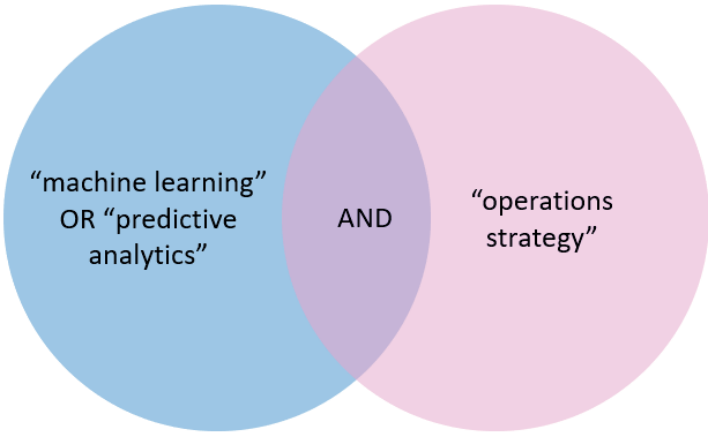

Figure 1. Search terms.

The search expression was limited to title, abstract and keywords. Only open-access papers written in English were searched and relevance filter was applied, as presented by Figure 2.

Figure 2. Search methodology.

Scopus presented 1293 papers and adherence test as applied to certify the assertiveness of search terms. On the following step, only high impact journals were included, rejecting 897 and resulting in 396 papers. Finally, as authors, we selected five machine learning studies that directly addressed each of Slack strategic pillars based on title and abstract details.

4 Results

Five papers published in high impact journals were selected from our Scopus search for our content analysis of their respective machine learning projects through Slack's strategic pillars (2009), as presented in Table 1.

Table 1. Machine learning selected studies.

The selected bibliographic portfolio presents only high impact journals with considerable impact on science community.

4.1 Content analysis

This section presents a brief content analysis of the selected studies, identifying their respective strategic achievements.

•Study 1 – Cost

A cost management project of the manufacturing sector was applied using a comparison of machine learning approaches to estimate the cost of jet engine components. Production volume and material cost itself were some of the predictor variables in the dataset composition. Loyer et al. (2016) applied five distinct algorithms and followed the machine learning literature in terms of predictive accuracy, goodness-of-fit, and also aspects as interpretability and computational time. Gradient Boosted Trees and Support Vector Regression presented superior accuracy and the best execution time, compared to all the other methods. On the other hand, Multiple Linear Regression, the worst performed algorithm in terms of accuracy, presented the best interpretability and easiness to fit and train. The study proved machine learning is an effective, affordable and competitive approach for statistical cost modelling in manufacturing processes. It is noticeable that cost is the main target of the study, but in the long term, Loyer et al. (2016) defend the cost estimation could be part of a decision system used by industrial engineers to identify outlier components. Hence, the benefits can be enhanced by the whole supply chain system, providing more flexibility and quality in

operations. A further research was addressed to apply the same analyses with other jet engine parts to certify whether the conclusions remain valid in other scenarios.

- **Study 2 – Speed**

Cavalcante *et al*. (2019) proposed a supplier selection model using supervised machine learning. The authors considered supplier performance data with delivery date and quantity delivery to predict supplier dependability with on-time delivery, together with a make-to-order simulation model that involved suppliers, internal material flow and delivery forecasts to customers. Regarding to machine learning techniques, random forest, linear regression and k-nearest neighbors were performed along with hybrid algorithms. The combination of both approaches brought risk mitigation strategies in supply chain management. The redesign of supplier base and supplier investment analysis are an important contribution. Complementarily, the digital scope of machine learning and simulations provide a digital manufacturing analysis, enhancing a consistent velocity gain and cost reduction with a better supplier portfolio management. The study, however, needed to leave behind some estimations of probabilities of highly unpredictable events to take advantages from smart manufacturing data to predict supplier proneness to disruptions.

- **Study 3 – Quality**

Machine tool automation for quality defection improvement in manufacturing segment, can promote higher quality products in order to achieve competitive advantages. A case-study was investigated by Correa *et al*. (2009) on a machine learning project where surface roughness was defined as a predictive indicator for quality predictions. The researchers compared Bayesian Networks (BN) to Artificial Neural Networks (ANN) and tried a variety of measures and models with the same dataset, and as a result, Bayesian networks presented a superior assertiveness on quality prediction. It is important to recognize that this machine learning application is not limited to reinforce higher quality products, but also to provide a reduction in production time, since it also promotes a reduction in operational time with under-quality products and enhances speed with a faster work time in operations. These solutions proved to increase quality results on a very high level, but also request a distinguished expertise on the BN and ANN algorithms.

- **Study 4 – Flexibility**

A predictive maintenance case-study project was applied with a multiple classifier machine learning method. Since maintenance issues are unstable, it is a challenging task to find the best quantifying measures to predict failure risks and costs with assertiveness. Therefore, Susto *et al*. (2015) proposed a training algorithm of multiple classification modules with distinct prediction approaches to provide performance tradeoffs on frequency of unexpected breaks and unexploited lifetime. The authors successfully applied their proposed method in a semiconductor manufacturing company, where the chosen process was the replacement of tungsten filaments used in ion im-

plantation, one of the most critical processes in semiconductor industries. Some of the predictor variables were pressure, position and quantity of electric charge. Support vector machines and k-nearest neighbors were the two chosen algorithms to perform, and the multiple machine learning classifiers working in parallel provided predictive knowledge to improve decision-making and feed the maintenance management system, to minimize downtime and its costs. This method highlights the improvements on flexibility and cost reduction which for Susto et al. (2015), can be even better when a second training iteration is applied minimizing the whole operating costs. Nevertheless, flexibility is an important achievement, from a lower downtime to an efficient maintenance management, in which operations become consequently faster and more flexible.

- **Study 5 – Dependability**

The degree of reliable products and processes brings critical indicators of a well performing industry, since they demonstrate the control and analysis of parameters in the production process. In some cases, the last step for product inspection is made by a cold test and trials, but even with all the applied control, a defect can appear only when the product is operating at a costumer. Ko *et al*. (2017) demonstrate a case study of an automated analysis tool, providing better product dependability using Lenzerini's formula combined to binary genetic algorithm-based wrapper approach. The case was applied using alter-sales service data from a heavy machine industry, which could identify engines with high probability defects before shipping the products to customers. This method highlights the importance of applying machine tool automation to increase dependability while reducing extra costs on the number of inspected items, human resources, and consequently, on the efficiency. Moreover, the case study also suggests that further studies need to be made so the machine learning model can find defects earlier than what was proposed using quality data from the machines' suppliers and the whole manufacturing process.

4.2 Operations strategy matrix

An operations strategy matrix analysis, presented by Table 2, was built based on a relation of the previous content analysis through Slack *et al.* (2009) strategic pillars.

Table 2. Operations strategy matrix analysis.

	COST	SPEED	QUALITY	FLEXIBILITY	DEPENDABILITY
Study 1	x		x	x	
Study 2	x	x			x
Study 3	x	x	x		
Study 4	x	x		x	
Study 5	x		x		x

The present classification is given by the authors based on the previous content analysis, since it was perceptible that machine-learning projects brought competitive advantages in at least three of the five strategy dimensions of Slack's literature. It was noticeable that even if the project was designed to follow a single dimensional specific target, it supported some extra strategic advantages in the long term. Additionally, cost reduction was an important achievement obtained by all the selected studies, which made convenient a visual understanding of the interrelationship among the strategic pillars achieved by the analyzed studies, presented by Figure 3.

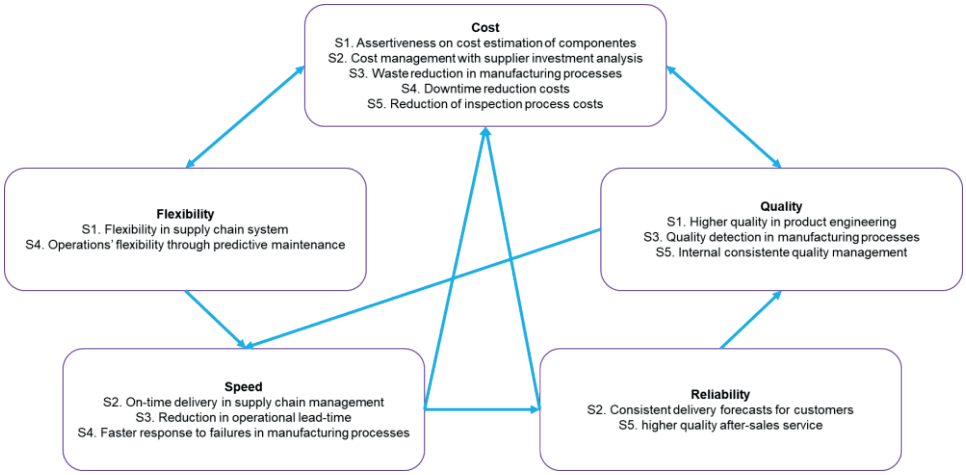

Figure 3. Interrelationships among strategic pillars.

The interrelationship illustrated reveals that only cost-flexibility and cost-quality have a mutual impact on each other, since all others present a single direction impact on another. Machine learning approaches of all studies had an impact on cost, even as a secondary competitive target or not specifically intended on their respective projects.

Quality strategic achievement was also meaningfully interrelated, reinforced by the implementation of a more consistent quality management of product engineering on Study 1 and a much more efficient quality inspection process provided by Study 5 after-sales service data. Speed, analyzed by Study 2 project, plays also a substantial role on influencing dependability for customers through on-time delivery together with a more consistent cost management of suppliers. Additionally, speed in operations is strengthened when a quality management or a predictive maintenance project is applied, as did Study 3 and 4, respectively.

The interrelationship among strategic pillars summarizes machine learning integration with operations strategy. Once the projects achieve better quality and make operations more efficient, they provide better economical results reaching cost and flexibility through accurate predictions of work execution. Therefore, depending on the

project context and its strategic directions, dependability can also be part of the competitive advantages in the medium to long-term.

5 Conclusion

This paper presents a simple and consistent preliminary investigative overview of how machine-learning projects have helped organizations to achieve consistent competitive advantages in many different dimensions.

The interrelationship analysis has indicated cost as the common achievement of all analyzed studies while flexibility and dependability are connected to others although with a less significant interrelationship. This event can possibly be explained by the fact that these both dimensions are often only reached in the long-term, but this is a preliminary hypothesis that demands further investigation.

We have contributed to reinforce machine learning, an important subfield of artificial intelligence, as a strategy key to organizational environment with our content analysis. The built of a matrix perspective over Slack's pillars can also be used as a guidance to collect additional studies of machine learning projects. This is the following step, since limitations of the present study are related to its small bibliographic analysis. We expect to extend this preliminary investigation to offer deeper conclusions with the expansion of our proposed interrelationship analysis. Another important limitation to address is that the present initial analysis was made according to authors' content analysis, so another further research step is a taxonomy application to reinforce our findings with an extension of the portfolio.

Another important further research is to go beyond the expansion and the taxonomy, and conjointly relate the decision organizational areas that provide the capabilities that needs to be mobilized in process that enable project results.

Abstract. The aim of industry 4.0 is to promote productivity and innovation by incorporating emerging IT technologies, where machine learning is playing a central role in this industrial revolution. In this sense, the production of new materials could take advantage of novel virtual testing approaches based on data science for supporting the design of new polymers. Nevertheless, the lack of data for learning virtual testing models constitutes a hard challenge for progressing in these innovative techniques. Therefore, it is especially important to create reliable databases for polymer study and make them available to the scientific community. In this work, we have focused on the generation of a trustworthy database of Refractive Index (RI) of synthetic polymers. This paper details the different types of errors found in the data source and the corrections made during the curation and cleaning of this database. Additionally, some Quantitative Structure-Property Relationship models for predicting RI, inferred without domain expert intervention, are presented and discussed for illustrating how virtual testing can be applied using this database.

Keywords: Refractive Index, Machine Learning, Polymer Database.

1 Introduction

At present, the world industry is going through a new revolution, known as Industry 4.0, which combines advanced production and operation methods with smart technologies that are integrated into organizations, people and assets. This revolution is driven by emerging new technologies such as artificial intelligence, big data analytics, nanotechnology, robotics and the Internet of Things (IoT), among others.

Consequently, organizations must recognise the technologies that best meet their needs to capitalize in them, because companies that do not understand the evolution and opportunities in business that Industry 4.0 brings are at risk of dropping market share. In this context, technologies based on machine learning are playing an important role in the innovation of production processes and, in particular, are having a huge impact in the discovery of new industrial materials [1].

A traditional project for development of new materials follows three main phases: design, synthesis and testing. During the first phase, different alternatives prototypes are designed for the potential new material. This design is guided by domain experts, which pursued some specific characteristics related to required industrial use for the future material. Then, the new materials are synthetized by polymerization reactions. Finally, specimens (physical samples) of them are tried by typical laboratory tests used in polymer science, such as the tensile test, in order to evaluate which polymeric material fulfil the desired industrial profile. Nowadays, this traditional process has been improved by the use of virtual testing models derived from machine learning methods [2]. Figure 1 illustrates how the use of virtual tests is being incorporated in the traditional process. This virtual testing phase makes it possible to predict relevant properties of the alternative prototypes even before synthesizing them, helping to prioritize the best candidate prototypes for the next steps of the polymer development project. Additionally, as a result of virtual testing, it is possible to rethink some design decisions and iteratively reformulate the original prototypes before moving to the more expensive phases of the project, thus saving money, resources and time [3].

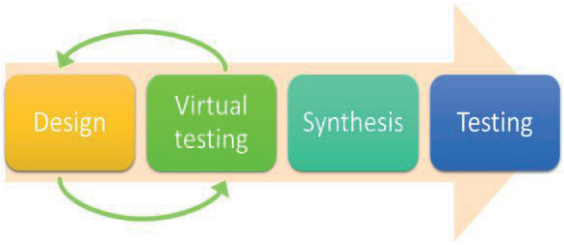

Fig. 1. Incorporating virtual testing in a traditional project for development of new materials.

These virtual tests are generated as Quantitative Structure–Property Relationships (QSPR) models inferred by supervised learning methods. In Polymer Informatics, QSPR models usually are regression models where a subset of molecular descriptors (*features*), which characterize the chemical structure of the molecules, are used for predicting the value of a target property under study. Figure 2 shows the sequence of steps for obtaining a QSPR model. First, the database to be used for learning the model must be defined and revised. In this step, it is important to revise that all required pieces of information be available for each polymer included in the database (polymer structure along with its corresponding Simplified Molecular Input Line Entry Specification (SMILES) code and the experimental value of the target property). If inconsistencies or mistakes are detected during this revision, a curation and cleaning step must be conducted in order to obtain a trusty database. After that, QSPR models can be inferred applying to main procedures: feature selection, where the most relevant

molecular descriptors for target property are identified, and models inference, where alternative QSPR models are generated by supervised learning methods. Lastly, an external validation of the models is executed for selecting the best QSPR models trying to avoid overfitting and correlations by chance.

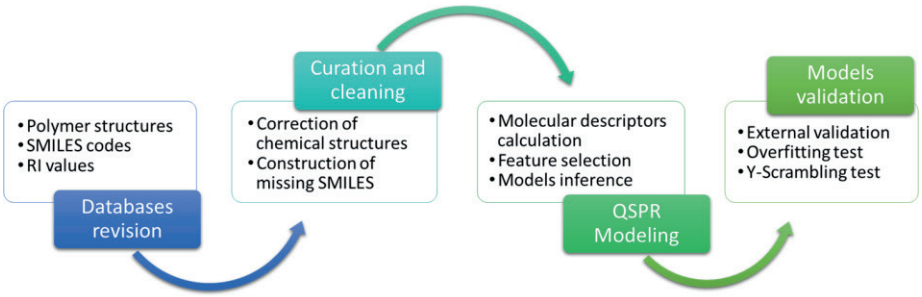

Fig. 2. Steps for generating a QSPR model for virtual testing.

Unfortunately, although this novel proposal can help to speed up the development projects of new polymers by supporting the design stage, the lack of data is slowing the progress and adoption of this innovative technology [3, 4]. Addressing this need, the "Materials Genome Initiative" was created in 2011, involving multiple US agencies collaborating to create policies, resources, and infrastructure that would support US institutions as they worked to rapidly discover and manufacture advanced materials with low cost [5]. Therefore, it is imperative to create reliable databases and make them available to the scientific community for supporting the incorporation of virtual testing in the polymer industry.

In this work we have focused on the generation, curation and cleaning of a database of Refractive Index (RI) of synthetic polymers, which is used in Quantitative Structure-Property Relationship (QSPR) predictive modelling. This property has special interest in the design of optical fibres, which combine two materials with different RI values: high RI (in core) and low RI (cladding). Although some databases that contain several polymers, together with their chemical structures and RI values, can be found in the literature, we have detected several mistakes and inconsistencies that must be corrected [6]. Besides, the repeating unit structure of the polymers and their computational representations in SMILES code are needed for QSPR modelling. Therefore, this report details the different types of errors found in the data source and the corrections made as part of the revision, curation and cleaning of this RI database. Finally, in order to illustrate the use of the RI database in virtual testing, the results of preliminary QSPR models generated by machine learning, without domain expert intervention during the modelling step, are presented and discussed.

Materials and Methods

1.1 Databases: curation and cleaning

Database Sources.

We have used the database reported by Jabeen et al., [6] for the purpose of making a fair performance comparison of our QSPR models with his reported model. This database contains 127 polymers, with their experimental RI values. However, during the database revision, we found some inconsistencies in terms of structure, property values and chemical names, so we began a process of curing and cleaning. To perform this cure, it was necessary to verify the data with other sources [7-12].

Data curation and cleaning methodology.

Data cleaning consists of detecting and correcting or removing incorrect or corrupt data from a database. We did a review of the database reported by Jabeen, collating the RI values and the polymer names with the databases reported by Bicerano [7], Duchowicz et al., [8], Xu et al., [9], Khan et al., [10], Seferis [11] and the chemical structure with PubChem [12]. Additionally, the database reported by Duchowicz was used for obtaining the SMILES codes, which are necessary for computing the molecular descriptors required for training our QSPR models. However, not all polymers were found in the Duchowicz's database, then the rest of the molecule SMILES codes were created by using Molinspiration Galaxy 3D Structure Generator tool [13].

During the review process of the Jabeen's database we found inconsistencies related to the polymer structures. Furthermore, some of them did not correspond to the reported name, and we also found some duplicate polymers. In this sense, we proceeded to make a structure correction due to the inconsistencies that we found and, additionally, we proceeded to develop the missing SMILES codes. Figure 3 shows the steps to curate the database. First, we have made a general revision of the reference database [6], checking polymer names, RI values and chemical structures. The second step was to carry out a detailed verification of each one of the structures, corroborating them against PubChem [12] and Sigma-Aldrich Product Catalog [14]. Since during the verification some errors were found in the structures, the third step was carried out by correcting the structures according to the information collated from the previous sources (Further explanation and examples of this step can be found in section 3.1). Then, in the fourth step, the property values were reviewed according to those reported in the databases of Bicerano [7], Duchowicz et al., [8], Xu et al., [9], Khan et al., [10], and Seferis [11]. After finding some errors, we proceeded to the fifth step, where they were corrected by homogenizing all RI values to four corrected decimal places. In the sixth step, we have made a revision of the SMILES associated with the polymers structure that we need to perform the cure. This revision was carried out by visualizing and verifying that the SMILES code of each polymer was structurally correct. For this, we have used the Molinspiration Galaxy 3D Structure Generator tool [13], which allows to obtain a visualization of the molecule corresponding to a certain SMILES code. In the seventh step, seeing that not all of the polymers reported by Jabeen et al., [6] were contained in the Duchowicz's database [8], we proceeded to develop the missing SMILES. Finally, in the eighth step, we have made a revision of the already curated database, visualizing

and checking that everything - i.e. polymer name, polymer structure, SMILES code, and RI value - is matching for each polymer.

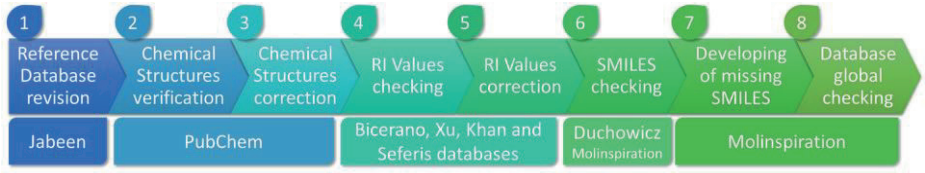

Fig. 3. Steps for the database curation process.

1.2 QSPR Modelling

Feature Selection.
The feature selection was made with the WEKA tool [15], using fixed seeds randomization in order to ensure reproducibility and default settings. For this purpose, several well-known methods were used to obtain a total 6 different subsets of molecular descriptors using 75% of the database (training dataset). The methods used were Correlation-based Feature Subset Selection (CFS) and Wrapper Subset Eval (WSE). The last feature selection method evaluates attribute sets by using a learning scheme. In particular, in this work, WSE was defined using different learning techniques: Linear Regression (LR), Neural Networks (NN), Random Forest (RF), Random Committee (RC), and K-Nearest Neighbours (KNN).

QSPR Models Inference.
To carry out the learning process and structure-activity modelling 5 different machine learning methods have been used on each subset: Linear Regression (LR), Neural Networks (NN), Random Forest (RF), Random Committee (RC) and K-Nearest Neighbours (KNN). Therefore, a total of 5 putative QSPR models were generated from each subset. The WEKA [15] implementation of each method was used.

We select one QSPR model for each subset for the next instance. The criterion to select the models is to keep the QSPR model with the highest R^2. This metric is used because it is the same reported by Jabeen's model [6] that will be used as reference performance in our work.

QSPR Models Validation.

External Validation. The goal of any machine learning algorithm is to learn a generalizable knowledge. Generalizability is the capability of the model to adapt appropriately to previously unseen data, but similar as that used to create the model. Underfitting occurs when the model does not fit the data well enough, and overfitting occurs when a model captures the noise of the data. External validation was performed in this work using the remaining 25% of the molecules in the database (validation dataset). In addition, we also used Roy's method [16] for classifying the QSPR models according to the quality of their predictions (Good, Moderate or Bad).

Chance correlations test. There is a risk of finding random correlations in QSPR modelling. Therefore, it is desirable to perform tests showing the performance of models built with the same target values but randomly permuted. Thus, the performances of the models fitted for random procedures should be much lower than the QSPR models obtained from the original target values [17].

2 Results and Discussions

2.1 Data Curation & Cleaning.

The importance of database quality used in supervised learning lies in ensuring that the information is adequately collected and curated. Therefore, a reliable dataset constitutes the key foundations for a meaningful knowledge extraction process. At the end of the learning process, the model is capable of mapping the input data (molecular descriptors) to the output data (target property) in a trustworthy way.

Despite the great effort involved in creating a new database, mistakes are often observed since the creation process is a manual one subject to human error. One of the main problems found in the database reported by Jabeen et al., [6] were the inconsistencies in the structures, and the IDs of the polymers also did not match with the IDs of the existing structures in the supplementary material.

A detailed revision of each polymer was performed. We found mistakes in 21 molecules of Jabeen´s database [6], but we will illustrate the curation and cleaning process only explaining a few representative cases. For example, we found that the Poly[oxy(methyl n-octadecylsilylene)] was duplicated but with different RI values, so we decided to solve this inconsistency by keeping the RI value reported in Bicerano's database [7]. Besides, we found that 16 polymers presented in Jabeen's database [6] contained errors in their chemical structure. For example, the Poly(2-ethoxyethyl acrylate), i.e. ID 37 in Table 1, lacked a carbon in the structure, therefore we added the missing carbon and developed the corresponding SMILES code. Figure 4 shows the structural difference.

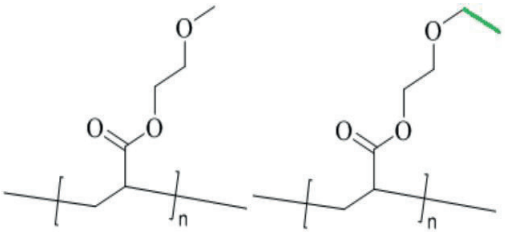

Fig. 4. The original structure is shown (left) and on the right the added carbon in green.

In all the cases that we had to correct the SMILES code, the Molinspiration Galaxy 3D Structure Generator tool [13] was used. For example, in the case of ID 37, which is poly(2-ethoxyethyl acrylate), we create the SMILES code: CCOCCOC(=O)CC, as shown in Figure 5.

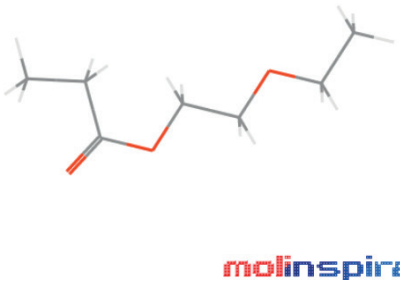

Fig. 5. The Poly(2-ethoxyethyl acrylate) represented by Molinspiration Galaxy 3D Structure Generator. The resulting SMILES code is as follows: CCOCCOC(=O)CC

Figure 6 shows the Poly[oxy(methyl n-octadecylsilylene)], i.e. ID 11 in Table 1. In this case, we verified that a carbon atom was wrongly located in the chemical structure. The carbon indicated by the cross was correctly relocated (highlighted in green). The resulting SMILES code is O[Si](C)(CCCCCCCCCCCCCCCCCC).

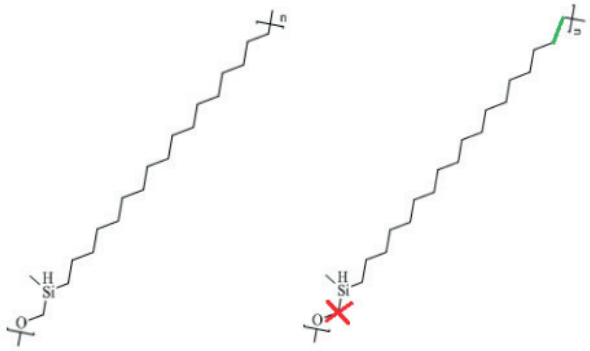

Fig. 6. On the left the original structure for Poly[oxy(methyl n-octadecylsilylene)] is shown and on the right its correction.

Regarding the RI values checking, we detected in Jabeen's database that several polymers with different structures have the same property value, which is an undesirable behaviour to QSPR modelling. For this reason, we looked up the RI values in the literature [7, 9-11], and we realized that the target values must be represented with four decimal places in order to denote those structural differences. Therefore, we have updated the property values, so now it is possible to differentiate the RI values for polymers with structural differences such as pairs ID 21-22, ID 25-26, ID 31-32, ID 46-47, ID 52-53, ID 69-70, and others. Figure 7 shows the structural representation of the polymers ID 46 (Poly (ethylene)) and ID 47 (Poly (2-fluoroethyl methacrylate)), where it can be seen that their structures are significantly different. Both have the same property value (1.476) in Jabeen's database, however, adding the fourth decimal place -taken from literature-, the difference in the property value can be appreciated (1.4760 and 1.4768 respectively). Finally, after a global and detailed checking, 126 polymers were included in the resulting database and used for QSPR modelling (see Table 1).

Fig. 7. Structures of two polymers: on the left the ID 46 and on the right the ID 47.

Table 1. Curated database of Refractive Index (RI) for 126 polymers.

ID	Name	RI
1	Poly(hexafluoropropylene oxide)	1.3010
2	Polytetrafluoroethylene	1.3500
3	Poly(trifluorovinyl acetate)	1.3750
4	Poly(pentafluoropropyl acrylate)	1.3850
5	Poly(dimenthyl siloxane)	1.4035
6	Poly(trifluoroethyl acrylate)	1.4070
7	Poly(2,2,2-trifluoro-1-methylethyl methacrylate)	1.4185
8	Poly(vinylidene fluoride)	1.4200
9	Poly[oxy(methyl n-hexylsilylene)]	1.4330
10	Poly(trifluoroethyl methacrylate)	1.4370
11	Poly[oxy(methyl n-octadecylsilylene)]	1.4430
12	Poly[oxy(methyl n-octylsilylene)]	1.4450
13	Poly(vinyl isobutyl ether)	1.4507
14	Poly[oxy(methyl n-hexadecylsilylene)]	1.4510
15	Poly(vinyl ethyl ether)	1.4540
16	Poly[oxy(methyl n-tetradecylsilylene)]	1.4550
17	Poly(oxyethylene)	1.4563
18	Poly(propylene oxide)	1.4570
19	Poly(3-butoxylpropylene oxide)	1.4580
20	Poly(vinyl n-pentyl ether)	1.4590
21	Poly(3-hexoxylpropylene oxide)	1.4590
22	Poly(vinyl hexyl ether)	1.4591
23	Poly(4-fluoro-2-trifluoromethylstyrene)	1.4600
24	Poly(vinyl n-octyl ether)	1.4613
25	Poly(vinyl 2-ethylhexyl ether)	1.4626
26	Poly(vinyl n-decyl ether)	1.4628
27	Poly(2-methoxyethyl acrylate)	1.4630
28	Poly(tert-butyl methacrylate)	1.4638
29	Poly(4-methyl-1-pentene)	1.4650
30	Poly(3-ethoxypropyl acrylate)	1.4650
31	Poly(n-butyl acrylate)	1.4660
32	Poly(vinyl propionate)	1.4665

33	Poly(vinyl methyl ether)	1.4670
34	Poly(vinyl acetate)	1.4670
35	Poly(ethyl acrylate)	1.4685
36	Poly(3-methoxypropyl acrylate)	1.4710
37	Poly(2-ethoxyethyl acrylate)	1.4710
38	Poly(isopropyl methacrylate)	1.4728
39	Poly(1-decene)	1.4730
40	Poly(propylene) (atactic)	1.4735
41	Poly(vinyl sec-butyl ether) (isotactic)	1.4740
42	Poly(dodecyl methacrylate)	1.4740
43	Poly(ethylene succinate)	1.4744
44	Poly(tetradecyl acrylate)	1.4746
45	Poly(vinyl formate)	1.4757
46	Poly(ethylene)	1.4760
47	Poly(2-fluoroethyl methacrylate)	1.4768
48	Poly(isobutyl methacrylate)	1.4770
49	Poly(methyl acrylate)	1.4790
50	Poly(oxymethylene)	1.4800
51	Poly(n-hexyl methacrylate)	1.4813
52	Poly(n-butyl methacrylate)	1.4830
53	Poly(2-ethoxyethyl methacrylate)	1.4833
54	Poly(n-propyl methacrylate)	1.4840
55	Poly(ethyl methacrylate)	1.4850
56	Poly(3,3,5-trimethylcyclohexyl methacrylate)	1.4850
57	Poly(vinyl butyral)	1.4850
58	Poly(2-nitro-2methylpropyl methacrylate)	1.4868
59	Poly(1,1-diethylpropyl methacrylate)	1.4889
60	Poly(methyl methacrylate)	1.4893
61	Poly(2-decyl-1,4-butadiene)	1.4899
62	Poly(3-methylcyclohexyl methacrylate)	1.4947
63	Poly(4-methylcyclohexyl methacrylate)	1.4975
64	Poly(vinyl methyl ketone)	1.5000
65	Poly(sec-butyl α-chloroacrylate)	1.5000
66	Poly(1,2-butadiene)	1.5000
67	Poly(vinyl alcohol)	1.5000
68	Poly(2-bromo-4-trifluoromethyl styrene)	1.5000
69	Poly(ethyl α-chloroacrylate)	1.5020
70	Poly(2-methylcyclohexyl methacrylate)	1.5028
71	Poly(1,1-dimethylethylene)	1.5050
72	Poly(cyclohexyl methacrylate)	1.5066
73	Poly(tetrahydrofurfuryl methacrylate)	1.5096
74	Poly(1-methylcyclohexyl methacrylate)	1.5111
75	Poly(2-hydroxyethyl methacrylate)	1.5119
76	Poly(vinyl chloroacetate)	1.5130
77	Poly(N-butyl methacrylamide)	1.5135

90	Poly(vinyl chloride)	1.5390
91	Poly(sec-butyl α-bromoacrylate)	1.5420
92	Poly(cyclohexyl α-bromoacrylate)	1.5420
93	Poly(2-bromoethyl methacrylate)	1.5426
94	Poly(2-bromoethyl ethacrylate)	1.5426
95	Poly(ethylmercaptyl methacrylate)	1.5470
96	Poly(1-phenylethyl methacrylate)	1.5487
97	Poly(p-isopropyl styrene)	1.5540
98	Polychloroprene	1.5580
99	Poly(methyl α-bromoacrylate)	1.5672
100	Poly(benzyl methacrylate)	1.5679
101	Poly(m-cresyl methacrylate)	1.5683
102	Poly(phenyl methacrylate)	1.5706
103	Poly(2,3-dibromopropyl methacrylate)	1.5739
104	Poly(ethylene terephthalate)	1.5750
105	Poly(vinyl benzoate)	1.5775
106	Poly(o-chlorobenzyl methacrylate)	1.5823
107	Poly(m-nitrobenzyl methacrylate)	1.5845
108	Poly(2-methylstyrene)	1.5874
109	Polystyrene	1.5920
110	Poly(o-methoxy styrene)	1.5932
111	Poly(p-bromophenyl methacrylate)	1.5964
112	Poly(N-benzyl methacrylamide)	1.5965
113	Poly(p-methoxy styrene)	1.5967
114	Poly(pentachlorophenyl methacrylate)	1.6080
115	Poly(o-chloro styrene)	1.6098
116	Poly(phenyl α-bromoacrylate)	1.6120
117	Poly(N-vinyl phthalimide)	1.6200
118	Poly(2,6-dichlorostyrene)	1.6248
119	Poly(chloro-p-xylylene)	1.6290
120	Poly(β-naphthyl methacrylate)	1.6298
121	Poly(2-vinylthiophene)	1.6376
122	Poly[oxy(2,6-diphenyl-1,4-phenylene)]	1.6400
123	Poly(α-naphthyl methacrylate)	1.6410
124	Poly(p-xylylene)	1.6690
125	Poly(α-vinyle naphthalene)	1.6818
126	Poly(N-vinyl carbazole)	1.6830

Molecular Descriptors Computation.
The DRAGON tool [18] was used to calculate 3839 molecular descriptors for each of the 126 molecules in the database. Therefore, a 95% correlation filter was applied to avoid molecular descriptors that provide redundant information. This filter reduced approximately to 82% of all the descriptors. Finally, 690 molecular descriptors that characterize the molecules and integrate the database were included.

In this way, the definitive database contains 126 curated molecules characterized by 690 molecular descriptors. It was split into two datasets, one saved as a training dataset (75%) and the other one saved as a validation dataset (25%). The value range of the property Refractive Index is from 1.301 to 1.683 for this database.

2.2 QSPR Modelling

Feature Selection
A total of 6 molecular descriptor subsets were selected from the initial pool of 690 molecular descriptors by using 6 different methods. In Table 2, all the subsets, together with used methods and cardinalities are listed. The cardinality for all subsets is higher than the reported by Jabeen et al., [6], which is 4. However, a popular rule suggests that there should be at most one descriptor for every five molecules of the dataset used [19]. It is noteworthy that the 6 selected subsets meet this rule, because they are below to 25 descriptors.

Table 2. Results of the Feature Selection process, selection method, and cardinality of the six subsets selected.

Subset	Feature Selection Method	Cardinality
Subset 1	CFS	16
Subset 2	LR	23
Subset 3	NN	9
Subset 4	RF	11
Subset 5	RC	10
Subset 6	KNN	23

QSPR Models Inference.
In total, 30 models were inferred by training each of the 6 subsets with 5 learning methods. In all cases Leave-One-Out (LOO) was applied. In Table 3, the QSPR model with the best performance, in terms of coefficient of determination, denoted R^2, and the learning method used to infer it, are shown for each subset.

In particular, the best models inferred from subsets 2, 3, and 4 achieve performances above 0.90 of R^2 during the training stage. Therefore, we decided to select these models to continue with the next stage.

Table 3. Results of the QSPR Models Inference process to the best models, value of R^2 and learning method employed

Subset	Inference: R^2	QSPR Method
Subset 1	0.8438	RF
Subset 2	0.9750	LR
Subset 3	0.9012	LR
Subset 4	0.9118	RC
Subset 5	0.8608	RC
Subset 6	0.8538	RF

QSPR Models Validation

External Validation. For the three QSPR models selected in the previous stage, an external validation was executed using the validation dataset saved at the beginning of the experimentation for this purpose. In Table 4, the results of the external validation for each model, the gap in terms of R^2 between training and external validation performances, the classification of the predictions according to Roy's Method [16], and the model's cardinality are shown.

Table 4. Results of external validation in terms of R^2, Mean Absolute Error (MAE), R^2 Gap, and the classification of performance by Roy's method (Roy's Class) for each model.

Subset (cardinality)	Validation: R^2	MAE	R^2 Gap	Roy's Class
Subset 2 (23)	0.8694	0.0176	0.1056	Good
Subset 3 (9)	**0.9097**	**0.0181**	**-0.0086**	**Good**
Subset 4 (11)	0.9048	0.0161	0.0071	Good

Considering the performance of the reference model published by Jabeen et al., [6], which reached 0.8820 of R^2 during the external validation and a R^2 Gap of 0.05, we decided to discard the best QSPR inferred from Subset 2. On the other side, both Subset 3 and Subset 4 present similar behaviours in terms of performance, significantly overcoming the reference model [6]. Nevertheless, note that Subset 3 has a negative R^2 gap value. This means that the QSPR model associated with this subset obtained a higher R^2 in the external validation than the obtained in the training. In other words, this model has better generalization than the models learned from Subsets 2 and 4. This could indicate that the Subset 3 is the best alternative for modelling the structure-activity relationship among the 6 subsets.

In addition, considering the errors in the model's predictions, an evaluation MAE-based was carried out following Roy's method [16]. This method classifies the model predictions into three categories: Good, Moderate or Bad. All models were classified as Good (see Table 4). In this case, the Roy method was not helpful in discarding models because they all have the same classification. However, it helps to know that they are reliable predictions.

In summary, a rigorous external validation of QSPR models was properly done, and the model inferred from Subset 3 was selected to continue to the next stage. This decision is supported by two main observations: is the one with the lowest cardinality and has a negative R^2 gap value. In other words, the possibility of overfitting is rejected, because the predictive capability does not fall (in fact it increases) for unknown data (validation dataset). From this point, this QSPR model learned from Subset 3 using the LR method will be denoted as our best QSPR model.

Chance correlation test. Our best QSPR model is chosen for executing the chance correlation test. In this case Y-Scrambling is used, which consists of randomly mixing the Y (target) values. This test was run 100 times, using the molecular descriptors of Subset 3 and LR method, and finally the mean value performance of the QSPR random models trained in these trials is $R^2 = 0.0258$ and the standard deviation is 0.0422. Thus, we conclude that the QSPR model inferred from Subset 3 is a recommendable option for RI prediction, because it overcomes the reference Jabeen's model performance and, also, the risks of overfitting and chance correlation can be discarded. However, our model has a higher cardinality (9) than the Jabeen's model (4), which is a not desirable characteristic because the models that use several molecular descriptors usually have a more complex physicochemical interpretation.

3 Conclusions

The quality of the data to be used in supervised learning processes always has a central impact on the reliability of the models inferred by these techniques. On the other hand, we know that in the field of material sciences the efforts to provide consistent data sources are high. Nevertheless, the integration of results from different experiments is a complex task, where there are multiple factors that lead to the introduction of mistakes. For this reason, even the databases provided by the scientific literature are subjected to rigorous review processes; they may contain inaccurate or wrong data. Consequently, the checking, curing and cleaning of the databases constitute a mandatory step in any QSPR modelling project in Polymer Informatics.

In this work, we have presented a process of curing and cleaning of a database to be used in the QSPR modelling of the Refractive Index of polymers. In this regard, it should be noted that the generality of the steps proposed for this process allows its application to the curing of other databases in Polymer Informatics. In this sense, the importance of physicochemical knowledge was demonstrated to achieve the correction of chemical structures and their corresponding computational representations guided by an expert in the domain. In this way, it contributes to improving the knowledge extraction process, since the final performance of the QSPR models is increased because of the availability of more reliable data, as can be seen in the models reported in this work.

However, although the models that we have obtained using machine learning methods have achieved a promising performance, it is also true that they constitute "black box" models, i.e., models whose interpretability in physicochemical terms is not always easy to establish. For this reason, it would be desirable that a domain expert could intervene in the process of design of the QSPR model being assisted by

supervised learning methodologies. In particular, the use of strategies and tools for active learning may constitute an alternative to take advantage of expert knowledge. In this regard, we plan to use the VIDEAN software [20] in the future. This tool allows us to evaluate the role of alternative subsets of descriptors for the definition of a QSPR model, by using interactive visual analytics. In this way, we can achieve more interpretable models that employ a smaller number of descriptors. Moreover, taking into account the principle of Occam's razor, it is known that the fewer variables used in the definition of a model, the simpler and more generalizable it is the model.

Abstract. With the recent advances in automation and information technologies that triggered the ongoing transformation of production systems into cyber-physical systems (CPS), many industrial organizations have been recently adopting data collection technologies to improve the efficiency and effectiveness of their processes. The Big Data Analytics are being used to analyze large amounts of data and help improve different aspects of an industrial operation. As enterprises face challenges such as increasing costs, quality control and operations. Systematizing how to apply data analytics to improve their processes and practices is, hence, a relevant issue. This paper contributes to this by providing an understanding of how to develop a data analytics process management in manufacturing industries. First, it reviews the existing literature related to data analytics, focusing on analysis and information requirements for manufacturing process and framework. Second, it discusses the major functionalities of data analytics process presented in the literature review, focusing on features that are useful for process management. Finally, it presents and discusses the implications for future research of a conceptual framework for the definition of data analytics process management.

Keywords: Big Data Analytics, Data Analytics, Process Architecture BDA, Operations Strategy

1 Introduction

With the recent advances in automation and information technologies that triggered the ongoing transformation of production systems into Smart Manufacturing based on cyber-physical systems (CPS) and implementation of Internet of Things (IoT), many industrial organizations have recently adopted data collection technologies to improve the efficiency and effectiveness of their processes. Also, with the growth of available data in industrial organizations data analytics has played a major role on manufacturing process, creating challenges for people and machines for data gathering, preparation, analysis and visualization.

The implementation of Big Data Analytics (BDA) in manufacturing processes has potential performance benefits in customer satisfaction, operation expenses and productions productivity [1]. According to Platts, operations managers need to formulate strategic manufacturing planning to achieve enterprise goals, each enterprise has diverse operation practices, but there are four features characteristics of robust and successful methodologies for operations management: procedure, participation, project management and point of entry [2]. Also, to reach operations management goals, organizations need an accurate and efficient performance indicators to guarantee that data gathered is transformed in usable information. According to Bourne et al., based on a study presented by Pettigrew, to generate an accurate performance indicator is important consider organizations fundamental resources for performance indicators development that are concept, context and process. [3] Big Data Analytics aims to assist business organizations to achieve improved understanding of data, and thus, make efficient and well-informed decisions. However, implementing Big Data Analytics at industrial operations is hazy and depends on each scenario and technology used. It is also important having a well-defined systematic architecture design for Big Data Analytics that comprises modern and legacy systems as presented in the studies of [4][5].

This paper contributes by providing an understanding of how to develop a prescriptive data analytics process management in manufacturing industries. Considering the operations strategy indicators performance analysis, based on [2] and [3], using the main concepts of Pettigrew.

First, it reviews the existing literature related to data analytics, focusing on analysis and information requirements for manufacturing processes using the systematic literature review framework called Proknow-C. Second, it discusses the major functionalities of data analytics process by presenting what is available in the literature, focusing on features that are useful for process management. Third, it presents and discusses the implications for developing a data analytics architecture and recommendations with a framework considering data analytics stages and tasks. Finally, concluding with a conceptual framework based on literature review for the definition of data analytics process management.

2 Research Design

This section presents recent research findings in terms of approaches and principles for big data analytics process in industrial organizations and it discusses current practices.

Developing an architecture for data analytics process is complex and diversified. Understand requirements, tools and perspectives from literature is fundamental. Thereby, for this purpose we develop a literature review that follows the steps of the method Proknow-C. According to Afonso et al. [6], Proknow-C literature review framework consists of systematic steps of the literature review in order to have a better portfolio of scientific documents, providing a structured and rigorous procedure, which minimizes the use of randomness and subjectivity in the process of literature review.

The first stage of the literature review consists on defining areas of research interest. In this research, we focused on data analytics architecture and process so we use the

main areas as Data Analysis, Industrial Process Management and Process Architecture. Then, the next stage of the research is to define the research string and databases. Considering the previous stage we define main search keywords to construct the string that is (("" Big Data "OR" Analytics "OR" BDA ") AND (" Architecture "OR" Framework "OR" Method "OR" Method "OR" Procedure "OR" Process ") AND (" Manufacturing ")). With a definition of the string, it was possible to define a database to the literature research; we used Web of Science and Scopus. Considering those databases, we start the research considering documents written in English and excluded repeated documents, which resulted in 2308 documents. Subsequently we selected documents that have title and abstracts in line with BDA or data analytics process architecture research, which resulted in 203 documents. Considering that batch of documents, we develop a document classification of scientific recognition based on document citation impact. Applying this classification analysis to the documents we found out 62 documents including book chapters, scientific articles, conference papers and journals with a considerable scientific recognition. The distribution of the documents by year are presented in Figure 1.

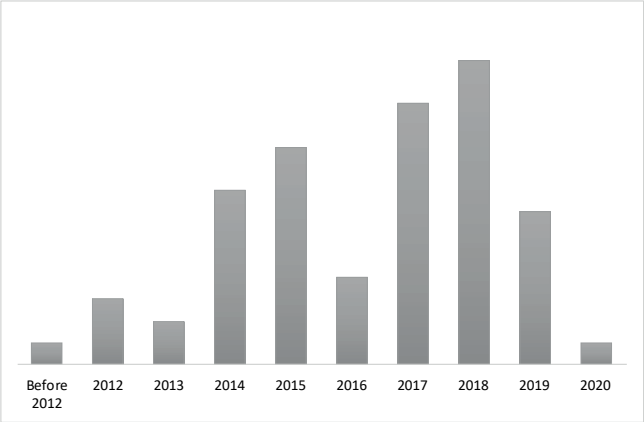

Fig. 1. Distribution of 62 papers by year.

Thereat, to develop a literature review focused on data analytics process architecture; we analyze documents content and context to guarantee that the documents are in accordance with the study. Considering the methodologies for manufacturing strategies formulation, we develop a scientific literature review and use a classification of operations performance strategy concepts based on [2] and [3]. According to the authors, to develop a process architecture it is important to consider strategic operational concepts, as well as company performance indicators. In addition, operations managers need to formulate a strategic manufacturing plan to achieve organization objectives, considering that each company has its different practices to operate.

According to Platts [2], there are four main features characteristics of robust and successful methodologies for operations management, that are: procedure, participation, project management and point of entry. In addition, another highlight to consider in data analytics process architecture is to develop intuitive and accurate performance

indicators. As presented by Bourne et al., based on Pettigrew concepts, the organization fundamentals resources to develop performance indicators are: concept, context and process. To validate the documents considering operations management strategy and performance indicators we develop a matrix using this two concepts based on area of the study [3].

First, we analyze the 62 documents and select each area of data analytics process architecture that was classified in Process Architecture BDA, Process Architecture and Data Analytics, Theories of BDA and Simulation. We consider items that are treated as data analytics process architecture, and if those architecture and process includes concepts of BDA. Thus, on the second step we follow the context of operations strategy and performance indicators, we define the context of the documents, considering if is a theoretical, hypothetical or practical study.

Define context is important, since some documents present case studies, there are documents of computer science data analytics and others related to the BDA process and theories. If, in the analyzed documents, is a case study it is considered a hypothetical or practical document, we continue to validate as an operations strategy and performance indicators matrix. So on, we validate the concept of the document, which are the resources, in this step we define resources used at the case studies which are the data analytics resources (e.g. tools and techniques of data analytics), also process resources (e.g. tools and techniques to process architecture) considering each step. Finally, considering operations management strategy and performance indicator we validate the process, in that we define participants (e.g. individual or group study), project management (e.g. if the participants are from managing, supporting or operational group), also we define the point of entry of the study, which is define expectations, understanding and agreement of the managing group.

After the literature review using operation strategy and performance indicators matrix, we define that some documents do not refer to data analytics process architecture. Thereby, we decide to exclude documents with specific contents in the area of computer science which relevance is related to the technical implementation of data analytics. As well, articles that cover areas correlated with the BDA, but that do not present it as the main area of process architecture, or even a fundamental step for the data process analysis. Considering this analysis, we came out with 23 documents, which are separated in four main areas: Process Architecture BDA, Process Architecture and Data Analytics, Theories of BDA and Simulation, presented in Figure 2.

Fig 2. Distribution of 23 papers main areas.

3 Results of the Systematic Literature Review on Big Data Analytics Process Architecture

Performing the literature review analysis we could verify that a construction of the data analytics process architecture could be represented in several areas. To develop a data analytics process architecture, it is important to understand the initial stage of data development, which could be represented by cyber-physical systems. According to Lee et al., it is important to define the connectivity to real-time data acquisition from the physical world, also the data analytics management that constructs the cyber-space. Another important point to understand when developing processes architecture in data analytics is smart manufacturing [7].

As presented by Tao et al. [8], industrial organizations use big data analytics to refine manufacturing process, the concept of data-driven smart manufacturing provides a full range of services to reduce losses and enable significant increases in manufacturing efficiency and improvements and product performance. In addition, simulation papers present the role of data analytics in manufacturing based on simulation context, using data analytics as direct use of simulation as data analytics application, or use the simulation for supporting data analytics applications [9].

Considering literature review present in many areas of application of data analytics in process architecture development, we define some recommendations to develop a framework of data analytics process architectures. Also, in the next section we will discuss each of its five layers.

3.1 Data Gathering

The first step that must be considered in the control of a BDA process architecture is related to data gathering, in that step is important to consider language, format and type of data. According to [10], it is important to create a multi-source heterogenous big data systems specifying which language will be used. The construction of an accurate cyber-physical systems enable data gathering to measure and control data indicators. Data gathering stage consider what is the type of data and how to select proper sensors. [7]

Data gathering depends on type and dimensions of data to develop data analytics process architecture. Data could be structured, semi-structured or unstructured. Dutta & Bose, present a case study with a variety of data gathered that could be separated in structured, which has a common language and interoperability (e.g. ERP database, charts) and unstructured data, that is represented by images, social media, text and other types of data (e.g. web site, excel sheets, streaming video) [11].

Hence, to develop and accurate data analysis it is important that process architecture consider the use of more than one type of data. Considering [12], the structured data is a relational database that has the same language, format and model of data. Semi-structured data could present some irregularities at the model. There is also unstructured data, which is raw and does not have a data model. It is a large number of data, without the same format or language. At construction of a reference architecture authors present

some extractions of each type of data using different tools to gather data as Scribe-Hadoop, MySQL and Kafka.

Considering [13], the authors presents a system architecture to implement intelligent predictive maintenance. In Data Gathering phase, data from several sources is collected and stored in MySQL database (e.g. operators and quality department). According to [9], is important to ensure that your data collection is generated according to principles of Big Data for analysis, there are four main manufacturing data characteristics: volume, veracity, variety and velocity. Considering these dimensions, authors propose the use of MTConnect Generation as a generation module to streaming the data and translate it into XML-based MTConnect.

3.2 Data Preparation

Data preparation is an important step to conduct transformation of raw data into usable and assertive data, considering that are many ways to transform data into information: using models, tests, statistics it depends on each project. This layer is the process between the gathering layers to process layer, it is the stage where you clean, standardize, validate and reformat the data to be able to analyze it [14].

According to [15], data preparation is an important stage of data transformation in big data analytics. To achieve that, there are some preprocessing operations to implement in datasets as noise reduction, outlier detection, anomalies removal, feature extraction, to create uniform datasets. In addition, [16] presented at CRISP-DM a reference model that considers the preparation level tasks as cleaning transform and model data. Another use of data for manufacturing analysis is presented by [17], the authors propose an architecture which is divided in extract, transform and load data and manufacturing process analysis. Then, they also propose extraction of process information with Mapper and Reducer of Hadoop framework and after that store the data.

After data preparation, cleaning, formatting and standardization it is possible to develop an effective data analytics. At this stage, it is important to define storages to collect and distribute data systems. As presented by [18] the preparation stage is important to preprocessing algorithms, some recommended tools to prepare data are Apache Pig to classify raw data and Apache Hive to generate basic tables from metadata.

3.3 Data Analytics

Considering the data was gathered and prepared, the next stage is to develop accurate information and efficient indicators.

According to [8] there is a variety of techniques of data modelling and analytics as clustering, machine learning, large scale computing. At this point, the efforts from data analytics engineer and the operator are very important to validate and develop a model with credible data and accomplish information with performance indicators. To implement a case study the authors use a variety of data to develop analytics using BR neural network, a smart failure diagnosis and cluster analysis. Also, considering data

analytics, quality information is important to develop dependable data models. To create a quality prediction model it is important to use some classifications algorithms as decisions tree, random forest and artificial neural network as analysis techniques, they used the R language to deploy the quality model, also used the RandomForest library to random forest and net library for artificial neural network. [19].
According to [20], the data collected need to have high dimensionality and large sample size to develop accurately indicators, these characteristics are important to analyze data in a more effective way. Big data analytics has a diversified range of research as simulation, maintenance, quality, and manufacturing. The use of analytics in predictive manufacturing is represented in the journal of [21]; use the predictive manufacturing to develop a model based on fuzzy unordered induction algorithm to predict performance of manufacturing. Data mining is one of the important steps of data analytics, according to [22] data mining need to consider two functionalities, first metric oriented root cause analysis which identify circumstances under which metric is selected. Second is the structure analysis that is based on clustering of selected process, thereunto authors presented some tools to data mining such as Java using WEKA.

According to [23], to develop manufacturing IoT is important to define the principle categories of data analytics, according to complexity and methods. The classifications of data analytics approaches are descriptive, diagnostic, predictive and prescriptive. Also, the authors develop a representative case study and use each category of data analytics. Another approach into big data analytics presented by [24] is complex atomic events, that are a mass of events that are a combination of methods, techniques and tools to analyze a mass of events in real-time to obtain accurate information to implement data analytics. Also Krumeich et al., introduce MapReduce that is a tool that decomposes a problem into independent subproblems that are distributed and solves by mappers.

3.4 Data Visualization

Defining a data visualization tool is an important task for the implementation of data analytics architecture, it provides information for operations strategy management that aims to decision making. There are a large number of ways of data visualization as a considerable numbers of charts, graphics, and tables and there are some specific platforms that are used for data visualization such as Tableau and PowerBi.

According to [18], there are plenty ways of data visualization that could be applied, in the case study the authors represented findings using charts and tables, also some examples of computer-aided engineering. Another tool to visualize graphical indicators is JFreeChart, use for root cause analysis or structure analysis; also there are WEKA for decision tree visualization [22]. Also, creating visual data is important to considerate the interface aspect since the user need to be well informed about data analyzed. According to [20], a data scientist needs to be careful on each tool or types of charts, which will be used to display the information.

Big Data systems need to be user-friendly and intuitive to provide a fast-response and enable users to search information. Another functionality of data visualization is for business intelligence, a user intuitive interface that has performance management,

operations strategy indicators and financial goals could improve decision-making. According to [12], there are solutions that offer intuitive visualization tools that consider user experience capabilities as Tableau, Karmasphere and Datameter.

3.5 Data Stakeholder

Considering the literature review developed at this paper, we propose. The data stakeholder stage. As presented in scientific study of Platts, the four main features characteristics of robust and successful methodologies for operations management, that are procedure, participation, project, management and point of entry. During literature review, we found a vast majority of papers presenting case studies of data analytics procedures and project management. As the aim of the paper is to provide a data analytics process architecture, reaching strategic operations to develop accurate indicators, we are considering also participation features and point of entry [2].

According to [2] the characteristics of project management methodology are adequate resourcing, agreed timescale and identify managing group, supporting group and operating group. In addition, participation methodology highlights individual and group commitments to support decision-making and develop workshops. To develop a data analytics architecture process framework we recommend to consider project management and participation aspects that will be present next. According to [25], data analytics uses model library to help the decision support. These decisions are targeted to different stakeholders and are available to continuous performance improvement as a component to dissemination.

Considering that premises, present at CRISP-DM [16] model business understanding as an initial phase that focus in understand project objectives and requirements from a business perspective, then converting this knowledge into a data mining problem definition and a preliminary plan designed to achieve the objectives. According to [24] is important to adapt and optimize business process. Also to create feedback channel from operations to business process execution to guarantee optimal business process. Develop a study based on interviewing manufacturing enterprises to define how the utilization of BDA changes manufacturing operations, and the results are that using BDA really enhances manufacturing performance, and such improvements can foster differential performance impacts on cost reductions, planning improvements, better prediction of events and enhance customer satisfaction. As a recommendation, the authors propose that enterprises should pay attention on BDA management capability, to create better utilizations of BDA in operations and process performance [1].

Develop a case study based on sustainability factors for manufacturing systems that present the importance of the participation of top management and executives to improve manufacturing organizational performance. Also, to enhance operational efficiency is important to integrate suppliers and customers. As one of the analysis presented management and leadership style the highest influence on BDA, also employees from all levels must participate in BDA adoption as a sustainable business performance [26].

Omar et. al [27] develop a framework considering the actors of business analytics ecosystems in manufacturing . As presented by Omar et. al [27]: 'Business units executives must recognize and solve problems based on evidence. This evidence is identified by personnel with analytical skills that apply statistical models to data. Also, business translator is responsible to bridge the work of analytical personnel to executives and managers. Top management sponsorship and buy-in is necessary to guarantee success. Finally, an IT team and external technology suppliers are necessary to provide the tools and processes needed for the aforementioned actors to generate value and deliver it to customers.'

Considering the literature review of operations management and BDA, we developed the data stakeholders stage. This is a data project management stage. When developing a data analytics project there are a range of enterprise areas involved. It is important to understand the business, but also your stakeholders. Developing an accurate and intuitive platform is important to guarantee better decision making, to do so, it is important to understand who will use the platform and how are the operations involved in the process that the platform will be applied. Understanding the context of the indicators (e.g. strategic indicator or operational indicator) is important to well inform your stakeholders. To do so, we propose that stakeholders participate in data analytics and data visualization stages as contributors to the development of indicators performance. The participation will be aimed at presenting insights and sharing knowledge about the process improvement and user experience through brainstorming and meetings. What we propose here is to create a multidisciplinary group with operational, supporting and management participants when necessary to develop data analytics indicators.

4 Proposed Big Data Analytics Process Architecture Framework

After literature review and discussion of the propositon of five stages, we propose a framework highlighting key aspects of big data analytics process presentend on Figure 3. To develop the framework we analyse all processes and architectures presented in the literature review and highlight similarities and differences. As presented in the literature review a majority of the documents present process architecture BDA recommendations, since gathering data to data visualization. According to [28], process and planning are the most prominent contributions of BDA, over 60% of the documents are architecture, platforms and frameworks.

Data Gathering is represented by CPS networks, it considers all the data providers in manufacturing site (e.g. sensors, RFID, ERP, excel sheets) at the end of this process we propose the use of a data storage based on literature review recommendations. At Data Preparion layer, as presentend in literature review an important step is to conduct transformation of raw data into usable and assertive data, we propose a process of gathering raw data, using a BDA tool presented on literature review, to transform, standardize and validate the data. In this step is important to mitigate data outliers, noise and anomalies.

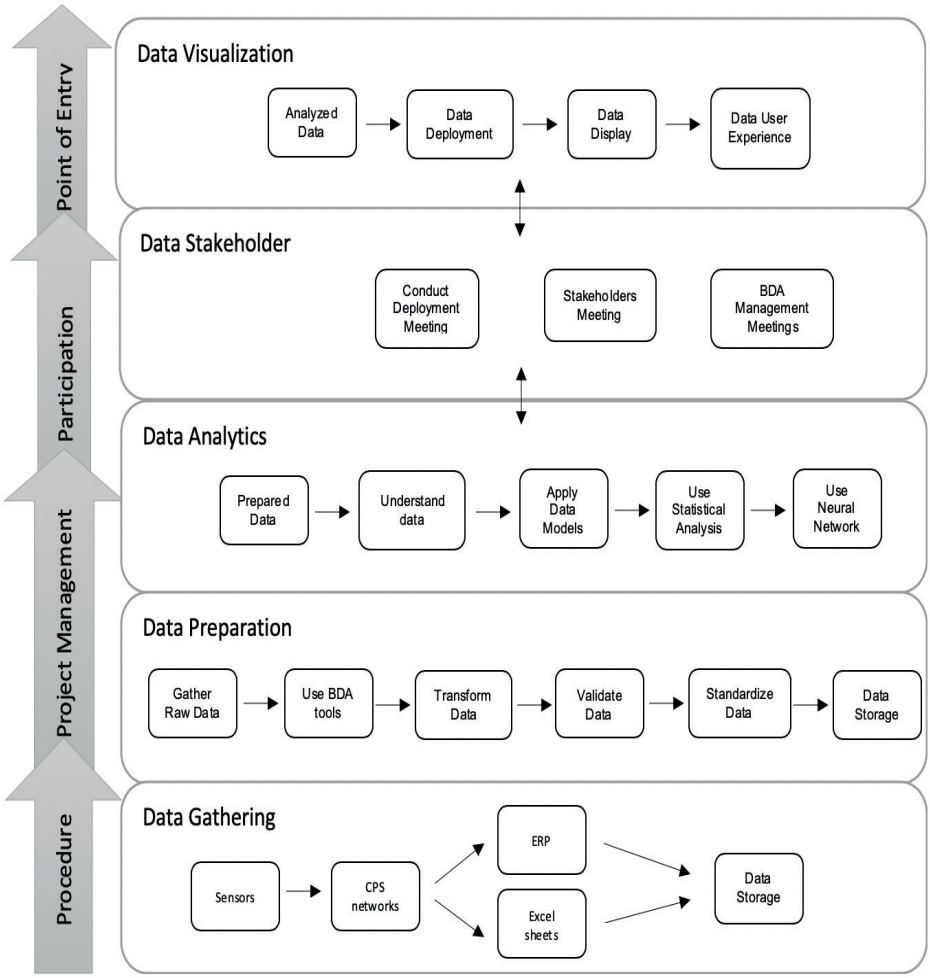

Fig. 3. Framework for Big Data Analytics Process Architecture.

Third layer is Data Analytics, it is important to develop the accurate information to develop accurate and efficient performance indicators to achieve organization's goals. At this stage, the data prepared will be transformed in information. To do so, it is important to understand data business, and to achieve that a data analytics group of study must understand which are the enterprise problems, goals and what they expect with the analysis. At this point we recommend a weekly meeting to allying stakeholders expectations with data analytics. It is important to highlight that, sometimes the data is not enough to develop better information, but when data analytics group meet with stakeholders, they could construct the paths to analyze data and achieve good performance indicators. After that, the data analytics group could apply the models of neural network, statistical models or other analyzes, it depends on what information

stakeholders need. At the end the group will conduct a deployment meeting with people involved on data transformation.

The fourth layer, Data visualization, according to our literature review this layer provides information for operations management strategy that aims to decision making. At this stage the data analyzed is displayed in performance indicators and informations in tables, charts and data visualization tools. At this layer it is important to guarantee that the data analyzed will present accurate business information. Also, it is important to guarantee good user experience, once the data will be used for different organization areas (e.g strategic, operational, support). To achieve that, stakeholders meetings will be required to develop indicators, after that information could be deployed.

The Data Stakeholder layer is represented without a prescriptive process considering. Considering [26], that presents factors for sustainable manufacturing BDA, one of the factors are management and leadership style which consider that all employees must participate to decide mission and vision of BDA adoption for sustainable business performance. Also, Data Stakeholder has interface process with data analysis and visualization, considering the importance of stakeholders from different management areas. It is important to understand the business, but also your stakeholders. Developing an accurate and intuitive platform is important to guarantee better decision making, to do so, it is important to understand who will use the platform and how are the operations involved in the process that the platform will be applied. The representation considers that stakeholders will participate during the process development of the two stages, presenting insights and requirements.

5 Conclusion

The paper presents recommendations for the development of Big Data Analytics Process Architecture according to literature review. The literature review is conducted using Proknow-C steps, in order to have a better portfolio of scientific documents, considering academic relevance for the study. Thereby, with the study, it is possible to notice that are authors which develop big data analytics process architectures for implementation and there are some recommendations of tools and techiniques. During the developmnet of the paper we noticed that architectures recommended by the selected authors, presented in the literature review, are not prescriptive to a generic situation, considering most being from case studies.

In this paper we present recommendations for implementing a BDA process architecture, considering what exists in scientific literature and some interesting points to be considered to develop a big data analytics process architecture. We recomend fives stages that are important to implement a data analytics project: data gathering, data preparation, data analytics, data visualization and data stakeholder. To define those stages we use documents with scientific recognition. After the literature review and recommendations we present a framework considering main processes and tasks to develop a big data analytics process architecture. For future research it would be interesting to carry out a practical application of the process to see if it will work in

different types of processes, since, as presented in the literature review, the process architecture could vary according to the case study.

Abstract. A preocupação das organizações em redução de custos com energia elétrica, seja para otimização da economia organizacional, cumprimento de requisitos regulatórios ou melhoria da imagem no mercado, estão cada vez mais percebidos e incorporados no mercado corporativo. Assim, o objetivo deste artigo é discutir modelos existentes sobre melhores práticas em eficiência energética em edifícios comerciais. Para atingir o objetivo, foi realizada uma revisão sistemática da literatura em dezesseis artigos relacionados à temática, buscando suas principais contribuições e pontos convergentes. A pesquisa apresenta um panorama das proposições existentes de Modelos de Melhores Práticas de Eficiência Energética em edificações e principais contribuições, e pode ser utilizado como referência para proposição de novos modelos, considerando os *gaps* identificados neste estudo.

Keywords: Modelos, Shoppings Centers, Melhores Práticas em Eficiência Energética

1 Introdução

Na realidade do mundo contemporâneo, muitas das atividades desenvolvidas dependem do uso da energia elétrica. O uso deste insumo representa um fator essencial ao desenvolvimento de produção, melhoria da qualidade de vida, e no progresso de um país. Desta forma, a geração de energia elétrica é tratada como um ponto vital no debate estratégico, político e econômico dos governantes. Assim, buscando melhores formas de processos, formas de produção e utilização energética com melhores técnicas e ferramentas, que visam otimização de custos, vêm à tona a eficiência energética.

A preocupação das organizações em redução de custos com energia elétrica, seja para melhoria da economia organizacional, cumprimento de requisitos regulatórios ou

melhoria da imagem no mercado, estão cada vez mais percebidos e incorporados no mercado corporativo. Neste contexto, surge a necessidade de se analisar como estão as práticas em eficiência energética. Assim, a questão de pesquisa do presente artigo é: Qual o estado da arte em relação a proposição de modelos de melhores práticas em eficiência energética em edifícios comerciais? Considerando o grande consumo energético que os edifícios comerciais representam, delimitou-se, para esta pesquisa, analisar apenas o contexto dos edifícios comerciais.

2 Metodologia

Os métodos de coleta de dados compreenderam o estudo e análise de artigos científicos encontrados nas principais bases de dados, as quais *Scopus* e *Web of Science*. A justificativa da escolha dessas duas bases se dá pela relevância que as mesmas possuem no âmbito da pesquisa acadêmica. Para isso realizou-se uma revisão sistemática da literatura nas duas bases, sem limite temporal, com o padrão: TS para a pesquisa na *Web of Science* e *Tittle* - ABS - *Key* para pesquisa na *Scopus*, chegando em um total de 271 artigos que foram submetidos em processo de primeira filtragem, por meio de leitura prévia dos títulos para verificar alinhamento com o tema da pesquisa. Para finalizar o processo de filtragem, com o segundo filtro, os artigos foram submetidos à leitura integral para confirmar o alinhamento ao tema da pesquisa, e finalmente compor o Portfólio Bibliográfico (PB). Assim, chegou-se em 16 documentos, que fazem parte do portfólio bibliográfico final utilizado para esta pesquisa.

3 Resultados e discussões

Dentre a análise dos 16 artigos relacionados na proposta metodológica, o estudo inicia-se com a apresentação do *benchmark* de Chung, Hui e Lam (2006) onde os autores analisam esse método, como importante ferramenta para promover o uso eficiente de energia elétrica em edifícios comerciais.

Em outro estudo (JUAIDI *et al*., 2016) os autores apontam como estratégia de eficiência energética a automação dos sistemas de iluminação conforme demanda e tempo, ocupação de ventiladores com controle de utilização, emprego de cronogramas de manutenção. Também, Li e Li (2018) apresentam dentro dos processos de *benchmarking,* a validação de análise dos dados do desempenho energético, sobre o foco de identificação do potencial da economia de energia.

A utilização de lâmpadas de LED também foi analisada em outros estudos Toleikytè, e Bointner (2016), como proposta de melhor iluminação para os seus usuários e colaboradores. Neste estudo considera-se que a eficiência energética de *shoppings centers* deve estar embasada na estruturação políticas e planejamentos de metas que visam a economia na energia elétrica. Sobre o debate de estratégias de redução da demanda de energia elétrica, Raimondi et al. (2018), consideram o emprego de sistema de automação predial, para a maximização de economia de energia pela utilização de sensores que modulam o fluxo luminoso e o emprego de uso de claraboia, incentivando o uso da luz natural. A tratativa sobre a recursos naturais, percebida por Fitzge-

rald E Woods (2007), está direcionada aos mecanismos mecânicos de ventilação natural, com o objetivo de melhorar o resfriamento da área de alta densidade de um shopping: a praça de alimentação.

Os Sistemas de Ventilação e Ar Condicionado - *Ventilation and Air Conditioning Systems* (HVAC) também foram tratados, onde Mondal e Bhattacharya (2014) questionam a centralização de controle principal de ventilação, consumindo dessa forma maior quantidade de energia, quando se considera um sistema de controle distribuído, pode-se perceber uma redução do consumo de energia. Essa sugestão, representou no estudo uma diminuição do consumo de energia, assim como a redução de utilização de recursos como o cobre, plástico e aço, necessários para a confecção das peças (REBOLLO et al., 2016). Outros pesquisadores indicam a utilização a ferramenta, *Building Management System* (BMS), apontando essa como uma assertiva de estratégias na gestão eficaz de energia elétrica (CANBAY, HEPBASLI, GOKCEN, 2004).

Duas abordagens um pouco diferentes foram percebidas nos apontamentos de Fu e Zhang (2012) retratam projetos futuros, não se preocupando apenas em designs tecnológicos e desenhos futurísticos. Também, estudos de Fasiuddin, Budaiwi e Abdou, (2009) sugerem estratégias de custo zero, que podem ser utilizados na redução do consumo de energia elétrica, tais como: controle do termostato, controle de uso noturno, cronograma programado de operações.

Ainda dentro das propostas verificadas para a redução do consumo de energia, Çağlar (2011) trata em seus estudos um comparativo sobre o isolamento térmico, relacionando um edifício sem isolamento em comparação a um que possui isolamento e que utiliza diferentes fontes térmicas. No debate sobre as considerações sobre eficiência energética, Wang et al. (2006), apresentam uma metodologia de um diagnóstico que objetiva a identificação do baixo desempenho energético, assim como a verificação de suas causas.

Com base na concepção do design da construção, Aste e Del Pero (2013) debatem que as estratégias para melhorar a eficiência energética devem estar incorporadas não somente no planejamento de novas estruturas, novos edifícios; mas devem fazer parte na reutilização de estruturas antigas. Entrando um pouco em indicadores de eficiência energética, Pan (2011) traz a utilização do software *Energy Plus*, onde os parâmetros podem ser calibrados e detalhados de acordo com a conveniência do local, visando a redução do consumo de energia. Antunes, Carreira e Silva (2014) os autores identificam uma lacuna entre o gerenciamento de eficiência energética e sua implementação prática, e como proposta sugerem um Modelo de Maturidade em Gerenciamento, com base na ISO 50001.

4 Conclusões

O presente estudo verificou os mais variados esforços que contribuem para o uso otimizado da energia. Percebe-se e crescente preocupação com o debate de eficiência energética, destacando-se medidas de adoção em construções, onde essas preocupações são incorporadas já na concepção do projeto, edificação e manutenção.

Neste contexto, considerando a questão de pesquisa apresentada, constatou-se que proposições de modelos de avaliação de melhores práticas em eficiência energética ainda são pouco explorados. Assim, surge uma lacuna de pesquisa, que pode propor mais modelos de avaliação.

Abstract. Las técnicas tradicionales de evaluación de eficiencia, DEA, asumen la hipótesis de que los valores de *inputs* y *outputs* son determinados con certeza. Sin embargo, en el mundo real, muchos procesos de producción involucran a menudo datos que son imprecisos, vagos o ambiguos. En estos casos, la imprecisión o vaguedad puede ser expresada como una función de pertenencia dentro del ámbito de la lógica difusa. Si bien se han desarrollado varios modelos DEA-Fuzzy (FDEA) para manejar la incertidumbre en *inputs* y *outputs*, las aplicaciones para medir eficiencia en bancos han sido escasas.
El objetivo de este trabajo es aplicar en forma comparativa el modelo DEA-CCR y el método FDEA propuesto por Guo y Tanaka, que surge como una extensión del modelo CCR clásico. Este método, proporciona una medida de eficiencia para cada unidad evaluada a partir de vectores de *inputs* y *outputs* difusos triangulares simétricos.
Se utilizan estos métodos para evaluar la eficiencia técnica de las principales entidades bancarias de capital público de los estados que son parte o asociados al MERCOSUR. El estudio se realiza sobre las entidades bancarias nacionales de 9 países del MERCOSUR, en actividad durante el año 2019.
Se puede concluir que el modelo FDEA utilizado es aplicable y proporciona una medida de la eficiencia de las entidades bancarias a diferentes niveles de posibilidad, consistente con la proporcionada por el método DEA clásico.

Keywords: DEA-Fuzzy – Eficiencia - Imprecisión

1 Introducción

La evaluación de la eficiencia surge como un instrumento de apoyo a la toma de decisiones en el ámbito público y empresarial. Un aspecto relevante a considerar en la toma de decisiones es la naturaleza de la información disponible. Aunque existen problemas donde los datos suelen estar definidos de forma precisa, hay otros en los que se trabaja en escenarios donde los datos son imprecisos, vagos o se identifican con términos lingüísticos.

El análisis del desempeño se ha convertido en una parte vital de las prácticas de administración en la industria bancaria. Sin embargo, aunque la literatura internacional reporta un gran número de estudios que se han llevado a cabo, la gran mayoría se ha realizado en países desarrollados, con poca o ninguna atención a las economías emergentes. Hay algunos estudios en Latinoamérica que sí se enfocaron en la medi-

ción de eficiencia, utilizando modelos no paramétricos, específicamente DEA, [1], [2], [3], y [4].

Entre las aplicaciones que utilizan modelos DEA para estimar la eficiencia en bancos, la mayoría de ellas asume que los *inputs* y *outputs* son conocidos con absoluta precisión. Sin embargo, en el mundo real, muchos procesos de producción involucran a menudo *inputs* y *outputs* que son muy difíciles de medir de una forma exacta.

A pesar de la existencia de diferentes tipos de enfoques difusos para manejar la vaguedad y la incertidumbre dentro del ámbito de los modelos DEA [5], el método de nivel α de [6] es uno de los más utilizados por la información que proporciona. Resolver este modelo en un nivel de α dado, produce una eficiencia de intervalo para la unidad de toma de decisiones (DMU) bajo evaluación.

El objetivo de este trabajo es evaluar la eficiencia técnica de las principales entidades bancarias de capital público de los estados que son parte o asociados al MERCOSUR., aplicando comparativamente un modelo DEA clásico y uno fuzzy (FDEA).

2 Mercosur

Las economías estables, con sistemas financieros sólidos y bien organizados y legislación clara y estable, tienden a ofrecer un ambiente más propicio para la generación de resultados positivos y pueden influir en la eficiencia con que utilizan sus recursos.

El Mercado Común del Sur (Mercosur) fue formalmente creado el 26 de marzo de 1991, con la firma del Tratado de Asunción por los gobiernos de Argentina, Brasil, Paraguay y Uruguay, con el objetivo de lograr una mayor integración de las economías de los países miembros y acelerar el proceso de desarrollo económico. La República Bolivariana de Venezuela, ingresó plenamente al Mercosur en 2012, aunque se encuentra suspendida en todos los derechos y obligaciones inherentes a su condición de Estado Parte, por el Protocolo de Ushuaia. El Estado Plurinacional de Bolivia, se encuentra en proceso de adhesión. Además, el Mercosur tiene como Estados Asociados a Chile, Colombia, Perú, Ecuador, Guyana y Surinam.

Se trabaja, con especial importancia, en aspectos relacionados al sistema financiero con el objetivo de armonizar las normas que rigen el funcionamiento de los sistemas financieros de los países para obtener un nivel adecuado de solidez y transparencia.

3 Modelos y Metodología

DEA es una metodología de programación matemática, desarrollada específicamente para medir la eficiencia de un conjunto de unidades homogéneas (DMUs). Calcula la eficiencia relativa de cada unidad, con respecto al conjunto de todas las unidades analizadas. En una primera instancia, se calcularán los índices de eficiencia de cada banco mediante la aplicación de un modelo DEA con retornos constantes de escala orientado a productos [7].

Uno de los enfoques para modelar la incertidumbre dentro del ámbito de DEA, comprende los métodos DEA fuzzy (FDEA), que parten del álgebra de los conjuntos

difusos [8] para tratar la borrosidad y vaguedad en circunstancias de incertidumbre. Los modelos FDEA que se encuentran en la literatura son usualmente clasificados de acuerdo a cuatro enfoques generales ([9], [10]): enfoque de la tolerancia, enfoque del nivel α, enfoque del ranking difuso, y enfoque de la posibilidad.

En el enfoque del ranking difuso, la idea principal es encontrar los puntajes de eficiencia difusa de cada DMU usando programas lineales difusos que requieren ordenar el conjunto difuso. Este enfoque fue inicialmente desarrollado por Guo y Tanaka, [6]. Ellos propusieron un modelo difuso CCR en el cual las restricciones difusas fueron convertidas en restricciones ciertas, a través de predefinir el nivel de posibilidad y utilizar la regla de comparación para números borrosos.

La eficiencia difusa de cada DMU bajo evaluación con *inputs* y *outputs* simétricos triangulares difusos se obtiene para cada nivel α de posibilidad como un número difusos triangular no-simétrico.

4 Análisis y Resultados

La evaluación de eficiencia se realizará sobre las Entidades bancarias de capital público más representativas de cada uno los estados que son parte o asociados al Mercosur. El estudio se realiza sobre entidades bancarias nacionales de 9 países del Mercosur, en actividad durante el año 2019, excluyendo los bancos de Venezuela, Guyana y Surinam de los que no se dispone de información homogénea.

A fin de realizar un estudio transversal (*cross-sectional*), los datos se obtienen de la información Contable e Informes económico financieros, que cada entidad publica periódicamente en sus respectivas páginas de internet.

Es importante destacar que, en este trabajo, se determina el *output* bancario utilizando el enfoque de activos, donde los bancos son considerados intermediarios financieros. Las variables a utilizar, se clasificarán en *inputs* y *outputs* utilizando el enfoque de intermediación, que tiene en cuenta el rol tradicional de las entidades financieras que transfieren activos financieros desde unidades superavitarias hacia unidades deficitarias. El enfoque de intermediación, siguiendo a [11], se ha utilizado con una selección restringida de variables. En cuanto al tipo de variables a utilizar, serán en su mayoría variables de flujo, que se seleccionarán del Estado de resultados de los Estados Contables de las entidades.

En cuanto a las variables a utilizar en el proceso de trasformación de *inputs* en *outputs* se considerarán: como *inputs*, Depósitos y Gastos de operación, como representación de los fondos tomados (capacidad prestable), y de las remuneraciones de empleados y gastos necesarios para el funcionamiento del banco. Como *outputs*, Ingresos financieros e Ingresos por servicios, que reflejan los resultados obtenidos por el banco de su actividad financiera y de intermediación.

De la aplicación del modelo clásico con retornos constantes a escala (CCR) *output*-orientado, se obtuvieron 5 unidades eficientes y 4 ineficientes: Banco República Oriental del Uruguay, Banco Estado de Chile, Banco Agrario de Colombia y Banco Unión Bolivia. De la aplicación del modelo FDEA *output*-orientado, se obtuvieron resultados de eficiencias coincidentes, pero con valores de eficiencia difusos a través

de números triangulares. Estos resultados difusos permiten identificar, a diferentes niveles de posibilidad, los intervalos difusos de la eficiencia determinada con el modelo DEA clásico.

5 Conclusiones

En este trabajo se propone la utilización de dos modelos DEA, uno clásico y otro difuso, para evaluar las eficiencias de las entidades bancarias de países del Mercosur. En el caso del FDEA se utilizaron datos de *inputs* y *outputs* difusos. Las eficiencias obtenidas son números borrosos que reflejan la incertidumbre o vaguedad inherente a los problemas evaluados. Se puede concluir que el modelo DEA difuso utilizado, extiende el modelo clásico CCR a formas más generales donde se pueden incorporar datos nítidos, difusos e híbridos. Proporciona, además, información sobre la incertidumbre asociada a la eficiencia calculada, ya que permite identificar intervalos difusos, a diferentes niveles de posibilidad, de la eficiencia determinada con el modelo DEA clásico. Debido a que siempre existe incertidumbre en la información disponible, los modelos difusos de DEA pueden desempeñar un papel importante para los problemas de evaluación que existen de manera integral en el mundo real.

Resumen: El análisis de la eficiencia de una red de Centros de Atención Primaria de Salud (CAPS) adquiere relevancia debido a que los servicios provistos en este nivel de atención son financiados mediante fondos públicos. Existen diversos métodos de medición de la eficiencia de una unidad de producción que permiten evaluar su desempeño y proponer estrategias de mejora. En particular, para las instituciones proveedoras de servicios de salud existe una vasta literatura que utiliza el análisis envolvente de datos (DEA). En este trabajo se aplica el DEA para evaluar la eficiencia técnica de los CAPS del partido de Bahía Blanca (provincia de Buenos Aires, Argentina). Para ello, se agrupan los CAPS según las especialidades disponibles (enfermería, clínica médica y pediatría) y se emplea: un modelo DEA BCC *output* orientado y un modelo de Supereficiencia para evaluar la eficiencia técnica en cada grupo. Los resultados difieren entre los grupos. En los que tienen las 3 especialidades, la mayoría de los CAPS son eficientes. Por el contrario, en los CAPS que tienen enfermería y clínica médica, así como los que solo tienen enfermería, la mayoría de los CAPS son considerados ineficientes. Se concluye que puede aumentarse la eficiencia, a partir de incrementar las consultas y/o reducir la cantidad de horas de trabajo, en el uso de los recursos públicos asignados al primer nivel de atención en el partido de Bahía Blanca lo cual permitiría mejorar las condiciones de acceso de la población más vulnerable a la atención de la salud.
Palabras claves: Eficiencia técnica, Centros de Atención Primaria de la salud, Bahía Blanca.

1 Introducción

El análisis de eficiencia técnica en las unidades de producción (tales como industrias, empresas o instituciones) permite determinar, dada una cantidad de insumos, la máxima producción posible, o bien dado un nivel de producción estimar la menor canti-

dad de insumos necesaria. Así, se puede establecer si una unidad de producción se encuentra operando eficientemente o por debajo de sus posibilidades de producción. De tal forma, a partir de la estimación de la eficiencia técnica de cada unidad de producción se puede comparar lo que efectivamente cada una produce con lo que podría estar produciendo dado el nivel de recursos utilizado con el fin de determinar posibles mejoras en su desempeño.

La eficiencia de una unidad de producción se puede medir con indicadores de eficiencia parcial que relacionan un solo producto con un solo insumo o con métodos que suponen la existencia de una función de producción mediante la cual se estima la cantidad máxima de producción dada una cantidad de insumos [1]. Esta frontera de producción, que permite estimar la eficiencia relativa de cada unidad de producción [2], se puede construir a partir de: i) métodos paramétricos, que requieren especificar una forma funcional para los datos, como por ejemplo el Análisis de Frontera Estocástica y ii) métodos no paramétricos, que no requieren dicha especificación, dentro de los que se encuentra el Análisis Envolvente de Datos (en adelante DEA).

La metodología DEA estima fronteras de producción eficientes que permiten comparar el nivel óptimo y el nivel observado en las unidades de producción buscando establecer una frontera virtual de eficiencia técnica y comparando cada unidad de decisión (en adelante, DMU) con esa frontera. La solución óptima se obtiene resolviendo un problema de programación lineal que consiste en maximizar la relación insumo-producto de cada una de las DMUs. Su principal ventaja es que, además de permitir la comparación entre diferentes insumos y productos de varias DMUs, permite efectuar optimizaciones individuales para su mejoramiento frente a un punto de referencia virtual calculado con base en la información del conjunto. Por tales motivos el DEA se ha convertido en una herramienta valiosa para los análisis comparativos de eficiencia, particularmente en el sector público [3].

En el caso particular de los servicios provistos en las instituciones del primer nivel de atención de salud, que corresponde al nivel del sistema de servicios de salud que provee bienes y servicios de salud de menor nivel de complejidad, durante la década del ´90 los trabajos destinados a estudiar la eficiencia han sido menos habituales y en general, se empleaban en países como Estados Unidos, Inglaterra y España. Sin embargo, en los últimos veinte años han aparecido trabajos que analizan la eficiencia de los centros de salud proveedores de estos servicios principalmente en países en vías de desarrollo [4-8]. La técnica empleada con mayor frecuencia para analizar la eficiencia de estas organizaciones es el DEA [9]. En particular en Argentina, esta técnica ha sido empleada para evaluar la eficiencia técnica de 295 instituciones del primer nivel de atención distribuidas en distintas regiones del país a partir de información del año 2011 [10].

En el partido de Bahía Blanca (Argentina) funcionan 56 centros de atención primaria de la salud (en adelante CAPS) que dependen de la Secretaría de Salud Municipal (en adelante SSM) y brindan servicios de salud de bajo nivel de complejidad principalmente a la población sin cobertura de salud, con excepción de la colocación de vacunas incluidas en el calendario nacional de vacunación. El funcionamiento de estas instituciones se financia con fondos públicos, principalmente del nivel municipal de gobierno, por lo cual adquiere relevancia realizar un análisis de la eficiencia técnica de los mismos.

En este contexto el objetivo de este trabajo consiste en realizar un análisis de eficiencia de los CAPS del partido de Bahía Blanca para identificar entre ellos, cuáles son las instituciones "relativamente eficientes" y las "relativamente ineficientes", en que se diferencian y qué medidas de gestión podrían implementarse para mejorar su desempeño.

2 Metodología

Se aplicó la metodología DEA, técnica no-paramétrica, determinística, que recurre a la programación matemática para estimar fronteras de eficiencia y evaluar la eficiencia de unidades de producción homogéneas entre sí (DMUs), en este caso los CAPS. Este método permite calcular la eficiencia relativa para cada una de las CAPS, comparando sus *inputs* y *outputs* respecto a todos los demás CAPS.

Por las características del problema se utilizó inicialmente un *modelo DEA BCC output* orientado [11] debido a que, frente a la falta de información sobre el producto final en estas instituciones se define un modelo empírico en el cual es deseable analizar la factibilidad de expandir los *outputs* para los *inputs* considerados [12]. El enfoque orientado a productos, también es el adoptado para el estudio de la eficiencia en otras organizaciones proveedoras de servicios en el sector público debido a que, si bien los *inputs* son los manejados por las DMUs, existen barreras que impiden reducir o incrementar sus niveles, por lo cual es apropiado utilizar esta orientación donde se busca maximizar la producción considerado como dado el nivel de insumos.

Posteriormente se aplicó el *modelo Supereficiente* [13] para analizar las características de las DMUs con mejor desempeño.

2.1 Modelo DEA BCC *output* orientado

El *modelo DEA BCC output* orientado busca la maximización de la producción, dado el nivel de *inputs*, teniendo en cuenta el supuesto de rendimientos variables a escala [14]. Se asumieron retornos variables a escala debido a que existe una amplia distancia entre los valores máximos y mínimos de los *inputs* y *outputs* [15]:

$$\text{Max}_{\varphi,\lambda,s^+ s^-} \quad z_0=\varphi+\varepsilon\left(Is^+ + Is^-\right) \qquad (1)$$

$$\lambda Y=\varphi y_0+s^+$$
$$\lambda X=x_0-s^-$$
$$\vec{1}\,\lambda=1$$

φ denota la puntuación de eficiencia
λ es el vector(nx1) de pesos o intensidades
Y matriz de *Outputs* de orden sxn
y_0 representa el vector *Output* de la unidad que está siendo evaluada
X es una matriz de *Inputs* de orden mxn
x_0 representa el vector *Inputs* de la unidad que está siendo evaluada

Is+ vector de holguras *Output*
Is- vector de holguras *Input*

Una unidad será calificada como técnicamente eficiente si y solo si φ*=1 y todas las holguras son nulas s*+=0, s*-=0. En caso contrario la unidad será calificada como ineficiente. La eficiencia técnica *Output* de la unidad evaluada será igual a 1/φ*.

Aquellos CAPS que sean eficientes se ubicarán sobre la frontera y tendrán un coeficiente de eficiencia igual a uno mientras que los CAPS ineficientes estarán por debajo de la frontera obtenida y tendrán coeficientes de eficiencia menores que uno.

2.2 Ranking de eficiencia

Generalmente el modelo anterior obtiene más de una DMU con φ*=1, esto es, varias unidades compartiendo el primer lugar. En particular, el supuesto de rendimientos variables a escala adoptado conduce a clasificar como eficientes a una alta proporción de la DMUs. En ciertos casos, resulta interesante obtener un ordenamiento total de las DMUs.

Para romper con estos empates, Andersen y Petersen [13] proponen una modificación al modelo clásico, excluyendo a la unidad evaluada de una de las restricciones. Esto permite que existan DMUs eficientes con valor mayor a uno. A este modelo se lo conoce con el nombre de *modelo Supereficiente*. En este trabajo se lo utilizará conjuntamente con el *modelo BCC* para analizar la eficiencia técnica de los CAPS de Bahía Blanca.

2.3 Selección de las variables del modelo

En primer lugar, dado que los CAPS pueden variar relativamente según el tipo de especialidades médicas y no médicas que producen, se armaron *clusters* de CAPS para poder aplicar el método DEA que requiere DMU homogéneas [16]. Los grupos se armaron considerando únicamente las tres especialidades básicas del primer nivel de atención (enfermería, medicina familiar o medicina clínica y pediatría). Las características de los grupos y su tamaño se detallan a continuación:

> *Cluster* 1: está integrado por 31 CAPS que producen al menos consultas de enfermería, medicina familiar o clínica médica y pediatría.
> *Cluster* 2: compuesto por 13 CAPS que producen al menos consultas de enfermería y medicina familiar o clínica médica pero no de pediatría.
> *Cluster* 3: agrupa a 5 CAPS que solo producen servicios de enfermería.

Se excluyó un CAPS de la localidad por no pertenecer a ninguno de los grupos definidos. Asimismo, no se consideraron en el análisis los CAPS de Cerri y Cabildo, dos localidades que conforman el partido de Bahía Blanca, porque tienen distintas características de funcionamiento.

En segundo lugar, se aplicaron los modelos DEA a los grupos definidos. Para determinar la cantidad de *inputs* y *output*s en cada caso se utilizó la siguiente ecuación [17]:

$$n° \textit{ inputs} + n° \textit{ outputs} \leq (n° \text{ DMU}/3) \quad (2)$$

En este análisis, los *inputs* se refieren a los insumos empleados por cada CAPS, mientras que los *outputs* son los productos ofrecidos por los mismos. Entre los insumos se consideraron, por un lado, las horas anuales ofrecidas por el personal de salud para el año 2018, desagregado en tres especialidades (Enfermería, Medicina familiar o Clínica Médica y Pediatría) y, por otro lado, el espacio físico de cada establecimiento medido en metros cuadrados. Por su parte, entre los productos/servicios prestados, se consideraron las consultas efectivamente realizadas en cada uno de los CAPS distinguiendo según la especialidad (Enfermería, Medicina familiar o Clínica Médica y Pediatría), también para el año 2018. Estas variables *inputs* y *outputs* variaron en los modelos según el grupo de CAPS estudiado (Tabla 1).

Tabla 1. Variables utilizadas para el análisis DEA

	Cluster 1
Variables *Input*	• *x1*: Cantidad de horas trabajadas de Enfermería (2018) • *x2*: Cantidad de horas trabajadas de Medicina familiar o Clínica Médica (2018) • *x3*: Cantidad de horas trabajadas de Pediatría (2018) • *x4*: Superficie de cada CAPS (m2)
Variables *Output*	• *y1*: Consultas anuales de Enfermería (2018) • *y2*: Consultas anuales de Medicina familiar o Clínica Médica (2018) • *y3*: Consultas anuales de Pediatría (2018)
	Cluster 2
Variables Input	• *x1*: Cantidad de horas trabajadas de Enfermería (2018) • *x2*: Cantidad de horas trabajadas de Medicina familiar o Clínica Médica (2018) • *x4*: Superficie de cada CAPS (m2)
Variables *Output*	• *y1*: Consultas anuales de Enfermería (2018) • *y2*: Consultas anuales de Medicina familiar o Clínica Médica (2018)
	Cluster 3
Variables *Input*	• *x1*: Cantidad de horas trabajadas de Enfermería (2018)
Variables *Output*	• *y1*: Consultas anuales de Enfermería (2018)

Fuente: elaboración propia

Para determinar las horas ofrecidas por cada profesional se utilizó información proveniente de informantes claves de la SSM mientras que la cantidad de consultas se obtuvo de los Informes de Producción provistos por el Departamento de Epidemiología y Calidad de la SSM.

Se utilizó el DEA Solver de Excel para las estimaciones dado que permite realizar el análisis hasta para 50 DMU [18].

Como paso previo a la aplicación de la metodología DEA se calcularon medidas descriptivas básicas (media, desvío estándar, máximo, mínimo) de las variables bajo

análisis en cada grupo de CAPS. Es importante aclarar que si bien el cálculo de indicadores de productividad parcial para cada DMU es sugerido como un indicador de consistencia entre las distintas metodologías disponibles para analizar eficiencia [19] solo fueron calculados para el *cluster* 3.

El método DEA generaliza la medida de la eficiencia para un único *output* e *input* de una DMU, medida por el cociente *output/ input* transformando los múltiples *outputs* e *inputs* para cada DMU en un único *output* e *input* virtual [12]. En este sentido, a diferencia de los indicadores de productividad parcial, el método DEA permite reflejar la eficiencia global de todos los *inputs* empleados [20].

3 Resultados

A continuación, se presentan las estadísticas descriptivas y los resultados de los dos modelos para cada uno de los *cluster*.

Para los CAPS con al menos Enfermería, Medicina familiar o Clínica médica y Pediatría (*cluster* 1) los resultados descriptivos se muestran en la Tabla 2.

Tabla 2. Estadística descriptiva *Cluster* 1

La mayoría de los CAPS (21) presentan eficiencia técnica pura output y, por lo tanto, determinan la frontera eficiente, bajo el supuesto de rendimientos variables. El resto de los CAPS (3,5,6,9,13,17,18,23,26,28) son calificados como ineficientes, ya que podrían aumentar el *output* con la misma cantidad de recursos; por ejemplo, los CAPS 17 y 18 tienen las puntuaciones de eficiencia técnica (*output)* más bajas de aproximadamente del 48% y el 46%, respectivamente.

Complementando lo anterior, en la Tabla 4 se presenta la mejora potencial (en %) que debería experimentar cada DMU ineficiente en sus *inputs* y *output* para situarse en la frontera y ser eficiente en el sentido de Pareto Koopmans; es decir, cuando no se puede reducir ningún insumo o aumentar ningún producto sin aumentar o reducir otro insumo o producto, respectivamente.

Tabla 4. Proyección de mejora (%) del *Cluster 1*

Fuente: elaboración propia.

Se observa que algunos de los CAPS ineficientes para mejorar su eficiencia no solo deberían incrementar la cantidad de consultas en sus especialidades, sino que también deberían reducir la cantidad de horas que actualmente tienen disponibles de las distintas especialidades. Esto podría ser interpretado de la siguiente manera: las CAPS ineficientes podrían atender a una mayor cantidad de pacientes con sus recursos actuales e incluso algunas deberían reducir la cantidad de horas ofrecidas para consulta.

Hay algunas excepciones, el CAPS 26, debería aumentar muy poco la cantidad de consultas anuales sin modificar prácticamente las horas de recursos humanos para llegar a ser eficiente y el CAPS 17 debería aumentar las consultas, pero no debería reducir las horas de ningún recurso humano para llegar a ser eficiente.

Los valores de proyección de mejora porcentuales para las consultas de pediatría en los CAPS 3 y 5 se explican por la ausencia de producción de ese *output* durante para el periodo en las mencionadas DMU que, en términos absolutos, representan 681 y 1151 consultas, respectivamente.

Por otro lado, los resultados del modelo de superficiencia muestra el ranking completo de las DMUs. En la Tabla 5 se presenta una extracción del resultado del modelo con las puntuaciones obtenidas por los CAPS eficientes. Se destaca la performance de la DMU 31 que obtuvo un puntaje de eficiencia de 5,87. Este CAPS contó para el período analizado con 1320 horas de enfermería, 1100 horas Clínica/General, 176 horas de Pediatría y 78,46 metros cuadrados obteniendo como resultado 2.392 consultas de enfermería, 1931 consultas de Clínica/General y 233 consultas de pediatría.

Tabla 5. Supereficiencia- Orden *Cluster* 1

Fuente: elaboración propia

De los 13 CAPS que lo componen 6 fueron calificados como eficientes y 7 operando con ineficiencia técnica, es decir, que podrían mejorar su performance. Tal es el caso del centro de salud 38 que obtuvo la peor eficiencia relativa (35%). A continuación, en la Tabla 8 se detalla los porcentajes de mejora que deberían alcanzar cada una de las estas CAPS ineficientes para llegar a serlo.

Tabla 8. Proyección de mejora (%) del *Cluster 2*

DMU	*inputs*			*output*	
	x1	x2	x4	y1	y2
CAPS 32	0,00%	-19,29%	-6,37%	93,41%	27,89%
CAPS 37	-26,36%	-88,80%	-42,22%	118,62%	33,14%
CAPS 38	-19,01%	-66,54%	0,00%	189,05%	189,05%
CAPS 40	-80,00%	-73,30%	-10,52%	46,59%	75,89%
CAPS 41	-59,09%	-92,98%	-56,20%	30,38%	26,94%
CAPS 42	-63,47%	-77,12%	0,00%	44,79%	44,79%
CAPS 43	0,00%	-71,26%	-6,99%	181,54%	31,40%

Fuente: elaboración propia

En este caso se observa que los 7 CAPS ineficientes podrían mejorar su desempeño incrementando los dos servicios producidos, así como también reduciendo la cantidad de insumos utilizados, con la excepción de los CAPS 32 y 43 que no deberían reducir la cantidad de horas de Enfermería.

A continuación, en la Tabla 9 se exhibe parte de los resultados del modelo supereficiente para los CAPS que trabajan con eficiencia técnica. En este se puede observar que la unidad sanitaria 36 se ubica primera entre los CAPS eficientes del *Cluster* 2, aunque no presenta amplias diferencias con las otras DMUs.

Tabla 9. Supereficiencia - Orden *Cluster* 2

DMU	*Score*	DMU	*Score*
CAPS 36	1,04	CAPS 34	1
CAPS 39	1,01	CAPS 35	1
CAPS 33	1	CAPS 44	1

Fuente: elaboración propia

Por último, para el *Cluster* 3, en la Tabla 9 se presentan las estadísticas descriptivas.

Tabla 9. Estadística descriptiva *Cluster* 3

Variables	**Media**	**Desvío**	**Mínimo**	**Máximo**	**DMUs a las que corresponde el Valor Mínimo**	**Máximo**
x1	1320,00	0	1320	1320	45,46,47,48,49	45,46,47,48,49
y1	7300,60	5317,92	1581	12948	49	48

Fuente: elaboración propia

En la tabla 10 se presentan los resultados del modelo BCC *Output* Orientado y la proyección de mejora (%) para las unidades ineficientes. Se obtuvieron valores de eficiencia menor a 1 para cuatro (4) de las cinco (5) DMUs. En particular, en este caso al considerar un único *input* y un único *output* los resultados de este modelo son idénticos a los que resultan del proceso de calcular indicadores de productividad parcial para cada CAPS y compararlos con el valor obtenido por la mejor DMU.

Tabla 10. Eficiencia BCC *Output* Orientada y Proyección de mejora (%). *Cluster* 3

DMU	**Eficiencia (1/φ)**	**Orden**	**Referente eficiente**	***Inputs*** **x1**	***Output*** **y1**
CAPS 45	0,71	3	CAPS 48	0,00%	40,86%
CAPS 46	0,85	2	CAPS 48	0,00%	17,25%
CAPS 47	0,13	4	CAPS 48	0,00%	644,57%
CAPS 48	1,00	1	CAPS 48	---	---
CAPS 49	0,12	5	CAPS 48	0,00%	718,98%

Se observa que todas las DMUs deben incrementar la cantidad de consultas de enfermería para aumentar su eficiencia técnica, pero ninguna debería reducir la cantidad de horas de personal utilizadas. Las DMUs 47 y 49 serían los CAPS que mayor aumento deberían tener en las consultas anuales de Enfermería dados los recursos que disponen (Tabla 10).

4 Consideraciones Finales

El análisis de la eficiencia por tipo de CAPS permitió calificar la eficiencia relativa según el perfil de atención de los mismos. Para los CAPS que por lo menos tienen *enfermería, medicina familiar o clínica médica y pediatría* se observó que la mayoría son eficientes. Los CAPS ineficientes de este grupo pueden incrementar las consultas de todas las especialidades y/o reducir las horas de trabajo de algunas especialidades para incrementar su eficiencia técnica. De los CAPS que por lo menos tienen *enfermería y medicina familiar o clínica médica* más de la mitad se consideraron ineficientes. En este caso, estos podrían mejorar su performance incrementando las consultas y/o reduciendo las horas de trabajo en la mayoría de los casos. Las horas de trabajo que no son necesarias en los CAPS ineficientes de estos grupos podrían ser reasignadas a actividades no asistenciales dentro del CAPS o bien a otros CAPS de la red de acuerdo a la necesidad de servicios. Finalmente, para los 5 CAPS que solo tienen *enfermería*, los resultados mostraron que solo 1 es eficiente. Los CAPS ineficientes deben incrementar la cantidad de prestaciones ofrecidas para alcanzar la eficiencia técnica. Adicionalmente el modelo supereficiente aplicado a los grupos de CAPS donde varias DMUs resultaron eficientes muestra que en el *Cluters 1* existen instituciones con un desempeño desatacado entre las 21 clasificadas como eficientes mientras que en el *Cluters 2* no existe amplia diferencia entre los *score* de eficiencia de las DMUs con eficiencia técnica.

Es importante destacar que la técnica empleada obtiene los valores de eficiencia de cada unidad de producción a partir de la comparación con las restantes. Las recomendaciones obtenidas en cualquier caso son tecnológicamente factibles de realizar al ser calculadas a partir de aquellas unidades que presentan mejores prácticas. En este sentido, es importante aclarar que el tamaño de espacio donde se brinda la atención, es un insumo que, a diferencia de las horas disponibles de personal de las distintas especialidades, no puede ser fácilmente modificado por las autoridades sanitarias, al menos en el corto plazo. Sin embargo, la proyección de mejora indicada por el modelo para este *input* podría interpretarse en el sentido de que un CAPS podría operar en un espacio de mayor o menor tamaño según el signo de la proyección de mejora y esta información podría ser empleada por las autoridades sanitarias para tomar decisiones relativas a la reasignación de actividades o servicios ofrecidos en los distintos CAPS de la red.

Este trabajo presenta limitaciones relacionadas con las variables empleadas para medir los *inputs* y los *outputs* que se explican por la dificultad para conseguir información sistematizada en el sistema de servicios de salud. La especificación de la función de producción empleada, cuando las variables utilizadas para medir los resultados del proceso de producción son las consultas, plantea el inconveniente de que no necesariamente todas las visitas son adecuadas. Para resolver el problema de la ineficiencia asociada a las consultas innecesarias se han propuesto otras medidas de resultados que podrían utilizarse en los modelos DEA.

Por tal motivo sería importante perfeccionar el trabajo considerando más *inputs* y *outputs* de los analizados, tales como vacunas aplicadas o actividades de promoción realizadas en el CAPS y de este modo obtener datos más precisos, que permita realizar un análisis de eficiencia integral, considerando todos los CAPS y refleje las acti-

vidades de prevención y promoción de salud que se realizan en los centros de salud en el primer nivel de atención y constituye uno de sus más relevantes *outputs*.

Abstract. The healthcare product manufacturing industries are constantly changing, so they must find new ways to remain competitive in the market. With the concepts of Industry 4.0, they search for new methods to integrate and optimize manufacturing processes. Seeking to contribute with optimization of the production control in CNC machining lines of a healthcare product, this research develops a system of data extraction and representation using an interoperable approach, called System ADCS 4.0. By its use, it is possible to share data in a systematic and structured way, so the management environment can control the production line process, evaluating the quality and productivity indicators of the company in an automated way. It consists of an application that receives the data from the machine and translates it into a proper ontology, developed during this research. This way, the data will be treated according to semantic rules, by the application of an inference engine, generating knowledge, that will support professionals to take assertive decisions based on the data generated and displayed in a dashboard. Forms were created, using the BonitaSoft, to represent the results obtained from the application of the System ADCS 4.0, which consists in the representation of the indicators and the defects that occurred during the machining process. The developed system helps companies to increase the productive process by reducing cost, time and it also helps professionals in the decision-making process.

Keywords: Industry 4.0, Healthcare Product, Data Collecting, Semantic Interoperability, Machining.

1 Introduction

The healthcare product manufacturing industry is constantly challenged to seek new technologies to attend to the demands of the consumers, who expect more complex products with a higher level of customization [1]. In this way, industries must find new

ways to remain competitive in the market. Considering that the healthcare industry is tightly connected to the welfare and lives of people, the industry must perform a thorough and accurate analysis of its products. In this scenario, with the Industry 4.0, it is possible to integrate and flexible manufacturing processes, aiming for optimized production, with efficiency and quality to attend current demands [2][3][4].

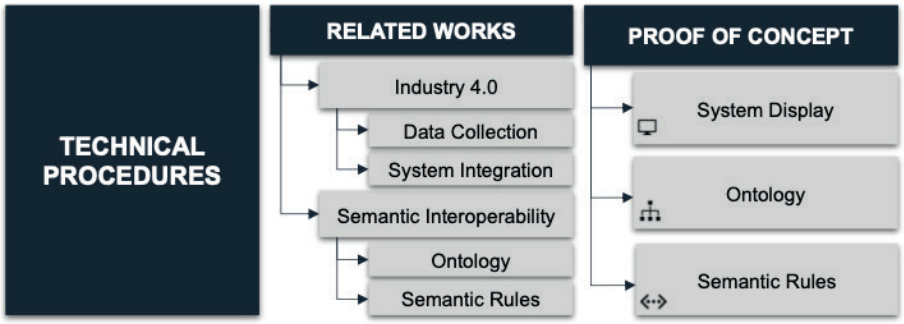
To better attend market demands, companies must develop a technological infrastructure capable of supporting the high flow of data through different development teams and multiple data systems, requiring a well-defined structure between the different phases and areas of the development process, to ensure the correct exchange of data in the production process.

Through semantic interoperability, autonomous systems can communicate and share data through interconnectivity, ensuring that they are shared between different areas as well as their correct understanding.

Considering this scenario, this research aims to develop a system to optimize the production control in CNC machining lines of a healthcare product, processing the production performance data automatically, reducing the problems during the planning of the line, which could cause impacts on process costs, among others. In this context, the research main objective is to develop a method of knowledge representation that collects data and monitors productive performance in machining machines of a healthcare product, using an ontological and interoperable approach, seeking the improvement of the production control.

To illustrate the path taken to achieve this objective, the following topics will be discussed throughout this article: Materials and Methods – used as tools for the technical development of research; Related Works – it consists of the study of different works and authors to understand the main themes linked to the research; Approach – in this topic, it will be illustrated and described the system's operation model; Proof of Concept – throughout this topic, the system's operation model is applied in a healthcare segment, to verify the consistency of the proposed method; Results Discussion – after this application, the results obtained from it were discussed and evaluated; Conclusion – this topic is the final one to synthesize the results and the achievement of the objectives.

2 Materials and Methods



This research has an applied nature and an exploratory scientific objective because a problem situation will be mapped and explored to find a functional solution, by applying a pre-existing context. As the information analyzed is difficult to measure and seeks to analyze the quality of them, a qualitative approach was used. To achieve the objective of the research, the technical procedures (Fig. 1) were a literature review on works related to industry 4.0 and Semantic Interoperability, followed by a proof of concept, to evaluate the operation of the proposed method [5].

The following materials were used in the development of the research:

- Protégé – used for the creation of ontology, as well as for the application of an inference engine that consumes semantic rules, created in SWRL.
- Excel - used for creating and exporting semantic rules in SWRL language.

- BonitaSoft – used to describe the procedures performed by the ADCS 4.0 system, as well as to create the forms that represent the display of the results.

Fig. 1. Technical Procedures

3 Related Works

3.1 Industry 4.0

Industry 4.0 is understood as an integration between manufacturing processes, as well as information and communication technologies, especially the Internet-of-Things, which consists of real-world connection and communication, integrating intelligent systems into industrial processes [6][7]. Industry 4.0 emphasizes the e extension of a traditional manufacturing system to an integrated system, based on the connectivity of the platforms used in the industry, enabling the management of factories with complex and interconnected systems and machining processes, generating greater efficiencies in logistics operations [8][9][10].

The concept of Digital Manufacturing is linked to several advanced manufacturing techniques, such as Agile Manufacturing, MGrid, Rapid Prototyping, Additive Manufacturing, CNC, among others [11][12]. These concepts are also closely linked to Advanced Manufacturing, which seeks to assist in the constant increase of the efficiency of industrial processes, saving resources, and providing better products [13] These techniques are alternatives to traditional models, involving high-level technology and pioneering methodologies, which can deliver products and prototypes more quickly, involving multiple domains [14].

Through Industry 4.0, industries seek to achieve greater industrial performance by integrating processes and product connectivity [15]. Smart objects share information autonomously, such as their location, history, status, etc. This is due to the Internet of Things, which can connect all devices to an internet network. With the help of Big Data and Cloud-Computing, this information is collected, stored, and evaluated from various sources, supporting decision making, optimizing processes, saving energy, and. improving system performance [16]. By using the Internet of Things, it is possible to link the internet with the data collection system, making an integrated system, and with that, it is possible to handle and analyze a huge quantity of data without misunderstandings or loss of information [17].

3.2 Semantic Interoperability

Semantic interoperability is the communication capacity of autonomous systems through the use of common standards, allowing the sharing of data through interconnectivity, ensuring that the data shared between different areas has its meanings understood correctly throughout all phases of the product development process of a healthcare product. This is fundamental in the industrial processes since problems with data access and also the sharing of data from different sources and different systems can bring conflicts in the decision-making process [18][19][20][21].

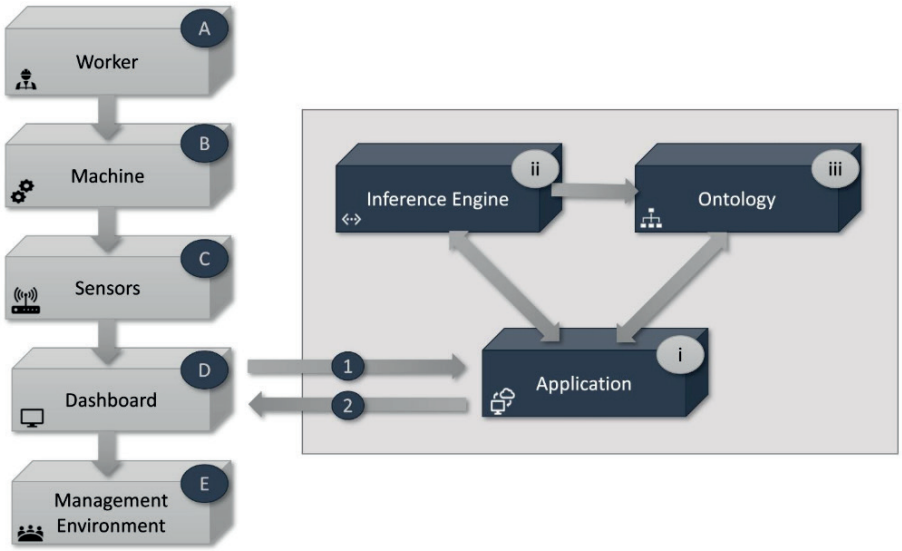
By using an ontological approach, it is possible to describe and share data in a systematic and structured way, taking into consideration that ontology is an abstraction of a complex concept and, consequently, it is necessary to understand what one wishes to represent clearly so that there is no misunderstanding [22][23].

An ontological approach is a formal and explicit description of concepts, which are defined in classes, described by properties and attributes. This approach consists of classes, relationships, axioms, individuals, and functions. Classes represent a set of individuals with common properties, in addition, they are organized, usually in taxonomies, hierarchically through appropriate relationships. Relationships are associations between classes, in which their image determines a concept, through the representation of interactions between the elements of the classes. Axioms are always true conditions, in order to analyze the consistency of ontology. Individuals are entities that belong to classes that are used to represent specific elements, which are the data of ontology [23][24][25].

To ensure the sharing and veracity of data, ontologies in Web Ontology Language (OWL) can be used during the production development process of a healthcare product. Thus, to ensure the quality and productivity during this process, the relationships between the manufacturing data and the final product are translated into semantic rules, and to achieve this objective, it is used the Semantic Web Rules Language (SWRL) to represent that, by inferring new data, relationships, and it is also capable of producing results automatically by running an inference engine, that will translate the rules and extract knowledge from their results [26][27][28][29].

This inference engine infers knowledge in the ontology, from the application of semantic rules, this engine will cross the data, generating new knowledge from its predetermined conditions [30].

4 Approach of Automated Data Collection 4.0 System



The research project was applied in a hospital production environment of the Institute of Bioengineering Erasto Gaertner (IBEG), located in Brazil in the city of Curitiba. IBEG is a national manufacturer of fully implantable Vascular Access Catheter indicated for people with long term treatment.

The company has a team of technicians specialized in machining, electropolishing, and assembly. The workpieces, which are the catheters, are produced through machining processes on Computer Numeric Control (CNC) machines. Nowadays, the data collection from the machining process is done manually by the workers, which may cause some troubles during the data documentation. The company constantly uses this data to make decisions that are very important for production control and the

evaluation of the indicators. Therefore, if the data is not accurate, the management environment can make wrong decisions that may harm the company and, especially, its customers.

Considering this scenario, this research seeks to improve the data collection process, by implementing a system able to support the company and the workers, through the automated data collection. Seeking to illustrate the process flow, it was possible to elaborate on an architecture that shows the system's operation, which represents all the stages of the production line (Fig. 2).

Fig. 2. Architecture of the Automated Data Collection 4.0 System.

Initially, an agent is required to perform his work (Detail A of Fig. 2). He is responsible to operate the CNC machine (Detail B of Fig. 2) and he must insert the system code on it to start the machining process. Then, the machine reads the code and starts to operate. After that, the sensors (Detail C of Fig. 2), installed inside the machine by a specialized company, will measure the machine data, like cycle time, cutting time, cutting speed, and vibration. Once the machining has ended, the workpiece that was machined will be measured manually and its data, as well as the machine data listed before, will be sent to a Dashboard (Detail D of Fig. 2), a virtual platform, where you can view the machine's performance indicators in an accessible way.

Connected to this dashboard, the system's application (Detail i of Fig. 2) will process the data to populate the ontology (Detail iii of Fig. 2). After populating the ontology, the application will apply the semantic rules through the inference engine (Detail ii of Fig. 2), in the ontology. This application, then, checks if there are any inconsistencies on the inference and until there is no inconsistency left, the application will correct them. But, if there is any inconsistency that cannot be automatically corrected, the dashboard must contact the responsible for the machine to correct the inconsistency manually. After the application of the inference engine on the ontology, the knowledge

generated will be sent back to the Dashboard (Detail D of Fig. 2), in which the management environment will analyze it and take necessary actions for the manufacturing process (Detail E of Fig. 2).

The dashboard shows the knowledge according to the parameters of quality and productivity through these indicators. At the end of the Automated Data Collection 4.0 System (ADCS 4.0) process flow, the dashboard organizes all the collected data in the machining process schematically, so that the Management Environment can make the necessary decisions, based on the data showed on the Dashboard.

5 Proof of Concept

5.1 System Display

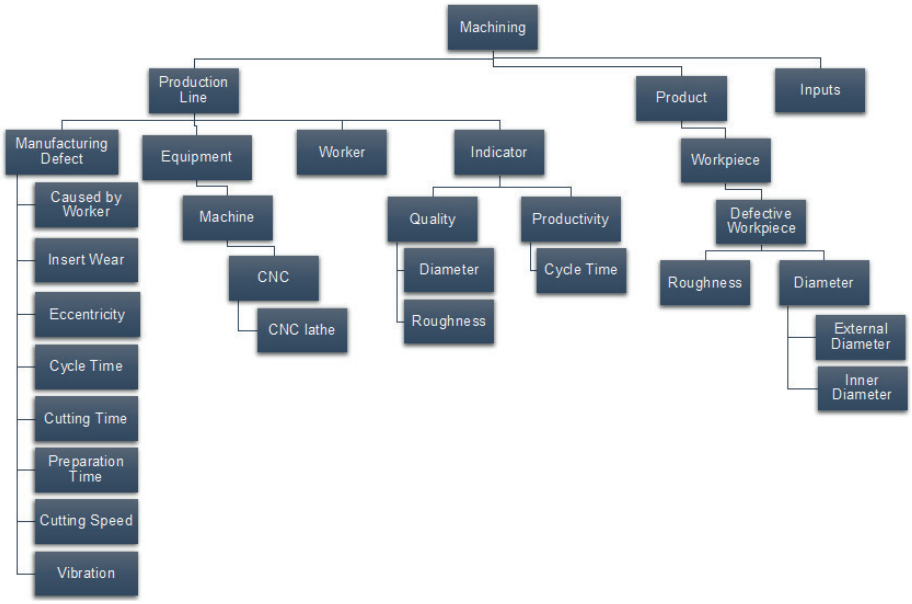
The communication between the application and the dashboard, the application will process the information generated by the inference engine and the ontological base that will feed the platform of the dashboard from an outsourced company. The system, connected to an ontological database developed using the ontology editing software, Protégé, infers the data through a taxonomy created for ontology.

The dashboard will provide information to the system, forming a communication bridge between the software and the dashboard. The dashboard has an interface that presents the data to the company through graphs and tables according to the selected metrics and the KPIs.

The communication will be realized by importing and exporting files in .CSV (comma-separated-values), a format for storing information whit data separated by commas. The information will be exported by Excel software in a .CSV file template. The advantage over this file model is that it has a universal language and several applications can read, facilitating the import and export of data.

The data presented on the dashboard is generated from the collection made by sensors present in the machining machines. These sensors collect data as cycle time, cutting time, cutting speed, vibration, and preparation time. The data is sent to populate the ontology.

5.2 Ontology



The construction of an ontology was one of the main focuses of this project, considering that by using an ontology, it is possible to represent a reality without misunderstands during the data sharing, by determining relationships between the data, to generate knowledge.

Aiming the ontology construction, it was necessary to determine a taxonomy that took into account all the steps involved in the machining process of healthcare workpieces in order to make the model as comprehensive and efficient as possible, from the machine and worker, till the application and dashboard.

Considering the proposed taxonomy model as shown in Fig. 3, the main classes are listed as production line, product, and inputs. Each blue rectangle represents a fragment of the taxonomy, whether a class or subclass. If a form cannot be unfolded, it is considered as an individual, else it is considered as a class or a subclass. The first subclass elaborated and analyzed within the production line class was the possible

defects that occur in a manufacturing process. Subsequently, the subclasses of the equipment class were included, which considers the equipment used for the machining process.

Fig. 3. Taxonomy of Machining.

The subclass "worker" was elaborated to control which worker was operating the machine in each shift of the production. In this way, it is possible to build a history of defects per shift so that improvements can be made assertively.

In addition to considering all the parties involved in the production process of the workpieces, the characteristics of the workpiece were considered, since these are the main factors that interfere in the quality indicators of the Biotechnology Institute of the Erasto Gaertner Hospital. Moreover, as the workpiece produced has a very important function for the health of the patients who use it, constantly controlling the number of defects found in the workpiece is essential. The characteristics that are most likely to suffer defects caused by a machining process, such as the external diameter, internal diameter, and roughness of the workpiece, were raised and selected.

Another indicator is taken into account in taxonomy and that needs attention and monitoring by the administrative environment is the productivity of the line in question. For this, it is necessary to evaluate the cycle time of the machining process, to ensure the demand of workpieces is met and that the company avoids waste or possible problems in the machine that may delay machining. Finally, resuming the importance of monitoring the characteristics of the machined hospital workpiece, the "Product" class was created separately from the production line, thus paying attention to the characteristics of the workpieces mentioned above. This ontology model receives assistance from semantic rules so that the inference engine infers on ontology, hierarchizing the information according to the model of the ADCS 4.0.

5.3 Semantic Rules

By creating the semantic rules, it is possible to determine a cause and effect relationship between the individuals, classes, data, and properties, to create knowledge that, in this scenario, will help professionals during the analysis of the production control, by showing them the quality and productivity indicators, and also the defects occurred during the machining process of the healthcare product.

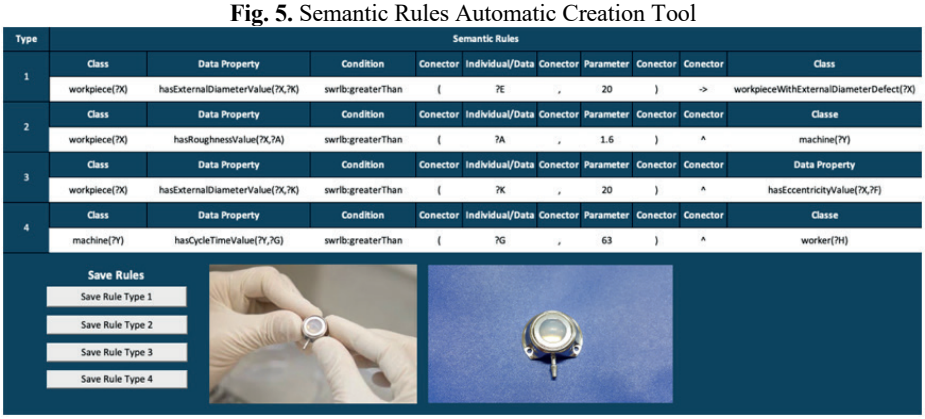
For the creation of the semantic rules, it was necessary to understand what would be necessary to infer, to ensure the quality of the product and productivity, by identifying the parameters defined as ideal to create cause and effect relationships between individuals. Thus, it was necessary to conduct a research on the machining processes, verifying the parameters that can interfere in the final quality of the product, which has an acceptable maximum roughness of 1.6 mm, internal diameter of 12mm and external diameter of 20mm. In this way it is necessary to analyze the parameters that can negatively interfere with its machining, such as the insert wear, that can't be greater than 1.5mm, the cutting speed can't be greater than 110m/min. The vibration of the machine cannot be higher than 187 rpm. The eccentricity of the workpiece in the machine is also analyzed, and it must be close to zero to ensure the quality of the workpiece.

The cycle time is used to analyze the productivity indicator because if it is greater than 63 seconds, it means that problems occurred in the machining of the workpiece, which can be caused both by the operator, or by the preparation time, which can't be greater than 30 seconds, and the cutting time, not exceeding 33 seconds.

From the definition of cause and effect between the variables, it was possible to create semantic rules, using the SWRL (Semantic Web Rule Language), since this allows combining rules with ontologies developed in OWL, inferring new knowledge with the application of an inference engine.

The Fig. 4 shows a rule created, which this rule is interpreted as follow: if the machine "Y" has cycle time value "G", if "G" is greater than 63, the machine "Y" is operated by worker "H", the "Y" machine has a preparation time value "I", and if "I" is greater than 30, it is inferred that the "Y" machine has a defect of preparation time, and operator "H" causes the defect. All the preceding information of the symbol (à) is the body, and if this is true, what follows the symbol (head) will also be.

Fig. 4. Semantic Rule Example



"machine(?Y) HasValueOf TimeCycle(?Y,?G) swrlb:greaterThan(?G,63) ^ worker(?H) OperatedByWorker(?Y,?H) ^ hasPreparationTimeValue(?Y,?I) swrlb:GreaterThan(?I,30) → DefectOfPreparationTime(?Y) DefectCausedByWorker(?H)"

To automate this process, a program was developed in spreadsheet software, capable of exporting the rules created so that the user can copy and paste them into the Protégé software on the ontology. First, it was necessary to create the rules, as previously presented, and with this, the elements used in their constructions were perceived, they are classes, object properties, data property, conditions, connectors, individuals/data, and parameters.

A spreadsheet was created in Excel with all these elements, mentioned above, one in each column, by filling them with the data of the ontology, enabling the creation of

a tool, using lists in the Excel software tool itself, allowing the selection of an element within each column, filling the respective cell. From this tool, presented in Fig. 5, and with the use of macros in Excel, it is possible to export each type of rule to a new worksheet, and from that, the user can copy the rule, in this new worksheet, and paste it into the Protégé software, inserting the semantic rule in the ontology, ensuring the functionality of the tool.

Fig. 5. Semantic Rules Automatic Creation Tool

Through this tool and with the application of an inference engine, new knowledge is generated, and its results are displayed in the Dashboard for the management environment of the company. For proof of concept, the results are displayed in a form by Bonita software.

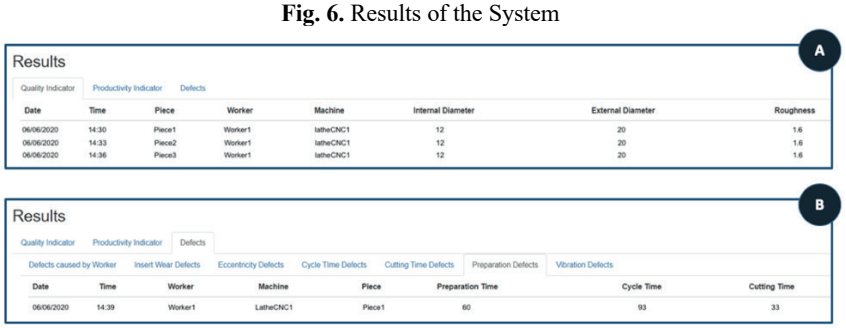
These results are productivity indicators, analyzing cycle time, quality, analyzing the roughness and diameter of the workpiece, as well as resulting in the indication of defects occurred in the manufacturing process.

6 Results Discussion

During the development of this project the ADCS 4.0 was built, and it can collect data in an automatically and interoperable way for the production control in CNC machining lines. From a literature review, the concepts of Industry 4.0, interoperability, ontology, manufacturing, and machining processes, were studied and used to structure the project.

Through the system application, the machining process data are displayed to the management environment by forms created using the software "BonitaSoft". The forms show the data according to the KPIs in analysis about the machine and the manufacture of the pieces in a daily and weekly parameter, to assist the management environment through the analysis of the production control. The dashboard also shows the data inferred from the ontology, which are the quality and productivity indicators, such as the defects that occurred during the manufacturing.

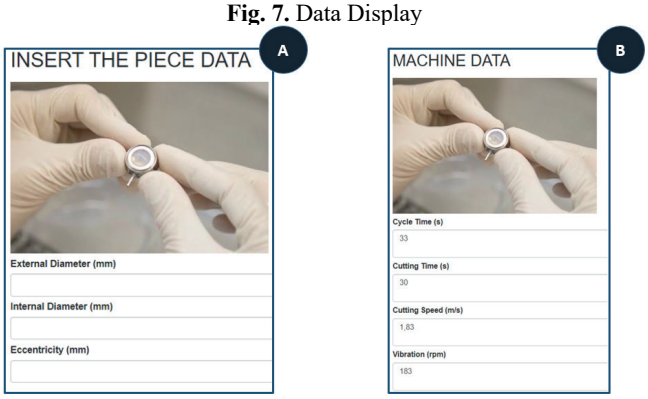
The developed system brings qualitative benefits to the production. The collection and storage of data that was performed manually are now done digitally, which brings more precision in data collection and security in their storage. If this process is



performed manually, there may be the presence of human mistakes in the data collecting, and as they are stored on paper they can easily be lost, for example.

In addition to bringing more security to the productive control, automation also improves the quality and time of production. All records that needed to be done manually on paper by the operator, can now be done automatically, saving production time.

As shown in the Detail A of Fig. 6, the quality of the piece is measured by the values of the inner diameter, outer diameter, and roughness. The defects of the piece are measured with several parameters, as shown in the Detail B of Fig. 6: defects caused by the operator, defects caused by insert wear, defect in eccentricity, defect in the cycle and cutting time, defect in preparation time, and defect in vibration. These data are displayed together with the date and the time of production, the name of the operator, the piece number, and the machine number, and they are inferred by applying an inference engine through the semantic rules.



.

Fig. 6. Results of the System

The data displayed about the piece is internal diameter, external diameter, and eccentricity, shown in the Detail A of Fig. 7. The data presented about the machine cycle and cutting time, cutting speed, and vibration, as shown in the Detail B of Fig. 7. And the weekly data are insert wear, number of parts produced, and time of operation of the machine, the number of problems reported, and the roughness of the samples collected.

Fig. 7. Data Display

These indicators were selected for the production control because, after a field visit at the study company, it was confirmed that these were the most appropriate data for a good production control. Those data were already collected by the company, but the collection was realized manually by the operator and recorded on paper, which could generate many errors in the productive control.

The ADCS 4.0 contributes to the reduction of product development time because it automates the process of evaluating quality and productivity indicators. It also informs the management environment about the defects that interfere with these indicators, so that they can be solved as soon as possible, as well as contributes to the professional's decision-making process, without misunderstandings during the data sharing between all the stages of the manufacturing process.

7 Conclusion

A system was created for data collection, discarding the traditional and manual model. As shown earlier, it was possible to develop a virtual platform prototype for inserting and illustrating the data about the machine and pieces. In this way, it is possible to represent how the information would be displayed to the management environment, facilitating the visualization of the data, and supporting workers in the day-to-day work.

With this system, it is possible to perform a more efficient production control, monitoring all factors that can interfere with the company's indicators. With this, it is possible to raise the level of the organization generating financial gains, reducing processes time, and minimizing the defects, following the Lean Management and Industry 4.0 principles.

It was not possible to perform the data sensing in the machines, so the data used were approximated values, which can interfere with the conclusions about production if compared to the results obtained from real data on production. If the data were collected in a real application, the results can be significantly modified, influencing directly the company's assertive and agile decision making.

It is suggested, for further works, to apply this project using data from the machine sensors from a real production process, so that the results obtained could be more accurate, and also, it could help real companies to improve the production control.

Resumo. O objetivo deste estudo é descrever o desenvolvimento de uma máquina paletizadora para empresas que manufaturam produtos fracionados, dentre as quais inclui-se as alimentícias, calçadista, farmacêutica, automotiva, gráfica, eletroeletrônica, de materiais de construção, entre outras. Nesse contexto, observa-se problemas ocorridos pelo processo manual utilizado nas empresas, dentre os quais destacam-se as doenças relacionadas ao trabalho ocasionada pelos esforços e repetição das atividades. Desta forma, o desenvolvimento e aplicação do equipamento visa auxiliar a minimização ou eliminação das mesmas. Para isto, o referencial teórico adotado aborda os temas inovação, Processo de Desenvolvimento de Produto (PDP) e os tipos de carregamentos para o processo de paletização. Para atingir o objetivo, utilizou-se técnicas como por exemplo, a Matriz da casa da qualidade, Brainstorming e função global do produto e dividiu-se em tarefas dentro das fases de projeto informacional, conceitual e detalhado a partir do modelo de [15]. No estudo de caso, obteve-se as especificações-meta do produto no projeto informacional, na fase de projeto conceitual selecionou-se a concepção mais adequada e por fim, no projeto detalhado demonstrou-se o projeto com maiores detalhes. Utilizando essa metodologia desenvolveu-se o projeto de um equipamento novo no mercado, considerando uma alta produtividade, diminuindo os riscos com doenças relacionadas ao trabalho e respeitando as normas regulamentadoras de segurança.

Palavras chave: Inovação, Processo de desenvolvimento de produto, Paletização.

1 Introdução

Segundo [15], o Processo de Desenvolvimento de Produtos (PDP) visa desenvolver e atender a demanda de novos produtos no mercado, agregar novas tecnologias e adaptar a novos padrões. Isto é, através deste processo que as empresas criam novos equipamentos para satisfazer a necessidade dos clientes.

Assuntos como conforto e segurança, juntamente com características fisiológicas e psicológicas dos usuários possibilitam a criação de um relevante projeto [8].

Em virtude da globalização dos mercados, crescimento da variedade de produtos e a diminuição dos seus ciclos de vida, a aplicação de uma metodologia cientificamente embasada e suficientemente detalhada orienta o desenvolvimento de novas tecnologias auxiliando na inovação, ocupando-se desde a concepção e aplicação de novos produtos inovadores. Deste modo os novos procuram satisfazer segmentos específicos do mercado, associado a novas tecnologias e adequações a novos produtos e restrições legais [15].

Diante dessa realidade, a aplicação de uma metodologia científica no processo de desenvolvimento auxilia na inovação dos produtos, desde a concepção de ideia até a venda do mesmo, sendo isto um dos principais fatores no aumento da concorrência entre empresas.

As indústrias que manufaturam produtos fracionados, entre elas, alimentícia, calçadista, farmacêutica, automotiva, gráfica, eletroeletrônica, de materiais de construção, necessitam paletizar os produtos. A paletização dos produtos ocorre pela compactação, proteção, organização e praticidade da carga nos processos de armazenagem, expedição e transporte. Portanto, a paletização é um processo importante na manufatura de produtos, instigando as empresas a buscar soluções para diminuir ou cessar problemas ocorridos por doenças relativas ao processo manual e aumentar a produtividade.

Um estudo realizado pela Pesquisa Nacional da Saúde (PNS) em 2013, 3.568.095 (2,44%) da população tem diagnosticado problemas sobre Distúrbios Osteomusculares Relacionadas ao Trabalho (DORT), que são lesões ocasionadas por esforços repetitivos em decorrência do trabalho [1].

Estes sistemas automatizados economizam tempo e eliminam a necessidade de atividades pesadas de paletização manual no final da linha de embalagem, garantindo padronização, ergonomia aos colaboradores, segurança no processo e proteção ao produto final.

Neste contexto, o presente artigo tem como objetivo, descrever o desenvolvimento de uma máquina paletizadora para empresas que manufaturam produtos fracionados. Diante do contexto, pretende-se com o desenvolvimento do equipamento utilizando ferramentas do modelo de PDP, alcançar melhorias no processo de paletização com aumento da produtividade, diminuir tempo e custos com manutenção e minimizar ou cessar as doenças relacionadas ao trabalho causadas por esforços repetitivos.

2 Revisão Bibliográfica

Segundo [16], ao lançar um produto novo ao mercado entrega-se uma nova proposta de valor ao cliente, o que pode ser observado na forma de mínimas alterações. Além disso, a inovação pode ser percebida a partir de pequenas alterações, quase imperceptíveis aos usuários, até modificações que podem alterar a vida da sociedade [10].

Ao analisar a inovação em indústrias de fabricação de máquinas e equipamentos na Pesquisa de Inovação (PINTEC) em 2014, do Instituto Brasileiro de Geografia e Estatística (IBGE) cerca de 40% implementam inovação em produtos e/ou processos

(2657 empresas no total de 6588) e aproximadamente 33% implementam inovação organizacional e/ou em marketing (2191 empresa no total de 6588).

2.1 Processo de Desenvolvimento de Produto

Conforme [15], "Desenvolver produtos consiste em um conjunto de atividades por meio das quais busca-se chegar às especificações de projeto de um produto e de seu processo de produção". Além disso, o processo de desenvolvimento (PDP) pode ser definido como o conjunto de atividades que envolvem a maioria dos setores na empresa, tendo por finalidade modificar os requisitos do mercado em produtos ou serviços, que sejam economicamente acessíveis [5].

O PDP leva em conta os recursos tecnológicos disponíveis, a estratégia competitiva e de produto adotada pela empresa, abrangendo desde a captação das necessidades do cliente até o lançamento final e posteriormente retirada do mercado do antigo [2-15].

Para [2], as principais vantagens do desenvolvimento integrado são: redução do tempo de desenvolvimento, redução de modificações do projeto e aumento da qualidade sob diversos aspectos.

O modelo proposto por [15], conforme representado na (Fig. 1), unificou estudos de caso, modelos, metodologias e melhores práticas aperfeiçoadas ao longo dos anos anteriores. Este modelo baseia-se nos conceitos de Stage-gate.

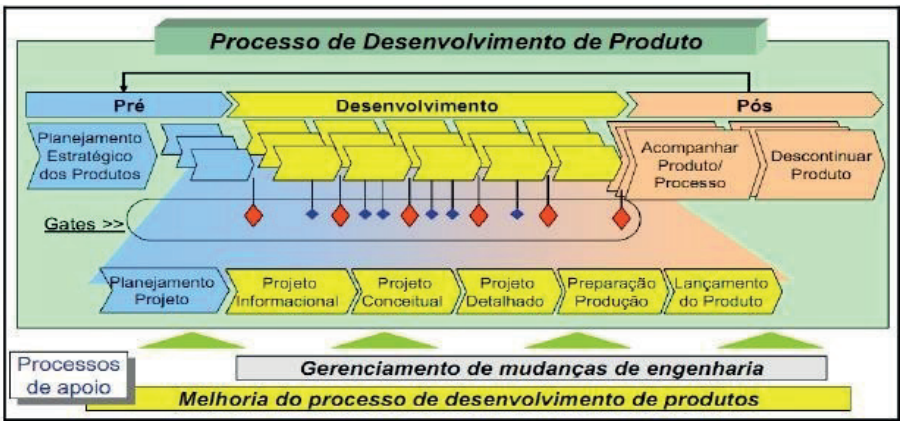

Fig. 1. Modelo unificado para o processo de desenvolvimento de produtos.

Para [12], as fases (Stages) são estipuladas pela entrega de diversos resultados. Quando agrupados geram um novo progresso para o desenvolvimento do produto. Enquanto os Gates são as transições de fases, os resultados obtidos são analisados, e verifica-se se o projeto deve continuar, além de corrigir diferenças de custos com o projeto inicial [14].

2.2 Processo de Paletização

Um paletizador é uma máquina que fornece um meio automático para empilhar caixas ou outras mercadorias e produtos em um palete para transporte e armazenamento eficientes. O ato de colocar caixas ou outros tipos de embalagem sobre paletes para manuseio, movimentação ou armazenamento pode ser feito manualmente por uma pessoa ou automaticamente por uma máquina paletizadora.

Para equipamentos mais automatizados há vários benefícios no carregamento de paletes como redução nos custos de mão de obra, aumentos na taxa de transferência, confiabilidade, reduções de tempo de inatividade, flexibilidade com os novos designs de paletizador atuais, segurança e ergonomia [13].

Para automatizar o processo de paletização deve-se decidir qual tecnologia utilizar. Tanto o carregamento formado por camadas quanto o carregamento robótico têm aplicações distintas. De acordo com a velocidade de camadas por minuto, utiliza-se um paletizador que se adequa melhor para a aplicação.

Conforme [6], o "Transporte manual de cargas designa todo transporte no qual o peso da carga é suportado inteiramente por um só trabalhador, compreendendo o levantamento e a deposição da carga". Portanto, a utilização contínua do corpo nesta função auxilia no desgaste de tendões, articulações e grupos musculares provocando lesões na coluna vertebral, tendinites, bursites e lesões musculares na região dorsal e lombar.

Há algumas soluções que podem ajudar no processo, como um encosto onde utiliza-se para guiar o processo de carregamento e que ajuda o trabalhador a gastar menos tempo alinhando o produto, além de um elevador com dispositivos de auxílio, como por exemplo atuador pneumático, facilitam o processo e são especialmente projetados para funções de paletização [13].

Ainda existem os processos semiautomáticos com máquinas ou robôs, possibilitando eliminar os riscos de lesões ergonômicas em trabalhadores e reduzir o erro do operador. O carregamento semiautomático adequa-se para altas velocidades que não justificam o custo de completa automação, mas requer uma solução para prevenir lesões de trabalho [13].

Ainda segundo o autor, as máquinas completamente automáticas são melhores ergonomicamente, pois possuem velocidade de paletização alta e são os mais eficientes tipos de equipamentos para paletizar. Porém, podem ser as mais caras, dependendo da velocidade da máquina, sofisticação de acumuladores, esteiras, distribuidor e outros mecanismos auxiliares. Outro processo automático, mas como o carregamento robótico, é utilizado e representa um alto investimento, mas o que pode salvar o custo inicial é a redução do custo de trabalho e aumento da eficiência, podendo construir vários paletes de várias linhas de produção.

São estabelecidos os principais tipos de paletização robóticos:

- Braços articulados: Nesta aplicação segura-se o produto recebido por um ou diversos braços articulados, e então posiciona-se no correto palete, considerando qualquer tipo de produto;
- Pórticos: O produto fica imóvel enquanto a ponte aérea move-se para frente e para trás pegando o produto e designando na localização correta.

Como exemplo de aplicação da paletização robótica, consideramos um problema de distribuição em uma produção industrial constituída por múltiplas linhas, utilizadas em centros de distribuição de produtos. Nesses casos, as caixas precisam ser empilhadas das correias transportadoras para os paletes com relação aos pedidos dos clientes. Sendo assim, as caixas atingem o paletizador no transportador principal de um sistema de coleta de pedidos, posteriormente um transportador de distribuição empurra as caixas para vários transportadores e finalmente, os braços robóticos posicionados no final destes destas linhas posicionam o produto em um palete localizado em um dos locais de empilhamento [11].

3 Metodologia

3.1 Modelo de Referência para o PDP

Entre os diversos modelos de PDP, escolhe-se para o estudo com maior detalhe o modelo unificado de [15], preferencialmente em virtude de maiores detalhes nas fases a serem desenvolvidas, com objetivo de descrever o desenvolvimento de um produto conhecido como máquina paletizadora para empresas que manufaturam produtos fracionados.

Ainda, empregou-se no desenvolvimento a ideia pertencente ao projeto de manufatura e montagem (DFMA – Design for Manufacture and Assembly). A utilização dos conceitos de DFMA tem por finalidade a diminuição de custos essenciais aos processos de manufatura e montagem do projeto. Por consequência, foram desenvolvidos elementos de simples fabricação e materiais com baixa mão-de-obra. Com o uso do DFMA, foi otimizado a aplicação de componentes normalizados no projeto.

Com o propósito de simplificar a compreensão sobre o modelo adotado, dividiu-se em fases (F), ferramentas (Fm) e tarefas (T) recomendadas para o desenvolvimento.

3.2 Ferramentas (Fm) do Projeto

As Fm utilizadas para a elaboração das tarefas das fases de planejamento do projeto, projeto informacional, projeto conceitual e projeto detalhado serão expostas a seguir:

Fm1 - Reunião com a equipe de projeto: Abre-se espaço para troca de informações com os demais integrantes da equipe. As reuniões tornam-se sempre sendo um divisor de águas para o sucesso do projeto [3].

Fm2 - Consulta a informações técnicas: Colher informações referentes à dados técnicos, imagens, vídeos e patentes de equipamentos paletizadores. Esta pesquisa pode ser feita por visitas técnicas, e-mails, acesso à web sites de empresas nacionais e internacionais, consulta a catálogos, acesso ao site do Instituto Nacional da Propriedade Industrial (INPI) e visitas as feiras de exposição.

Fm3 - Pesquisa com clientes: As pesquisas são divididas em qualitativas e quantitativas. Na qualitativa são identificadas as características do produto e na quantitativa realiza-se questões que ajudem com a pesquisa de informações para que se chegue aos objetivos de pesquisa [2].

Fm4 - Matriz da casa da qualidade: A matriz da casa da qualidade (QFD) faz a transformação da voz do cliente para a opinião técnica. A opinião do cliente descreve o que o produto necessita ter. As entradas para elaboração do QFD são feitas por entrevistas com possíveis clientes [2].

Fm5 – Brainstorming: Brainstorming é um método intuitivo de geração de soluções que consiste em um coordenador convidar um grupo de pessoas, sendo este grupo multidisciplinar, onde é exposto o problema. Os membros apresentam as alternativas que lhe vêm à cabeça, sendo evitado qualquer tipo de crítica sobre as soluções apresentadas.

Fm6 - Função global: Adquire-se a função global pela análise dos requisitos funcionais incluso na lista de especificações-meta do produto. A função vai sendo desdobrada em funções de menor complexidade. A elaboração da função total do produto ajuda a equipe de desenvolvimento a entender o que realmente se aguarda do produto projetado [15].

Fm7 - Matriz morfológica: Define-se inicialmente o problema, então são pesquisadas formas alternativas para resolução do problema. A matriz proporciona uma avaliação das prováveis configurações do produto. A combinação destes elementos serve de influência para novas ideias.

Fm8 - Matriz de decisão: Realizado a matriz morfológica, devem-se juntar os princípios de solução, respeitando a compatibilidade física e geométrica entre as soluções. São possíveis diversas combinações. A matriz sugere a utilização das especificações técnicas de projeto e os valores resultantes da QFD [15].

Fm9 - Consulta a padrões de cálculo: A equipe de desenvolvimento utiliza padrões de cálculos já consagrados de elementos de máquinas e manuais de fornecedores, que contém sistemas computacionais para ajuda nos cálculos [15].

Fm10 - Software 3D: A equipe de desenvolvimento pode modificar diversos parâmetros, como dimensões, tolerâncias e tipos de materiais e verificar instantaneamente os impactos ocorridos no projeto [15].

3.3 Projeto Informacional

Desenvolve-se nesta fase o conjunto de informações, denominado especificação-meta do produto. Essas especificações orientam a geração de soluções, orientam critérios para avaliação e de tomada de decisão utilizados nas etapas decorrentes do processo de desenvolvimento. Esse conjunto de informações deve refletir as características que o produto deverá ter para atender às necessidades dos clientes [15].

Para [2] o projeto informacional "destina-se à definição das especificações de projeto do produto. Nesta fase acontece a primeira reunião da equipe de desenvolvimento, para apresentação do plano de projeto" Uma vez iniciado, são realizadas seis tarefas (T) que buscam a definição dos fatores de influência no projeto do produto.

T1 – Pesquisar informações técnicas: tem por finalidade coletar informações que contribuam para a equipe de projeto a entender melhor o problema, sendo utilizadas as Fm1 e Fm2 [15].

T2 – Definir ciclo de vida do produto: auxilia o desenvolvimento do produto, mapeando ao longo do caminho os materiais, a fim de identificar as necessidades na origem, uso e descarte dos produtos, utilizando a Fm2.

T3 – Identificar os requisitos dos clientes: reconhece os desejos e necessidades dos clientes de máquinas paletizadoras, deixando essa linguagem mais apropriada ao desenvolvimento de produto. Para esta tarefa, utiliza-se a Fm3.

T4 – Definir os requisitos do produto: converte os requisitos dos clientes em requisitos do produto. Devem ser definidas as características de engenharia que menciona as funções e grandezas físicas referentes ao produto, realizada usando a Fm1 [3].

T5 - Hierarquizar os requisitos do projeto: organiza os requisitos de acordo com a equipe de projeto a fim de organizar em forma hierárquica. São utilizadas as Fm1 e Fm4 [3].

T6 – Determinar as especificações do projeto: nesta atividade procura-se especificar os requisitos de projeto, concedendo informações como valores e metas desejáveis, a maneira de avaliação e as características a serem evitadas na realização do requisito. Utiliza-se as Fm1 e Fm2 [3].

3.4 Projeto Conceitual

Segundo [2]: "Esta fase destina-se ao desenvolvimento da concepção do produto".

O projeto conceitual tem a função de fornecer convicções de projeto para o novo produto. Deve-se satisfazer a expectativa do cliente e distinguir o seu produto com relação aos concorrentes [4].

Ainda segundo o autor, os dois segredos do projeto conceitual são gerar o maior número de ideias possíveis e escolher a melhor de todas. Para [9], a geração de conceitos necessita muita criatividade, pois as invenções são feitas nesta fase. Para [2], o projeto requisita ter grande conhecimento nesta fase.

Conforme o projeto informacional, esta fase é dividida em quatro tarefas que orientam ao desenvolvimento da concepção do produto.

T7 – Definir a função global do produto: representa a relação entre as entradas e as saídas que especificam a função principal do produto. Esta tarefa auxilia a equipe de desenvolvimento a sintetizar o que se aguarda do produto projetado. Aplicam-se as Fm1 e Fm6 [15].

T8 – Definir as subfunções do produto: acontece a decomposição da função global em funções parciais, sendo elas em menor grau de complexidade. A estrutura é dividida até atingir um nível satisfatório de complexidade. Nesta tarefa emprega-se as etaps Fm1 e Fm6 [15].

T9 – Desenvolver princípios de solução: nesta tarefa são atribuídos diversos princípios de solução que atendam as especificações da estrutura funcional já definido na tarefa T8. A equipe de desenvolvimento deve criar várias soluções alternativas para o problema. Passa-se do abstrato ao concreto, da função a forma. Empregam- se as etapas Fm1, Fm5, Fm7 e Fm8 [15].

T10 – Desenvolver alternativas de solução e selecionar a mais adequada: desenvolver o maior número possível de princípios de solução para cada função, compara-se e combina-se soluções e então, seleciona-se por meio de análise comparativa a

mais inovadora concepção para o produto. Emprega-se as etapas Fm1, Fm5 e Fm9 [15].

3.5 Projeto Detalhado

O projeto detalhado tem como objetivo desenvolver e finalizar todas as especificações do produto para serem encaminhados à manufatura e às outras fases (F) do desenvolvimento [15].

Desenvolve-se nesta fase os sistemas, subsistemas e componentes (SSC). Aqui ocorre a documentação final e aspecto do produto. Simultaneamente são realizados o planejamento do processo de manufatura e os recursos do projeto [15]. A fase é dividida em duas tarefas que direcionam ao desenvolvimento as especificações do produto.

T11 – Dimensionar SSC`s: busca-se dimensionar os SSC`s da paletizadora através de equações, observadas principalmente em livros e catálogos. Este procedimento tem a função de estimar as dimensões do elemento verificado no projeto conceitual. Utiliza-se as Fm1 e Fm9 [15].

T12 – Projetar SSC`s: a partir de um dimensionamento inicial, há o início da elaboração dos SSC`s em um software de desenhos tridimensional (3D). Com ele é possível identificar prováveis interferências, maneiras de montagens, análise de movimentos, peso e resistência [7]. Esta tarefa utiliza-se as Fm1 e Fm10.

4 Desenvolvimento projeto máquina paletizadora de caixas

O sistema de carregamento definido para o estudo é o de alto nível, com o propósito de atender as necessidades de uma agroindústria do estado de Santa Catarina situado no Brasil. O material transportado são caixas de papelão de 15 kg com dimensões de 600 mm x 400 mm x 150 mm para comprimento, largura e altura, respectivamente. Para o tamanho do palete, será seguido a norma ABNT NBR 8252 – Dimensões básicas, de 1200 mm X 1000 mm X 145 mm para comprimento, largura e altura, respectivamente. Com o processo de paletização completo, o palete terá uma altura de 2200 mm e uma massa de 1200 kg.

Ainda, o projeto tem por intuito evitar problemas de saúde dos colaboradores no setor de paletização, seguindo normas regulamentadoras, como a NR12 e NR17 e aumentar a produtividade, tendo um ciclo do processo em média de 12 minutos.

Sendo assim, o desenvolvimento do projeto está dividido nas fases de projeto informacional, conceitual e detalhado conforme o modelo unificado PDP descreve.

4.1 Projeto Informacional

T1 - Pesquisar informações técnicas: Nesta tarefa buscou-se informações para auxiliar a equipe de desenvolvimento a entender o problema do projeto. Primeiramente, elaborou-se um banco de dados com imagens e vídeos de paletizadores de caixa disponibilizado no mercado nacional e internacional. Também, documentou-se as informações

através de buscas na internet, visitas em feiras e empresas. Com isto analisou-se os produtos concorrentes, processo de operação do produto e normas de segurança.

T2 – Definir ciclo de vida do produto: Auxiliou o processo de projeto a determinar o que foi realizado nas diversas operações de uma máquina paletizadora.

Durante este ciclo evidenciaram-se: projeto de produto, fabricação, montagem, operação e manutenção. Na fase de projeto de produto buscou-se desenvolver segundo exigência do cliente, sendo o equipamento altamente funcional e sem apresentar ameaça aos operadores e mantenedores. Na fabricação empregou-se materiais com baixo custo de aquisição e menor atividades dos processos de transformação. Na montagem, a padronização dos parafusos a fim de facilitar a fabricação. Para operação os objetivos no ciclo de vida são de não expor os operadores a risco de acidentes. Na operação de manutenção não expor o mantenedor a riscos de acidentes e facilitar a manutenção.

T3 – Identificar os requisitos dos clientes: Para saber quais são as principais necessidades dos clientes, aplicou-se um questionário em algumas empresas da região oeste de Santa Catarina. As questões tiveram o propósito de montar a casa da qualidade e averiguar os principais problemas enfrentados das empresas atualmente. Todas as empresas possuíam o sistema de paletização, com maior quantidade para o sistema manual. Os requisitos dos clientes estão ilustrados na tabela 1.

Tabela 1. Requisitos dos clientes

Requisitos dos clientes	Valores	Requisitos dos clientes	Valores
Simplicidade na operação	3	Robustez	4
Baixo custo de aquisição	3	Alto desempenho funcional	5
Qualidade do equipamento	4	Peças padronizadas	5
Segurança na operação	5	Baixo ruído	5
Dimensões (layout)	3	Utilizar o menor número possível de componentes	4
Durabilidade dos componentes	5	Fácil Instalação	3
Alta tecnologia	3	Fácil manutenção	4
Ergonômico	4	Dispensar mão-de-obra especializada	4
Design do equipamento	2	Minimizar impacto ambiental	4

Levando em consideração esses aspectos, observou-se que os entrevistados necessitam um equipamento seguro, funcional, de baixo ruído e com peças padronizadas, facilitando a montagem e manutenção.

Nas demais questões, observou-se com esta pesquisa que o principal problema enfrentado das empresas se trata de ergonomia. Verificou-se que os colaboradores exercem posturas inadequadas, com repetição excessiva dos movimentos na coluna vertebral, podendo provocar posteriormente lesões musculares, tendinites, bursites, além de expor-se ao risco de acidentes.

T4 - Definir os requisitos do produto: Nesta tarefa, buscou-se a tradução das necessidades dos clientes, resultante dos questionários, para uma linguagem mais técnica, como a da engenharia. Estes requisitos, conforme tabela 2, são expressões padronizadas possíveis de serem mensuráveis por algum tipo de sensor.

Tabela 2. Requisitos do produto

Requisitos do produto	Uni.	Requisitos do produto	Uni.
Forma construtiva		Frequência de manutenção	Qtd/ano
Componentes normatizados	Un.	Capacidade de produção	Kg
Custo do equipamento	R$	Nível de ruído	dB
Inovação tecnológica		Higienização	
Resistência dos materiais	Mpa	Peso	Kg
Número de peças	Qtd.	Tempo do processo	Min
Custo de manutenção	R$	Dimensões	mm
Custo de instalação	R$	Componentes recicláveis	Un.
Componentes simples	Un.	Potência consumida	kW

T5 - Hierarquizar os requisitos do projeto: Nesta tarefa tornou-se necessário ranquear os valores do cliente para cada requisito do produto, além de analisar o relacionamento existente entre os requisitos de projeto, sendo assim nesta tarefa foi utilizada Matriz da casa da qualidade.

Para classificar os requisitos do produto, atribui-se valores de 5, 3 e 1 para forte, médio e fraco relacionamento, respectivamente. Posteriormente, multiplicaram-se os relacionamentos com os requisitos do cliente já disponibilizado na T3.

Realizado a matriz da casa da qualidade, percebeu-se que a ordem decrescente dos requisitos com maior pontuação foi:

1. Componentes normatizados;
2. Forma construtiva;
3. Inovação tecnológica;
4. Custo do equipamento;
5. Resistência dos materiais;
6. Custo de manutenção;
7. Número de peças;
8. Custo de instalação;
9. Frequência de manutenção;
10. Componentes simples;
11. Nível de ruído;
12. Capacidade de produção;

4.2 Projeto Conceitual

T7 – Definir a função global do produto: Descreveu-se nesta fase a função que o produto executa e justificou-se a sua existência, caracterizando as entradas e saídas associadas ao processo de paletização.

A função global intitula-se como “paletizar caixas”. Determinou-se “caixas” pelo motivo de abranger diversos produtos e fácil manuseio. Com o fluxo de material, energia e sinal, pode-se empregar um diagrama de bloco e representar as conexões entre as entradas e saídas do sistema.

Desse modo, entram-se na função global a energia elétrica, materiais como caixas e paletes e o sinal de status da máquina. Na saída, espera-se alcançar energia elétrica, trabalho realizado, vibração e ruído, como material tem-se as caixas organizadas sobre o palete e sinal como status de deslocamento. Portanto, desenvolveu-se o esquema ilustrado na (Fig. 2).

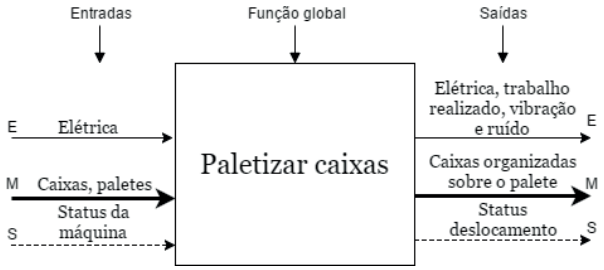

Fig. 2. Esquema da estrutura global

T8 – Definir as subfunções do produto: Desdobrou-se a função global até chegar às funções elementares, salientando as diversas funções que a integram. Elas posteriormente serão usadas na matriz morfológica, simplificando a próxima etapa do projeto.

T9 – Desenvolver princípios de solução: Depois de identificar as subfunções do produto, nesta tarefa determinou-se diversos princípios de soluções para cada função da estrutura funcional do produto. Com a tarefa executada, esses princípios devem ser combinados, efetuando-se várias formas de alternativas e soluções.

T10 – Desenvolver alternativas de solução e selecionar a mais adequada: Depois de conhecido os princípios de solução, determinou-se as alternativas de construção segundo os princípios de solução mais compatíveis, que atendam a caracterização do projeto e tenham combinações promissoras. Com essa matriz, apresentam-se quatro alternativas de soluções julgado promissoras, que posteriormente serão estudadas na matriz avaliação. Nem todas as alternativas foram analisadas na matriz de avaliação, por não ser viável tecnicamente e/ou economicamente.

Determinou-se uma concepção como referência que deve gerar menos dúvidas sobre o funcionamento e é então defrontou-se com as concepções restantes. Define- se qualquer concepção que alcançar uma contagem total maior que a referência para prosseguimento do projeto.

Para diferenciar as soluções, foi atribuída uma nota entre -3 a 3, conforme discussão com a equipe de projeto. Após isto é multiplicado com o peso relativo dos requisitos do cliente já apresentados na tabela 1 e realizado um somatório para indicar qual a melhor solução. Aplica-se nesta tarefa a matriz de avaliação, também conhecida como método de Pugh.

Conforme tabela 3, a concepção 2 obteve maior pontuação entre as outras soluções, que apresentou as principais vantagens como: qualidade do equipamento; dimensão reduzida, o que facilita a instalação de diversos equipamentos em série; design do equipamento com as sua forma física e funcionalidades atraentes.

Tabela 3. Requisitos dos clientes

Requisitos do cliente	Peso relativo	Soluções 1 (REF)	2	3	4
Simplicidade na operação	3		-1	-2	+1
Baixo custo de aquisição	3		-1	-2	0
Qualidade do equipamento	4		+2	+1	+1
Segurança na operação	5		+1	+1	0
Dimensões (layout)	3		+2	-1	+1
Durabilidade dos componentes	5		0	+1	-1
Alta tecnologia	3		+1	+1	-1
Ergonômico	4		+1	0	0
Design do equipamento	2		+2	+1	+1
Robustez	4		0	-1	+2
Alto desempenho funcional	5		+1	+1	+1
Peças padronizadas	5		0	-1	-1
Baixo ruído	5		+1	+1	-2
Utilizar o menor número possível de					
Fácil Instalação	3		0	-2	-1
Fácil manutenção	4		-1	-1	+1
Dispensar mão-de-obra especializada	4		-1	-2	0
Minimizar impacto ambiental	4		+1	0	+1
Total +		0	10	8	8
Total -		0	4	8	5
Peso total		0	34	-5	7

Legenda:

+3 quando a solução é atendida de modo imensamente superior à referência
+2 quando a solução é atendida muito melhor que a referência
+1 quando a solução é atendida melhor que a referência
0 quando a solução é atendida tão bem quanto a referência
-1 quando a solução não é atendida tão bem quanto a referência
-2 quando a solução não é atendida muito pior que a referência
-3 quando a solução não é atendida de modo imensamente inferior à referência

4.3 Projeto Detalhado

Na etapa inicial desta fase dimensionou-se os SSC's e simultaneamente a criação de seus detalhamentos. Portanto, para a escolha dos materiais definiu-se um equipamento fabricado em AISI 304, com propósito de evitar a oxidação precoce. Para os perfis de deslizamento escolheu-se como material o PEAD (Polietileno de alta densidade) por se tratar de um material que exerce sua função e tem um baixo custo comparado aos demais polímeros. Em relação aos tubos de recolhimento da plataforma, selecionou-se o material de alumínio, pois tem boa resistência e baixa densidade, diminuindo o esforço dos motoredutores que tracionam a plataforma.

T11 – Dimensionar SSC`s: Os cálculos servem para averiguar as especificações realizadas no projeto conceitual. Devem-se considerar os componentes e características mais decisivas para satisfazer os requisitos do produto [15].

Nesse contexto, utilizou-se para alguns SSC's, o SolidWorks Simulation, que é capaz de testar e auxiliar a tomar a melhor decisão. Este software possibilita a análise das tensões, deformações e deslocamentos as quais os SSC's estão submetidos, não sendo necessário a produção de protótipos.

T12 – Projetar SSC`s: Para o desenvolvimento dos desenhos e documentações dos SSC's da paletizadora projetou-se com o SolidWorks como software de CAD. O equipamento completo está representado na (Fig. 3).

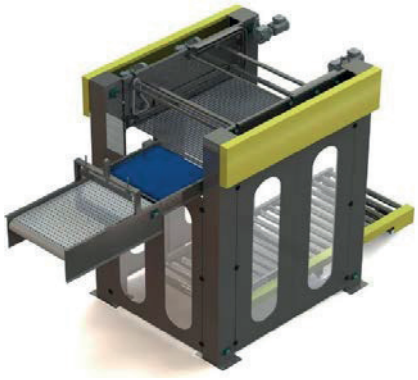

Fig. 3. Paletizadora de caixas desenvolvida em projeto 3D

O processo de funcionamento da máquina paletizadora inicia-se pela esteira viradora, a qual, recebe as caixas da linha de produção. Esta caixa deve estar centralizada e com uma distância considerada entre outra caixa para um bom funcionamento do equipamento. A sua função é girar as caixas em 90º, 180º ou 270º. Utiliza-se um sistema de acumulação para não ocorrer alguma adversidade no conjunto de paletização.

Após a caixa deixar a esteira viradora, ela é transportada na esteira de aceleração. Sua função será de despachar a caixa com uma velocidade maior do que de entrada para que a próxima etapa de paletização (empurrar caixas) ocorra sem haver imprevistos.

O conjunto principal, desenvolve uma função bastante importante no paletizador. Suas funções são de empurrar as caixas para formar a camada, descer o conjunto secundário próximo ao palete, comprimir a camada em todos os sentidos e recolher a plataforma para que a camada seja colocada cuidadosamente sobre o palete.

Empurram-se as caixas lateralmente para que outras caixas ocupem o lugar delas, formando uma camada. Emprega-se um sistema com atuador pneumático para função, por alcançar altas velocidades e ser de fácil armazenagem e transporte. Formada a camada, o conjunto secundário é transportado próximo ao palete por correntes tracionados.

Com o conjunto secundário já próximo ao palete, deve ser recolhido para que a camada fique em cima do palete. Este conjunto é composto por vários roletes fixados em duas correntes. As caixas que compõem a camada são transportadas com os roletes até determinado local, onde se deparam a uma peça com objetivo de manter elas no espaço delimitado. Simultaneamente, as camadas são comprimidas e posicionadas em local específico semelhante à disposição do palete.

Utiliza-se o transportador de palete para movimentar a carga até um ambiente de fácil retirada por equipamentos apropriados para o serviço. Assume a função de base quando o conjunto secundário ainda está em funcionamento e deve ser guiado no momento de posicionar o palete sobre o transportador. É composto por um conjunto de roletes suportado por mancais de deslizamento. As rodas dentadas dos roletes são ligadas em pares. Por se tratar de um conjunto de corrente, devem-se utilizar carenagens que assegurem a proteção recomendada. Projetou-se um sistema de elevação enclausurado, com propósito de diminuir riscos de acidentes a operadores.

Como principais características deste equipamento, tem-se: baixo custo comparado com modelos robóticos; uso de esteiras e corrente, facilitando a manutenção; diminuição das subfunções comparadas aos demais equipamentos; transferência das camadas movendo-se próximo ao palete, que tem posição fixa, a fim de diminuir o esforço dos motoredutores; redução no espaço físico utilizado para localização do equipamento, possibilitando instalar outros equipamentos, ou aumentar o local de transporte de cargas e/ou movimentação de pessoas.

5 Conclusão

Para atender as necessidades dos clientes, o PDP baseado no modelo de [15], torna-se primordial para lançamentos de novos produtos, almejando a superioridade comparando-se com os demais concorrentes. As atividades do PDP proporcionam o desenvolvimento do projeto com mais segurança diminuindo as incertezas e facilitando as escolhas, proporcionando um produto final com tempo reduzido no desenvolvimento, qualidade e preço competitivo no mercado.

O tema selecionado tem sua relevância para automatizar o processo de paletização, tão comum em diversos tipos de produtos. A partir do uso de um equipamento desenvolvido neste artigo e consequentemente o afastamento do sistema manual, obtém-se a diminuição dos problemas ocorridos por doenças ocasionadas a partir de esforços repetitivos e alcança melhorias significativas ergonomicamente. Visto que o sistema manual pode-se tornar o gargalo em uma linha de produção

A automatização do processo reduz os números de colaboradores nesta função, sendo assim, podem ser deslocados para outras atividades e minimiza os erros ocasionados por pessoas.

Portanto com a utilização do modelo PDP no desenvolvimento do projeto, percebeu-se maior facilidade nas resoluções dos problemas e na divisão das tarefas e atividades possibilitando o desenvolvimento com simplicidade e segurança.

As atividades futuras do artigo estão relacionadas ao detalhamento do plano de manufatura, uso de novas ferramentas, como FMEA e elaboração de um manual de utilização e manutenção.

Abstract. This work presents an active learning methodology called Project-based learning (PBL) for developing artificial intelligence (AI) in a computer vision course of an undergraduate engineering degree.

The objective of the course was to develop image recognition capabilities using Deep Learning (DL)/Machine Learning (ML) technics in real-world problems. The PBL learning methodology helped students search for real-world problems, develop complex solutions, and generate synergy among team members. The main role of the professor was to advise, guide and motivate the students throughout the course. The pedagogic innovation with active learning methodologies offered the professor the opportunity to create a dynamic motivating learning environment based on experiences. Each undergraduate engineering student had the opportunity to develop the skills and techniques of their profession: teamwork, proactivity, innovation, and leadership. The results obtained by the student teams showed problem-solving, including the use of automatic navigation equipment with AI, detection of the malaria parasite, recognition of non-human individuals to control vehicular traffic.

Keywords: artificial intelligence, artificial neural network, image recognition, machine vision, project engineering.

1 Introduction

Learning AI technics establishes new challenges to teaching at the university level. Technological changes reduce the life cycles of products and services [1]; The professor and the students must incorporate new technics to their competences during the elective period. [2] presented the PBL methodology for learning computer vision: its main advantages are associated with motivating students to undertake individual and team-based learning, the discovery of new concepts, and the capacity to develop real-world problems by presenting a simple problem [3].

The weaknesses of the PBL methodology regarding the difficulty to establish levels of compromise and learning with all students are mentioned in [4]. However, the PBL methodology [5]–[12] characteristics are defined by a variety of components and reduce the desertion, lack of motivation, or self-esteem of the students [13]–[16]. The components of the PBL philosophy established by the authors [17]–[19] are (1) define a problem starting point, (2) organize the projects, (3) define the teams, (4) guide or advise the participants -by the professor-, and (5) establish interdisciplinary learning.

The PBL methodology has a great capacity to address varied problems in engineering: design of software systems [20]–[24], electric systems [25]–[28], energetic systems [29], [30], microelectronics [31]–[33], medical applications [34], [35],structural engineering [36], [37] and mechatronics [38], [39].

The capacities of the university laboratories allow engineering students to develop and implement complex Works. Over the last years, DL/ML technics have allowed images of the multiple databases to be identified and classified accurately [40], [41]. The selection of the image classification technique must consider the response times, the accuracy of the image or video categorization, the energy expenditure, and the image size and analysis method [42]. The image recognition techniques recognized for their precision and analysis speed are YOLO [43] and single shot detector (SSD) [44] based on end-to-end algorithms, and the region proposal method with convolutional neural networks (CNNs) [45].

The authors of [10], [46]–[49] present works undertaken by undergraduate students through the integration of educational objectives of science, technology, engineering, and math (STEM). The support of experts allows teams of motivated students to be developed, using easy access technological capacities such as Raspberry [50], Python [51], and low-cost sensors and controllers [52]. Some complex problems addressed in these semester courses are autonomous drones [53], robotic arms with AI [46], and DL for classification of image data bases [54]–[56].

2 Materials and methods

The cooperation among students for [57], is a powerful tool in complex environments and develops learning abilities and professional skills among students. The traditional teaching methods limit the movement of students: [57] indicate the dramatic change in the learning environment and the participant requirements at the classroom with active methodology techniques.

The teaching of engineering and sciences through the creation of a functional product should improve by using the main characteristics of the PBL methodology; (1) small student work groups, most of the time, without the presence of a tutor, (2) realistic, professional and large magnitude tasks, (3) tasks that cover only a small part of the class contents, (4) reading to deepen the technical content, (5) group work oriented towards a product, (6) learning new knowledge and abilities, (7) dividing tasks to obtain better products, (8) improving abilities that are strongly interrelated with other courses from the training, (9) focusing on the project work and less on the class,

(10) individual responsibility -critical for project development-, and (11) assessing the final developed product [58]–[60].

The application of the PBL methodology transforms the professor´s role, which is to guide workgroups. [61] points out the need to perform large scope work focused on the student, with collaborative workgroups to solve real-world problems. The obtained knowledge and skills are required for self-management, teamwork, leadership, time management, communication and problem-solving, and the ability to use technology-based tools [62]–[65].

This model allowed responsibilities to be assigned to different student groups, who are transformed into active actors of their education [66]–[68].

The project approach -disintegrating the project into delimited problems- facilitates teamwork, creates task specialization, and increases the depth of the content applied by the teams [69]–[71].

The final objective of the course is to establish a work team, search for a real-world problem and solve it using DL/ML technics for the classification of images. The project was addressed from the engineering perspective, developing (1) the design and engineering of the product, (2) the technical studies, (3) the software engineering (4) the prototype and (5) the functional tests of the product [72]–[74]

2.1 Course Description

During semester planning, the third-year AI class was considered, supported by one professor and two students in their last year of study. The activities were established on a schedule with weekly deliveries of convergent activities. This model allowed multiple activities to be performed in parallel; speeding up the project term [75], [76]. The student teams (3 to 5 people) could choose problems based on their technical abilities, skills, and intellectual interests.

The development of the course was performed in a laboratory composed of one computer per student. The DL technics were prepared and presented by the teams using the PBL methodology. Each exhibition was followed by a feedback activity from the professor and questions from the other teams. The weekly activity included a discussion regarding project portfolios and their possible technological solutions.

Finishing the first stage of 6 weeks, the teams presented their chosen project, the state-of-art of the problem, and the technics required for the solution.

During the second stage of the course, lasting 8 weeks, students established two forms of communication, (1) the communication between each team and the teacher to receive advise on the most difficult points of the project and (2) communication between all the teams and the professor in the classroom. This communication in classes is essential to ensure the delivery of all the technical course content, and peer learning; it is necessary to stimulate opinions among the groups to reduce the learning curve for project development.

Finally, in the third 2-week stage the students must validate their prototypes, deliver the project documentation and give a final presentation with a functional prototype.

2.2 Computer Vision Projects

The computer vision projects selected by the teams addressed a variety of problematics, from automation of naval autonomous equipment with AI, detection of the malaria parasite, and recognition of non-human individuals to control vehicular traffic.

All the teams presented their functional prototypes of image classification at the end of the course.

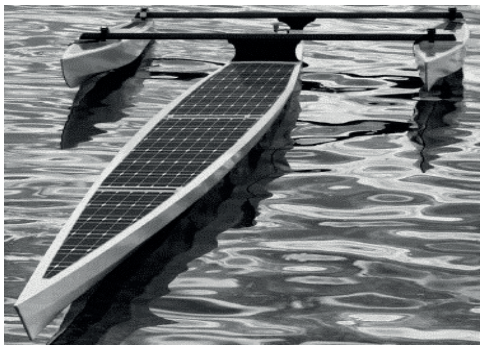

Fig. 1. Prototype of a manned auto embarkation, fed through solar energy

3 Result and discussion

Over this last decade the advances in the design and construction of autonomous marine robots improved substantially for the application to exploration, oceanographic science, and marine engineering. The remote vehicles must be controlled by human operators in real time. This work is laborious and repetitive: the operators must be highly trained to face complex trajectories and recognize the marine environment [45].

The autonomy of the marine equipment can be addressed using acoustic and visual sensors. The use of acoustic sensors is widely used in marine applications, however, the visualization of marine elements at close distances to the boat, require the use of visual sensors [77]. The use of the computer vision technique known as DL precisely identifies marine equipment, marine fauna, and landscapes. These visual sensors must have the capacity of image recognition based on computer vision technics [78], [79].

For the recognition of floating objects an open-source library for automatic learning -called TensorFlow- was used (version 1.7 compatible with operative systems of 64bits as Ubuntu 16.04), which can build and train neural networks. To initiate neural training the open-source model called MobileNet was used: it provides an efficient vision for mobile devices, using an entry resolution of 224 pixels and with relative sizes [80]. The technological solution was installed in a Raspberry Board to analyze the surroundings and command of the anti-collision system of the autonomous embarkation (Figure 1).

3.1 Project Materials and Methods

The start of neural training was carried out on a Notebook Lenovo Ideapad 110 (Processor 2.5 GHz and storage capacity of 1 TB). MobileNet was set to select images of 224 pixels that even though they provide better resolution and require more processing time, will deliver higher classification accuracy. Acceptance of these images in relative sizes will be established in the settings.

Along with the setting process, the monitoring tool TensorBoard that comes incorporated in Tensorflow will also be activated. The selection of the neural network model was done by taking into account some restrictive system parameters with 1 Gb of RAM memory and a 32 Gb memory disk that comes in the Raspberry Pi-Plate [81], [82], to use the trained network with its updates. The selection of the Raspberry-MobileNet system is associated with low energy levels to detect objects in real-time.

The retraining is executed by loading the image databases that were prepared for the initial layer. Considering restrictions of visible light from 500 to 700 nm, the position of the camera where the sun does not obstruct the image capture and the size/visibility of the object, excluding images during the night, with visibility below 400 nm.

Each category can contain a minimum of 20 images [83] (with no size distinction), in this case, a repertoire of 300 images was included in a category in ".jpg" format, obtained from "image-net.org" and from "google images", considering a training of 500 steps. Retraining can extend up to 4.000 iterations, this method is used to improve test performance; the results obtained in the training did not detect performance variations using both kinds of iterations.

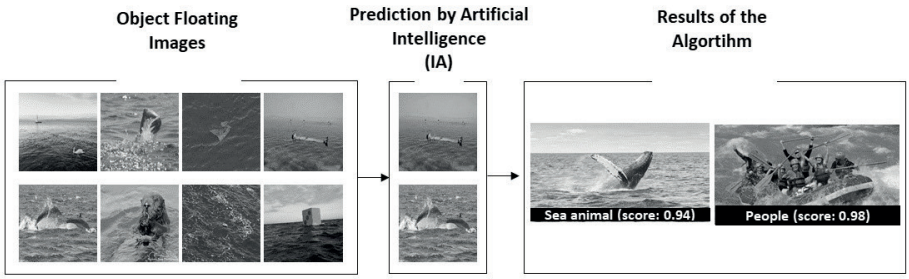

Fig. 2. Diagram of predictive model by artificial intelligence

Test procedure: for retraining the following stages were followed (Figure 2): (1) retrain through the loading of images, (2) results of the neural training with categories included, (3) experimentation with external images to those used previously, (4) results of floating object recognition [84].

3.2 Project Results

In figure 3 and table 1 the validation accuracy of the images or the percentage of images correctly labeled are displayed. The X axis shows training progress, and the Y axis shows the accuracy for entry resolution at 224 pixels for the different relative sizes used in the training tests of floating objects (0.25, 0.50, 0.75 and 1.0).

The Train line presents the accuracy of the training data model, while the validation line shows the accuracy of the set of tests. For this case, the train graphics have an upward trend, while the Validation graphics are below them; the model is over adjusted and starts memorizing the training set instead of understanding the general patterns in the data.

For this experimental phase, the progress of the model´s cross entropy must be analyzed to understand the improvement of the learning process.

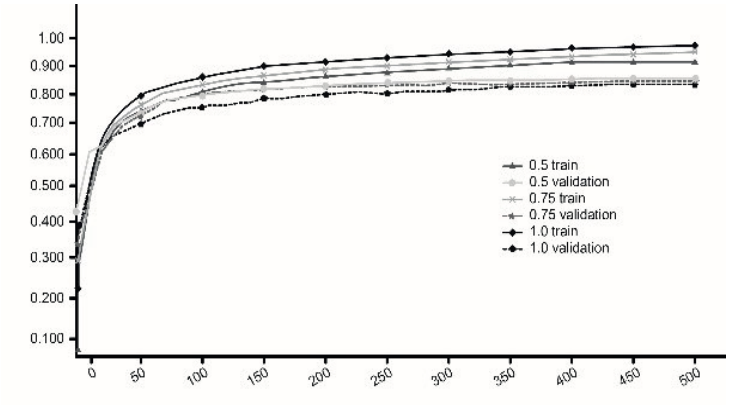

Fig. 3. Occurrence graphic by sizes relative to MobileNet

The objective of the training is to reduce the loss to ensure learning: keeping the declining trend through the discard of short-term noise.

Table 1. Accuracy data of the model.

Name	Smoothed	Value	Step	Relative
Mobilenet 0.50 224/train	0.9195	0.9700	499.0	15s
Mobilenet 0.50 224/validation	0.8497	0.8500	499.0	15s
Mobilenet 0.75 224/train	0.9447	0.9800	499.0	15s
Mobilenet 0.75 224/ validation	0.8439	0.8900	499.0	15s
Mobilenet 1.0 224/train	0.9716	0.9400	499.0	16s
Mobilenet 1.0 224/ validation	0.8348	0.7900	499.0	156s

The script executed 500 training iterations. Each step chooses ten images at random from the training set with its bottlenecks (penultimate layer responsible for classifica-

tion) in the cache and introducing them into the final layer to obtain predictions. Those predictions are compared to the real labels to update the weights of the final layer through the backward propagation process. The repetition of the process improves the accuracy of the neural network. Once the experiment is finished a final evaluation of the test accuracy is performed with a set of new images. This test evaluation is the best performance estimation of the model trained in the classification task. The accuracy values vary between 80% and 95%. Each experiment modifies the predictive capacity due to the random character of the neural process in the selection of images. The results are represented in figure 4; in the X axis shows the quantity of iterations, Y axis the accuracy of entry resolution 224 pixels with the different relative sizes evaluated (0.25, 0.50, 0.75 y 1.0).

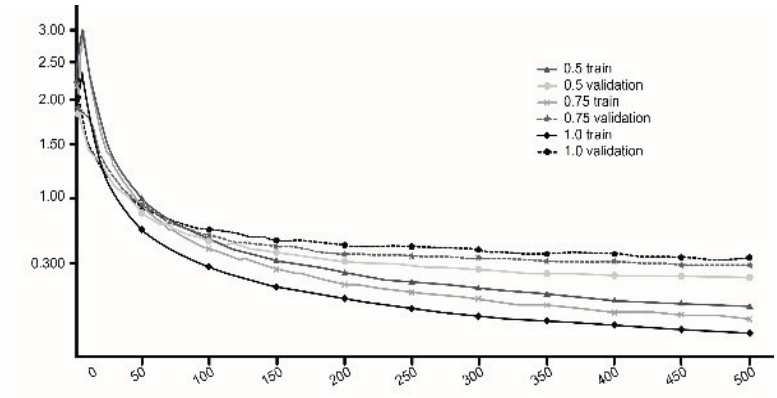

Fig. 4. Graphic of entropic cross by relative sizes at MobileNet

The great number of samples in the database provides the algorithm with a better opportunity to learn and provides a more specific database for training, which in turn allows the accuracy of the model to be improved [85], [86]. Finally, the obtained results with the modified CNN are compared with the results obtained using others benchmark CNN trained for the detection of floating and non-floating objects [87]–[89], obtaining improved performance in the recognition and classification of images. Table 2 presents the test results of the selected categories, which can be compared with the retraining results of a network, achieving better results than non-trained networks [90].

3.3 Project Discussion

We trained a CNN to detect floating objects in the sea for the navigation of a manned auto embarkation, powered by solar energy with a Raspberry central system. The results of the proposed CNN training were better than the results obtained from the compared CNN. This supports future work towards the optimization of the behavior of autonomous boat decisions, for example, by measuring the distance, size and relative speed of floating objects. We expect this experience to help practitioners in the

process of retraining the CNN and in the application of this method to improve the image's recognition process.

Table 2. Average percentage of the recognition assertiveness of objects for the applied methodology.

Category	TensorFlow CNN re-train	MatLab	Inception	Yolo
Boat	0.9642	0.7595	0.3033	0.7420
Dock Maritime	0.8634	0.20000	0.5012	0.0000
Iceberg	0.9140	0.6000	0.0000	0.0000
Obstacle	0.9714	0.6000	0.0791	0.0000
People	0.9381	0.6800	0.0000	0.7960
Sea Animal	0.9675	0.8200	0.8376	0.0000
Submarine	0.9995	0.9195	0.4692	0.1200
Waterfowl	0.9724	1.0000	0.2720	0.8300
Eave	0.9714	0.4800	0.3508	0.0000

Detection and recognition of floating objects in the sea is a theme of great importance in the fields of civil protection, environmental care, and applications for maritime navigation. In this study, we proposed retraining CNN that detect floating objects in real-time using the prototype of an autonomous navigation vessel, fed through a solar energy system. For the detection of floating objects, a neural network was trained in 9 categories which were compared with other existing methods, achieving superior levels of recognition than the proven methods.

3.4 Assessment

The competencies assessed in each project correspond to the tuning model for Latin America. The assessment model considered a matrix activity with learning results. Assurance of student learning was achieved through the compliance of the learning factors [91], [92]. It used a series of questions qualified by the 5-point Likert scale and seeks to compare the different variables between the projects developed during 2019 using the master class learning methodology with the execution of individual AI projects versus the AI project using the PBL methodology. The results are shown in Table 3.

To establish the effectiveness of the PBL method, a control group was established (35 students) to execute a null hypothesis of equality of means among the averages of the control group using the learning method of masterclasses and the course with PBL methodology (42 students). The statistical test was rejected when the average of the

course with the PBL methodology was higher than that of the course used as a control group.

Both groups started the semester with an initial knowledge test and the accepted hypothesis test; the two groups had similar knowledge at the beginning of the semester.

Table 3. Results of student's self-assessment using five-point Likert surveys of master class learning group (35 students) and the PBL group (42 students)

Question	PBL Mean	Master Class Mean
Did you apply your abilities of abstraction, analysis, and synthesis during the development of the project?	4.3	4.0
During the development of the project, did you delve into knowledge and experience of the study and profession field?	4.0	3.5
During the development of the project, did you improve the way you communicate in another language?	3.0	1.5
During the development of the project, did you develop your abilities to use technology and communication tools?	4.8	4.5
During the development of the project, did you increase your ability to search and analyze information from several sources?	4.3	2.5
During the development of the project, did you increase your ability to motivate and work around a common goal?	4.5	2.0
During the development of the project, did you feel that your ability to work independently improved?	4.1	2.5
During the development	4.1	2.6

of the project, did you think your ability to formulate and manage projects improved?	

The student's perception, reflected in survey's results, is aligned with the subject and the graduation profile objectives: To acquire the necessary knowledge, skills and attitudes to perform in the management, and the improvement of production and services systems; in administrative management, entrepreneurship and innovation; and in organization's strategy context, applying their ability to lead interdisciplinary teams, and their theoretical and practical knowledge in the Engineering field.

Teachers positively evaluate self-management, leadership, and creativity developed by students during activities inside and outside of class. In particular, the considerable increase in communications and interactions between peers and teachers outside of class time. These self-managed activities by student teams to achieve project goals are supported by oblique communication platforms such as social networks.

The expected result of learning using the PBL technique is that students know the concept of neural networks and artificial intelligence, its components, the research on its applications, and the recommendations about its use.

4 Conclusions

Through PBL, engineering students developed the design of the product, (2) the technical studies, (3) the software engineering (4) the prototype and (5) the functional tests of the product. This multidisciplinary work allowed students to quickly join the management of complex engineering projects.

The model proved to exceed the traditional model for large magnitude projects; most of the students complied with the due dates of the assigned tasks, demonstrating an appropriate level of work and commitment with the project. At the beginning, the students felt lost when facing a new work methodology; professor guidance secured their curiosity and interests to highlight their selected areas, providing support to other teams, and reaching the finish line as a large team.

PBL driving force might be copied in other complex projects for different study areas; this contributes to the development of personal skills, teamwork, leadership, autonomy, and personal initiative.

Finally, the university directives established an economic contribution to develop the active learning methodology in other engineering courses. The reuse of knowledge and techniques learned by students and teachers allows increasing the technological defiance for higher engineering courses, reducing the learning time in student teams.

The students perceptions during the development of the course with the PBL techniques are opposed, they accept and reject the method; the analysis of the experiences will allow us to visualize the benefits and propose continuous improvement of the learning process.

Manuel Vargas, PhD in Engineering Sciences, mention Industrial Engineering Mention, from the University of Santiago de Chile, Chile. M.Sc. mention Industrial Engineering, from the University of Santiago de Chile, Chile and Industrial Civil Engineer, University of Santiago de Chile, Chile. Teacher Department of Industrial Engineering, University of Santiago de Chile. Research areas: artificial intelligence, dynamical systems and education research.

Tabita Nuñez, Industrial Engineering, Faculty of Engineering and Technology, Universidad San Sebastián. Research areas: computer vision.

Miguel Alfaro, PhD in Automatic Production from the University Henri Poincare, Nancy, France; Master's in engineering sciences, mention in Economic Engineering from the Pontifical Catholic University of Chile. Director of the Department of Industrial Engineering, University of Santiago de Chile. Research areas: nonlinear dynamical systems, artificial intelligence in manufacturing systems and agent-based modeling systems.

Guillermo Fuertes, PhD. In Engineering Sciences, mention Industrial Engineering, from the University of Santiago de Chile, Chile. M.Sc. mention Industrial Engineering, from the University of Santiago de Chile, Chile. Agroindustrial Engineer, from the National University of Colombia, Colombia. Research, areas: operation management, nanotechnology, supply chain management, dynamic systems and education research.

Sebastian Gutierrez, Director of Research of the School of Economics and Business of "Universidad Central de Chile". Doctor in Administration Sciences, in the area of investigation of International enterprise, a doctoral thesis supported by Fondecyt Regular. He obtained a Scholarship for an Experimental Design Course, Nuffield, Oxford, UK, and further training in entrepreneurship education, Babson College, USA. He has 10 years of experience as a pre- and post-graduate university professor.

Rodrigo Ternero, PhD (c). In Engineering Sciences, mention Industrial Engineering, from the University of Santiago de Chile, Chile. M.Sc. in Environment, from the Uni-

versity of Santiago de Chile, Chile and Teacher in Physics and Mathematics, from University of Santiago de Chile, Chile. Research, areas: dynamic systems, supply chain management, artificial intelligence and physics phenomena.

Jorge Sabattin, PhD. Engineering Sciences, Mention Industrial Engineering, from the University of Santiago de Chile; Master's in engineering sciences, mention Industrial Engineering, from the University of Santiago de Chile. He is currently a professor at the University Andres Bello.

Leonardo Banguera Arroyo, PhD in Engineering Sciences, Industrial Engineering, University of Santiago de Chile; Master in Integrated Management System and Industrial Engineer at the University of Guayaquil. Professor of Industrial Engineering, University of Guayaquil, Ecuador. Research areas: Reverse Logistics, Supply Chain and Sustainability.

Claudia Durán San Martín graduated in Industrial Civil Engineering from the University of Chile, Chile in 1999. She obtained her M.Sc. and Ph.D. in Industrial Engineering Sciences at the University of Santiago de Chile in 2011 and 2015, respectively. Her areas of research interest are data science and management decision making between private companies and public organizations. During this time, she has participated in multi-disciplinary research projects that have been developed in some local companies in the mining, energy and services sectors. Dra. Durán has written several articles for conferences and journals related to electricity, electronics, and computing. She is currently a professor of the Industrial Civil Engineering degree at Universidad Tecnológica Metropolitana.

Maria Alejandra Peralta, Master in Education and Bachelor of Mathematics from University of La Serena. Academic from the Department of Sciences at the Universidad Católica del Norte.

Abordaje de conceptos de matemática en proyectos interdisciplinarios

Pablo Carranza[1]

Keywords: Didáctica de la matemática, Enseñanza por proyectos, Molino Savonius.

1 Abstract extendido

El aprendizaje por proyectos es un tipo de propuestas pedagógico-didáctica tendiente a favorecer la apropiación de saberes por parte de los estudiantes, y esto para todos los niveles educativos [1],[2],[11],[12][16],[18].

En particular, en enseñanza de la matemática, el aprendizaje por proyectos suele interceptarse con otro enfoque, el que se interesa a la modelización. Esta última siendo entendida como una suerte de proceso con potencialidades didácticas que relaciona un contexto real con un conjunto de conceptos abstractos.

En este sentido, se destaca el denominado ciclo de modelización que comienza en una problemática de la realidad, luego se sintetizan sus características y variables fundamentales acorde al problema a resolver, a continuación esas características y variables son puestas en relación en un modelo a los fines de producir razonamientos y conclusiones que serían imposibles o muy difíciles de alcanzar por observación directa del contexto de referencia. A nivel didáctico siempre, se insiste en la importancia que esos razonamientos producidos en el modelo regresen al contexto de referencia que motivó su convocación y esto con la intención de facilitar la atribución de sentido al aprendizaje por parte de los estudiantes [3],[5],[8].

A su vez, existe consenso tanto en la complejidad como en la riqueza de los conceptos de matemática que los docentes abordan con sus estudiantes. Para dar cuenta de esa riqueza y complejidad, algunos autores introdujeron el concepto de registro semiótico [6],[7],[14][15], destacando que muchos de los saberes, para su integral comprensión, deben ser aprendidos en los diferentes registros en los cuales ellos se manifiestan. Así es posible identificar el registro numérico, el gráfico, el simbólico, el coloquial, etc. Todos necesarios de ser transitados para una apropiación integral de los conceptos por parte de los estudiantes [4],[10],[13].

En esta comunicación compartiremos algunos resultados obtenidos en el marco de un proyecto de investigación acreditado y financiado por la Universidad Nacional de Río Negro (UNRN), Argentina, donde nos interesamos a analizar las potencialidades que presentan los proyectos interdisciplinarios para abordar, en particular, conceptos

de matemática. Para ello, durante el año 2018 se llevó a cabo un proyecto con estudiantes de la Tecnicatura Superior en Mantenimiento Industrial (TSMI) en la cátedra de Matemática consistente en el cálculo, construcción e instalación de molinos del tipo Savonius [17]. Este proyecto fue financiando por la Secretaría de Políticas Universitarias (SPU) en tanto que proyecto de extensión.

La potencialidad aquí retenida trata sobre las posibilidades que permitió el proyecto de abordar conceptos de matemática en sus diferentes registros semióticos en el contexto de modelizaciones que respondían a demandas del proyecto. Para ello, el equipo de investigación se basó principalmente en tres tipos de fuentes: registros de audios de clase, registro de notas de los dos docentes a cargo de la cátedra y archivos en Geogebra y Hoja de cálculo producidos en clase.

La figura 1 ilustra el tipo de molino al origen del proyecto interdisciplinario desarrollado con los estudiantes de la TSMI. Cabe acotar que la cátedra de matemática, es del tipo cuatrimestral (desde Marzo a Junio), su plantel docente está compuesto por un investigador en didáctica de la matemática (autor del artículo) y un ingeniero civil. Los estudiantes por su parte, ingresantes a la carrera, son de orígenes muy variados y con edades comprendidas entre los 18 y los 50 años. El grupo suele tener una proporción de mujeres de aproximadamente el 25 por cierto.

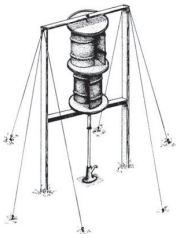

Fig 1. Esquema de Molino Savonius

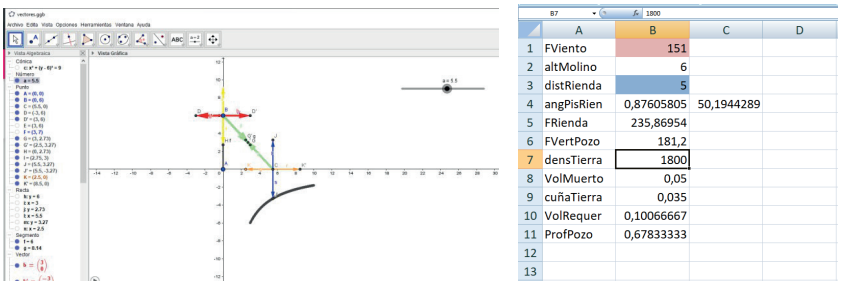

El enlace de abajo envía a un vídeo corto donde puede observarse la instancia final consistente en la instalación de dos molinos por parte de los estudiantes de la TSMI, uno en un puesto rural (La Margarita) en cercanías de la localidad de El Cuy, el otro en un puesto rural (Horno Viejo) perteneciente al ejido de Sierra Colorada.

https://www.youtube.com/watch?v=889fvPzVK1g

La potencialidad observada consistente en la posibilidad de abordar conceptos de matemática en diferentes registros semióticos por medio de modelizaciones se observó en reiteradas oportunidades. Por razones de espacio se sintetiza aquí solo un caso: el referido al estudio de las riendas tensoras del molino. Ese estudio se realizó en dos softwares, uno llamado Geogebra (www.geogebra.org), el otro en Hoja de Cálculo.

El estudio en Geogebra respondió a una necesidad del proyecto de analizar, si las riendas tensoras soportarían diferentes esfuerzos en caso de anclarlas, por necesidad, más cerca o más lejos respecto del molino de lo originalmente previsto. El estudio en

Hoja de Cálculo se orientó a determinar la profundidad del pozo donde se anclarían las riendas tensoras.

Fig 4. Captura de pantalla de estudios realizados en Geogebra y en Hoja de Cálculo

Por razones de espacio, nos limitaremos aquí al concepto de vector abordado en las dos modelizaciones y sus tres características: dirección, sentido y módulo. El estudio en Geogebra fue del tipo relacional: luego de la construcción, un deslizador controlaba la posición del punto de anclaje y la opción rastro de Geogebra permitía observar la variación de los esfuerzos en función de la ubicación de la rienda. En la vista gráfica, no solamente se abordó el concepto en el registro semiótico gráfico ponderando aspectos referidos a dirección y sentido, sino que también se observaron nociones vinculadas a descomposición de vectores, equivalencia, y relación entre módulos. En la vista algebraica por su parte, los vectores fueron representados en el registro numérico y simbólico por sus coordenadas cartesianas.

Por su parte, el archivo en Hoja de Cálculo, al tener el objetivo de determinar la profundidad del pozo en función de un conjunto de variables, entre ellas la distancia de anclaje, se abordó el módulo de vectores en el registro numérico y algebraico [9].

En otras palabras, ambos estudios se complementaron no solo para abordar las nociones de dirección sentido y módulo sino también para tratar el concepto de vector en diferentes registros semióticos.

A modo de síntesis y en función de lo observado en el proyecto llevado a cabo, los proyectos interdisciplinarios pueden resultar un contexto rico en posibilidades de abordaje de conceptos disciplinares, en particular de matemática. Las modelizaciones poseen la potencialidad de analizar el contexto de referencia y de facilitar conclusiones que serían prácticamente imposibles de elaborar de manera intuitiva. Por último, destacamos que las modelizaciones realizadas resultaron de utilidad a las cuestiones a resolver en el proyecto, por lo que el ciclo de la modelización se realizó de manera completa.

A modo ilustrativo, en la instalación del molino en el puesto Las Margaritas, los pobladores realizaron los pozos más cerca de lo previsto. Se pudo observar a los estudiantes debatir y recuperar la modelización en Geogebra y acudir al archivo en Hoja de Cálculo disponible en sus celulares para determinar la profundidad a la que deberían estar los pozos (en el min 0:32 puede observarse a los estudiantes aumentando la profundidad de los pozos). Ese ejemplo de utilización en el campo, representa el fun-

cionamiento del ciclo de modelización donde los conceptos no solo son de utilidad para comprender fenómenos sino también para intervenir en ellos.

Resumen. Este trabajo se basa en una primera experiencia académica sobre el dictado de las materias del ciclo superior de matemáticas complementado con el uso y programación en la plataforma OCTAVE. Fue puesta en práctica para las carreras de Ingeniería en Alimentos e Ingeniería en Biotecnología de la Universidad Nacional de Río Negro durante los años 2019-2020.

Palabras Claves. Matemática Superior. Cálculo Multivariado. Métodos Numéricos. OCTAVE. Aprendizaje Virtual en Ingeniería

1 Introducción

Esta adecuación de los contenidos de matemática y la incorporación de elementos de programación en el entorno OCTAVE surge a partir de las observaciones realizadas por los pares evaluadores en la acreditación de la carrera de Ingeniería en Biotecnología de la Universidad Nacional de Río Negro en el año 2018. El dictado de las dos materias de Matemática del ciclo superior (que están en el 2do. año del plan de la carrera referida) se comparte con alumnos de Ingeniería en Alimentos. Durante los primeros diez años de la creación de esta última carrera, se dictaron dichas materias en la forma tradicional, una referida a Cálculo Multivariado y la restante referida específicamente a la temática de Ecuaciones diferenciales ordinarias y en derivadas parciales.

2 Cambios realizados

Los cambios propuestos en el dictado de las dos materias apuntan a satisfacer requerimientos de la Comisión Nacional de Evaluación y Acreditación Universitaria (CONEAU) en Argentina con el fin de nivelar los contenidos de la disciplina con los de carreras análogas de otras universidades nacionales. El principal desafío fue diseñar ambas materias de manera que conjuguen todos los conceptos de Cálculo Multivariado, Ecuaciones Diferenciales y Métodos Numéricos de forma tal que se aborden

con una herramienta de programación donde se desarrollan los cálculos y post-procesamiento de datos necesarios con el fin de que obtengan una visión temprana sobre el alcance de la aplicación de estas herramientas informáticas, que además serán útiles en su futura actividad profesional como en otras asignaturas posteriores de la carrera, tanto sean orientadas al cálculo numérico como las de laboratorio. Bajo esta óptica, la currícula íntegra de estas dos materias, que se dictan en cuatrimestres consecutivos y tienen cargas horarias semanales de 6 hs (A. Cálculo Multivariado) y 4 hs (B. Métodos Numéricos), respectivamente, fue desarrollada en su totalidad pero además adecuada y complementada con el uso de OCTAVE [1] y programación en dicha plataforma. Cabe señalar que por tratarse de un *software* libre, se dispone de tutoriales muy completos en Internet.

A continuación, en los apartados que siguen se mencionan los temas abordados en cada una de las materias (A y B), cómo se fue acoplando la utilización de una herramienta de programación a lo largo de todo el cursado (C. Herramientas de programación), y finalmente, los desafíos y readecuaciones que se hicieron para afrontar las dificultades que la pandemia por SARS-CoV-2 (COVID-19) originó en el cursado presencial habitual de las materias originando el dictado virtual de las mismas (D. De la presencialidad a la virtualidad). Por último, se presentan algunas conclusiones.

A- Cálculo multivariado

El programa de la materia fue diseñado para contener los temas tradicionales de un curso de análisis matemático referido a funciones de varias variables, partiendo un afianzamiento con la geometría del espacio, con las superficies más reconocidas, las operaciones vectoriales más utilizadas para tener una métrica y calcular así distancias y ángulos, y reconocer en ese entorno las ecuaciones de rectas y de los planos. Posteriormente se abordaron los siguientes tópicos: representación de funciones en el espacio, límite y continuidad de funciones de dos o más variables. Una vez finalizados estos contenidos, se desarrolló todo lo referido a la noción de derivadas parciales, diferenciabilidad y aproximaciones de funciones, para concluir este capítulo con problemas de optimización sin y con restricciones. A continuación, se introdujeron conceptos de integración múltiple, incluyendo los cambios de coordenadas más usuales. Este último tema posibilitó el desarrollo de la última unidad de la materia que se refiere a Cálculo Vectorial, que incluye campos vectoriales, integrales de línea y teorema fundamental y de Green, nociones de rotacional y divergencia, superficies paramétricas, integrales de superficie y los teoremas de Stokes y de la divergencia. La referencia bibliográfica básica fue sustentada mediante la utilización del libro de Stewart [2]. Una selección de ejercicios de cada unidad temática fue sugerida para la práctica de los nuevos contenidos.

B- Métodos numéricos

Partiendo de una introducción al análisis del error se analizaron las aproximaciones de valores funcionales empleando las series de Taylor, se introdujo la derivación numé-

rica para evaluar la medida del error cometida con las distintas expresiones que se emplean y también se calcularon aproximaciones de raíces por el método de Newton, entre otros. En segundo lugar y referido a problemas de trabajo con matrices, se estudiaron distintos métodos de resolución de sistemas lineales incluyendo los que usan la descomposición LU, Gauss-Seydel y Jacobi, apuntando al trabajo con sistemas de grandes dimensiones. Un capítulo especial fue dedicado al de aproximación de funciones, considerado regresión lineal y polinómica, polinomios de interpolación de Lagrange y splines cúbicos y además polinomios trigonométricos para el caso de funciones periódicas. En cuanto a ecuaciones diferenciales ordinarias se vieron los métodos más representativos en cuanto a la resolución numérica, como Euler y Runge-Kutta, mientras que se trabajó la resolución exacta por medio de la Transformada de Laplace, que es un tema requerido especialmente para el dictado de las materias de control del ciclo superior de las carreras involucradas. Además se consideraron ecuaciones en derivadas parciales elementales y, por un lado su resolución exacta por medio de separación de variables y los métodos clásicos que emplean series de Fourier y numéricamente aproximando las derivadas con diferencias finitas. La bibliografía básica y clásica adoptada para el dictado de esta materia es el libro de Chapra y Canale [3]. Dada las limitaciones horarias de clase, hay cuestiones temáticas que debieron verse solo abreviadamente o a nivel informativo.

C- Herramientas de programación

De manera simultánea con el desarrollo de los conceptos de Cálculo Multivariado (A) se elaboró un programa de introducción a la programación, donde se abordaron los conceptos de especificación de un problema, generación de un algoritmo, escritura del código e implementación de esquemas depuración de códigos (*debugging*) mediante la trazabilidad de los mismos. Se introdujeron los conceptos básicos de las herramientas de programación como son las sentencias secuenciales, ramificación, lazos y los esquemas de programación modular (funciones).

El esquema de aprendizaje de cada uno de estos temas mencionados se realizó en distintas etapas mediante trabajos prácticos que conectaban gradualmente los temas abordados de Cálculo Multivariado; donde los alumnos incorporaron la sintaxis y semántica utilizada por la plataforma utilizada (OCTAVE), los comandos básicos, clasificación de variables, asignaciones, operaciones matemáticas y manipulación de expresiones y polinomios. A partir de la utilización de los comandos básicos de programación se pudieron realizar operaciones básicas de suma, resta, multiplicación y potencia de vectores y matrices y también se desarrollaron algoritmos que van desde la extracción de submatrices hasta la verificación de propiedades matemáticas. La evaluación de estos trabajos prácticos (tps) se efectuó a partir del envío electrónico por parte de cada uno de los alumnos, de un informe para cada trabajo práctico, incluyendo archivos de tipo *script*, que contenían los comandos necesarios para la resolución de cada ejercicio.

En relación con los contenidos anteriores, desde OCTAVE, en primer lugar se hizo especial énfasis en lo referido a graficación de funciones y trazado de curvas en

dos y tres dimensiones, en particular rectas y planos. Esto permitió representar curvas de nivel y trazas de funciones y también de superficies cuádricas en el espacio. Además, se consiguió visualizar la noción de derivadas parciales y posteriormente los planos tangentes a una superficie diferenciable. La representación de superficies en el espacio tridimensional resultó muy útil para la visualización de dominios de integración y para las aplicaciones de integrales triples. Resulta muy interesante la representación de superficies paramétricas empleando OCTAVE, reconociendo en ellas las típicas curvas reticulares en las imágenes que se obtienen.

Sobre los contenidos abordados en la materia de Métodos Numéricos (B), se observa que los conocimientos sobre la plataforma OCTAVE representan actualmente un alto porcentaje de la materia, puesto que todos los temas mencionados en el apartado, fueron programados y resueltos en ese entorno. Dentro de los ejemplos analizados, se consideraron problemas específicos de aplicación tanto en la industria de Alimentos como en Biotecnología.

Puntualmente, los problemas de ajustes de diferentes curvas de polinomios fueron planteados como problemas de optimización tanto en la plataforma OCTAVE como en EXCEL, donde los alumnos se familiarizaron con los diferentes *solvers* y problemas específicos de la optimización como son los valores iniciales, funciones objetivos, tolerancias de convergencias, entre otros.

De esta manera, debemos destacar que las herramientas computacionales permitieron incorporar y resolver cuestiones de cálculo que no sería posible de abordarlas de otra manera, complementando en forma muy eficaz el proceso de aprendizaje de los estudiantes.

D- De la presencialidad a la virtualidad

Forzados por el contexto de la pandemia mundial por el virus SARS-CoV-2 (COVID-19) nos vimos obligados a recurrir a herramientas virtuales para poder disponer de un ambiente donde los estudiantes y docentes pudiéramos abordar los conceptos y temas propuestos en los planes de las materias mencionados. Todo esto implicó: para los docentes proponer y realizar en tiempo real un cambio rotundo en los aspectos didácticos y pedagógicos acostumbrados para presentar estas materias y para los alumnos un gran esfuerzo de adaptación a la nueva metodología. En esta situación, la conectividad y los sistemas informáticos jugaron un rol fundamental.

Desde la Universidad de Río Negro se cuenta con un entorno virtual que es la plataforma PEMTIC, donde están alojadas sus aulas virtuales. En años anteriores a 2020, el sitio de las materias en consideración en esta plataforma fue utilizado estrictamente como repositorio para la bibliografía y los trabajos prácticos de las mismas y para la comunicación con los alumnos fuera de los horarios de clase mediante el uso de un foro. Esta situación se transformó completamente ante la virtualidad del dictado de las materias impuesta por las circunstancias ya conocidas. Las clases de las materias y las consultas fueron instrumentadas mediante la utilización de la plataforma *Meet* desarrollada por Google, disponible desde la cuenta GSuite de la Universidad, la cual no solo soporta multiusuarios en línea sino que también permite grabar las exposiciones

y realizar presentaciones a todos los participantes mediante la opción de compartir pantalla. En este sentido, los alumnos podían consultar sus dudas y mostrar sus resoluciones al resto de la clase, generando un ambiente más colaborativo que el que se encuentra generalmente en las clases presenciales. Del mismo modo, al concluir las clases teóricas se podían evacuar dudas sobre las presentaciones realizadas ya grabadas, y además, si era necesario se generaba nuevo material con aclaraciones particulares que también era compartido con los alumnos mediante archivos digitales subidos al repositorio del aula. Las clases grabadas se compartían mediante un enlace desde Google Drive después de la finalización de cada clase. Es importante destacar que el dictado de las materias no solo estuvo modificado y adecuado por los docentes mediante el estudio de las herramientas computacionales disponibles, sino que también fue fundamental contar con el soporte a la docencia en la utilización de herramientas tecnopedagógicas. Este sustento fue fundamental para la mejora de la educación a distancia, donde el conocimiento de dichas plataformas educativas facilita al docente la creación de puntos de encuentro para ejecutar las "nuevas" prácticas docentes que se necesitaban en este nuevo contexto y donde también se dispone de un foro de consultas en el que participan docentes de la Universidad y personal profesional preparado para abordar los inconvenientes que pudieran surgir y para promover la utilización de las herramientas disponibles y de las que se han ido incorporando en el último tiempo.

Respecto a las evaluaciones de los estudiantes resultó una cuestión compleja, por cuanto se quiso sostener el formato de evaluación con desarrollo por parte de los alumnos. Dado que estos podían disponer al momento de la evaluación de todo el material dictado en clase, la bibliografía e Internet, entre otras fuentes, las evaluaciones se realizaron conformando distintos grupos de alumnos, elegidos con algún criterio de acuerdo con el desempeño observado durante las clases. Es importante mencionar que las tareas de evaluación fueron ajustadas para ser aplicadas en ambas materias en grupos de estudiantes menores a 15 (quince) alumnos. Dentro de las actividades de evaluación se encontraba el formato *Tarea*, que se encuentra entre las actividades del aula virtual de la plataforma Moodle de la Universidad. La idea de las evaluaciones en cuanto a la parte matemática, apuntaba a resolver ejercicios que no se abordaran mecánicamente, dado que hoy se dispone de *softwares* que resuelven inmediatamente gran parte de los ejercicios tradicionales, solo con un poco de habilidad, y además que demostraran fehacientemente la comprensión de definiciones y expresiones y aplicarán otros resultados teóricos de un modo no automático. De esta forma se evaluaron contenidos por medio de varias tareas, algunas de las cuales tenían el rango de parciales.

Un hecho para destacar dentro de la Plataforma PEMTIC es la incorporación reciente de la herramienta H5P, que permite intervenir presentaciones y videos, entre otras actividades que pueden plantearse a partir de la misma. Esto significa que se puede volver interactivo un recurso de la materia, donde el alumno se limitaba hasta este momento a ver y/o escuchar. De esta forma, con el mismo material empleado en las clases teóricas se pueden generar nuevas actividades como autoevaluaciones, evaluaciones y proponer nuevos desafíos. Ya se realizaron algunos ensayos con esta herramienta H5P interviniendo videos en la materia de Cálculo Multivariado. Se espera

incorporar esta herramienta en las presentaciones de la materia Métodos Numéricos donde se desarrollan los contenidos, a modo de cierre de cada una de las clases semanales, durante el segundo cuatrimestre 2020.

Otra actividad planificada con los alumnos fueron las presentaciones grupales de a dos o a lo sumo tres alumnos. Esta actividad también fue evaluable, donde cada grupo designó un representante encargado de comunicar dudas y preguntas a los profesores. Los temas abordados en las presentaciones estaban relacionados completamente con la utilización de la plataforma OCTAVE y, en algunos casos particulares, sobre otras herramientas de presentación utilizadas que no eran de conocimiento general de los alumnos tanto de Power Point como Prezi. La cantidad de exposiciones realizadas en las dos materias demuestra una sustancial mejora de los estudiantes en el desarrollo de habilidades orales, de expresión y de organización, generando un gran impacto en la motivación y formación de los estudiantes en una etapa temprana de la carrera.

Cabe destacar que todas estas pautas mencionadas son de aplicación en cursos con una cantidad de alumnos no demasiado grande, por lo que cursos numerosos deberían readaptar los ítems mencionados, principalmente en las evaluaciones y exposiciones.

3 Conclusiones

Las adaptaciones del dictado de las materias de Cálculo Multivariado y Métodos Numéricos y los cambios realizados y a nivel de curricular y metodológicos, permitieron dar curso a todas las observaciones realizadas por los evaluadores de CONEAU, en el proceso de acreditación de la carrera de Ingeniería en Biotecnología. La experiencia del dictado presencial de ambas materias en 2019 pudo ser mejorada pese al contexto de virtualidad durante 2020. Las razones que encontramos para justificar estos logros son:

1. Ampliación de las metas en el dictado de la materia de Cálculo Multivariado (A) con la incorporación de contenidos y tareas específicas que hacen al uso y programación en OCTAVE. De no haberse realizado esta tarea durante el primer cuatrimestre, resultaría inalcanzable cumplir los objetivos de implementación de algoritmos en toda la temática de la materia de Métodos Numéricos (B), que se dicta en el segundo cuatrimestre.

2. Mejor organización y aprovechamiento del horario de clases. Se destinó un tiempo a las clases teóricas y otro tiempo de consultas generales. Además, durante el desarrollo de las dos materias y clase a clase, se designaron alumnos para preparar y exponer ejercicios seleccionados de los trabajos prácticos, en la clase siguiente. Esto constituyó también en una actividad individual evaluable y además esto último dinamizó, sobre todo, las clases virtuales, haciendo explícita la actividad y participación oral en clase de todos los estudiantes.

3. Mantener un canal de comunicación permanente con los alumnos.

Por otra parte, entendemos también que la mejoría realizada en el dictado tiene un efecto positivo en el alumnado por cuanto además de los contenidos mínimos que requiere el dictado de estas materias, se ha estimulado el desarrollo de otras destrezas

como son la escritura de informes, la oralidad, la preparación del material para exposiciones con el manejo de herramientas diversas a elección y también el trabajo grupal.

En cuanto al impacto de estas modificaciones en el dictado de ambas materias dentro la carrera, cabe destacar tres aspectos distintivos:

1. Al concluir el ciclo anual, los estudiantes que participaron activamente de este dictado 2020 manejan un conjunto de herramientas especialmente útiles de cara al cursado de materias más complejas que deberán enfrentar en su carrera a partir del próximo año. Esto redundará en beneficio del dictado, objetivos y profundidad de desarrollo de tales materias, dado que la preparación de base del alumnado ha mejorado.
2. Alumnos de esta cohorte, que ya han aprobado o promocionado estas materias son los únicos estudiantes regulares de la carrera en condiciones de desempeñarse en las mismas como ayudantes alumnos y ya han sido convocados a tal fin para el año próximo.
3. Como tarea adicional, se diseñaron actividades para enlazar los contenidos de Matemática de materias anteriores, donde los estudiantes presentaron a sus pares de primer año la metodología de trabajo que enfrentarán en las materias de Matemática de segundo año de sus carreras y además compartieron con ellos la resolución de problemas concretos y que les eran familiares, explicando en forma completa el modo de abordarlos dentro de la plataforma OCTAVE.

Agradecimientos

G.R.I agradece a la Universidad Nacional de Río Negro en virtud del subsidio otorgado a través del PI - 40A806 (2019)

Resumen. Sabemos que generar competencias de trabajo en grupo en los y las estudiantes de ingeniería es un desafío latente en los últimos años. Si bien la mayoría de las y los docentes podría asegurar que dan actividades para que se desarrollen en grupo, serían muy pocos/as los/as que dirían que han enseñado a trabajar en grupo. Por otro lado, la actual situación de distanciamiento social y de clases no presenciales ha resultado en un gran número de trabajos prácticos grupales como estrategia de enseñanza-aprendizaje virtual. En este trabajo, se exponen 2 actividades desarrolladas en la materia Gestión de la Calidad cuyas estrategias didácticas se basan en el Estudio de Casos y el Juego de Roles, mediante el trabajo grupal y se utilizan Autoevaluaciones y Coevaluación cómo métodos para el aprendizaje y mejora continua del hecho de trabajar en grupos formados aleatoriamente. En los casos abordados deben aplicar las herramientas AMFE (Análisis Modal de Fallos y Efectos) y el Diagrama de Causa y Efecto (Ishikawa) y QFD (Despliegue Funcional de la Calidad). Posteriormente, todos completan una grilla de auto y co-evaluación, programada en la plataforma Moodle, donde se evalúan aspectos como compromiso, respeto, integración en el grupo, escucha y preparación. Los resultados indican que la experiencia significó un crecimiento personal de la habilidad de trabajar en grupo, principalmente por el espacio de reflexión y retroalimentación generado.

Keywords: Coevaluación, Autoevaluación, trabajo en grupo.

1 Introducción

Desde hace varios años en Argentina la formación universitaria de los y las futuros ingenieros e ingenieras está transitando un camino de revisión de las formas de enseñanza y aprendizaje instaladas [1-2].En este contexto aparece la noción de competencia que pone en el tapete la "pertinencia de una formación que se limita a transmitir las disciplinas teóricas y a desarrollar capacidades generales sin referencia a su contexto de utilización" [3]. Desde esta perspectiva, se busca la formación de profesionales competentes, es decir, para el caso de la ingeniería, de un sujeto capaz de realizar las tareas

requeridas adecuadamente de acuerdo a los estándares de su profesión. Dentro de las competencias requeridas, este trabajo focaliza las denominadas competencias psicosociales, en especial las referidas a las relaciones interpersonales.

El/la profesional en ingeniería en su trabajo diario no solamente se relaciona con otros sujetos, sino que la tarea que realiza necesita del trabajo en grupo o trabajo en equipo[1]. Es amplia la bibliografía que enumera los beneficios del trabajo grupal y la necesidad de que el/la ingeniero/a aprenda el trabajo colaborativo. Es posible plantear que aunque los planes de estudio actuales en muchos casos presentan dentro de las incumbencias de ingeniería la capacidad de trabajar en equipo y de liderar grupos de trabajo [4], sumado al reconocimiento, por parte de los/as docentes universitarios y de los/as estudiantes, del valor que tiene esta capacidad para tener éxito en la labor profesional, la mayoría de los planes de estudio y programas universitarios no incluyen la enseñanza de esta competencia como objeto de enseñanza [5].

¿En qué radica el valor del trabajo en equipo? Desde que nace el hombre aprende a vivir en el mundo por la relación que establece con los otros. El grupo constituye un tiempo y espacio compartido en que construye sus habilidades, conocimientos y valores entre otros que le van a permitir habitar el mundo. A lo largo de la vida participamos en infinidad de grupos y de una forma intuitiva aprendemos a relacionarnos o, cuando no lo logramos, nos alejamos del grupo. Sin embargo, las demandas actuales del mundo laboral exigen que el profesional desarrolle tareas más complejas que demandan una actitud flexible y abierta, producción de conocimiento para dar respuesta a situaciones imprevistas y la participación en la gestión y control de su propia tarea, entre otras [3]. Estos cambios en las exigencias laborales hacen imprescindible el trabajo en equipo como forma colaborativa de trabajo. Sin embargo, la reunión de un conjunto de sujetos no siempre lleva a un trabajo en equipo. Un grupo es un conjunto de sujetos que se relacionan cara a cara con una cierta historia, objetivos compartidos y una trama vincular [6]. Cada miembro tiene habilidades, experiencias y saberes propios, formas de actuar, de sentir y de ver la realidad que resultan enriquecedoras a la hora de resolver una tarea pero que deben articularse, combinarse, manifestarse y ponerse en juego para realizar un trabajo. Es por ello que se hace necesario convertir al trabajo en grupo en un objeto de enseñanza en los espacios de formación profesional.

Una de las estrategias didácticas más utilizadas en la modalidad virtual de enseñanza ha sido los trabajos grupales, ya sean trabajos prácticos, trabajos de investigación, de reflexión, aprendizaje basados en problemas, entre otros [7-10] en los cuales se espera que se resuelva una consigna junto a otros/as, obteniendo un producto final que debe ser entregado o presentado para su evaluación y/o calificación, y que generalmente estas últimas resultan en una devolución general del grupo y no de cada uno de sus integrantes. En este sentido, es importante reflexionar acerca de cómo acompañamos a nuestros alumnos/as en el proceso de aprendizaje de un determinado tema al darles una consigna a resolver dentro de un grupo. La bibliografía y la experiencia nos dicen que el trabajo en grupo generalmente es positivo en relación al aprendizaje. Sin embargo, sabemos que a trabajar en grupo se aprende y que, además, cada grupo es particular y

[1] Aun cuando diferentes autores diferencian el trabajo en grupo con el trabajo en equipo en esta comunicación tomamos como sinónimos ambas expresiones.

pueden haber fuerzas que generen sinergia o por el contrario, que generen división. Tal como menciona Zarzar Charur [11] la dinámica del grupo se define como "la interacción de todas las fuerzas que entran en juego desde el primer momento en que el grupo se reúne, y que van variando en intensidad y dirección".

Si bien en la modalidad presencial, una devolución individual y personal que nutra el proceso de aprendizaje, podría hacerse mediante algún método de observación dentro del aula, claramente si la actividad se resuelve fuera de esta, la observación ya no es un método viable. En ese caso, la autoevaluación y la evaluación entre pares (o coevalaución) son potenciales medios que permiten obtener una evaluación personal de cada integrante del grupo. Lo que se propone es que el control de la evaluación deje de situarse irrevocablemente en las manos del/a docente y se transfiera a los/as alumnos/as. En este sentido, numerosos estudios demuestran que la evaluación confiada exclusivamente al docente, no favorece el proceso hacia la madurez y la creatividad que las instituciones educativas tratan de lograr [12], y que por el contrario, dichos estudios enuncian que la mayor parte de los/as estudiantes aprenden a evaluar su trabajo cuidadosamente, con honestidad e introspección, si se habilitan los medios para valorar su propio aprendizaje y/o el de sus compañeros/as. Los procesos de autoevaluación y de coevaluación permiten orientar al/a estudiante en el rol del/a docente, ya que lo involucra con las peculiaridades del proceso de evaluación, (contribuyendo así, al desarrollo de habilidades en este sentido) y lo/a ubica dentro del análisis del alcance de los resultados de aprendizaje esperados [13].

Entonces las preguntas que surgen son ¿Enseñamos a trabajar en grupo? ¿Damos acompañamiento a dicho trabajo? ¿Ha sido positivo abordar determinado tema desde el trabajo grupal? ¿Aporta la evaluación y la coevaluación al proceso de enseñanza aprendizaje? En el presente trabajo se tuvieron en cuenta dichas preguntas para planificar las actividades grupales a desarrollar durante el cuatrimestre de modo que las mismas sean acompañadas desde la cátedra, procurando enseñar a trabajar en grupo y esperando un efecto positivo de este sobre el aprendizaje de los contenidos.

Los objetivos de este trabajo son presentar una experiencia de aprendizaje grupal utilizando la autoevaluación y la coevaluación, y analizar los resultados y devoluciones de los participantes para mejorar los métodos utilizados, procurando replicar las estrategias utilizadas. El presente trabajo comienza relatando la experiencia de clase desarrollada, su contexto, objetivos de aprendizaje, estrategias didácticas y metodología evaluación. Posteriormente, se publican los resultados de los instrumentos de auto y coevaluación utilizados y se analizan cuantitativa y cualitativamente los mismos, describiendo situaciones generales y particulares encontradas. Por último, se plantean las principales conclusiones obtenidas y los potenciales trabajos futuros ligados a esta experiencia.

2 Experiencia

2.1 Contexto

Los/as participantes de las presentes actividades corresponden a los alumnos de la asignatura "Gestión de la calidad" del primer cuatrimestre del año 2020, situada en el segundo año del plan de estudio de la Tecnicatura en Operaciones Industriales, de la Universidad Nacional del Sur, ciudad de Bahía Blanca, Argentina. La moda de edad del alumnado es de 20 años. Sin embargo, dado que es una carrera nueva pensada para atender la demanda de la industria local, muchas personas que ya se encuentran trabajando en distintas áreas industriales también transitan la carrera, y estas rondan la edad de los 40 años. Por otro lado, dado la división departamental de la Universidad, cabe aclarar que, dicha asignatura también se dicta en el segundo cuatrimestre del quinto año de la carrera de Ingeniería Industrial.

El contexto que caracterizó el desarrollo de clases de la presente experiencia fue la condición de aislamiento social dada por la pandemia COVID-19, que demandó que desde el inicio al final del curso la metodología de trabajo sea virtual y remota. Esta situación llevó a la cátedra docente a pensar distintas alternativas que signifiquen disminuir la distancia con los/as alumnos/as, así como, desarrollar estrategias que sean desafiantes y motivadoras para los/as estudiantes en la modalidad virtual.

2.2 Objetivos de aprendizaje

Considerando las experiencias de clase a desarrollar en el presente trabajo, se definieron los siguientes objetivos de aprendizaje:

- Aprender a trabajar en grupo a partir de la autoevaluación y coevalucón.
- Conocer, comprender y aplicar en un caso concreto las herramientas de la mejora de la calidad: Diagrama de causa efecto, AMFE y QFD.

2.3 Estrategia didáctica

Trabajo Práctico Grupal.
Las estrategias didácticas desarrolladas se centraron dentro de dos Trabajos Prácticos Grupales, con un tiempo de 2 semanas para resolver cada uno. El primero abordaba los contenidos de las Herramientas de la Calidad, dadas por el Análisis de Modo y Efecto de Fallas (AMEF), Diagrama de Ishikawa, y el segundo la herramienta Análisis QFD o de Despliegue Funcional de la Calidad.

El curso fue divido, mediante la generación aleatoria de grupos de Moodle, en 4 grupos (A, B, C y D), quedando 10 integrantes en cada uno. La justificación de dicha división aleatoria se fundamenta en el interés por desarrollar la habilidad de trabajar en grupo con personas que no están acostumbrados/as a trabajar y que tal vez tengan otras metodologías y maneras de pensar. Situación potencial que vivirán próximamente en sus trabajos. Estos grupos se mantuvieron durante todo el cuatrimestre.

Consignas.

Para el primer trabajo practico, la cátedra preparó un caso a partir de un estudio real encontrado en la web. La estrategia del Estudio de Caso consiste en utilizar un caso real o adaptado como disparador y vehículo para abordar los contenidos deseados a través de un aprendizaje activo de los/as estudiantes y nutrido y enriquecido por la reflexión y el debate del trabajo en grupo. Es decir, el método de casos es una excelente oportunidad para trabajar en grupo, dando lugar a que discutan ideas, analicen distintos puntos de vistas, reflexionen sobre los nuevos contenidos y tal cual se enuncia en [12], lograr como resultado la construcción de una mayor tolerancia hacia las ideas de los demás, una disposición a escuchar las opiniones ajenas y un mayor confort cuando se trata de expresar un punto de vista. En el caso desarrollado para el primer trabajo práctico, se detallaban los procesos realizados en una industria láctea, desde el ingreso de la materia prima hasta la obtención del producto final. En base a dicha descripción, cada grupo debía realizar un AMEF (o FMEA por sus siglas en inglés), el cual es un procedimiento que permite identificar fallas en productos, procesos y sistemas, así como evaluar y clasificar de manera objetiva sus efectos, causas y elementos de identificación, para de esta forma, evitar su ocurrencia y tener un método documentado de prevención. Además de utilizar la información suministrada, si lo consideraban necesario, podían realizar alguna investigación extra del proceso. Dado que el proceso era muy extenso, a cada grupo se les asignó un conjunto de subprocesos, buscando equilibrar el trabajo a realizar.

Por otro lado, dentro del caso, se plantea una problemática puntual que demanda un análisis para determinar las posibles causas. Para ello, la segunda parte de la consigna especifica que deben realizar un Diagrama de Ishikawa (o también conocido como de Causa-Efecto o de Espina de pescado), cuya metodología sostiene que todo problema es originado por alguna de las macrocausas que plantea (Maquinaria, Métodos, Personas, Ambiente, Materiales y Mantenimiento), y estas deben ser analizadas y probadas, una a una, a fin de comprobar cuál de ellas está realmente causando el efecto (problema) que se quiere eliminar, y determinar así la causa puntual a abordar. La consigna aquí, consiste en realizar un Juego de Roles (*role playing*) es decir un juego de simulación que consiste principalmente en la representación de situaciones reales, donde cada participante debe actuar o defender un rol o papel, interactuando bajo determinadas reglas con el resto de los partícipes [14-15]. Según [16] los juegos de roles se caracterizan por demandar la toma de decisiones, y esto hace que estén orientados hacia el futuro, en tanto que dan la oportunidad al participante de tomar decisiones sobre problemas reales y observar las consecuencias más previsibles, así como de reorientar dichas decisiones en función de las retroalimentaciones recibidas. Entre los valores psicopedagógicos que aportan los juegos de simulación como estrategia metodológica, se destacan su potencialidad para repasar conocimientos y habilidades, desarrollar el aprendizaje existente y descubrir aspectos deducibles a partir de este y como elemento motivador [16-17]. Además, el juego de roles permite analizar los problemas relacionados con las relaciones humanas y fortalece la capacidad de la empatía [18]. Según [19] se mejora la experiencia educativa, ya que promueve el pensamiento crítico y las habilidades analíticas, el fomento de las competencias de comunicación oral y escrita, y el fomento de la confianza de los/las estudiantes [20].

Específicamente, en el Juego de Roles solicitado en el trabajo práctico, cada integrante del grupo debe tomar el rol de una de las personas del equipo de trabajo encargado de encontrar la causa del problema (Gerente de producción, Jefe/a de turno de producción, Responsable de mantenimiento electromecánico, Responsable del laboratorio, Responsable del control de calidad, Responsable de seguridad e higiene, Operador/a de higienización, Operador/a de planta, Operador/a del sector de envasado). Para ello, deben simular el proceso de analizar un problema para encontrar su causa mediante la metodología propuesta por Ishikawa. Brevemente, esta consiste en realizar una "tormenta de ideas" debatiendo sobre todas las causas que podrían originar el problema, y luego ir desagregando cada una, respondiendo a la pregunta ¿por qué? reiteradas veces, descartando algunas y seleccionando otras como causas principales. La causa final a seleccionar mediante el diseño del diagrama, la decidirá cada grupo, pero debe ocurrir dentro de alguno de los subprocesos asignados a cada equipo. Aprovechando el auge de las videollamadas, la simulación debía ser realizada en algún software/plataforma que permita su grabación, y esta sería parte de los archivos a entregar como resolución del Trabajo Práctico. Por otro lado, se aclaró que el video no debía durar más de 15 minutos y que cada participante debía especificar en el video que rol estaba desarrollando.

Para el segundo Trabajo Practico, también se planteó un caso armado por la cátedra, el cual expone la situación y desafíos de una empresa al diseñar su Plan Estratégico. En el mismo se muestran 3 archivos que contienen datos relevados de entrevistas a los clientes, un diagrama que sintetiza dichos datos y un cuadro de relación entre las necesidades del cliente y las necesidades de la empresa. Con toda esta información y las consideraciones que piensen pertinentes deben completar el cuadro característico del análisis QFD, y eso será el archivo que deben entregar para su calificación. Cabe aclarar que dicha resolución no está atada a una única respuesta correcta, sino que pueden darse diferentes matices dentro de un rango de lo que se considera como "bien resuelto", donde se contempla la coherencia integral del cuadro y los fundamentos dados en cada caso. Sin embargo, es de esperar que el producto final resultará más nutrido si se da un análisis integral desde el grupo, intercambiando ideas e interpretaciones de los detalles del caso planteado.

2.4 Evaluación

Pautas del trabajo en grupo y criterios de evaluación.

Antes de pasar a la presentación de las actividades se establecieron las pautas para el trabajo en grupo y se comentaron que al final de la actividad, realizarían una coevaluación y autoevaluación respecto al cumplimiento de dichas pautas. Se proyectaron las pautas establecidas por Wassermann [12] y se preguntó si deseaban sacar o agregar alguna más. Asimismo, se conversó brevemente sobre los posibles roles que podrían surgir dentro del grupo y la importancia de reconocerlos y tomar conciencia de su existencia como medio para el funcionamiento eficiente del grupo y la generación de sinergia.

A la par de la publicación de las consignas para el desarrollo de los trabajos prácticos, se comunicó el sistema de evaluación. Este estuvo dividido entre la evaluación que haría la cátedra, la autoevalución y la co-evaluación. Para la primera, los criterios de

evaluación fueron: Entrega en tiempo y forma completa, aplicación correcta de las metodologías AMFE, Causa-Efecto y QFD, fundamentaciones realizadas en cada caso, creatividad y resolución coherente y acorde. En base a estos se asigna una calificación dada por Aprobado, Aprobado con correcciones o Rehacer. Para las auto y co-evaluaciones en base a las pautas definidas en [12] se exponen los criterios de evaluación, las cuales se realizarán luego de entregar la resolución de las consignas. Los instrumentos utilizados se detallan en las siguientes secciones.

Instrumentos para la Auto y Co-Evaluación

Aprovechando la plataforma virtual *Moodle* a través de la cual se desarrolló la asignatura en el mencionado cuatrimestre, se utilizó el módulo "Taller" en el cual es posible la evaluación entre compañeros/as. En este, luego de cargado un trabajo, cada integrante del grupo tiene acceso a un cuestionario para autoevaluarse y evaluar a los demás integrantes del grupo. El mismo estuvo compuesto por una planilla y una pregunta abierta de retroalimentación general. Como se mencionó en la introducción, en esta experiencia se proponen instancias de autoevaluación y coevaluación para aprender y mejorar el trabajo en grupo. Es decir, las evaluaciones están centradas en el proceso de trabajo grupal y no en el producto final. Es por esto que los criterios de evaluación tienen que ver con el cumplimento de las pautas establecidas y el desarrollo de habilidades consideradas propicias para un buen y eficiente desenvolvimiento dentro de un grupo de personas. La planilla utilizada se muestra en la Tabla 1. En el espacio de retroalimentación general, se especificaba que el objetivo del mismo era que desarrollen un comentario sincero que signifique una crítica constructiva que pueda ayudar a la persona evaluada a mejorar su desempeño dentro de un trabajo en grupo. El espacio era el mismo en la coevaluación como en la autoevaluación. Una vez completado el cuestionario, se debe esperar a que todos/as los miembros del grupo completen esa fase, para que puedan visualizar las evaluaciones realizadas, las cuales se muestran de forma anónima. Asimismo, se calcula un promedio entre las calificaciones dadas y las recibidas. Si bien hay muchas variantes en este módulo, así fue como se utilizó en la cátedra.

Tabla 1. Planilla de autoevaluación y coevaluación

Criterio a evaluar / Indicadores	**Calificación asignada**			
	1	**2**	**3**	**4**
¿Respetó y consideró las ideas y opiniones de los demás?	Nunca	A veces	Generalmente	Siempre
Preparación y manejo de los contenidos al momento de desarrollar el trabajo:	Malo	Regular	Bueno	Muy bueno
Participación durante el desarrollo de la actividad	Malo	Regular	Bueno	Muy bueno
Focalización e iniciativa en el desarrollo del trabajo.	Malo	Regular	Bueno	Muy bueno
Grado de integración de los demás miembros del grupo (Considerar actitudes de cohesión	Bajo	Moderado	Medio	Alto

del grupo, interés por la opinión de los demás, iniciativas de integración a los/as compañeros excluidos por la razón que fuera, búsqueda de consensos, etc.)				

2.4.1 Encuesta final

Finalizado el periodo de clases y evaluaciones, se les pidió a los/as estudiantes que completen un formulario de Google, el cual pretendía generar un último análisis y reflexión del trabajo en grupo experimentado. El mismo recolectó información acerca de quién cumplió cada rol mayoritariamente dentro del grupo y qué rol sintieron personalmente que se desarrollaron mejor. Para ello se plantearon preguntas para que indiquen quien desarrolló cada uno de los roles, cuyas opciones de respuesta eran los integrantes del grupo. Basados en la clasificación de roles del texto de [21], y considerando la situación, contexto y experiencia a desarrollar, se indagó a cerca de: ¿Quién llevó el tiempo, agilizó el trabajo y focalizó en los momentos de dispersión? ¿Quién escribía las respuestas, transformando las repuestas habladas en respuestas escritas? ¿Quién moderaba la dinámica del grupo, haciendo participar a todos? ¿Quién buscaba información, aportando datos e ideas nuevas constantemente? ¿Quién evaluaba el cumplimiento de las consignas, realizando críticas constructivas en caso necesario? ¿Se desarrolló algún otro rol? ¿Quién lo hizo?

En esta encuesta también se pidió que indicaran en una escala del 1 al 5, donde 1 corresponde a “No me sirvió nada” y 5 “Me sirvió mucho”: ¿En qué medida consideras que las auto y coevaluaciones sirvieron para mejorar tu desempeño en el grupo? Y ¿En qué medida consideras que las auto y coevaluaciones sirvieron para mejorar el desempeño en el grupo de tus compañeros?

3 Resultados

A continuación, se publican los principales resultados obtenidos tanto del desarrollo en sí mismo de los trabajos prácticos como de los instrumentos de autoevaluación y evaluación entre pares, como se la encuesta final del curso. Los mismo son analizados cuantitativa y cualitativamente.

3.1 Evaluación del producto final

Como se mencionó anteriormente, la evaluación de los productos finales de cada trabajo práctico estuvo a cargo de la cátedra según los criterios establecidos. Para el primer trabajo práctico, dos grupos fueron calificados como Aprobados y los otros dos como Aprobados con Correcciones. En cada caso, se dio la devolución correspondiente a cada criterio de evaluación especificado. Con respecto a los videos de juego de roles entregados, se notó un gran compromiso y seriedad por parte de los y las estudiantes. Cabe aclarar, que en el juego de roles planteado no existía la instancia de evaluar las consecuencias de las decisiones tomadas, sino que, se apuntaba a analizar el proceso de la

toma de decisión. Lo cual pudo observarse muy bien en los videos entregados. Es decir, pude verse si realizaban un "brainstorming", si llegaban a una decisión o no, si la fundamentaban, si había un coordinador, entre otras cuestiones propias de la metodología Ishikawa

En el segundo trabajo práctico todas las calificaciones fueron de Aprobado, al cumplir con las especificaciones de la metodología QFD y los demás criterios de evaluación.

3.2 Cuestionarios de Autoevaluación y Coevaluación

En esta sección, se describen los resultados obtenidos en los cuestionarios de autoevaluación y coevaluación. En primer lugar, se hablar de los resultados de la planilla y luego del espacio de retroalimentación general.

Análisis de las planillas

Se analizaron todas las evaluaciones realizadas y para un análisis cuantitativo, se asignó un puntaje del 1 al 4 a las valorizaciones de la planilla, tal cual se muestra en la Tabla 1. De esta forma, se obtuvieron promedios y diferencias comparativas entre una instancia y la otra. Las mismas se muestran en la Tabla 2.

Tabla 2. Resultados promedios de las planillas de autoevaluación y coevaluación. Diferencias entre ellas y en cada instancia.

Grupo	Instancia	Promedio de calificaciones		Diferencias			Diferencias porcentuales		
		Autoevaluación	Otorgadas	O-A	Inst.2-Inst.1		O-A	Inst.2-Inst.1	
A	1	3.76	3.69	-0.07	-0.08	0.07	-1.90	-2.17	1.86
B		3.24	3.55	0.30	0.11	-0.21	8.54	3.31	-6.33
C		3.51	3.70	0.19	0.03	-0.15	5.02	0.81	-4.16
D		3.34	3.53	0.19	0.06	-0.04	5.26	1.68	-1.23
A	2	3.68	3.76	0.08			2.13		
B		3.36	3.34	-0.02			-0.58		
C		3.54	3.55	0.01			0.27		
D		3.40	3.49	0.09			2.46		

Las instancias 1 y 2 corresponden a las evaluaciones realizadas luego del primer y segundo trabajo práctico, respectivamente. Todos los grupos tienen un promedio entre 3 y 4 puntos, registrándose el menor puntaje de auto evaluación en el Grupo B (3.24) y el mayor en el Grupo A (3.76), ambos en la instancia 1. Para el caso de las calificaciones otorgadas promedio, la menor se ubica en el Grupo B (3.34) y la mayor en el Grupo A (3.76), ambos de la segunda instancia. Por otro lado, se observa que fueron mayoritariamente más autocríticos que críticos con sus compañeros ya que la diferencia entre calificaciones Otorgadas y Autoasignadas (columnas O-A) es positiva en casi todos los casos. También se realiza la comparación entre las evaluaciones de la primera instancia

versus la segunda y se destaca que las autoevaluaciones mejoraron y las otorgadas empeoraron. Separando las calificaciones, sólo el 1.3% de las evaluaciones corresponden a calificaciones de 1 o 2 puntos.
